O‘ahu encompasses the City and County of Honolulu. The County of Honolulu hosts a number of U.S. military facilities: Hickam Air Force Base, the Army’s Fort Shafter, the Army’s Schofield Barracks/Wheeler Army Air Field, the Coast Guard facilities at Barbers Point (Kapolei) and in Honolulu, and Pearl Harbor Naval Shipyard and Naval Station.

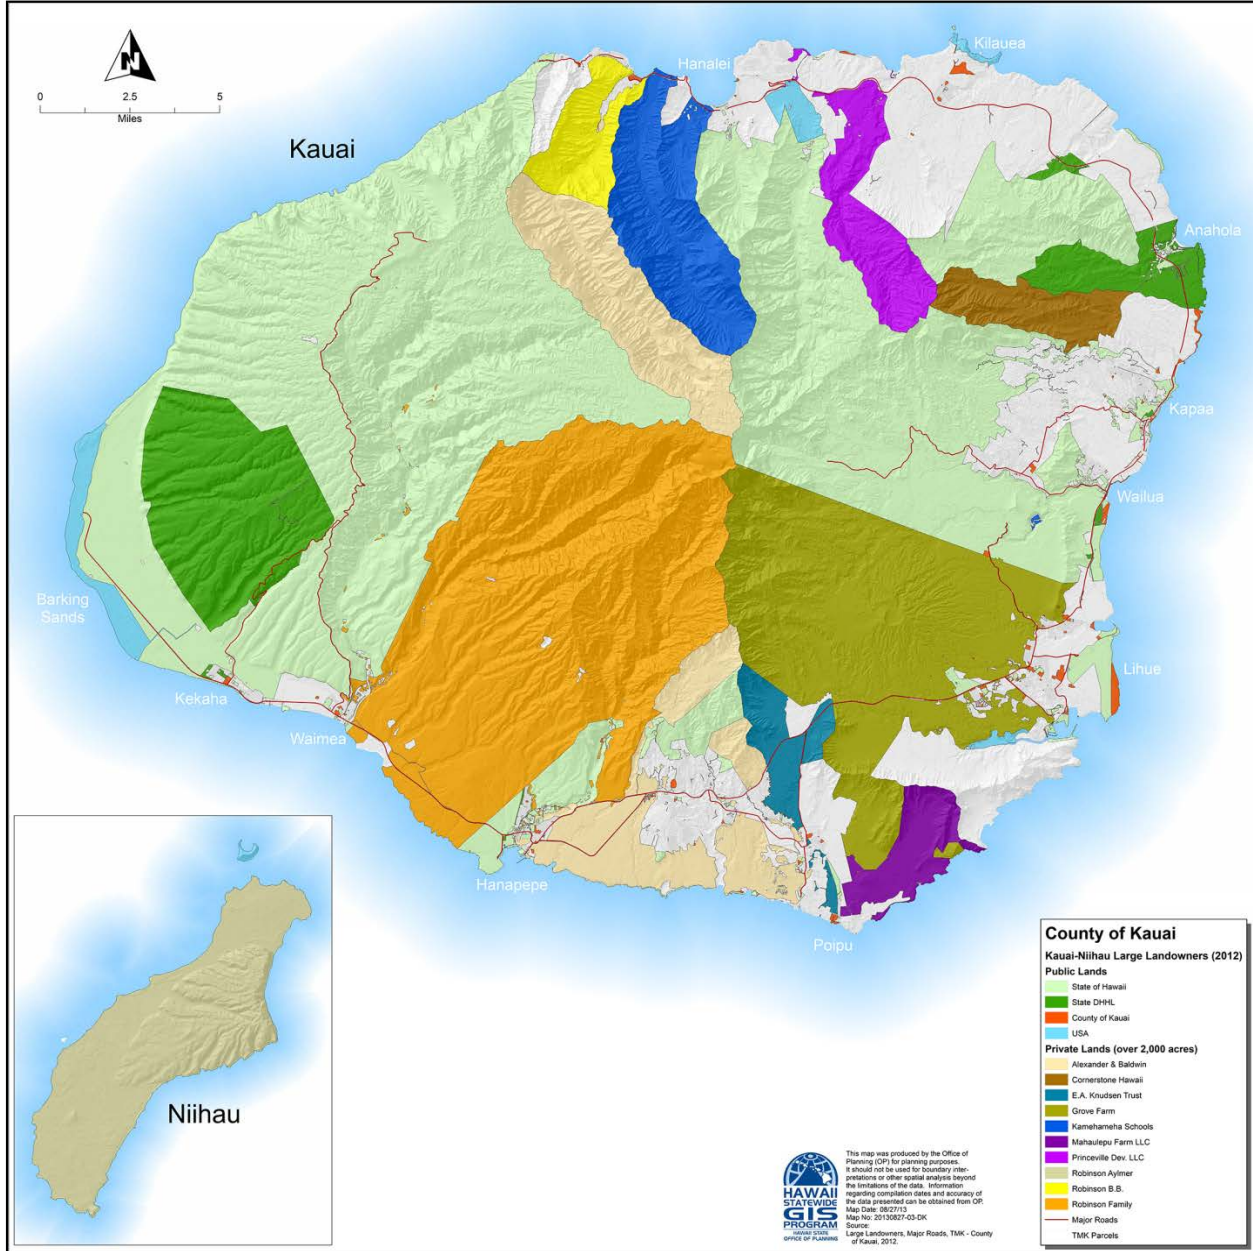

Figure 3-52. Land Ownership on Kaua‘i (Source: [Hawai‘i 2013a](#))

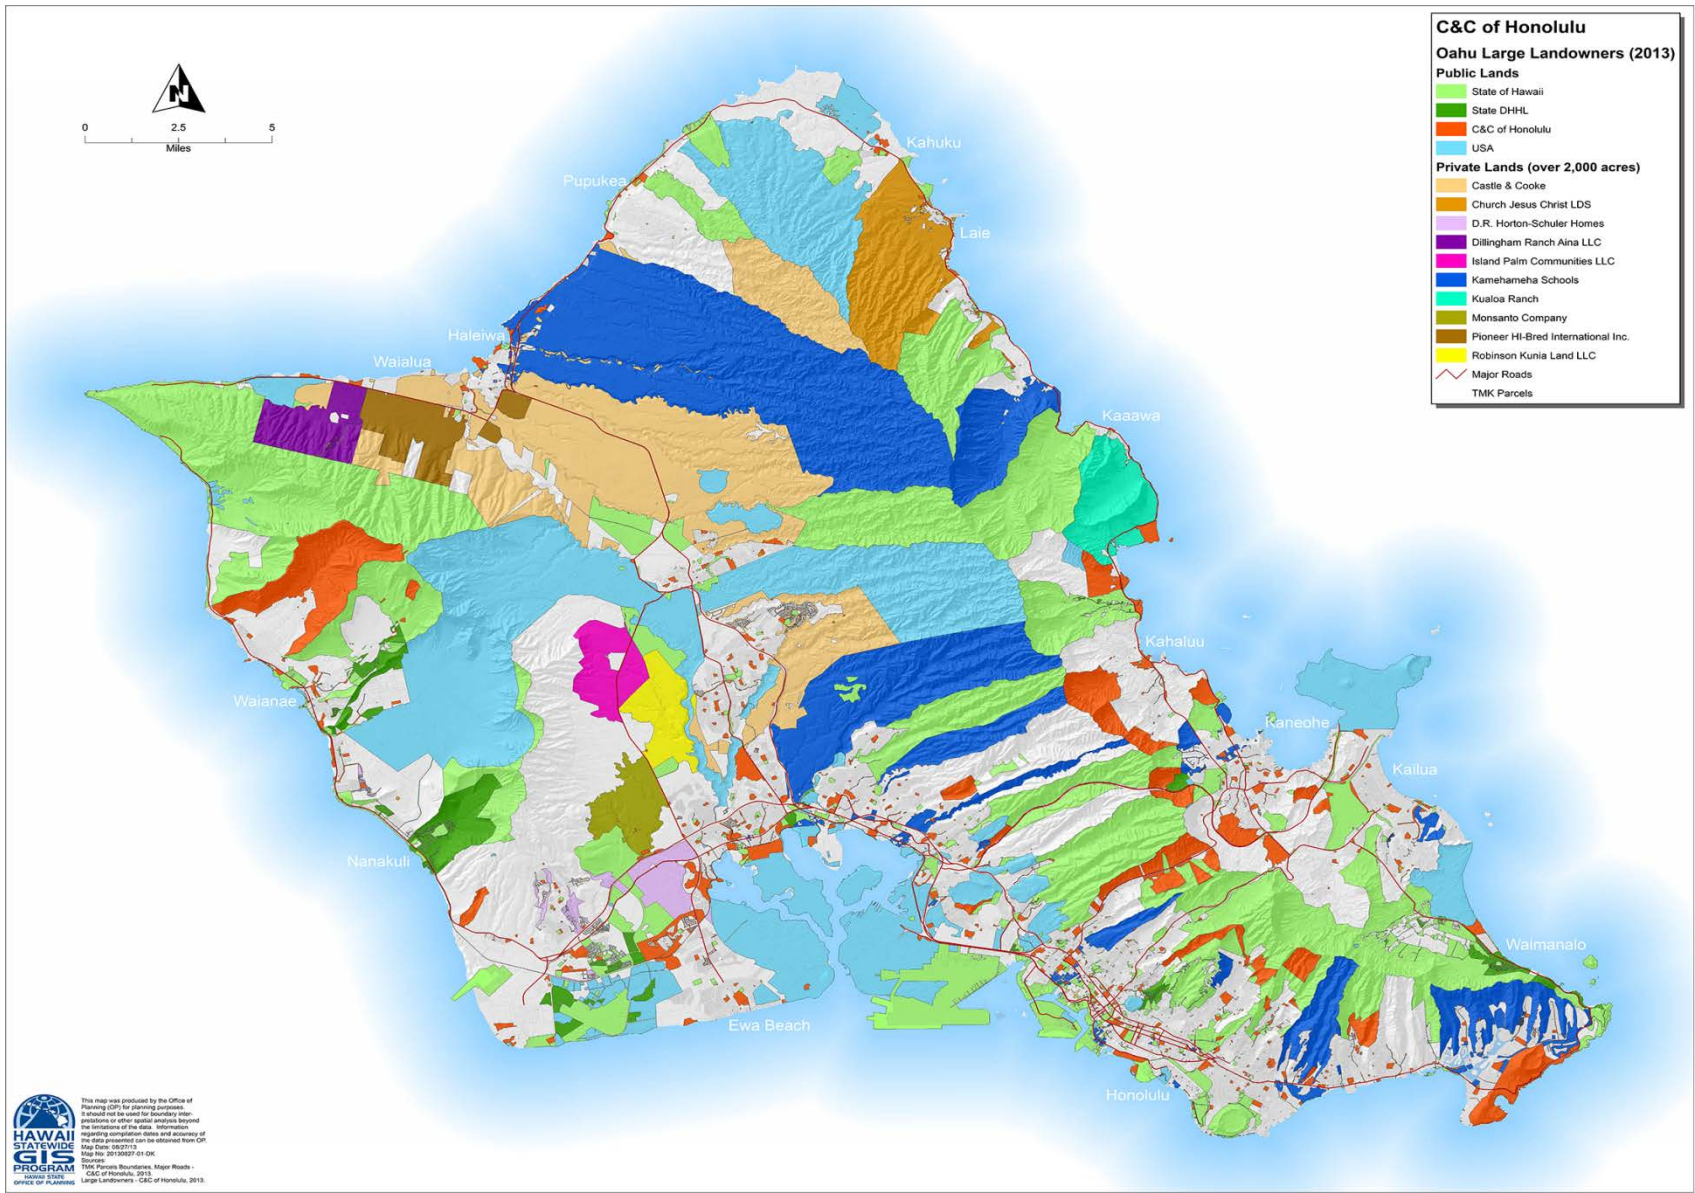

Figure 3-53. Land Ownership on O'ahu (Source: [Hawai'i 2013a](#))

3.5.1.3 Molokai

Molokai, with an area of about 260 square miles (approximately 166,400 acres), is the fifth largest of the six main Hawaiian Islands. [Figure 3-54](#) shows the largest landowners on the island of Molokai ([Hawai‘i 2013a](#)).

Land ownership on Molokai is distributed as follows ([Hawai‘i 2013a](#)):

State Government:	54,995 acres
Federal Government:	258 acres
Private:	101,935 acres

Molokai Properties Limited owns the Molokai Ranch and is the largest private landowner (over 60,000 acres) on the island. There is a small square of land, approximately 23 acres, ([Figure 3-54](#)) on the Kalaupapa Peninsula owned by the NPS. Though the NPS only owns a small portion of land within the Kalaupapa National Historical Park, the rest of the park is managed by the NPS through cooperative agreements with the State of Hawai‘i (see [Section 3.4.4.1.1](#)).

3.5.1.4 Lāna‘i

Lāna‘i, with an area of about 140 square miles (approximately 89,600 acres), is the sixth largest of the six main Hawaiian Islands. [Figure 3-55](#) shows the largest landowners on the island of Lāna‘i ([Hawai‘i 2013a](#)).

Land ownership on Lāna‘i is distributed as follows ([Hawai‘i 2013a](#)):

State Government:	265 acres
Federal Government:	5 acres
Private:	89,188 acres

Until recently, the principal island landowner, of more than 89,000 acres, was Castle & Cooke. Castle & Cooke, Inc. is a Los Angeles-based company that, at one time, was in the agriculture business. Through various mergers over time, the company became present-day Dole Food Company, the world’s largest producer of fruits and vegetables ([Dole 2014](#)). In 1996, Castle & Cooke divested from Dole, and today most of the company’s business is in real estate; specifically, residential, commercial, and retail development.

In 2012, Mr. Larry Ellison, Chief Executive Officer of the Oracle Corporation, bought the landholdings of the island from Castle & Cooke, which amounted to about 98 percent of the island’s land. The acquisition also included various commercial and residential properties and utilities ([New York Times 2012](#)).

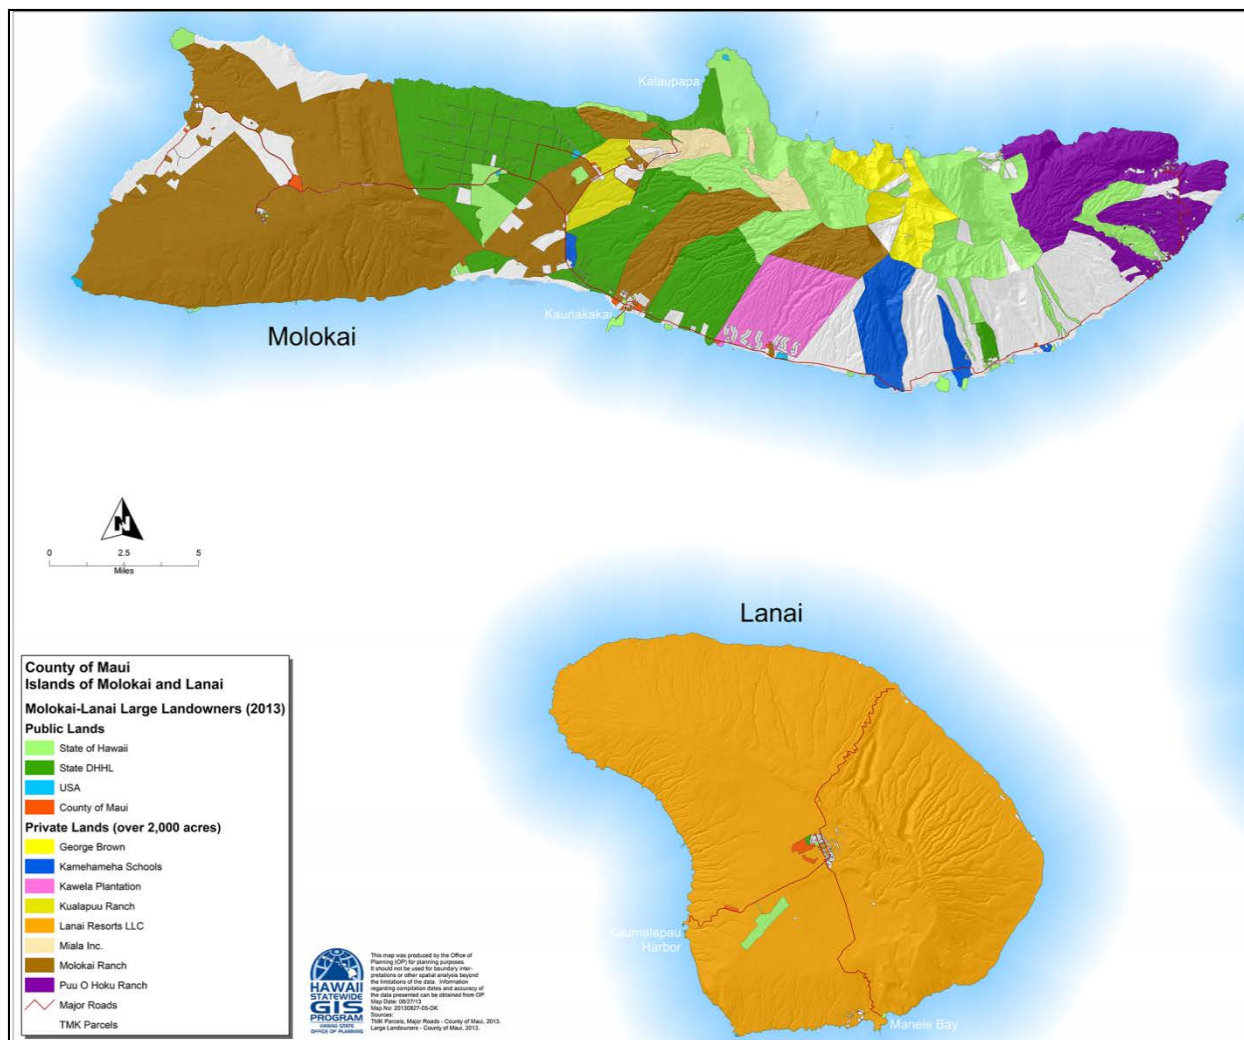

Figure 3-54. Land Ownership on the Islands of Molokai and Lāna‘i (Source: [Hawai‘i 2013a](#))

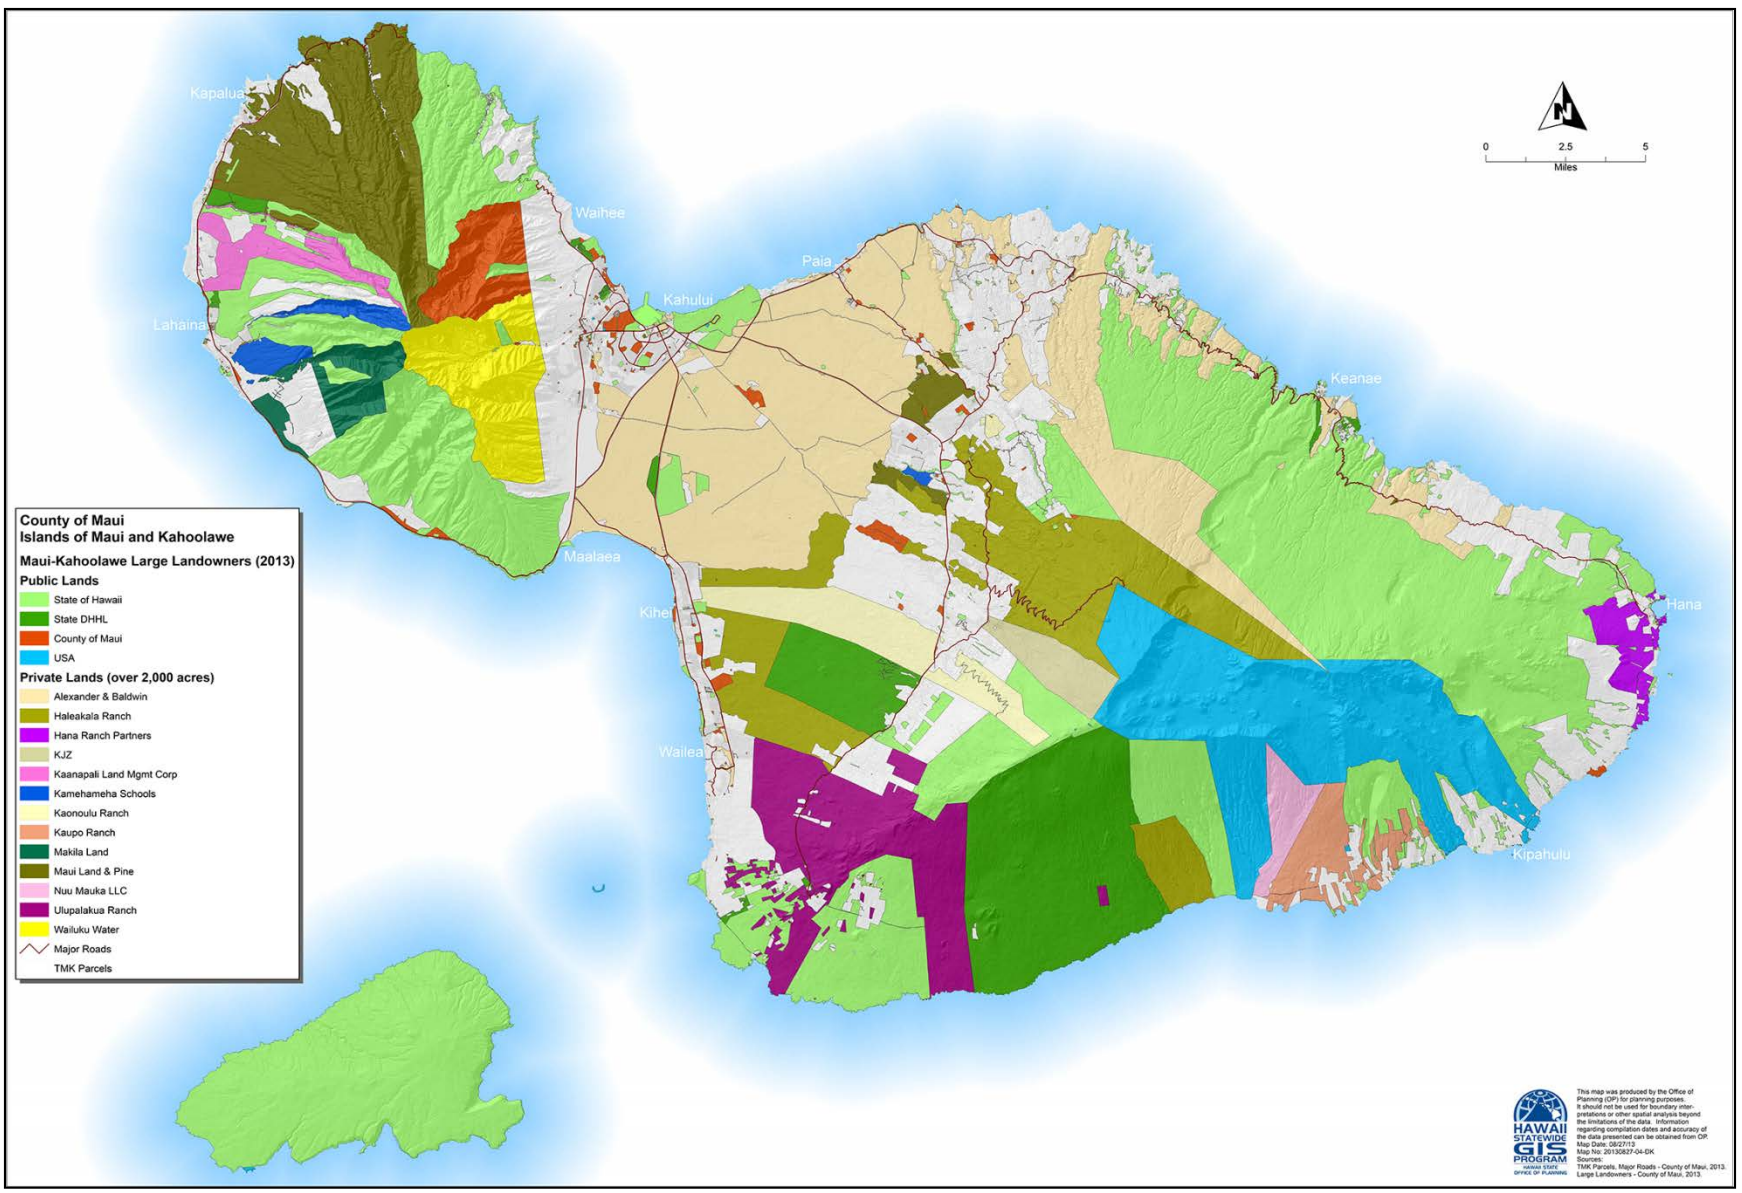

3.5.1.5 Maui

Maui, with an area of about 727 square miles (approximately 465,280 acres), is the second largest of the six main Hawaiian Islands. [Figure 3-55](#) shows the largest landowners on the island of Maui ([Hawai‘i 2013a](#)).

Land ownership on Maui is distributed as follows ([Hawai‘i 2013a](#)):

State Government:	149,138 acres
Federal Government:	33,659 acres
Private:	197,697 acres

Alexander & Baldwin owns the most private land on the island (over 92,000 acres). Alexander & Baldwin has been in the agriculture business and a real estate company for 142 years.

Affected Environment

Figure 3-55. Land Ownership on Maui (Source: [Hawai'i 2013a](#))

3.5.1.6 Hawai'i

Hawai'i, also called the Big Island, has an area of about 4,028 square miles (approximately 2,577,920 acres) and is the largest of the six main Hawaiian Islands. [Figure 3-56](#) shows the largest landowners on Hawai'i island ([Hawai'i 2013a](#)).

Land ownership on Hawai'i is distributed as follows ([Hawai'i 2013a](#)):

State Government:	1,391,522 acres
Federal Government:	432,205 acres
Private:	388,891 acres

State, county, and Federal government entities owns the majority of the island.

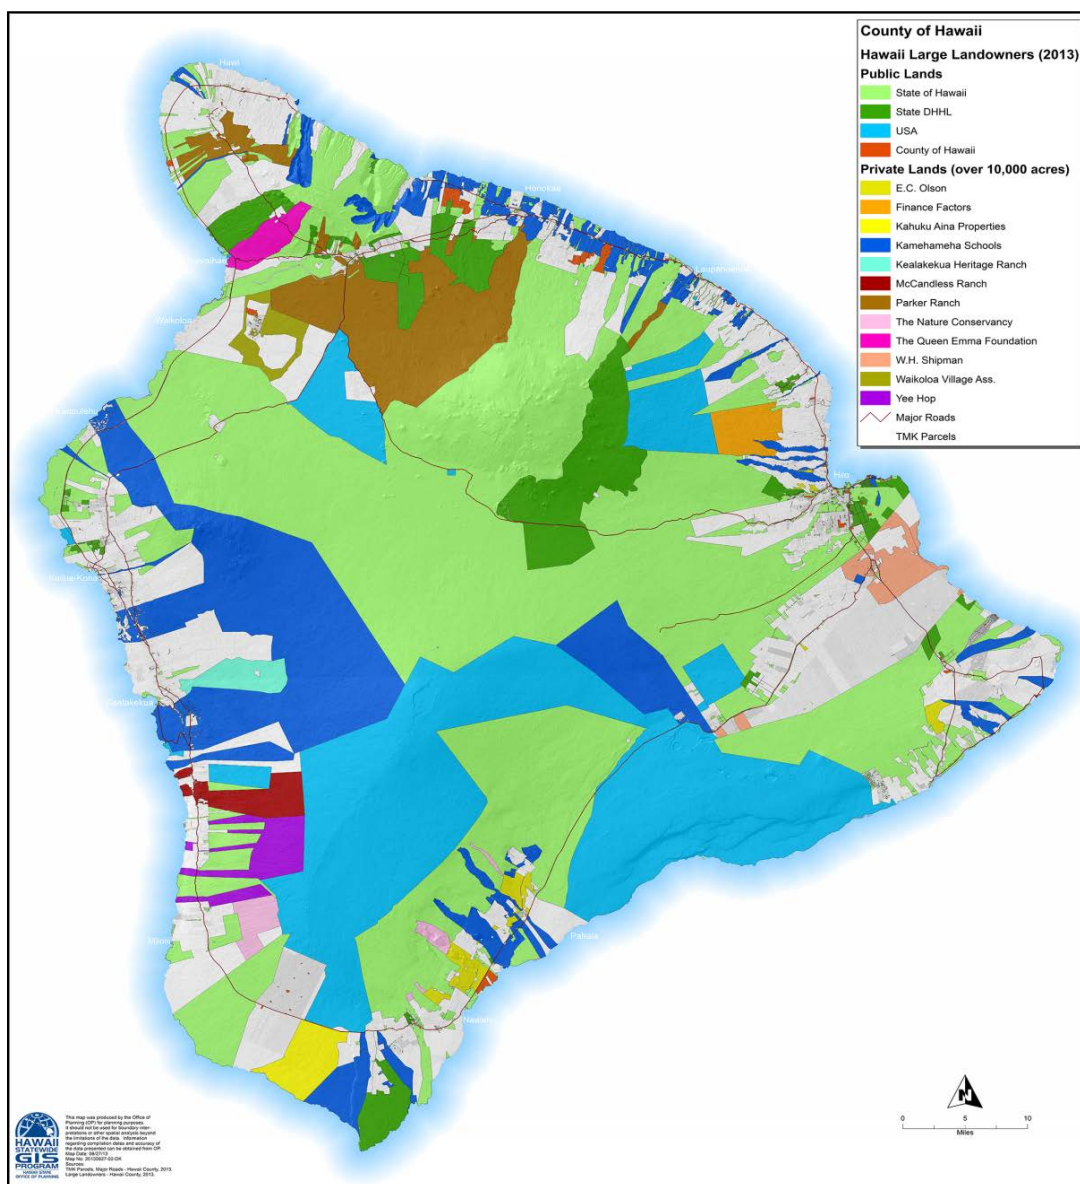

Figure 3-56. Land Ownership on Hawai'i (Source: [Hawai'i 2013a](#))

3.5.2 LAND USE

The Hawai‘i State Legislature adopted the State Land Use Law ([HRS 205](#)) in 1961. The Land Use Law establishes an overview framework on land use management whereby all lands in the State of Hawai‘i are classified into one of four districts:

- **Urban District** – Urban Districts generally include lands characterized by “city-like” concentrations of people, structures, and services. Urban Districts also include vacant areas for future development. Jurisdiction of these districts lies primarily with the respective county through ordinances or rules.
- **Rural District** – Rural Districts are composed of small farms intermixed with low-density residential lots with a minimum lot size of one-half acre. Jurisdiction over Rural Districts is shared by the State Land Use Commission and county governments. Permitted uses include those relating to or compatible with agricultural use and low-density residential lots. Variances can be obtained through the special use permitting process.
- **Agricultural District** – Agricultural Districts include lands for cultivation of crops, aquaculture, raising livestock, wind energy facilities, timber cultivation, agriculture-support activities (e.g., mills and employee quarters), and land with significant potential for agricultural use. Golf courses and golf-related activities may also be included in these districts, provided the land is not in the highest productivity categories for agriculture. As a means of protecting them from development, [HRS 205-4.5](#) restricts use of agricultural lands with productivity ratings of A or B, based on a five-class rating system from A at the highest productivity to E at the lowest (see [Section 3.1.1.1](#)). Permitted uses include specific renewable energy actions, often with stipulations or limits. For example, wind energy facilities are permitted within Class A or B areas provided they “are compatible with agricultural uses and cause minimal adverse impact on agricultural land.”
- **Conservation District** – Conservation lands are composed primarily of lands in existing forest and water reserve zones and include areas necessary for protecting watersheds and water sources, scenic and historic areas, parks, wilderness, open space, recreation areas, habitats of endemic plants, fish and wildlife, and all submerged lands seaward of the shoreline. Conservation Districts also include lands subject to flooding and soil erosion.

Each island also has county zoning ordinances, overlay zones, and other land use planning tools that can be applied within the four Statewide land use designations. Regarding the potential development of renewable energy facilities on any of the islands, the *Guide to Renewable Energy Facility Permits in the State of Hawai‘i Version 1, January 2013* ([DBEDT 2013a](#)) provides information on Federal and State Permitting, as well as ordinances and regulations for each county. The Guide also includes a checklist of approvals for energy development.

The following sections describe land use and island characteristics for the six main Hawaiian Islands.

3.5.2.1 Kaua‘i

Kaua‘i has four distinct regions, each with its own unique characteristics. The windward coast, which catches the prevailing trade winds, consists of the North Shore and East Side, while the drier, leeward coast encompasses the South Shore and West Side. One main road nearly encircles the island, except for a 15-mile stretch of sheer cliffs called the Na Pali Coast. The center of the island, Mount Wai‘ale‘ale, is completely inaccessible by car. One of the main land features on Kaua‘i is the Waimea Canyon and State Park. Pineapple and sugar plantations once dominated the agriculture industry; however, because these

crops could be produced cheaper in other countries, the plantations began closing and/or consolidating in the mid-1960s ([Kaua'i Plantation Railroad 2013](#)).

Kaua'i's land use planning is focused on maintaining the island's rural character. There are five planning districts on the island: Kawaihau, Koloa, Lihue, West, and North Shore. [Figure 3-57](#) shows the four Statewide land use designations.

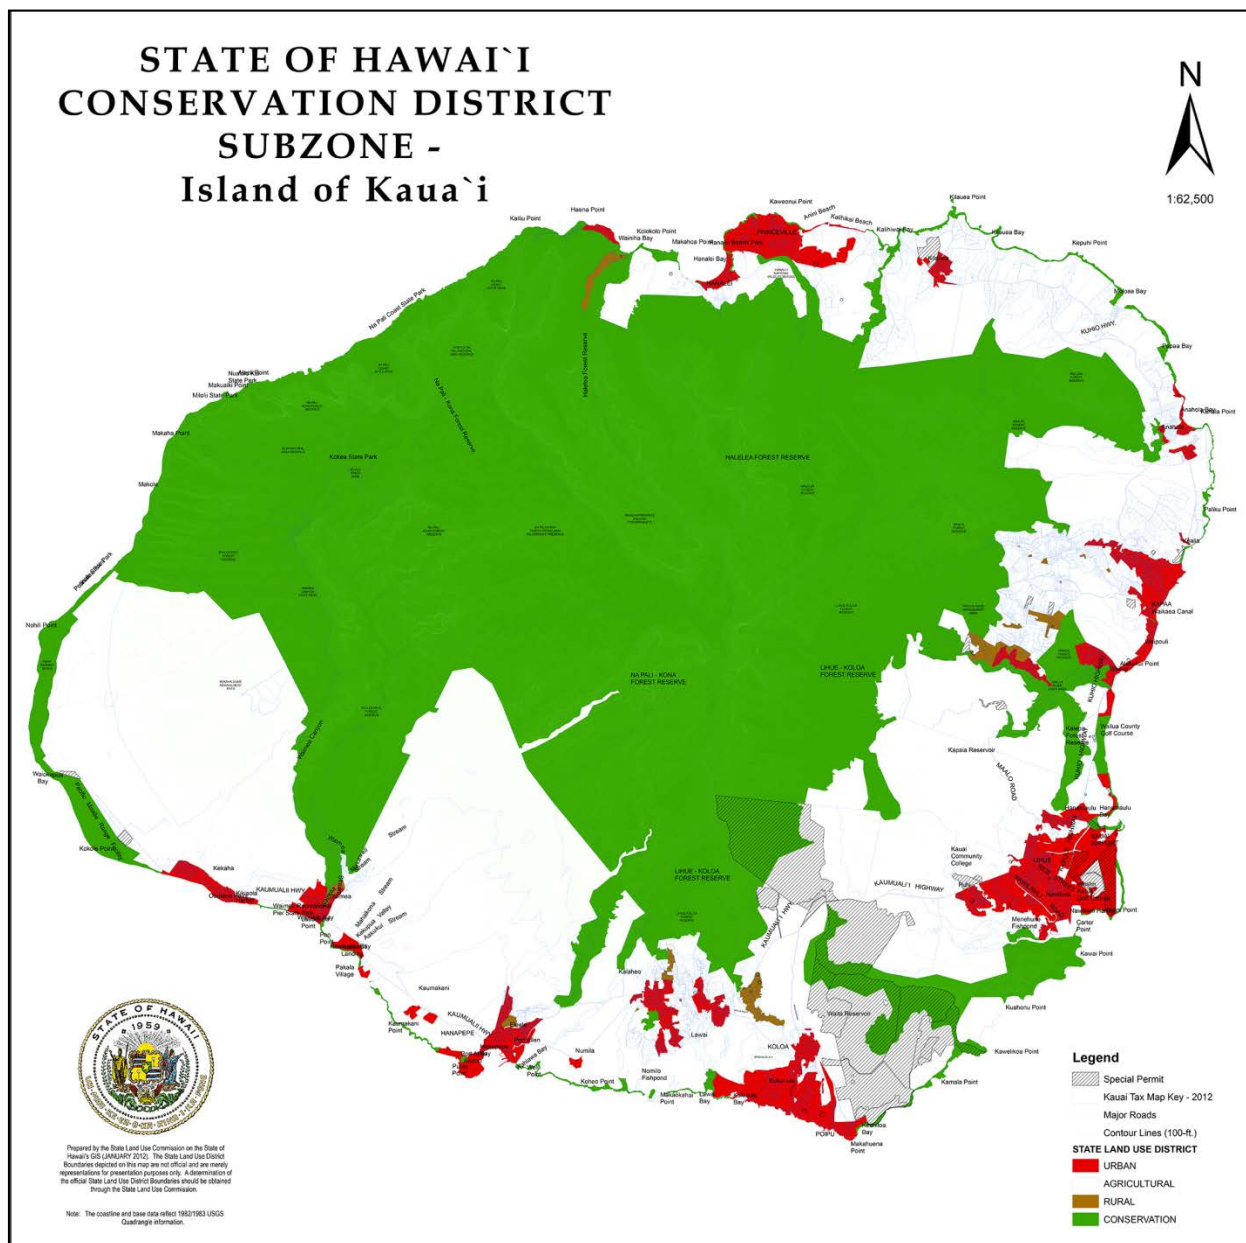

Figure 3-57. Statewide Land Use Designations on Kaua'i ([LUC 2012](#))

The *Kaua'i General Plan* ([County of Kaua'i 2000a](#)) includes detailed land use information for each district, including the following maps:

- Land Use Maps – Depict policies for long-range land uses with the following designations: Urban Center, Resort, Residential Community, Transportation, Military, Agriculture, Resources, Major Parks, Town Center, and Public Facilities.
- General Plan Heritage Resources Maps – Depict important natural, historic, and scenic resources.

The General Plan also establishes a vision for maintaining the island’s physical environment and character. In brief, the physical environment on Kaua‘i includes:

- Small towns and communities that have a distinct character and are compact rather than sprawling;
- Wide expanses of open lands—natural areas and lands in active cultivation—that provide separation between towns and communities;
- The relatively small scale and low heights of buildings; and
- The relatively small scale of Kaua‘i’s roads, the presence of natural vegetation along the roads, and the absence of medial concrete barriers.

Chapter 6 of the General Plan outlines the planning vision for enhancing towns and communities in Kaua‘i.

3.5.2.2 O‘ahu

O‘ahu hosts the City and County of Honolulu. [Figure 3-58](#) provides a map showing the four Statewide land use designations. The island is divided into eight regions, or development plan areas: the Primary Urban Center (Honolulu), East Honolulu, Central O‘ahu, ‘Ewa, Ko‘olaupoko, Ko‘olauloa, North Shore, and Wai‘anae. The City and County of Honolulu Department of Planning and Permitting is currently updating its *General Plan: Objectives and Policies* ([City and County of Honolulu 2002](#)) to cover physical development plans through 2035 ([City and County of Honolulu 2013a](#)). The discussion of land uses and land characteristics in the remainder of this section is presented in the order of the planning areas noted above.

3.5.2.2.1 Primary Urban Center

The Primary Urban Center includes the city of Honolulu, the largest city and State Capital, and main deepwater marine port for the State of Hawai‘i. The Primary Urban Center extends from Kahala to Pearl City, and crosses the valleys and coastline plains that characterize the island’s southern coastline.

Downtown Honolulu is the financial, commercial, and government center of Hawai‘i. The Arts District is a 12-block area bounded by Bethel and Smith streets and Nimitz Highway and Beretania Street. Kakako is a light-industrial district between Downtown and Waikīkī. The Ala Moana District, between Kakako and Waikīkī, is a major shopping area. Waikīkī is the tourist district of Honolulu, located between the Ala Wai Canal and the Pacific Ocean next to Diamond Head. Residential districts include Manoa and Makiki, located in adjacent valleys just inland of Downtown and Waikīkī; Nu‘uanu and Pauoa, located inland from Diamond Head; and Pālolo Valley, which parallels Manoa and is the most populated area on O‘ahu. Plans are to continue to enhance lifestyle choices for residents, provide business and economic development opportunities, and attract visitors ([City and County of Honolulu 2012a](#), [2012b](#)).

The United States military has a large presence in the greater Honolulu area. The Air Force’s Hickam Field shares runways with Honolulu International Airport and has merged operations with the Navy’s Pearl Harbor to become part of the Joint Base Pearl Harbor-Hickam. The Honolulu area also hosts the Army’s Fort Shafter, the Coast Guard Station Hawai‘i, and the Pearl Harbor Naval Shipyard.

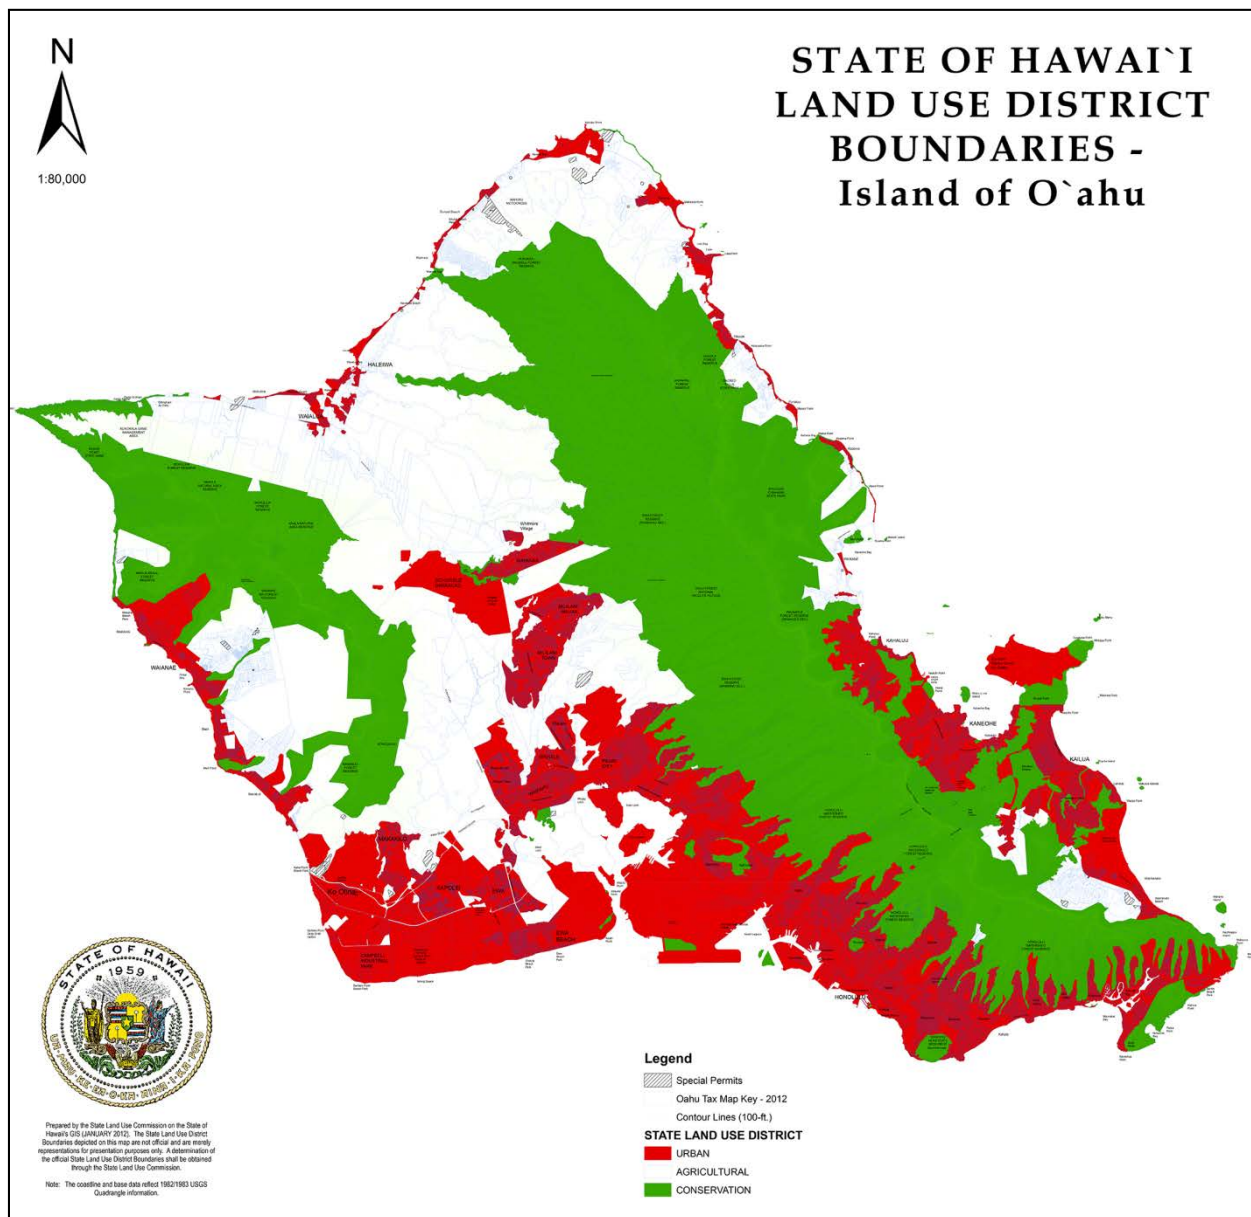

Figure 3-58. Statewide Land Use Designations on O`ahu ([LUC 2012](#))

3.5.2.2.2 East Honolulu

East Honolulu is directly east of the center of Honolulu, from Wai‘alae and extending east to Makapu‘u Point, the easternmost point on the island of O`ahu. Plans for East Honolulu supports containment of urban development and protection of agricultural areas. The City and County of Honolulu plans to preserve significant scenic views and natural areas ([City and County of Honolulu 2012a](#); [2012b](#)).

3.5.2.2.3 Central O‘ahu

Central O‘ahu plays a key role in implementing the land use and directed growth policies of the *General Plan Objectives and Policies* ([City and County of Honolulu 2002](#)). The towns of Waipahu and Wahiawa serve as gateways to ‘Ewa and the North Shore. Historically, these towns were headquarters for the sugar and pineapple plantations and support centers for the military. Beginning in 1968, Central O‘ahu began to play a role as a major area for housing development. Residential areas have been created in Mililani, above Waipahu and the H-1 Freeway in Village Park, Gentry Waipio, Waikele, and Royal Kunia. Central O‘ahu has become one of O‘ahu’s principal residential development areas ([City and County of Honolulu 2002](#)).

The 1,000-foot-high Leilehua Plateau is a prime agricultural region planted with fruits and vegetables, such as pineapple, coffee, and papaya, extending from the North Shore to the southern reaches of O‘ahu. The General Plan calls for maintaining the viability of agriculture, specifically in Central O‘ahu. The Wahiawa fields on the Leilehua Plateau contain the bulk of O‘ahu’s remaining pineapple fields, about 11,500 acres.

Most of the Waipio Peninsula lands were mostly used for sugar cultivation in the past. The General Plan supports continued use of these lands for diversified agriculture and aquaculture activities. A portion of the northernmost part of the Waipio Peninsula is used for active sports fields in conjunction with a soccer complex.

Wahiawa is a small, 100-year-old town about 30-miles from Waikīkī. The town hosts the 27-acre Wahiawa Botanical Gardens. Nearby, is the Army’s Schofield Barracks and Wheeler Army Air Field (about 18,000 acres in total). The base is separated from the town by Lake Wilson (also known as Wahiawa Reservoir). The base is considered to be the gateway to Kolekole, the lowest point in the Wai‘anae mountain range. The base has designated residential, commercial, and recreation areas. The major military bases of Schofield Barracks/Wheeler Army Airfield as well as the Pearl Harbor Naval Base are not expected to expand beyond their existing boundaries ([City and County of Honolulu 2002](#)).

3.5.2.2.4 ‘Ewa

‘Ewa is on the leeward side of O‘ahu, about 20 miles from downtown Honolulu. ‘Ewa once focused on sugar cane production, but is now a suburban growth center. Residential areas include ‘Ewa Beach on the south, Kalaeloa on the southwest, and Kapolei on the west. The ‘Ewa area is sometimes referred to as O‘ahu’s Second City, with its town center located in Kapolei. Plans envision protecting prime agricultural lands and natural, cultural, and historic resources. The County supports an urban type center in Kapolei ([City and County of Honolulu 2012a](#), [2012b](#)).

As does Central O‘ahu, ‘Ewa plays a key role in the county’s growth implementation policies. Campbell Industrial Park opened in the early 1960s, bringing industry and jobs to the leeward coast, which previously had been predominantly a sugar economy with a plantation lifestyle. In the 1970s, residential growth began in ‘Ewa with the development of Makakilo and ‘Ewa Beach. In 1977, the Honolulu City Council designated ‘Ewa as the location for a Secondary Urban Center on O‘ahu, centered in the Kapolei area, the Secondary Urban Center is now the focus of major economic activity, a housing development, and government services. The Kapolei area is a secondary employment center for industrial and resort areas, higher education, and office and retail activities.

Even though the area has developed into a second urban center, diversified agriculture on prime agricultural lands exists along Kunia Road and surrounding the West Lock Naval Magazine.

3.5.2.2.5 Ko‘olaupoko

Ko‘olaupoko extends from Makapu‘u Point in the southeast to Ka‘o‘io Point in the north. Included within the district are the largest windward towns of the island, Kāne‘ohe, Kailua, and Waimanalo, and four rural valleys.

Kāne‘ohe is the largest of several communities along Kāne‘ohe Bay and one of the two largest residential communities on the windward side of O‘ahu (the other is Kailua, which is discussed below). The commercial center of the town is spread mostly along the Kamehameha V Highway. There is very little agriculture in the area; the only commercial crop of any consequence is bananas. The town features the Ho‘omaluhia Botanical Garden.

The Marine Corps Base Hawai‘i lies between Kāne‘ohe and Kailua. The base occupies all of the Mokapu Peninsula, about 3,000 acres and includes on-base housing, shopping, and recreational facilities.

Waimanalo is close to Waimanalo Beach, but the Bellows Air Force Base separates the town from its namesake beach. An important airfield in World War II, the base now serves as military training and recreation areas for active and retired military and civilian employees of the U.S. Department of Defense. The Marine Corps Base at Kāne‘ohe Bay uses approximately 1,049 acres of the base as its Marine Corps Training Area Bellows. The town of Waimanalo has a small commercial center along the Kalaniana‘ole Highway.

Waimanalo has large agricultural areas in the valley that extend back toward the Ko‘olau Mountains from the center of town. Numerous plant nurseries operate in this area.

The Kualoa Valley is one of four valleys in the district. The Kualoa Ranch owns 4,000 acres within the valley. No longer a working ranch, the Kualoa Ranch now supports tourist activities such as hiking and horseback riding and has been the backdrop for a number of major movies. The other three valleys, Waiahole, Waikane, and Hakipu‘u are more rural, with a few small farms.

3.5.2.2.6 Ko‘olauloa

Ko‘olauloa extends from Kalaeokaoio in Kualoa to Waimea Bay, and inland is bounded mostly by the ridgeline of the Ko‘olau Mountains. The district is rural in character and has natural, scenic, and cultural areas. The town of Laie is of particular historical importance. Laie was a pu‘uhonua (a city or place of refuge), a sanctuary for fugitives. While a fugitive was in the pu‘uhonua, it was unlawful for the fugitive’s pursuers to harm the fugitive. The Church of the Latter-day Saints (Mormon) bought the sugar plantation named Laie in 1865. Both schools and church buildings were constructed in the ensuing years.

Laie is one of the best known Mormon communities and is the site of the Lai Hawai‘i Temple, the fifth oldest operating Mormon temple in the world. Brigham Young University-Hawai‘i is located in Laie. The Polynesian Cultural Center, the State’s largest living museum, also is in Laie. To the south of town is Pounders Beach, named for the pounding shorebreak; Hukilau Beach is located at the north end of town, at the mouth of Kahawainui Stream.

3.5.2.2.7 North Shore

The North Shore refers to the north-facing coastal area of O‘ahu between Ka‘ena Point and Kahuka Point. The largest settlement is Haleiwa. This area is best known for its massive waves, attracting surfers from around the world. Plans are to support diversified agriculture and commercial activity in the district, and

particularly in the towns of Haleiwa and Waialua, while retaining their historic character ([City and County of Honolulu 2012a, 2012b](#)).

Additional plans are to seek preservation of the region's rural character by preserving agricultural land and open space, and maintaining a land use pattern that reflects the use of the ahupua'a as a tool for physical and natural resource planning. The area in question is known as Wai'anae and is among Lualualei Valley, fringing the west side of O'ahu between Ka'ena Point, the Wai'anae Range, and Kamaile'unu Ridge. The Wai'anae Range is the eroded remains of an ancient volcano that comprises the western half of O'ahu.

3.5.2.3 Molokai

Molokai is part of Maui County. The County is in the process of updating the Molokai 2001 Community Plan ([County of Maui 2013a](#)). [Figure 3-59](#) is the map showing the four Statewide land use designations for Molokai.

Based on its physical characteristics, the island is divided into three main sections, West Molokai, East Molokai, and Central Molokai. The west end makes up about 30 percent of the total land area and is relatively dry with gentle slopes. The eastern half of the island makes up about 50 percent of the land area and is mostly mountains and gulches that are covered in rainforests and mixed mesic forests (see [Section 3.4.4](#) of this PEIS). The remaining 20 percent of the land mass makes up Central Molokai, which is relatively level and has soil suitable for cultivation. Monsanto Company leases about 1,850 acres of land on Molokai for cultivation. On Molokai, Monsanto mostly grows genetically modified corn seed crops, which are sold to commercial farmers on the mainland ([Lichtenstein 2013](#)).

The southern coast is lined almost entirely with coral reef, except where it was removed for the Kaunakakai Harbor. The northern coastline is mostly sheer sea cliffs 2,000 to 3,000 feet in height, making it inaccessible, except for the abutting peninsula of Kalaupapa. The Kalaupapa Peninsula hosts the Kalaupapa National Historic Park which is only accessible by foot, mule, or small plane.

Kaunakakai, located about midway along the southern coast, is the island's primary population and commercial center. There are also the small plantation communities of Mauna Loa and Kualapu'u, as well as the less compact rural Hawaiian homestead settlements, Ho'olehua and Kalmaula.

The southeastern coast contains a settlement pattern along Kamehameha V Highway, which becomes more rural and scattered as it extends from Kaunakakai to Hālawā Valley. The peninsula of Kalaupapa and some of the surrounding area on the northern coast constitute the County of Kalawao [this county was not included as part of the planning area in the 2001 *Molokai Community Plan* ([Molokai Planning Commission 2001](#))].

Kalawao County has two small unincorporated towns, Kalaupapa and Kalawao. Kalaupapa is the site of a former settlement for patients with Hansen's Disease (leprosy) first established in Kalawao to the east in 1866. Later the colony was moved to Kalaupapa, which was the site of a fishing village. At its peak, about 1,200 men, women, and children were in exile in Kalaupapa. King Kamehameha V enacted the isolation law, which remained in effect until 1969, when it was finally repealed. The colony is now part of Kalaupapa National Historical Park. There are three communities on Molokai as part of Maui County, Kaunakakai (once one of the summer homes of King Kamehameha V); Kualapu'u, a former pineapple cannery village; and Mauna Loa, mostly supported by the Molokai Ranch.

Molokai Properties Limited (MPL) is the island's largest landowner at over 60,000 acres. MPL owns and operates the Molokai Ranch, which is located primarily on the west end of the island, with three tracts of

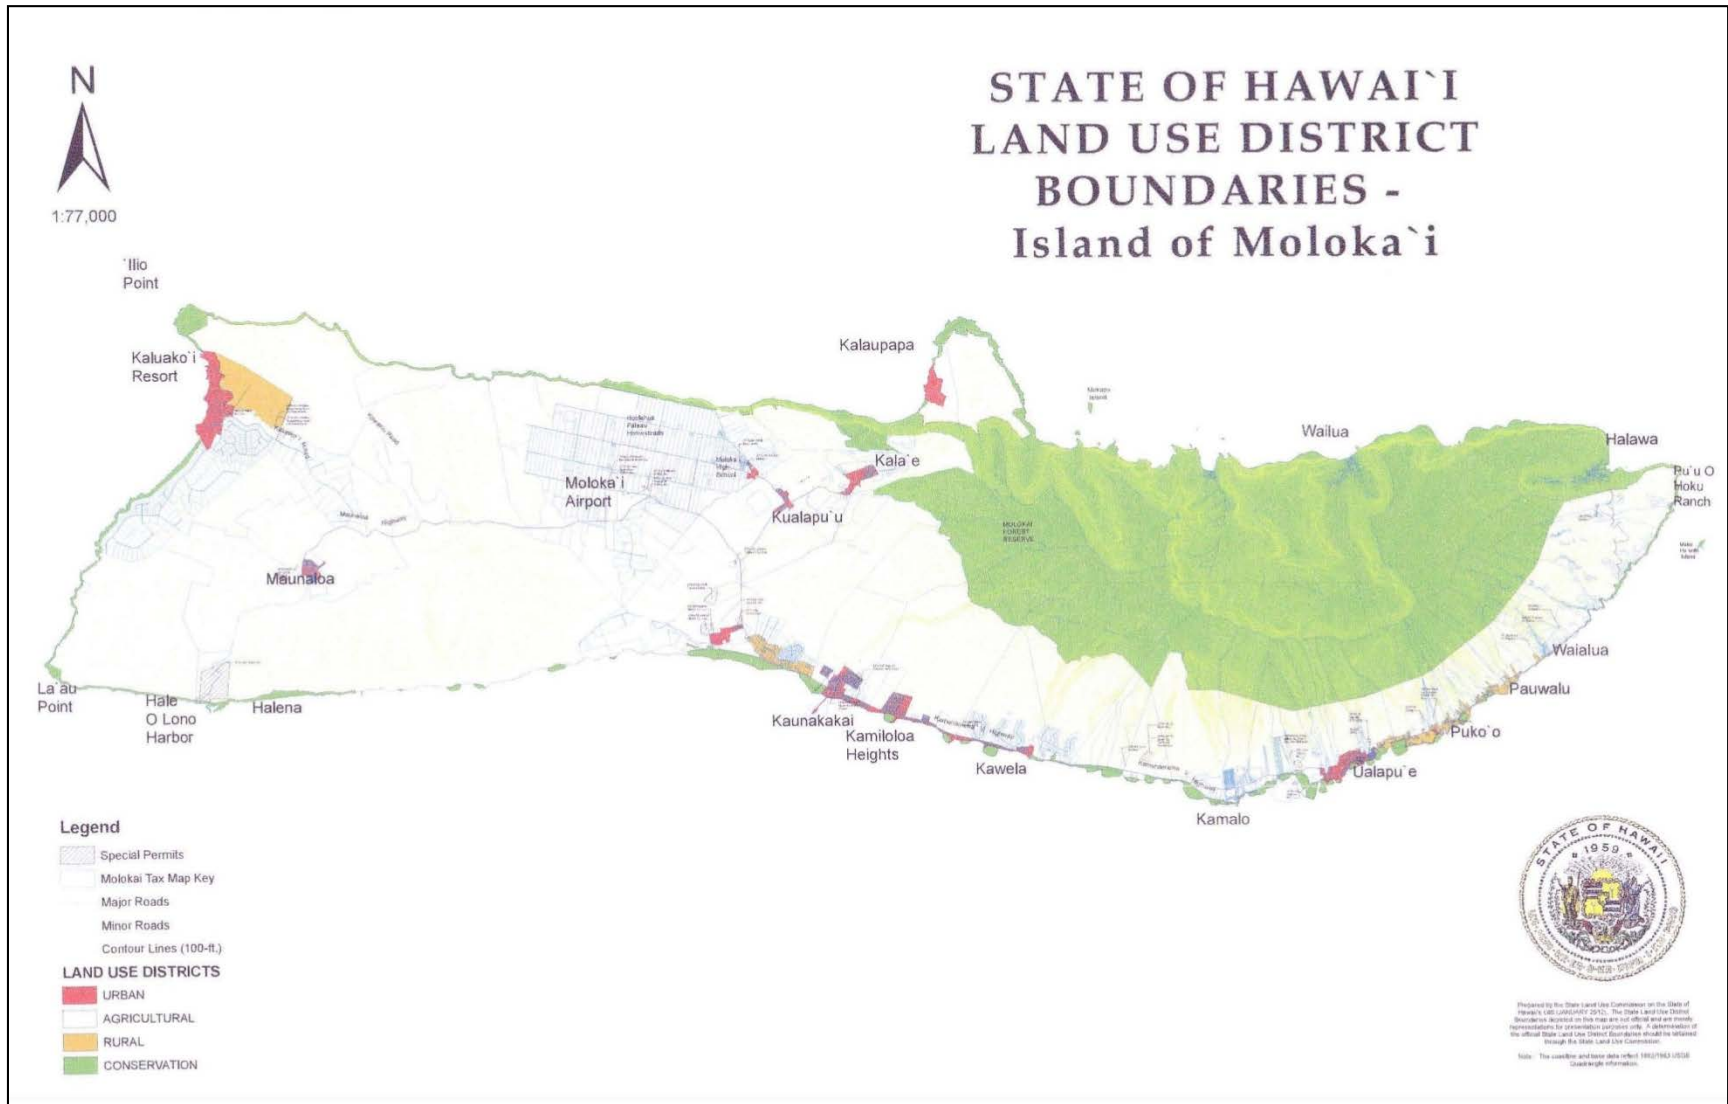

Figure 3-59. Statewide Land Use Designations on Molokai (LUC 2012)

land in Central Molokai. The boundary of the western property extends eastward from the western coast; from Ilio Point to Mo'omomi in the north, and from La'au Point to the Pala'au Homesteads to the south.

The main population center in West Molokai is the small town of Mauna Loa, headquarters of MPL. Along the shores south of Mauna Loa is Hale'o'Lono and Kolo Wharf. Mauna Loa Highway connects the west end of the island to the Molokai Airport, Kaunakakai, and the rest of the island.

MPL owns three tracts of land in Central Molokai. From west to east, the first tract encompasses Naiwa, Pala'au State Park, the area surrounding Kualapu'u town and Reservoir, and continues south to the Pala'au Homesteads. The second tract includes land immediately surrounding Kaunakakai and a large area including the Molokai Forest Reserve. The third tract is the Kamakou Preserve which consists of 2,774 acres of native rainforest ecosystem with a conservation easement managed by The Nature Conservancy. MPL also owns a 34-acre parcel south of the Kamakou Preserve at Kawela. This parcel is significant for its cultural history and archaeological sites.

In 2003, MPL and Ke 'Aupuni Lokahi (KAL) (a Molokai enterprise community) began discussions to create a community-based master land use plan for Molokai Ranch. KAL was formed in 1998 to develop a 10-year strategic plan to stimulate the island's economy. The planning process was formally launched in August 2003 as a KAL project under Project #47: Community-Based Compatible Development. In February 2004, the *MPL Community-Based Master Land Use Plan for Molokai Ranch* was included as part of the Project, and in November 2005, MPL published the Final Plan. The plan includes development of La'au Point, a 658-acre luxury residential development, and the permanent conservation of more than 50,000 acres of the Molokai Ranch. The proposed La'au Point development received heavy opposition; the project was terminated because the plan did not receive support. In 2012, the Molokai Ranch announced plans to develop a new strategy focusing on four pillars of business: Animal Husbandry, Authentic Hospitality, Renewable Energy, and Sustainable Agriculture ([Molokai Ranch 2014](#)).

3.5.2.4 Lāna'i

Lāna'i is part of Maui County, and its land use planning functions are supported by the Maui Department of Planning. [Figure 3-60](#) is the map showing the four Statewide land use designations.

Since the 1850s, all, or nearly all, of the island has been owned by various single owners. Land uses have been shaped by successive visions of Lāna'i as Mormon refuge, a sugar plantation, a pineapple plantation, and a resort island. Today, Lāna'i includes approximately 89,000 acres of land, of which only about 626 acres are classified as urban ([County of Maui 2012a](#)).

In 1922, James Dole purchased the island of Lāna'i and developed a vast pineapple plantation. It became the largest pineapple plantation in the world with over 20,000 acres devoted exclusively to growing pineapples. The Hawaiian Pineapple Company that Dole created later became the Dole Food Company. Starting in the 1960s the Hawaiian pineapple industry went into decline. The decline is mainly attributed to the fact that production costs of foreign-based pineapple canneries were approximately one-tenth the cost of producing pineapples in Hawai'i. Consequently, large commercial pineapple operations on Lāna'i ended in October 1992.

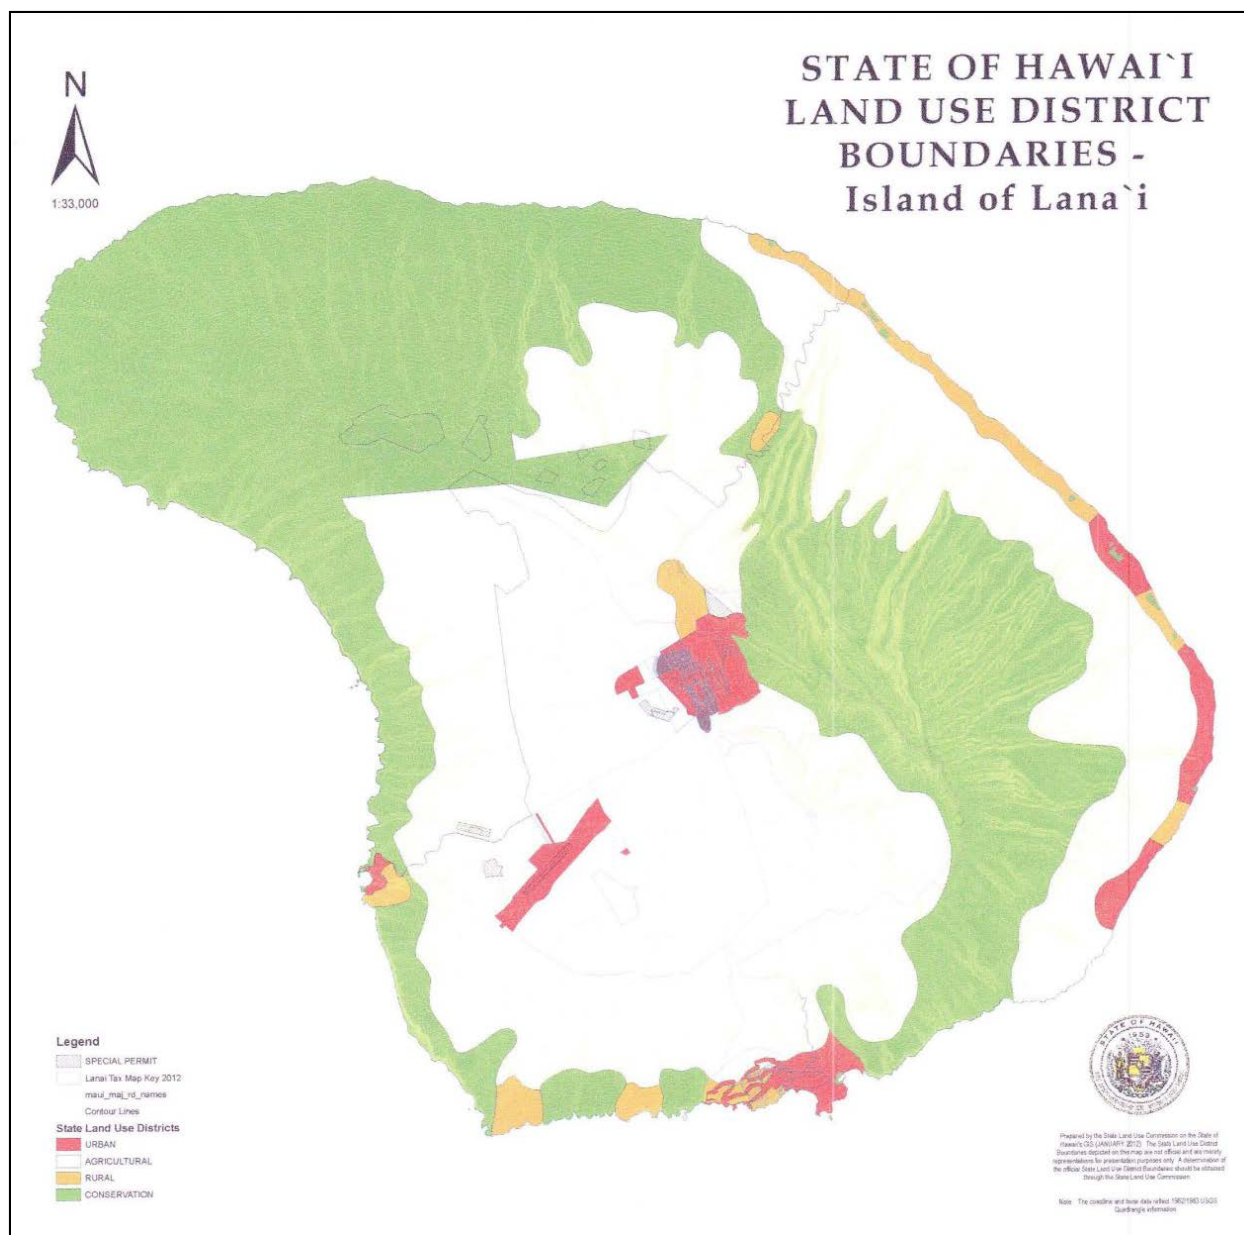

Figure 3-60. Statewide Land Use Designations on Lāna‘i (LUC 2012)

The once vast pineapple lands of Lāna‘i have now been converted to other uses, or remain fallow. The movement toward a resort economy for the island has resulted in two resorts. The first is on Manele Bay; the second is the upland lodge at Koele. The historic Hotel Lāna‘i is in Lāna‘i City.

The Palawai Basin has long been the central agricultural resource of the island. Still considered rural, the Miki Basin currently has more urban development than Palawai, with the island’s power plant and a solar farm. The airport is located farther west, between Miki Basin and Kaumalapau Harbor.

Other areas with minimal or no current urban development include ([County of Maui 2012a](#)):

- The beaches of the northeastern and eastern coasts, including Shipwreck Beach. Now abandoned, Club Lānaʻi was an oceanfront property near the remote Lopa Beach with a wharf once used by day-trippers from Maui;
- Maunalei ahupuaʻa, with the island's only perennial stream, was the site of a short-lived sugar plantation. Land in this valley was leased in recent years for taro cultivation. It remains a site of possible agricultural development.

In 2012, Lānaʻi issued its *Land Use Forecast* as part of the *Maui Island Plan: General Plan 2030*. The forecast determined that lands currently available for development would be capable of meeting future growth in the tourist industry through the year 2030 ([County of Maui 2012a](#)).

3.5.2.5 Maui

[Figure 3-61](#) shows the four Statewide land use designations for Maui, as well as the smaller unoccupied island of Kahoʻolawe. Kahoʻolawe is about 7 miles southwest of Maui. During World War II and up to 1990, the United States military used Kahoʻolawe for live-fire training and bombing. The U.S. Navy ended live-fire exercises in 1990. In 1993, the Hawaiʻi Legislature established the Kahoʻolawe Island Reserve, consisting of the entire island and its surrounding ocean waters in a 2-mile radius from the shore. By State law (Act 340 under [HRS 64](#), 1993), Kahoʻolawe and its waters can only be used for Native Hawaiian cultural, spiritual, and subsistence purposes: fishing, environmental restoration, historic preservation, and education. All commercial uses are prohibited. The island is listed on the *National Register of Historic Places* ([Napier 2006](#)).

Maui has three primary urban centers: Central Maui, West Maui, and South Maui. Encompassing the towns of Wailuku and Kahului, the area known as Central Maui has the majority of the island's urban development. The County government civic center, the island's primary airport and sole deep-water harbor, the University of Hawaiʻi Maui College, the island's primary business district, and vast acres of sugarcane fields make up the Central Maui area. Kahului also supports the island's primary industrial zones, large retail centers, and shopping malls.

West Maui has a string of coastal communities and mountainous areas. The stretch of coast between Lahaina and Napili is dominated by the resort industry due, in part, to its ocean access points that provide numerous recreational opportunities. The northeastern portion, stretching from Waiheʻe to Honolua Bay, offers vast open spaces and cliffs, ocean views, valleys, and streams.

The coastline that stretches from Māʻalaea to Makena is known as South Maui. Development along this area has generally occurred in a linear pattern between the shoreline and Piʻilani Highway, forming a continuous urban corridor that attracts a large tourism industry ([County of Maui 2012b](#), Introduction).

As is typical of rural land use patterns, South Maui consists of small towns, low-density residential development, open space, and an agricultural landscape. In recent decades, the character of the landscape stretching from Haiku to ʻUlupalakua and beyond has experienced a marked increase in lower-density residential sprawl. The implementation of a combination of rural planning tools and techniques can help influence the form of future development and mitigate its impact on the rural landscape.

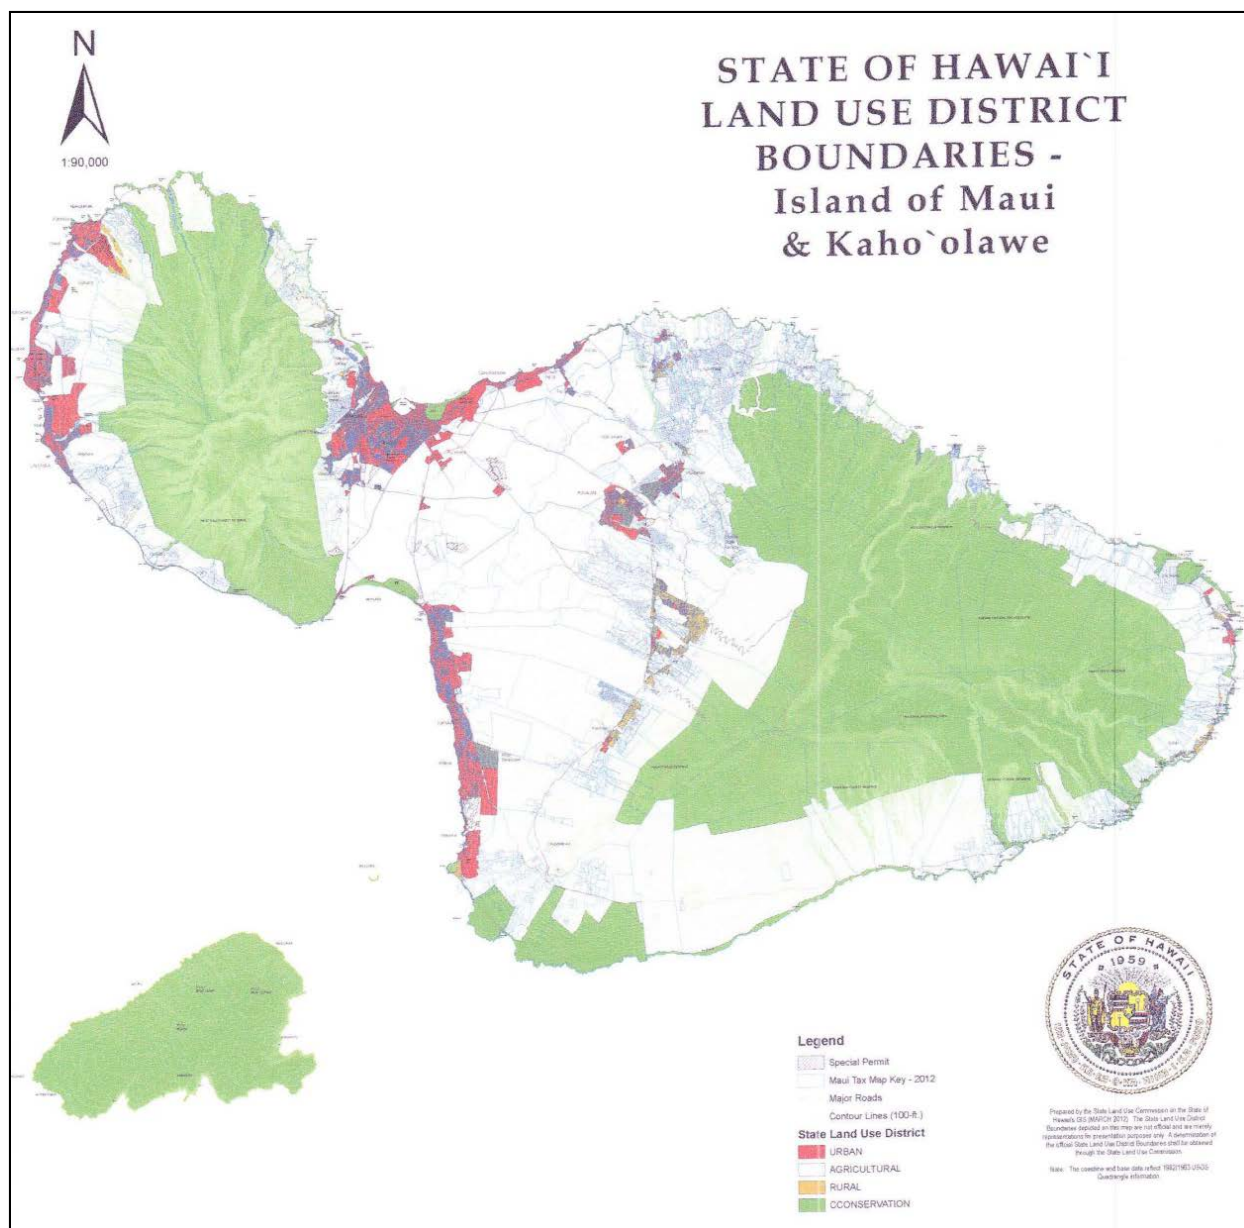

Figure 3-61. Statewide Land Use Designations on Maui ([LUC 2012](#))

The east two-thirds of the island are known as Upcountry Maui and East Maui. The Upcountry includes the small towns of Makawao, Hali‘imaile, Pukalani, and Kula, all of which are characterized by agriculture, ranching, and open space. Makawao has a long history of cattle ranching. East Maui represents a geographic area that comprises many small communities, natural areas, waterfalls, rugged coastline, and small-scale diversified agriculture. East Maui remains remote and generally accessible by the Hāna Highway.

The land use discussion in the *Maui Island Plan: General Plan 2030* focuses on agricultural, rural, and urban land. The State and County have enacted zoning laws to protect agricultural resources and promote agricultural activities. Agricultural land management is enhanced through a directed growth strategy that identifies areas appropriate for development, utilizing tools for agricultural protection such as zoning, transfer and purchase of development rights, and conservation subdivision design ([Maui 2012b](#)).

Chapter 8 of the *Maui Island Plan: General Plan 2030* focuses on directed growth plans. The chapter provides 20 directed growth maps.

3.5.2.6 Hawai'i

Hawai'i County covers the island of Hawai'i, also referred to as the Big Island. [Figure 3-62](#) shows the four Statewide land use designations for Hawai'i. Hawai'i's diversity includes tropical forests, mountains, active volcanoes, beaches, deeply eroded valleys, and expanses of grazing land ([County of Hawai'i 2005](#)).

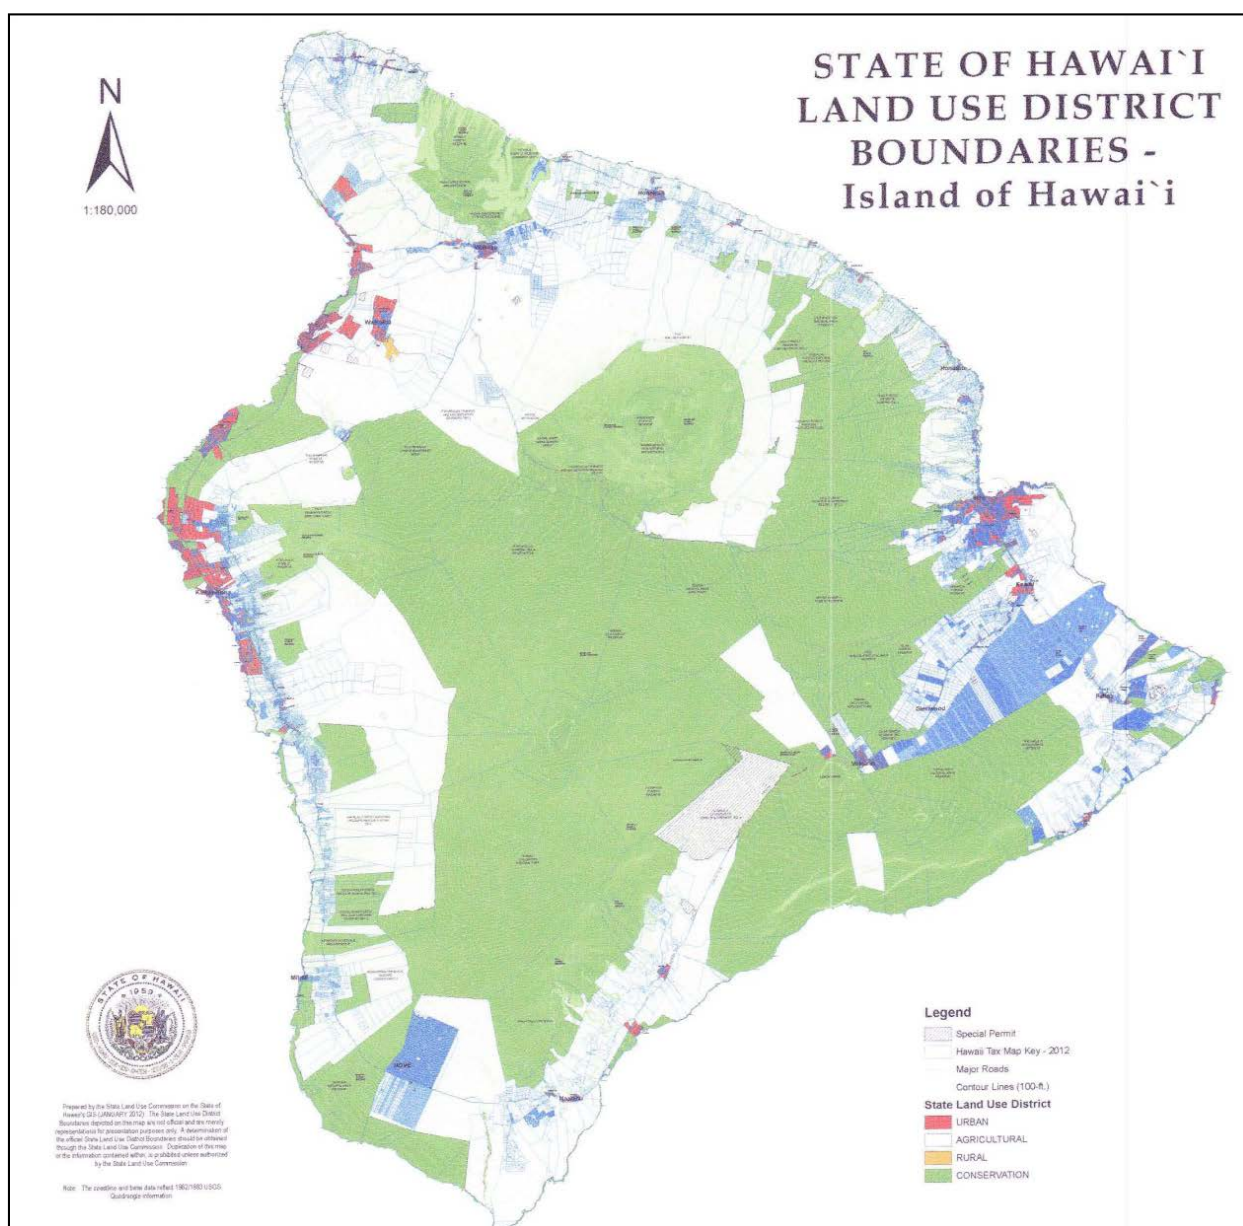

Figure 3-62. Statewide Land Use Designations on Hawai'i ([LUC 2012](#))

The following information is taken from the *County of Hawai'i General Plan* released February 2005 and as amended ([County of Hawai'i 2005](#)), unless otherwise noted. The plan covers the nine Hawai'i County-

wide development districts: Puna, South Hilo, North Hilo, Hāmākua, North Kohala, South Kohala, North Kona, South Kona, and Kau.

Almost 50 percent of the total land area in Hawai‘i is situated within the Agricultural District, including those with a high capacity or potential for agricultural use as well as those with low potential for productive activity. In addition to the agricultural land uses related to growing crops, agricultural land uses includes those related to packing, processing, and manufacturing the products. Although the latter uses have industrial characteristics, they are, nevertheless, agricultural in nature. With the demise of the sugar industry, thousands of acres of land have been removed from productive agricultural use and have either been converted to non-agricultural uses or lie fallow.

The State of Hawai‘i has set aside lands for agricultural activities to encourage continuation or initiation of agricultural operations. The State’s Agricultural Parks Program makes land available to small farmers at reasonable cost and with long-term tenure. There are four agricultural parks on the island, one each in the districts of Puna, South Hilo, Hāmākua, and North Kona.

Commercial activity in the county is characterized by the existence of the large urban centers in Hilo and around Kailua-Kona, several smaller centers and many rural neighborhood shopping centers are located in Honoka‘a, Kea‘au, Waimea, Kealahou, and Na‘alehu.

Trends reflect commercial development outside of Hilo’s older commercial core and a more decentralized pattern. The decentralization is reflective of the growing markets outside of the immediate environs of downtown Hilo and the general trend toward multi-centered urban areas. Similarly, commercial development within Kailua-Kona is extending north of its traditional commercial areas.

A portion of the county’s industrial activity, as noted above, is related to agriculture. These agricultural activities include processing coffee, macadamia nuts, meat products, tropical fruits, vegetables, and timber. There are endeavors in alternative energy and aquaculture activities at Keahole in the North Kona District and a geothermal-related development in the Puna District. Service-oriented industries, such as wholesaling, government facilities, printing, and bakeries are located close to population centers. The majority of such facilities are located within the South Hilo District.

Residential housing in Hawai‘i County traditionally has been single-family residential. In 1981, the State Legislature recognized the increasing cost of housing and the limitations of land for housing. Thus, the Ohana Dwelling provisions of Act 229, and the subsequent amendment to the Zoning Code allows the construction of a second dwelling on lots where one dwelling was already permitted.

The resort areas typically are designed with large proportions of multiple family residential units sold as occasional visitor units. This land use pattern has manifested itself in the North Kona and South Kohala resort areas.

Hawai‘i County’s primary resort centers are located along the coastal areas of Hilo in East Hawai‘i and North Kohala in West Hawai‘i. The North Kona and South Kohala districts are seeing the majority of proposed new resort development. Additional smaller-scale resorts may be developed in the mountains.

Open space on Hawai‘i island consists of lands zoned as “open” by the County of Hawai‘i as well as those the State Land Use Conservation District designates. The open zoning district permits golf courses, with a use permit, some recreational facilities, and various public and special areas (e.g., as restricted watershed areas and forest reserves). Potential natural hazard areas also are designated as open space. There currently is no County zoning district that calls for land to be preserved in a largely natural State.

State and Federal Government entities own the majority of the land on Hawai‘i island. Public lands include County, State, and Federal parks and beaches. The following is a breakdown of these public parks by district:

- Puna – Hawai‘i Volcanoes National Park and nine other County and State parks and beaches.
- South and North Hilo – 18 State and County parks and beaches, including the Liliuokalani Gardens and the Pana‘ewa Zoo.
- Hāmākua – Kalopa State Park, Waipio Beach, and the Waipio Valley Lookout.
- North and South Kohala – 16 State and County parks and beaches, including the Kaloko-Honokohau and the Puuhonua O Hōnaunau National Historic Parks.
- North and South Kona – 30 State and County parks and beaches, including access to five bays: Anaeho‘omalu, Heeia, Keauhou, Kīholo, and Kapua.
- Kau – 10 State and County parks and beaches, including part of Hawai‘i Volcanoes National Park.
- Other National Park Service units on the island include: the Pu‘ukoholā Heiau National Historic Park, and the Ala Kahakai National Historic Trail.

3.5.3 SUBMERGED LAND USE

This section discusses submerged land uses or ocean uses. The section starts with a discussion of general ocean bathymetry, or underwater topography. The sections that follow focus on submerged land uses including aquaculture, commercial fisheries, recreation and tourism, dump sites and munitions, dredged channels, undersea cables, and protected natural areas.

Submerged lands in Hawai‘i include all lands lying between the upper reaches of the waves on the shore and the seaward extent of the State’s jurisdictional limits ([Figure 3-63](#)).

The Office of Conservation and Coastal Lands (OCCL) and the Land Division of the Hawai‘i DLNR manage the publicly and privately zoned Conservation Districts of Hawai‘i, as well as the beaches and submerged lands of the State. The Land Division issues leases, easements, and rights-of-way for the use of submerged State lands. The OCCL serves several functions for the State, including the leasing of submerged lands, coastal zone permitting, and beach restoration. The OCCL reviews and administers Conservation District Use Applications necessary for leasing submerged lands ([TNC 2005](#)). [Section 3.7](#) of this PEIS provides an overview and background information on Coastal Zone Management.

3.5.3.1 Bathymetry

Bathymetry is the study of the underwater depths of water bodies. It is the underwater equivalent to topography. Bathymetric charts are typically produced to support safety of surface or sub-surface navigation and to show the relief or terrain and depths. [Figure 3-64](#) is a synthesis of a chart for the islands.

The University of Hawai‘i (School of Ocean and Earth Technology), USGS, and other scientific organizations have collaborated on numerous bathymetry studies related the Hawaiian Islands. Sources for more detailed island information can be found at <http://www.soest.hawaii.edu/hmrg/multibeam/>.

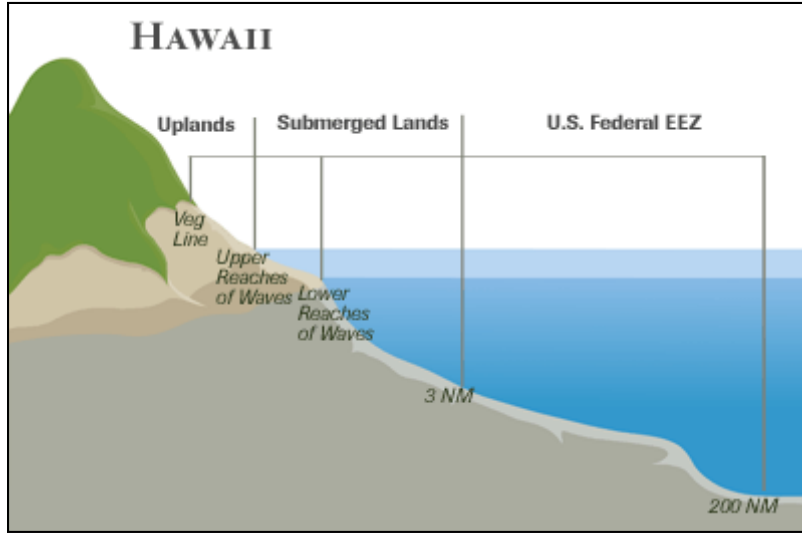

Figure 3-63. Submerged Land Designations in the State of Hawai'i

Figure 3-64. A General Bathymetry Depth Chart for the Main Hawaiian Islands

3.5.3.2 Aquaculture and Fisheries

Aquaculture is the controlled cultivation and harvest of aquatic plants and animals. Hawai‘i’s aquaculture industry consists of a Commercial Production Sector, which includes farming of a wide variety of species, and a Research Technology Transfer Sector, which provides technical assistance to the established and emerging aquaculture ventures in Hawai‘i.

Aquaculture operations produce both warm- and coldwater fish and shellfish, grown in fresh, brackish, and saltwater environments ([HDOA 2013a](#)). In 2011, Hawai‘i’s total aquaculture sales were about \$40 million. Algae sales accounted for about 63 percent of the total. Other products including ornamentals, finfish, shellfish, seed stock, broodstock, and fingerlings accounted for the remaining 37 percent ([HDOA 2013a](#)).

In 2010, the State had about 75 aquaculture operations; the latest information available by county (2008) indicated that the operations are located in Hawai‘i and Honolulu, Kaua‘i, and Maui counties ([NASS 2011](#)).

Open ocean fish farming, or offshore mariculture, is an emerging approach to raising fish in open ocean waters utilizing submersible cages or net pens. The locations chosen for open ocean aquaculture are in deeper and less sheltered waters, far from shore and sensitive ecosystems. Strong ocean currents sweep away feed residues and waste ([HDOA 2013b](#)).

The Hawai‘i Archipelago is 1,500 miles long with more than 740 miles of coastline. The [Hawai‘i Ocean Leasing Law](#) allows farm operations in the State’s warm, subtropical marine waters, within 3 miles of shore. Mariculture operations located in the offshore waters of Kona have successfully raised and harvested Hawaiian Kampachi sustainably.

Hawai‘i’s commercial marine fisheries are located in two geographical areas:

- The inhabited main Hawaiian Islands, with their surrounding reefs and offshore banks; the islands of Hawai‘i to Kaua‘i; and
- The mid-north Pacific Ocean, ranging from latitude 40 degrees north to the Equator, and from longitude, 145 degrees to 175 degrees east.

Commercial fishers are required to obtain commercial marine licenses and submit fishing reports to the Hawai‘i Division of Aquatic Resources. The *Commercial Marine Landings Summary Trend Report* (DLNR 2010) provides information on commercial fishing trends, pounds landed by species groups, fishing methods, and landings per port per island.

Information on commercial fishing, bottom fishing, and the location of artificial reefs can be found at https://dlnr.ehawaii.gov/cmls-fr/html/fishing_charts.html. The site also defines fishing restrictions. Impacts to commercial fishing from the renewable energy technologies and activities would be part of any project- or site-specific NEPA or HEPA review.

3.5.3.3 Recreation and Tourism

Hawai‘i hosted more than 9.5 million visitors during the 2011/12 timeframe. More than 80 percent of Hawai‘i’s visitors engage in recreation activities in the State’s coastal and marine areas, many of whom participate in scuba diving or snorkeling. Other popular marine recreation activities include ocean kayaking, parasailing, swimming, outrigger canoeing, and surfing. The Hawai‘i Division of Aquatic

Resources estimates that about 1,000 ocean recreation businesses operate on the major Hawaiian Islands ([HTA 2012](#)).

Coral reef areas are a focal point for much of this recreation use in terms of snorkeling and scuba diving, but these areas also are a natural resource that has social, cultural, environmental, and economic importance to the people of Hawai‘i. Studies have shown that most coral is below snorkeling depth. Scuba diving is not as common as snorkeling and is usually at sites with more resilient habitat ([HIMB 2014](#)). [Section 3.9](#) of this PEIS presents information on resorts and outdoor land- and water-based recreation activities in Hawai‘i. Interested parties may visit the Hawai‘i DLNR website that provides listings by island of State and County recreational sites, opportunities, and use restrictions, including a comprehensive list of beaches (<http://state.hi.us/dlnr/activities/>).

3.5.3.4 Former Dump Sites and Munitions

Sea disposal of excess, obsolete, unserviceable, and captured enemy munitions was an internationally accepted practice until prohibited by Congress with the *Marine Protection, Research, and Sanctuaries Act of 1972*. Prior to the 1970s, destruction alternatives generally were limited to burning, burial on land, or disposal at sea. In addition to disposal sites, a variety of munitions sites exist in the waters surrounding the islands. Some of these were former bombing targets such as those near Lāna‘i and Molokai. Military munitions inventory information and location maps for Hawai‘i can be found online at <http://www.denix.osd.mil/mmrp/MRSI/mmrp-results.cfm>.

The U.S. Armed Forces established specific procedures for munitions disposal beginning in 1917. These procedures, which defined depths and locations of disposal sites, became more stringent over time in an effort to reduce the possibility of recovery and accidental contact by the public. In 1944, the War Department required that chemical warfare material be disposed of in water at least 300 feet deep and 10 miles from shore ([Carton 2009](#)). By December 1945, the Department increased the disposal depth requirement to 6,000 feet for chemical warfare material and 3,000 feet for explosives and ammunition. The Department also required that disposal locations be published in a notice to mariners and on nautical charts ([DoD 2008](#)). Hawai‘i has four known locations of munitions dumps; all in the vicinity of O‘ahu. [Figure 3-65](#) shows the approximate locations around O‘ahu.

[DoD \(2008\)](#) provides tables for each of the known disposal sites and includes the type and quantity of the disposed munitions.

- Pacific O‘ahu HI-01 is approximately 10 miles from shore and at a depth greater than 1,500 feet. HI-01 contains bombs and projectiles with mustard gas, bombs with cyanogen chloride, and bombs with cyanide.
- O‘ahu HI-2 is approximately 10 miles from shore and at a depth greater than 1,500 feet. HI-2 has projectiles, shells, bombs, and stokes mortars containing mustard gas.
- O‘ahu HI-5 is more than 5 miles from shore and at a depth greater than 500 feet. The munitions include mustard gas in bombs and stokes mortars.
- O‘ahu HI-06 (O‘ahu Ordnance Reef) is about 1 mile from shore with a depth of 25 feet. The munitions include various calibers of cartridges, projectiles, naval gun ammunition, a mine, depth charge, a fragmentation bomb, and ammunitions boxes.

The Interisland Cable Ocean Floor Survey Reports ([DBEDT and SOEST 2010](#)) describe submerged munitions locations. Several similar reports are available from the Hawai‘i State Energy Office Website at <http://energy.hawaii.gov/resources/hawaii-state-energy-office-publications>.

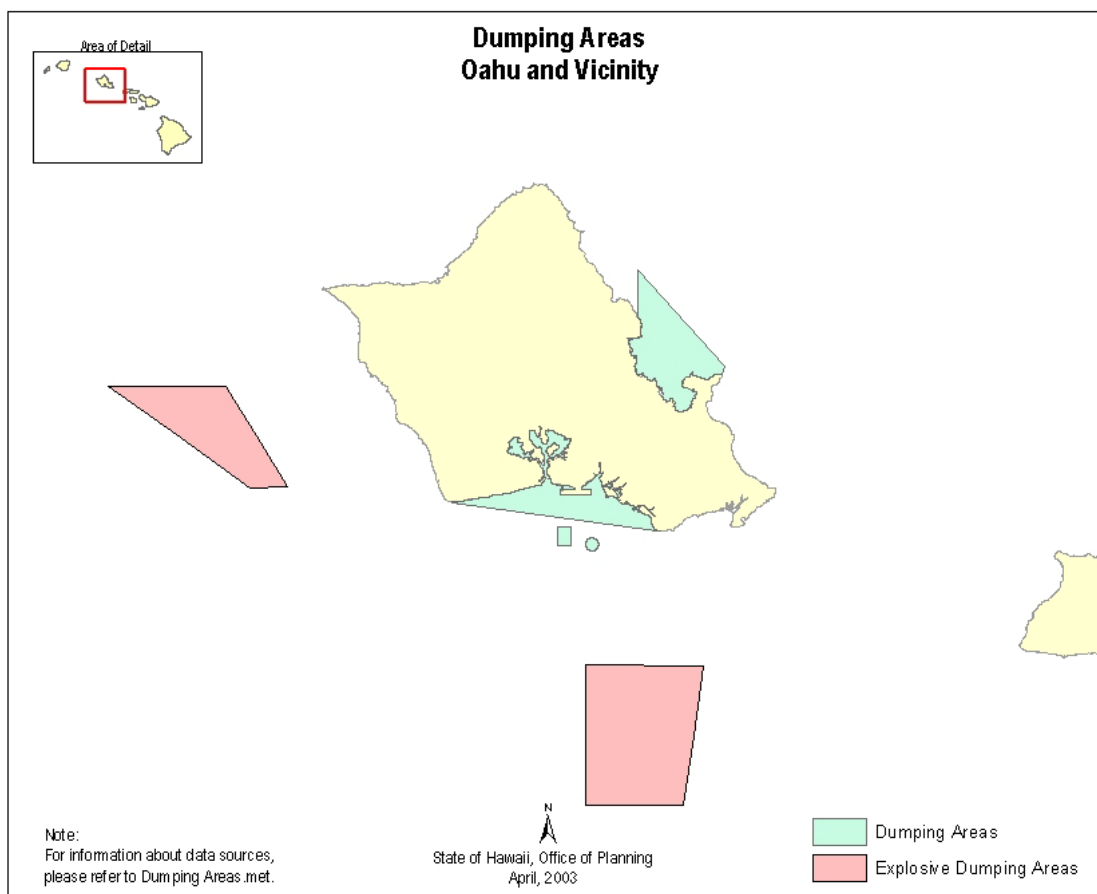

Figure 3-65. Known Munitions Dump Areas in the State of Hawai‘i

3.5.3.5 Dredged Channels

Dredging is an excavation activity or operation usually carried out at least partly underwater, in shallow seas, with the purpose of gathering bottom sediments and disposing them at a different location. This technique is often used to keep waterways navigable.

Removed sediment can be disposed of through a combination of onsite, upland disposal and offshore, open-ocean disposal, or used as beach nourishment. The volume of material removed varies based on the scope of the project and the characteristics of the sediment being removed. The EPA Region 9 (which includes the State of Hawai‘i) has designated five sites for ocean disposal of dredged material. Each site is managed according to a site management and monitoring plan. The offshore disposal areas around the Hawaiian Islands are ([Carton 2009](#)):

- South O‘ahu, off Honolulu
- Hilo, off Hawai‘i
- Kahului, off Maui
- Nawiliwill, off Kaua‘i
- Port Allen, Kaua‘i

The USACE shares a number of responsibilities with EPA regarding the ocean disposal of dredged material. The principle authority and responsibility for designating ocean sites for the disposal of dredged materials is vested with the EPA Regional Administrators (Hawai‘i Region 9). Accordingly, ocean dumping cannot occur unless a permit is issued by the USACE under the [Marine Protection Research and Sanctuaries Act](#), using EPA environmental criteria and subject to EPA concurrence (see <http://water.epa.gov/lawsregs/guidance/cwa/dredgdis>).

Numerous channel and harbor dredging projects have occurred within the islands over the decades. One of the more recent efforts is the Hawai‘i Kai Marina and Entrance Channel Maintenance Dredging, which issued an environmental assessment in January 2011. Other notable dredging projects include the Pearl Harbor Naval Base and projects on Mokauea Island, Lahaina, and South O‘ahu.

3.5.3.6 Undersea Cables

There are seven major transpacific submarine cable landings in Hawai‘i, distributed at five cable-landing stations as follows ([Submarine Cable Networks 2013](#)):

- Two telecommunications cable landing stations in Kawaihae on Hawai‘i island: the Spencer Beach Cable Landing Station for the Honotua cable system and the Samuel M. Spencer Beach Cable Landing Site for the Southern Cross cable system.
- Three telecommunications cable landing stations on O‘ahu: the Kahe Point Cable Landing Station for the Southern Cross; the Makaha Cable Landing Station for the Japan-U.S. Cable Network; the Keawaula Cable Landing Station for TPC-5 Cable Network, Telstra Endeavour (Australia-Hawai‘i Fiber Optic Cable System), Asia-America Gateway, and American Samoa Hawai‘i Cable.

Maps of the landing areas can be found at <http://submarinenetworks.com/stations/north-america/usa-Hawaii>. [Figure 3-66](#) shows existing telecommunications cables in red. The map also shows distances and depths.

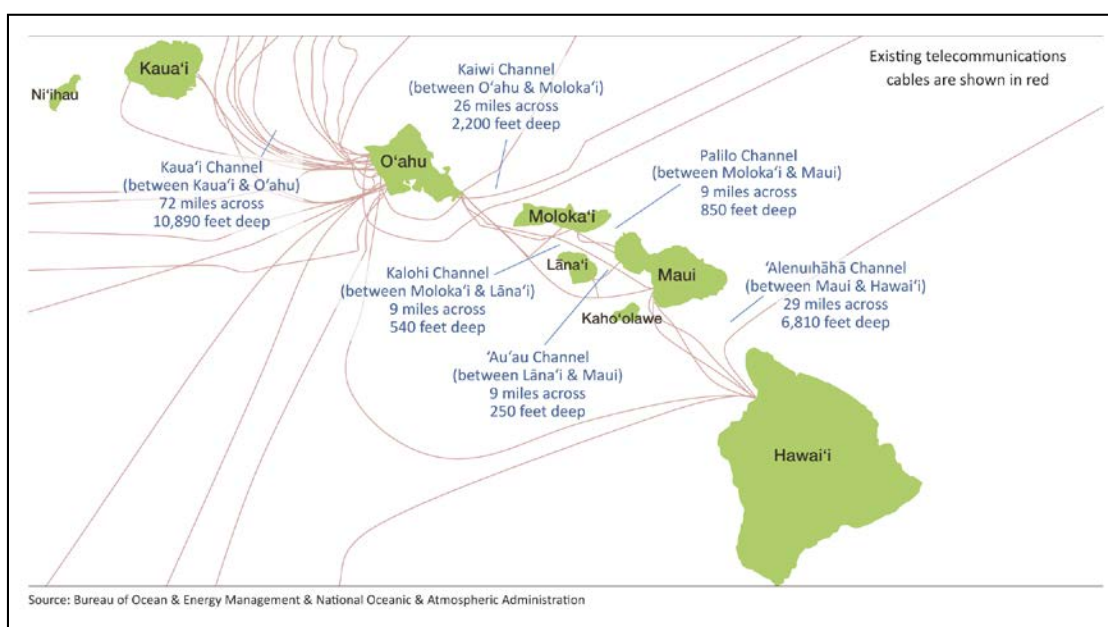

Figure 3-66. Telecommunications Cables in Hawai‘i

3.5.3.7 Protected Natural Areas

Marine Managed Areas are specific geographic areas designated by statute or administrative rule for the purpose of managing a variety of marine, estuarine, or *anchialine* resources and their uses. Anchialine resources are land-locked pools of water of varying salinity adjacent to the ocean (also known as tidal pools). These pools have indirect underground connections to the ocean and show tidal fluctuation water levels. Marine Protected Areas are a subset of Marine Managed Areas, and focus on protection, enhancement, and conservation of habitat and ecosystems ([Hawai‘i 2013b](#)). Some Marine Protected Areas have very few fishing restrictions and allow sustainable fishing, while others restrict all fishing and are “no take” areas ([NOAA 2013b](#)). In Hawai‘i, forms of Marine Protected Areas, such as Marine Life Conservation Districts, have been in use since 1967 ([Hawai‘i 2013c](#)). Protected areas can cover multiple purposes in addition to the direct marine environment, such as reef preservation and shoreline erosion.

Marine Life Conservation Districts are designed to conserve and replenish marine resources. Marine Life Conservation Districts allow only limited fishing and other consumptive uses, or prohibit such uses entirely. They provide fish and other aquatic life with a protected area in which to grow and reproduce. [Table 3-40](#) provides a summary of some of the key Marine Protected Areas in Hawai‘i.

There are more than 50 areas within the Hawaiian Islands that are designated Marine Managed Areas, Marine Life Conservation Districts, or Marine Protected Areas ([Figure 3-67](#)). A complete list is available at <http://marineprotectedareas.noaa.gov/dataanalysis/mpainventory/>. A mapping tool that provides visual representations of Marine Protected Area boundaries is available at <http://marineprotectedareas.noaa.gov/dataanalysis/mpainventory/mpaviewer/>. The areas established are consistent with Executive Order 13158, “Marine Protected Areas.”

Table 3-40. Size, Age, and Level of Protection for Key Marine Protected Areas in Hawai‘i (in order by acreage)

Island	Protected Area	Acreage	Year Established	Protection Level
Hawai‘i	Kealakekua	316	1969	Moderate
Lāna‘i	Manele	309	1976	Moderate
Hawai‘i	Old Kona Airport	217	1992	High
Maui	Molokini	210	1977	High
O‘ahu	Pupukea	178	1983	Low
Hawai‘i	Lapakahi	146	1979	High
O‘ahu	Hanauma Bay	101	1967	High
Hawai‘i	Waiopae	84	2000	High
O‘ahu	Waikīkī	77	1988	High
O‘ahu	Moku‘o‘Loe	74	1967	High
O‘ahu	Honolulu	44	1978	High
Hawai‘i	Waialea Bay	35	1985	Low

Source: [NOAA 2007](#).

Two additional unique areas warrant discussion. The first is the Hawaiian Islands Humpback Whale National Marine Sanctuary. Congress created the Sanctuary in 1992 to protect humpback whales. The sanctuary consists of five separate areas abutting six of the main islands and covers relatively shallow offshore areas. The second is the Papahānaumokuākea Marine National Monument. This area is situated in the northwestern portion of the Hawaiian Islands, located northwest of the island of Kaua‘i and the other main Hawaiian Islands. A vast, remote, and largely uninhabited marine region, the Monument encompasses an area of approximately 140,000 square miles ([Hawai‘i 2013a](#)). Because of its location, it would be unlikely that any of the potential activities or technologies would have any direct impact on this Marine National Monument.

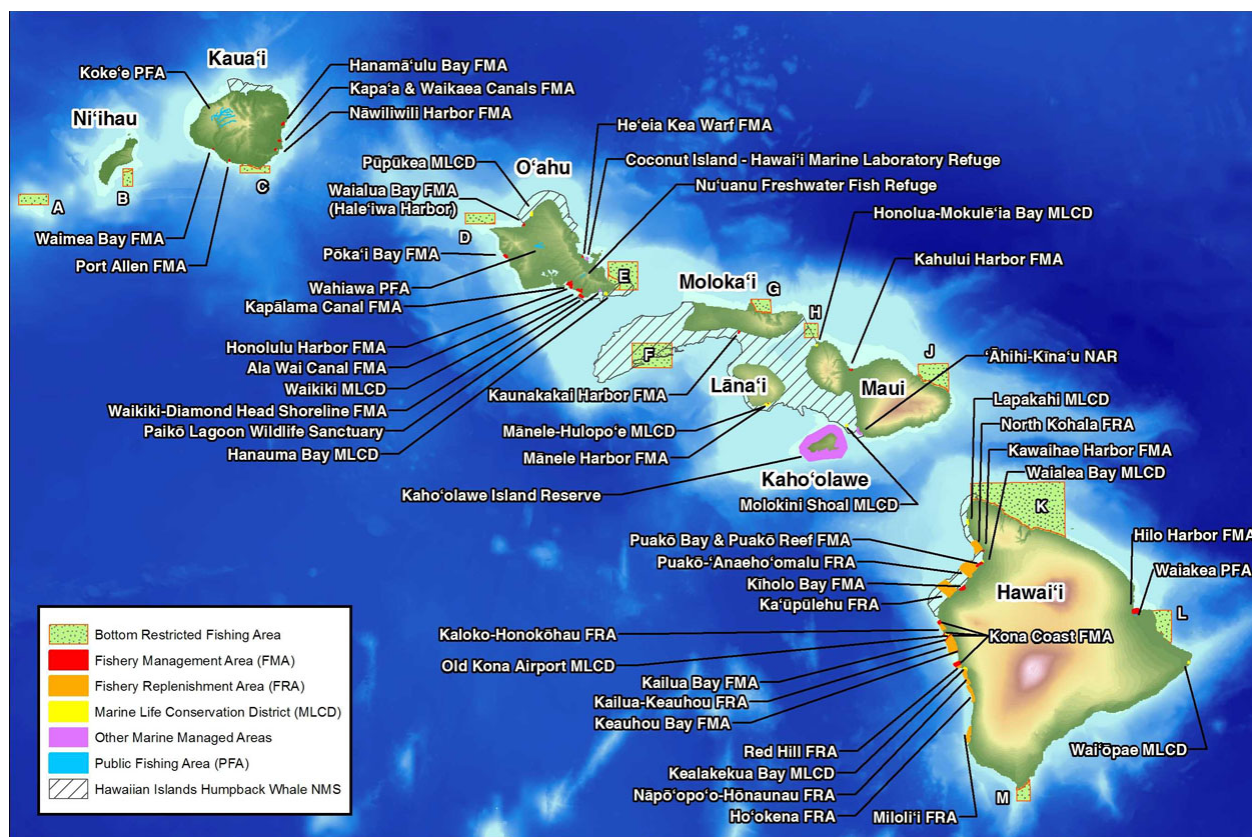

Figure 3-67. Restricted Areas Within the Hawaiian Islands

3.5.4 COMMON CONSTRUCTION AND OPERATION IMPACTS

3.5.4.1 Land Use

Typical impacts to land use from construction include ground disturbance (clearing, grading, and leveling of the construction site) and the temporary use of land required for construction laydown yards and storage and preparation areas. Construction and operation of access roads and utility corridors could also impact land use. Longer-term impacts from project operation could result in changes to land use and land ownership patterns, and could have potential compatibility issues with existing zoning and other local regulations if sited near coastal zones or other sensitive land use features.

3.5.4.2 Submerged Land Use

Construction of submerged projects in the marine environment would typically involve the installation of structures in the ocean including electrical and telecommunications cables; intake and discharge water pipelines; floating platforms with cable-tethered anchors; and submerged energy devices on the ocean floor. During construction, all of these structures could potentially cause temporary disruption of the marine environment including uses for commercial, recreational, and military purposes (both surface and subsurface). These impacts would be temporary and would be localized to the vicinity of the project.

Placement of projects in the marine environment could also have longer-term impacts. Submerged structures become potential obstacles to marine life and can influence the location and operation of future submerged and surface facilities. Any future actions would require investigation before locations were chosen to avoid conflicts with the existing structures.

3.5.5 COMMON BEST MANAGEMENT PRACTICES

3.5.5.1 Land Use

The following are BMPs related to land use construction and operation regardless of location:

- Maximize the use of previously disturbed lands;
- Avoid land requiring deforestation/descrubbing and/or significant slope leveling or grading;
- Avoid siting projects on prime or unique farmland;
- Avoid impacts on special use lands such as National Park Service lands, Wilderness Areas, National Wildlife Refuge System Lands, Wildlife Management Areas, National and Scenic Trails, traditional cultural properties and other culturally sensitive sites, critical habitat for special status species, and military operations areas and other regulated military lands;
- Consult with county agencies regarding potential impacts of developing within, adjacent to, or close to State or county special use areas such as parks;
- Use technologies and facility layouts and designs that would minimize land disturbance at a site;
- Avoid or minimize the use of lands that could adversely affect high-use land and ocean recreational areas used for surfing, paddling, fishing, hiking, and camping;
- Ensure lands considered are appropriately zoned for project development (e.g., industrial or energy development uses);
- Avoid land identified as incompatible for renewable energy development by county governments; and
- Consult with the FAA and/or appropriate DoD organization if project is close to airports or military lands.

In addition to the first BMP (maximize the use of previously disturbed lands), future renewable energy projects should also consider the use of degraded lands. EPA has implemented “RE-Powering America’s Land,” an initiative to encourage renewable energy development on current and formerly contaminated lands, landfills, and mine sites when the development is aligned with the community’s vision for the site. This initiative identifies the renewable energy potential of these degraded lands and provides other useful resources for anyone (e.g., communities, developers, industry, State and county governments) interested in reusing these sites for renewable energy development. More information on this initiative can be found at <http://www.epa.gov/oswercpa/>.

The State of Hawai‘i has several programs that focus on cleanup and redevelopment of brownfield sites (i.e., land with low-risk hazardous and petroleum contamination), including use for clean energy projects. The 1-MW solar photovoltaic power plant at the 12-acre Kapolei Sustainable Energy Park, a former industrial disposal site, is an example of redeveloping previously disturbed and contaminated sites for clean energy (<http://www.heco.com/heco/hidden/Hidden/CorpComm/Former-disposal-site-will-provide-clean-renewable-energy-for-Hawaii>). The HDOH Hazard Evaluation and Emergency Response Office, in collaboration with EPA Region 9, developed a brownfield inventory to promote brownfield redevelopment (see <http://eha-web.doh.hawaii.gov/eha-cma/Leaders/HEER/brownfields-redevelopment->

[program](#)). The inventory is accessible through an online geographic information system tool that shows location and site information of State- and Federally owned brownfield sites along with information on solar radiation and wind resources (see <http://arcg.is/1DZxPrE>). The HDOH is making an effort to include additional private brownfield sites from owners interested in having their sites assessed and cleaned up. The Hawai'i Office of Planning administers a Federally funded loan fund (Hawai'i Brownfields Cleanup Revolving Loan Fund) to assist public and private entities with cleanup that would make these sites available for redevelopment. The EPA also offers competitive and non-competitive grant assistance for brownfields assessment, cleanup, and revolving loans (see http://www.epa.gov/brownfields/grant_info/index.htm).

3.5.5.2 Submerged Land Use

The following are BMPs related to submerged land use for construction and operation:

- If required, obtain the necessary rights-of-way or easements and approvals for construction near and around existing subsurface utilities;
- Consider the location of protected and sensitive ocean habitats;
- Address ancillary onshore facilities in terms of local zoning and coastal zone management guidelines;
- Identify local fishing grounds and the areas of munitions dumps;
- Avoid or take necessary precautions when siting a project in the vicinity of submerged electrical and telecommunications cables and shore tie-ins; and
- Use bathymetric analyses to help determine the shortest distance to the desired depth; to avoid interfering with sensitive habitats, including coral reefs; to recognize the locations of existing undersea cables, dumps, and other structures; and to avoid or minimize impacts to fishing and recreation areas.

3.6 Cultural and Historic Resources

Hawaiian cultural and historic resources are rooted in an ancient and intricate culture first established by seafaring Polynesians branching out from the Marquesas Islands and central Polynesia hundreds of miles to the south of Hawai'i between 500 B.C. and A.D. 300. Native Hawaiians flourished on the islands 1,500 years before Western contact. They developed a complex society with a hierarchy of chiefs, an elaborate religion that gave the chiefs ultimate authority, and a system of irrigated agricultural fields and constructed fishponds that supported the dense population ([Langlas 1998](#)). Hawaiian cultural and natural resource management practices form the basis for why these valued resources are so important today, particularly to Native Hawaiians. As development continues to expand in Hawai'i, resolve to protect the remaining cultural and historic resources has strengthened. Developers must keep in mind all the renewable energy resources—sun, wind, land, volcanic materials, ocean, and streams—have major cultural significance to Native Hawaiian practitioners and their use must be treated with respect.

In addition to Native Hawaiian culture, Hawai'i has many generations of people with other ethnic backgrounds whose culture includes representative historic resources. Other significant historic resources that played a major role in the history of the United States include the pre-World War II military establishment and the preserved remains of resources following the attack on Pearl Harbor in 1941. A large majority of Hawai'i's existing built environment was constructed after 1947, which is significant as

symbols of education and empowerment. These symbols are evident post-World War II and include the shift from the turn of the century plantations and agrarian activities to more participation in business and politics ([DLNR 2012](#)).

During scoping meetings in September 2012 on Kaua‘i, O‘ahu, Molokai, Lāna‘i, Maui, and Hawai‘i, members of the public, including Native Hawaiians, provided unique cultural perspectives through oral and written comments and site-specific reports. These materials helped frame portions of the traditional cultural beliefs and practices discussions below. Residents of Molokai and Lāna‘i, for example, provided ethnographic references, videos, and archaeological reports addressing cultural locations and perspectives on those islands.

The affected environment for cultural and historic resources is presented in four areas: (1) regulatory setting, (2) traditional cultural beliefs and practices, (3) archaeological sites, and (4) historic buildings and sites. As applicable, discussions of resources in Hawai‘i start with a State overview then move to the individual islands.

3.6.1 REGULATORY SETTING

This section summarizes major, applicable Federal and State laws, regulations, and guidance that relate to the protection and preservation of cultural and historic resources and practices in Hawai‘i.

3.6.1.1 Federal Requirements

The major Federal requirements for addressing, evaluating, and developing mitigation measures for the protection of cultural and historic resources are identified below.

3.6.1.1.1 National Environmental Policy Act

The *National Environmental Policy Act* ([42 U.S.C. § 4321 et seq.](#); NEPA) is a Federal law that requires all Federal agencies to consider the potential environmental impacts of their proposed actions. To implement NEPA, all Federal agencies follow procedures issued by CEQ. CEQ’s implementing regulations for NEPA require that EISs, including PEISs, discuss the environmental consequences to historic and cultural resources [[40 CFR 1502.16\(g\)](#)].

3.6.1.1.2 National Historic Preservation Act: the Section 106 Process and the National Register of Historic Places

Federal agencies must also comply with the *National Historic Preservation Act* ([54 U.S.C. § 300101 et seq.](#); NHPA). Congress passed the NHPA in 1966 to develop a Federal historic preservation program in response to widespread public concern about the loss of historic properties due to the implementation of Federal programs such as the urban renewal program, the Interstate highway program, and the USACE Civil Works program. A key provision of the NHPA is Section 106, which requires Federal agencies to take into account the effects of their undertakings on historic properties and afford the Advisory Council on Historic Properties (ACHP) a reasonable opportunity to comment. This has evolved into a consultative process involving diverse stakeholders as well as the Federal agency. Agencies must consider effects on historic properties, defined in the NHPA as districts, sites, buildings, structures, and objects included in, or eligible for inclusion in, the *National Register of Historic Places* (National Register or NRHP), which is maintained by the Secretary of the Interior ([ACHP 2014](#)).

The ACHP has promulgated implementing regulations for Section 106, which can be found at [36 CFR Part 800](#). Federal agencies take into account the effects of any project carried out by them or that receives

Federal financial assistance, permits, or approvals by following the steps set forth in these regulations for identifying, evaluating, and resolving potential adverse effects to historic properties within the area of potential effects for the undertaking. As part of this process, Federal agencies consult with the relevant State Historic Preservation Officer (SHPO), a State official tasked with advising and assisting Federal agencies in carrying out their Section 106 responsibilities [54 U.S.C. § 306108; 36 CFR 800.2(c)(1)(i)]. The SHPO for Hawai‘i is the DLNR Historic Preservation Division (see <http://dlnr.hawaii.gov/shpd/>). Other possible consulting parties in the Section 106 process include Native Hawaiian Organizations (NHOs); representatives of county governments; applicants for Federal assistance or for a Federal permit, license or other approval; and individuals and organizations with a demonstrated interest in the undertaking [36 CFR 800.2(c)]. Federal agencies must also engage with the public during the process [36 CFR 800.2(d)].

The Section 106 process is concerned with potential adverse effects to historic properties, which are a subset of the historic and cultural resources that an EIS must discuss (see discussion above). Historic properties are “any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in, the *National Register of Historic Places* maintained by the Secretary of the Interior” and include “artifacts, records, and remains that are related to and located within such properties” and “properties of traditional religious and cultural importance to an Indian tribe or [NHO] and that meet the National Register criteria” [36 CFR 800.16(1)(1)]. The National Register is a list composed of districts, sites, buildings, structures, and objects significant in American history, architecture, archaeology, engineering, and culture [54 U.S.C. § 302101–302108].

To be considered eligible for the National Register, properties must meet the criteria for evaluation found at 36 CFR 60.4. Properties that may meet these criteria include, but are not limited to, pre-contact and historic era archaeological sites and features, ethnographic resources (including traditional cultural properties), historic sites, structures of various kinds and ages, and, within the National Park System, cultural landscapes. Traditional cultural properties are “eligible for inclusion in the National Register because of [their] association with cultural practices or beliefs of a living community that (a) are rooted in that community's history, and (b) are important in maintaining the continuing cultural identity of the community” (NPS 1998). Paraphrased, the criteria for evaluation include association with significant historical events; association with significant people in the culture’s past; embodiment of distinctive characteristics of a type, period, or method of construction; embodiment of the work of a master, or one that possesses high artistic value; and potential to yield information important to the culture’s history. Generally, properties that achieved significance within the past 50 years are excluded unless they are of exceptional importance. Like NEPA for historic and cultural resources, the Section 106 process does not require the preservation of historic properties, only that effects to these properties are taken into account.

CEQ regulations encourage integration of the NEPA process with other planning and environmental reviews, such as Section 106 of NHPA [40 CFR 1502.25(a)]. ACHP also encourages integration of NEPA and NHPA in its regulations (36 CFR 800.8). In fact, in 2013, CEQ and ACHP jointly issued a handbook that provides important and practical guidance on integration (CEQ and ACHP 2013). Federal agencies may choose to coordinate their NEPA and NHPA reviews, or they may choose a substitution framework, in which NEPA process and documentation are used to comply with Section 106.

Section 106 of the NHPA and the Section 106 regulations specifically include NHOs. For the purposes of Section 106, NHOs are “any organization which serves and represents the interests of Native Hawaiians; has as a primary and stated purpose the provision of services to Native Hawaiians; and has demonstrated expertise in aspects of historic preservation that are significant to Native Hawaiians” [36 CFR 800.16(s)(1)]. A Native Hawaiian is “any individual who is a descendant of the aboriginal people who, prior to 1778, occupied and exercised sovereignty in the area that now constitutes the State of Hawai‘i” [36 CFR 800.16(s)(2)].

Additionally, ACHP's Policy Statement on the ACHP's interaction with NHOs contains the commitments and principles that ACHP will implement when interacting with NHOs on matters relating to NHPA ([ACHP 2008](#)). The ACHP has also released a handbook on consultation with NHOs during the Section 106 process ([ACHP 2011](#)).

3.6.1.1.3 Archaeological Resources Protection Act

The *Archaeological Resources Protection Act* (ARPA) of 1979, as amended (Public Law 96-95; [16 U.S.C. §§ 470aa-470mm](#)) focuses "on the regulation of legitimate archeological investigation on public lands and the enforcement of penalties against those who loot or vandalize archeological resources" ([NPS 2014a](#)). ARPA applies only to archaeological sites on Federal and tribal lands. The Act specifically:

- Establishes professional standards for excavations;
- Governs the excavation or removal of archaeological resources on Federal and tribal lands;
- Describes prohibited actions, including trafficking, that affect archaeological resources, in addition to their unpermitted excavation and removal;
- Protects the confidentiality of archaeological resource locations on Federal and native lands
- Requires Federal land managers to "...establish a program to increase public awareness of the significance of the archaeological resources located on public and Indian lands and the need to protect such resources."
- Requires the major land managing departments of the Federal government to schedule and conduct archaeological surveys of the lands under their control to enable better protection of archaeological resources.
- Establishes both civil and criminal penalties for the destruction or alteration of archeological resources.

3.6.1.1.4 Antiquities Act

The *Antiquities Act of 1906* [[54 U.S.C. § 320301\(a\)-\(c\)](#)] makes it illegal to excavate or remove certain archaeological resources from Federal land without permission. The law establishes a permitting process for conducting archaeological fieldwork on Federal lands. It also allows the President of the United States to establish historical monuments and landmarks with the aim of protecting these sites from excavation or destruction of the antiquities they hold.

3.6.1.1.5 American Indian Religious Freedom Act

Federal agencies are also required to consider the effects of their actions on sites, areas, and other resources that are of religious significance to Native Americans, including Native Hawaiians. This requirement is established under the *American Indian Religious Freedom Act* (AIRFA) of 1978 ([Public Law 95-341, 92 Stat. 469](#)). AIRFA protects the rights of Native Hawaiians to have access to their sacred places, to worship through ceremonial and traditional rights, and to use and possess all objects considered sacred. It requires consultation with NHOs if an agency action will affect a sacred site on Federal lands.

3.6.1.1.6 Native American Graves Protection and Repatriation Act

The *Native American Graves Protection and Repatriation Act* (NAGPRA) of 1990 ([25 U.S.C. § 3001](#), [Public Law 101-601](#)) requires Federal agencies to consult with the appropriate Native American tribes, including NHOs like OHA, prior to the excavation of human remains and funerary objects on Federal and tribal lands. The law also extends to cultural items such as sacred objects and objects of cultural patrimony. It requires the repatriation of human remains found on Federal and tribal lands and in museums receiving Federal funds, and establishes a program of Federal grants to assist in the repatriation process. NAGPRA is considered one of the strongest pieces of Federal legislation pertaining to native peoples' remains and artifacts.

3.6.1.1.7 Abandoned Shipwreck Act

To discourage treasure hunters and others from damaging and looting abandoned shipwrecks, the *Abandoned Shipwreck Act of 1987* ([43 U.S.C. § 2101](#)) was passed. The law specifies that any wreck embedded within a state's submerged lands is the property of that state and subject to its laws and jurisdictions provided the shipwreck is determined to be abandoned. "The U.S. Government continues to hold title to shipwrecks to sunken U.S. warships ... no matter where the vessels are located" ([NPS 2014b](#)).

3.6.1.2 State Requirements

The State of Hawai'i recognizes that potential areas identified for renewable energy development projects are living cultural resources to the Native Hawaiian community and that there is an obligation to preserve and protect historic property and associated constitutionally guaranteed rights to use of the land and waters of the State. Historic property means any building, structure, object, district, area, or site, including heiau (temple) and underwater site over fifty years old. The State Historic Preservation Division (SHPD) under the DLNR is responsible for administering programs of the NHPA and other State mandates related to historic property and preservation ([DLNR 2012](#)). More specifically, the SHPD is responsible for programs related to archaeology, history and culture, and architecture. The SHPD is the official keeper of the [Hawai'i Register of Historic Places](#) (HRHP). The list formally recognizes districts, sites, structures, buildings and objects and their significance in Hawai'i's history, architecture, archaeology, engineering and culture. Hawai'i Administrative Rules and Revised Statutes identify the legal requirements for historic preservation in the State.

3.6.1.2.1 Hawai'i Administrative Rules (HAR)

Administrative rules pertaining to historic preservation consist of the following:

- [Chapter 197](#): Hawai'i Historic Places Review Board
- [Chapter 198](#): Hawai'i and National Register of Historic Places Programs
- [Chapter 275](#): Rules Governing Procedures for Historic Preservation Review for Governmental Projects Covered Under Sections 6E-7 and 6E-8, HRS
- [Chapter 276](#): Rules Governing Standards for Archaeological Inventory Surveys and Reports
- [Chapter 277](#): Rules Governing Requirements for Archaeological Site Preservation and Development
- [Chapter 278](#): Rules Governing Standards for Archaeological Data Recovery Studies and Reports
- [Chapter 279](#): Rules Governing Standards for Archaeological Monitoring Studies and Reports
- [Chapter 280](#): Rules Governing General Procedures for Inadvertent Discoveries of Historic Properties during a Project Covered by the Historic Preservation Review Process
- [Chapter 281](#): Rules Governing Professional Qualifications
- [Chapter 282](#): Rules Governing Permits for Archaeological Work
- [Chapter 283](#): Rules Governing Standards for Osteological Analysis of Human Skeletal Remains
- [Chapter 284](#): Rules Governing Procedures for Historic Preservation Review to Comment on Chapter 6E-42, HRS, Projects
- [Chapter 300](#): Rules of Practice and Procedure Relating to Burial Sites and Human Remains

3.6.1.2.2 Hawai'i Revised Statutes (HRS)

The main HRS associated with cultural and historic resource protection is referred to as [Chapter 6E](#) (as administered through [HAR Title 13](#)), the Historic Preservation Program, which provides for “the research, protection, restoration, rehabilitation, and interpretation of buildings, structures, objects, districts, areas, and sites, including underwater sites and burial sites, significant to the history, architecture, or culture of the State, its communities, or the nation.” Chapter 6E consists of four main parts; historic preservation program, monuments and memorials, Pacific war memorial system, and a miscellaneous category. Protection and preservation of cultural and historic resources on Federal and State lands is covered by applicable administrative rules and statutes. However [HRS 6E-10](#), “Privately Owned Historic Property,” also mandates the review and protection of historic property on or eligible for the HRHP that is on private property prior to construction, alteration, disposition or improvement of any nature.

3.6.1.2.3 Act 50: Hawai'i Session Laws of 2000

The Hawai'i State Constitution, other State laws, and the courts of the State require government agencies to protect and preserve cultural beliefs, practices, and resources of Native Hawaiians and other ethnic groups. To assist decisionmakers in the protection of cultural resources, [HRS 343](#), and [HAR 11-200](#) require project proponents to assess proposed actions for their potential impacts to cultural properties, practices, and beliefs. This process was clarified by the Hawai'i State Legislature in [Act 50](#), Hawai'i Session Laws 2000. Act 50 recognizes the importance of protecting Hawaiian cultural resources and specifically requires that EISs include the disclosure of the effects of a proposed action on the cultural practices of the community, and in particular the Hawaiian community, through preparation of cultural impact assessments. Cultural impact assessments should include information relating to practices and beliefs of a particular cultural or ethnic group or groups, which may be obtained through public scoping, community meetings, ethnographic interviews, literary review, and oral histories.

3.6.1.2.4 Act 85: Hawai‘i State Legislature (2013)

In August 2012, in response to a project proponent’s attempt to conduct archaeological review in phases of the project as it was developed, the Hawai‘i Supreme Court interpreted (and ruled) in *Kaleikini v. Yoshioka*, that compliance with the State’s historic preservation law requires that an archaeological survey must be completed for the entire project rather than in phases. In response to this ruling, the State Legislature passed Act 85 in 2013 to allow DLNR to approve a phased review of a project where: (1) the proposed project consists of large corridors or large land areas, (2) access to properties is restricted, or (3) circumstances dictate that construction be done in stages.

Act 85 requires a programmatic agreement between DLNR and the project applicant that identifies each phase and the estimated timelines for each phase. Persons dissatisfied with DLNR’s decision may appeal to the Hawai‘i Historic Places Review Board, and then to the Governor if they are dissatisfied with the Review Board’s decision. Public notice must also be provided by DLNR.

3.6.1.2.5 Hawai‘i Supreme Court Decision

The Hawai‘i Supreme Court in its decision in *Ka Paakai O Ka ‘Āina v. Land Use Commission*, [94 Hawai‘i 31, 7 P.3d 1068 \(2000\)](#) provides government agencies an analytical framework to ensure the protection and preservation of traditional and customary Native Hawaiian rights by preserving valued cultural, historical, and natural resources while reasonably accommodating competing private development interests.

The State and its agencies have an affirmative obligation to preserve and protect the reasonable exercise of customarily and traditionally exercised rights of Native Hawaiians to the extent feasible. The Court has described the analytical framework to fulfill this obligation by identifying the scope of valued cultural, historical, or natural resources in proposed project areas, including the extent to which traditional and customary Native Hawaiian rights are exercised in the area; to ascertain the extent to which those resources—including traditional and customary Native Hawaiian rights—will be affected or impaired by a proposed project; and to propose feasible action, if any, that should be taken to reasonably protect Native Hawaiian rights if they are found to exist.

3.6.1.2.6 Hawai‘i State Historic Preservation Plan

The purpose of the *Hawai‘i State Historic Preservation Plan* ([DLNR 2012](#)) is to guide efforts to preserve and protect the valuable historic properties and cultural sites located in the State of Hawai‘i. The plan establishes goals and objectives that the community has determined to be important for historic preservation. The statewide plan is required by NHPA [Section 101 (b)(3)(c)] for every state that participates in Federal historic preservation programs and receives funds from the Federal Historic Preservation Fund. The plan informs the State and county planning processes and is incorporated into their planning documents so that the preservation of cultural and historic resources becomes a part of the fabric of planning and doing business in the State of Hawai‘i. The plan also informs members of the community, including developers and contractors, as well as individuals, on the direction and implementation steps planned for historic preservation in five-year increments ([DLNR 2012](#)).

3.6.1.3 Native Hawaiian Consultation

Both Federal and State law require consultation with NHOs in certain situations. The U.S. Department of the Interior (DOI), through the Office of Native Hawaiian Relations, maintains an NHO notification list for purposes of identifying NHOs for project consultations, their jurisdictional locations within the Hawaiian Islands, and their scope of interest ([DOI 2013](#)). There are 72 NHOs on the list, 30 represent

interests associated with all of the islands, 30 on O‘ahu, 4 on Molokai, one on Lāna‘i, 10 on Maui, and 9 on the Big Island. There are no specific NHOs identified solely for the island of Kaua‘i. Except for the 30 NHOs that have interests associated with all of the islands, a few of the NHOs identified for each of the islands have interests on more than one island.

With respect to Hawaiian burials, it is vital to note that ohana members (lineal and/or cultural descendants) play major roles with the disposition of burial sites and human remains, and they must be engaged in consultation along with the SHPD and appropriate Burial Councils (<http://www6.hawaii.gov/dlnr/hpd/councils.htm>). Failure to undertake measures to avoid or mitigate impacts commonly results in protracted litigation and other kinds of problems.

Native Hawaiians have a saying: “‘A‘ole pau ka ‘ike i ka halau ho‘okahi” (Not all knowledge is learned in one school.) One source’s opinion may not be the only salient consideration; broader consultation with kama‘aina and cultural practitioners can yield more results when establishing significance criteria for resources. “Nana ‘ike Kumu” (Look to the source) is another Hawaiian saying that confirms that input from Hawaiian kupuna (elders) is always regarded highly, so their wisdom and knowledge should be sought during the consultation process. A helpful resource is the Aloha ‘Āina Guidance Document published by NOAA’s Hawaiian Islands Humpback Whale National Marine Sanctuary, which discusses the incorporation of Native Hawaiian resource management practices and traditions (http://hawaiihumpbackwhale.noaa.gov/council/council_aloha_aina_guidance.html).

3.6.2 TRADITIONAL CULTURAL BELIEFS AND PRACTICES

The importance of traditional cultural properties is evident in the strong cultural attachment Native Hawaiians maintain with their natural, physical, and spiritual surroundings. The values and beliefs associated with these places have been passed on through the generations and continue to root Native Hawaiians to their land and family. Native Hawaiians regard the environment as an integral component of their cultural heritage. The quality and abundance of natural resources within a Native Hawaiian community can be attributed to the persistence of ohana (family) values and practices in the conduct of subsistence activities still practiced by some individuals on the islands, especially Molokai and Lāna‘i. Davianna Pomaikai McGregor describes the significance of these values and their foundation in resource management:

“An inherent aspect of these ohana values is the practice of conservation to ensure availability of natural resources for present and future generations. These rules of behavior are tied to cultural beliefs and values regarding respect of the aina, the virtue of sharing and not taking too much, and holistic perspective of organisms and ecosystems that emphasizes balance and coexistence. The Hawaiian outlook that shapes these customs and practices is lokahi or maintaining spiritual, cultural and natural balance with the elemental life forces of nature” ([McGregor et al. 1996](#)).

These values along with ancestral knowledge about the land and its resources are currently reinforced through continued subsistence practices. Today’s practitioners stay alert to the condition of the landscape and its resources. They pay attention to both seasonal and life cycle changes in these resources and rely on these observations to preserve the natural and *cultural landscape* of their area. Unlike Western practice, the land is not a commodity to Hawaiians. Instead, it is the foundation of their identity, both spiritually and culturally, as evidenced by how closely linked their values are to the land and its resources ([DBEDT 2012a](#)). “They proudly trace their lineage to the lands in their region as being originally settled by their ancestors. The land is a part of their ohana and they care for it as they do the other living members of their families” ([McGregor et al. 1996](#)). Identifying and consulting with subsistence-living individuals and communities that could be affected by proposed renewable energy projects would provide

valuable information for future impact evaluations. The Aha Moku Councils on each island provide site-specific and resource-based methodologies for conducting community consultation processes using Native Hawaiian generational knowledge to address the health and welfare of environmental resources including how those resources relate to subsistence-living practices; detailed information can be found at <http://www.ahamoku.org/index.php/aha-moku/>.

The holistic view of the environment by Native Hawaiians relies on the interdependence of the natural resources including land, air, fresh water, ocean, plants, and animals. Native Hawaiians regard the natural elements in a balanced and harmonious manner with changes to one element effecting change in the others. Ancestral knowledge of the land was recorded and passed down through place names, legends, and chants associated with a particular district. Native Hawaiians recognize a vast polytheist hierarchy similar to the ancient Greeks. Within this hierarchy, one of the most famous is Pele, the volcano goddess. When one speaks of Pele in contemporary Hawai'i, her name is oftentimes spoken with reverence. Pele's home is in and around the active volcano, Kīlauea in Hawai'i Volcanoes National Park on the Big Island (['Iolana 2013](#)). The myth coincides with modern geological theories of shifting tectonic plates in the earth's crust, erupting lava, and geothermal venting. Native Hawaiian stewardship and use of cultural and natural resources are centered on the practices of malama aina (respect and conservation) and lokahi (harmony and balance). These practices were important principles for Native Hawaiians that ensured the sustainability of their resources. These principles were tied to the virtue of taking only what was needed and complemented the holistic perspective of organisms and ecosystems that allowed Native Hawaiians to live in balance with their environment ([DBEDT 2012a](#)).

Many historic and present-day Native Hawaiian cultural practices are important components of Hawaiian cultural resource evaluations since those practices represent deep, spiritual connections to the environment and the specific locations on and around the Hawaiian islands where they take place. Some specific examples include agricultural practices, gathering, fishing and hunting, canoe paddling, trail access, burial practices, and worshipping.

3.6.3 CULTURAL LANDSCAPES

In considering programmatic impacts to cultural and natural resources from potential renewable energy projects and associated facilities, it became apparent that a broader approach should be considered because some renewable energy technologies and potential siting of future projects, especially on the utility-scale, can be geographically large. Thus, for larger-scale projects, cultural resource evaluations may need to focus on cultural landscapes rather than project-specific footprints and individual cultural resource sites. However, some of the smaller-scale technologies, such as distributed solar power, can still benefit from a more site-specific cultural resource survey and evaluation approach.

A cultural landscape consists of physical elements of a geographic area, including both cultural and natural resources and the wildlife, associated with a historic event, activity, or person or exhibiting other cultural or aesthetic values through time. The NPS definition of cultural landscapes includes four types; designed landscapes, vernacular landscapes, historic sites, and ethnographic landscapes. These landscape types are not mutually exclusive. Designed landscapes can be historic gardens, planned residential communities, or parks; vernacular landscapes can be farms or ranches; historic sites include battlefields or places where significant historical events occurred; and ethnographic landscapes can contain a variety of natural and cultural resources that associated people define as important ([NPS 1998](#)). Each type of landscape must have historic significance (eligible for the NRHP) and historic integrity (ability to convey its historic significance). Cultural landscapes are listed on or eligible for listing on the NRHP as sites or

districts, but can also be included as traditional cultural properties. Cultural landscapes consist of the following 13 landscape characteristics:

- Buildings/structures
- Archaeological features
- Circulation patterns
- Constructed water features
- Cluster arrangement
- Cultural traditions
- Land use
- Natural systems and features
- Small-scale features
- Spatial organization
- Topography
- Vegetation
- Views/vistas

Native Hawaiian culture does not have a clear dividing line of where the cultural landscape ends and nature begins. There are several important components of the Hawaiian cultural landscape that warrant understanding such that interrelated Native Hawaiian perspectives can be addressed.

The ‘aina, wai (water), kai (ocean), and lewa (sky) were the foundation of life and the source of the spiritual relationship between people and their environment. Hawaiian moolelo, or traditions express the attachment felt between the Native Hawaiian people and the earth around them. In Hawaiian culture, natural and cultural resources are one and the same. Native traditions describe the formation (literally the birth) of the Hawaiian Islands and the presence of life on, and around them, in the context of genealogical accounts. All forms of the natural environment—from the skies and mountain peaks, to the watered valleys and plains, to the shore line and ocean depths—were the embodiments of Hawaiian gods and deities ([Maly 2001](#)).

Wahi pana (celebrated places) compose a large portion of the cultural landscape. They include all sites considered sacred by the Native Hawaiian people. These may take the form of heiau (religious temples), shrines, burial caves, graves, etc., that were built for religious or cultural purposes. Additionally, physical and geographic features associated with Hawaiian deities compose wahi pana and may include the sites of significant natural, cultural, spiritual, or historic phenomena or events. Ed Kanahale offers a description of the large range of places that can be described as wahi pana in *Ancient Sites of O‘ahu* by [Van James \(1991\)](#):

“The gods and their disciples’ specified places that were sacred. The inventory of sacred places in Hawai‘i includes the dwelling places of the gods, the dwelling places of venerable disciples, temples, shrines, as well as selected observations points, cliffs, mounds, mountains, weather phenomena, forests, and volcanoes.”

Domains of aumakua, or ancestral deities, add another component to the cultural landscape. Access to a family’s aumakua provided a way for Native Hawaiians to renew their ties to their ancestors. Within the domain of the aumakua, Native Hawaiians could experience hoailona, or natural signs and phenomena that would facilitate this reconnection. Thus, these areas are also a critical component to the Hawaiian cultural landscape. Finally, trails and roads are part of the cultural landscape because they provide access to cultural and natural resources that are used in all activity. By providing access to them, these trails and roads gain added importance as well ([McGregor et al. 1996](#)).

Each natural environment also contributes to the cultural landscape of the area. Streams and springs provide freshwater sources that are vital as habitats for [native species](#) and marine life, for taro and agricultural cultivation, and for domestic use. The importance of freshwater in the Native Hawaiian culture also elevates the importance of streams and springs. The shoreline, coral reefs, and ocean, both nearshore and offshore, provide another important element of the cultural landscape. By providing a place to gather food and medicine as well as an important setting for cultural and spiritual customs, the shoreline garners added importance. The forest and mountain areas are also part of the cultural landscape. Again, the area provides a place in which many Native Hawaiians gathered plants used for medicine, food, ceremonial adornment, and ritual offerings. It also provided a setting for Native Hawaiians to hunt pigs and other animals. Additionally, many spiritual customs were performed in the forest.

A vast array of components can be included in the Native Hawaiian cultural landscape: areas of cultivation, circulation networks, buildings, structures, facilities, irrigation systems, roads, tunnels, archaeological and historical sites, viewing points and visual corridors, and cultural resource and use areas. Particularly prominent examples of Hawaiian agriculturally based cultural landscapes include the broad valley floors whose wetlands were transformed and expanded into intricate systems of pond fields, ditches, and fishponds. In areas such as Hanalei on Kaua‘i, Ke-‘anae on Maui and Waipio on Hawai‘i, farmers still cultivate taro in these irrigated fields. Only by talking to community members and cultural practitioners are the important elements of these landscapes illuminated ([DBEDT 2012a](#)).

3.6.4 ARCHAEOLOGICAL SITES

Archaeological studies in Hawai‘i began early in the twentieth century with the pioneering work of William T. Brigham and John F. G. Stokes. Islandwide surveys of heiau and other aboveground sites continued throughout the pre-World War II period, but the excavation of subsurface sites did not begin until 1950, with Kenneth P. Emory’s work at Kuliouou Rockshelter (O‘ahu). Since then, archaeologists from the Bishop Museum, University of Hawai‘i, and other institutions (as well as private consultants performing extensive contract archaeology) have conducted excavations at several hundred archaeological sites. This work, together with thousands of radiocarbon dates from the sites, has yielded a rich record for constructing a detailed chronology of precontact history ([Kirch 1998](#)).

Hawaiian archaeology includes a wide range of site types, most consisting of dry-laid stone structures utilizing the natural geology (lava rock). The largest sites are typically the stone foundations of major luakini heiau (war temples), many covering more than 100,000 square feet. Smaller heiau are found throughout the Islands in a variety of platformed, walled, and terraced structures; many functioning as agricultural temples. Habitation sites typically were dispersed over the landscape rather than clustered, although some village-like aggregations apparently did exist. Precontact Hawaiian habitations consisted of groups of functionally separated structures, which are represented archaeologically by C- and L-shaped walls, rectangular enclosures, platforms, terraces, and other forms. In some areas, the ancient Hawaiians lived in rock shelters and lava tubes. Caves, lava tubes, and large sand dunes, served as burial places, and caves were also used as refuges.

Hawaiian subsistence was based on intensive forms of agriculture and aquaculture, and these have left their marks on the archaeological landscape as well. In windward and some leeward valleys with permanent streams, the islanders constructed terraces on alluvial plains and hillslope for the irrigated cultivation of taro. Stone-faced terrace complexes and stone-lined water ditches are major agricultural features in these regions.

Native Hawaiians practiced intensive aquaculture in large, loko kuapa (stone-walled fishponds) constructed on shallow reef flats. Altogether, approximately 449 ponds have been recorded, the majority of them on O‘ahu and Molokai, where the coastal geomorphology was highly conducive to pond

construction. Some of the larger ponds incorporated more than 500 acres and are estimated to have yielded as much as 365 pounds per acre annually, primarily of mullet and milkfish ([Kirch 1998](#)).

The State Inventory of Historic Places (SIHP) lists approximately 54,000 archaeological sites that are eligible for or identified in the HRHP and/or NRHP. Approximately 2 percent of those sites are actually listed on one or both of the Registers. A subset of the archaeological sites includes approximately 800 heiau. The State of Hawai‘i is unique in this perspective in that it is rich in archaeological sites that were not destroyed by early development, and therefore can still be identified, documented, or preserved ([DLNR 2012](#)). Nevertheless, the SIHP reflects only those archaeological sites that have been identified through surveys or other identification studies and should be considered a preliminary step in the literature review process for any site-specific projects being considered. A large percentage of Hawaiian lands have not been surveyed for archaeological resources and as a result, an unknown number of sites have yet to be identified and documented. For example, at Hawai‘i Volcanoes National Park on the Big Island, only 13 percent of the park has been surveyed for cultural resources and within that 13 percent, 300 archaeological sites and 14,000 prehistoric and pre-contact features have been identified. Therefore, the SIHP is not complete and should not be used without considering whether an area being researched has been surveyed and to what standard.

The sections below identify, by island, the numbers of archaeological sites on the SIHP that are eligible for, or identified on the HRHP and/or NRHP. In addition, general types of sites that appear on the HRHP and/or the NRHP are also identified along with some noteworthy examples to give the reader a better perspective of the archaeological resources present on each island.

3.6.4.1 Kaua‘i

The SIHP identifies approximately 2,100 archaeological sites on Kaua‘i; 135 are heiau.

Sites of particular note include the heiau complex at Wailua and Ke-ahu-a-Laka Halau Hula (dance platform) at Haena ([Kirch 1998](#)). Kāneiolouma Complex is a cultural site containing the remnants of an ancient Hawaiian village at Po‘ipū, Kōloa, Kaua‘i. The 13-acre complex contains numerous habitation, cultivation, sporting or assembly, and religious structures dating to at least the mid-1400s. It is considered sacred to the Hawaiian culture as well as an important cultural landmark for the residents of Kaua‘i.

Well-known burial sites on Kaua‘i include burial caves and the Anahola Dune Burials. The Alekoko (Menehune) Fishpond is another significant archaeological site located next to the Huleia Stream. A lava rock wall between the pond and the stream is 900 feet long and 5 feet high; archaeologists estimate the fishpond to be approximately 1,000 years old ([To-hawaii.com 2013a](#)).

3.6.4.2 O‘ahu

The SIHP identifies approximately 7,200 archaeological sites on O‘ahu; 145 are heiau. On O‘ahu, preserved and accessible heiau sites include Ulupō, Puuomahuka, Kane‘aki, and Keaiwa. Several fishponds (such as He‘eia) are still visible around the margins of Kāne‘ohe Bay. Two unique sites on O‘ahu are the chiefly birthing stones at Kukanihilo and the fortification notches at Nu‘uanu Pali, scene of the battle in 1795 between Kamehameha and Kalanikupule, high chief of O‘ahu ([Kirch 1998](#)). Kaniakapupu is an ancient historic site in Nu‘uanu on O‘ahu. King Kamehameha III built his summer palace there and the ruins of it are still visible today. An ancient heiau used to be located there as well ([To-hawaii.com 2013b](#)).

3.6.4.3 Molokai

There are approximately 2,500 archaeological sites on Molokai; 41 are heiau. Molokai is particularly noteworthy for the numerous stone-walled fishponds that line its southern coastline; a few are still used. Several large heiau sites are located in the Kamalo-Mapulehu area, and Hālawā Valley on the eastern end of the island is a virtually continuous archaeological complex of irrigated terraces and habitation sites (Kirch 1998). Iliiliopae Heiau is an ancient Hawaiian temple site. Built in the 13th century to serve as a temple for sorcerers, the heiau is one of the largest and oldest religious sites in all of Hawai‘i. It also may have served as a temple for human sacrifice (To-hawaii.com 2013c). There are also two national historic landmarks (NHL) on Molokai, Hokukano-Ualapue Complex and Kalaupapa Leprosy Settlement. The Kalaupapa NHL is located within Kalaupapa National Historical Park, which extends northward on a peninsula from the north-central part of the island. Archaeological resources within Kalaupapa National Historical Park show a vast variety of site types, extensive time range of habitation and land use, and exceptional preservation within a cultural landscape. Under NHPA Section 106 regulations, NHLs receive special consideration to resolve any adverse effects.

3.6.4.4 Lāna‘i

Approximately 1,900 archaeological sites are identified in the SIHP on Lāna‘i; 41 are heiau. Sites include Pu‘upehe Platform and the Kealiakapu Complex-Kaunolu Village. Halulu Heiau is one of the most impressive archaeological sites on Lāna‘i. The heiau once served as a place of refuge, built by King Kamehameha to challenge those who broke the law (Kirch 1998). Kahekili’s Leap is a rock ledge on Lāna‘i’s south shore. It was here where King Kamehameha’s warriors proved their bravery by leaping 80 feet into the ocean below (To-hawaii.com 2013d).

3.6.4.5 Maui

The SIHP identifies approximately 7,200 archaeological sites on Maui; 222 are heiau. Some of the sites include 18 archaeological districts and complexes, and numerous heiau and petroglyph sites. Preserved heiau sites on Maui include Pihana and Haleki‘i Piilanihale, and Wai‘anapanapa. A well-documented habitation complex is located in the Keoneoio Archaeological District near La Perouse Bay. The upland region of Kula was once a densely settled agricultural area, and remains of ancient Hawaiian dryland fields can still be seen (Kirch 1998). Recorded rock art sites include the Honokōwai, alae, and Papakea Petroglyphs.

3.6.4.6 Hawai‘i Island

Approximately 29,000 archaeological sites are identified in the SIHP on Hawai‘i; 275 are heiau. Sites consist of archaeological sites including complexes, districts, burial sites, and caves. Hawai‘i island contains a greater number of well-preserved sites, especially in the Kohala, Kona, and Kau districts, than any other island. Among the many temple sites are Mo‘okini and Pu‘ukoholā in Kohala, and Ahuena, Keeku, Hikiau, Hale O Keawe, and alealea in Kona. Large petroglyph complexes are found at Puako, Kalahuipuaa, Anaehoomalu, and Puu Loa. A significant and unique archaeological site is the footprints of Keoua Kiiahuula’s army, preserved in volcanic ash in the Kaii Desert from an explosion on Kīlauea in 1790, within the present-day Hawai‘i Volcanoes National Park (Kirch 1998). Mo‘okini Luakini Heiau in North Kohala is one of the oldest and most significant in all of Hawai‘i. The heiau still bears the large, flat stone where actual human sacrifices were made. The heiau was designated as Hawai‘i’s first registered NHL in 1963. The stone structure is much smaller than it used to be in ancient times, but its remains still measure 250 feet by 125 feet, with 6-foot high walls (To-hawaii.com 2013e).

3.6.5 HISTORIC BUILDINGS AND SITES

This section focuses on cultural resources other than archaeological (pre-contact) sites, which generally consist of historic districts, buildings, objects, or structures, but that can also be part of a cultural landscape. Most of these resources in Hawai‘i are from the time period after Western contact with Native Hawaiians in the late 1700s. The Federal regulations define a historic district as: “a geographically definable area, urban or rural, possessing a significant concentration, linkage, or continuity of sites, buildings, structures, or objects united by past events or aesthetically by plan or physical development” [36 CFR 60.3(d)]. Buildings are structures intended to shelter some sort of human activity such as a church, house, or barn [36 CFR 60.3(a)]. Objects are “material thing[s] of functional, aesthetic, cultural, historical or scientific value that may be, by nature or design, movable yet related to a specific setting or environment” [36 CFR 60.3(j)]. Structures differ from buildings, in that they are functional constructions meant to be used for purposes other than sheltering human activity and are “often . . . engineering project[s] large in scale” (e.g., aircraft, ships, and bridges) [36 CFR 60.3(p)].

The SIHP identifies approximately 850 buildings and districts Statewide that are eligible for or identified in the HRHP and/or NRHP. Although a district may be listed as one site, it can have numerous contributing resources (e.g., buildings). There are many more resources consisting of “objects” or “structures” also in the SIHP. Many structures in Hawai‘i may not have been evaluated yet for eligibility, or may have been determined to be eligible, but not yet officially listed. Sites that have not yet been formally listed or have not been determined eligible are treated as if they were eligible/listed, as required by State law, until eligibility can be determined. These are only the known resources, but many more likely exist and need to be considered during any site-specific evaluation. The population in the State grew relatively slowly until the 1960s, at which time construction increased dramatically. Those buildings are reaching the age of 50 years (historic property standard) and therefore significantly more buildings or districts are likely to be added. Since 2003, approximately 1,200 new properties per year have been added to the SIHP (DLNR 2012).

Prior to the nineteenth century Hawaiian architecture was based on thatch construction. Western contact altered Hawai‘i’s built environment. By the beginning of the twentieth century, thatched structures disappeared and were replaced by forms derived from Europe, North America, and Asia, which were based on wood and masonry construction. From the late 1800s onward, more sophisticated architecture emerged with many areas utilizing plantation-based building techniques. The post-World War II period eventually opened Hawai‘i to the world with a more international style of design (Hibbard 1998). Many of these structures survive today and retain prominent standing as historic resources in the State.

The sections below identify, by island, the numbers of historic buildings and sites on the SIHP that are eligible for, or identified on the HRHP and/or NRHP. In addition, general types of historic resources that appear on the HRHP and/or the NRHP are also identified along with some highlighted examples to give the reader a better perspective of some of the historic resources present on each island.

3.6.5.1 Kaua‘i

The SIHP identifies 77 historic buildings or districts on Kaua‘i. Some of the resources include 40 buildings, three bridges and others such as a lighthouse and locomotives. A prominent historic site on Kaua‘i is the Cook Landing Site. Captain James Cook happened accidentally upon the Hawaiian Islands in 1778 while in search of a Northwest Passage between England and Orient. Cook’s two ships first landed at Waimea on Kaua‘i (Langlas 1998). The Cook Landing Site was registered as a National Historic Landmark in 1935.

3.6.5.2 O‘ahu

The SIHP identifies 143 historic buildings or districts on O‘ahu. Some of the resources include eight historic districts, 185 residences, 20 military sites, 10 Hawaiian royalty sites and several churches and missions. Numerous residences appear on the SIHP, primarily because the county offers tax incentives for residences on the HRHP and does not for other property types at this time.

Of particular note on O‘ahu are the numerous historic military sites. During the 1930s and 1940s, O‘ahu was a major hub for the U.S. Pacific Naval Fleet, which figured prominently during World War II. Some of the well-known and preserved historic military installations and objects associated with the Japanese attack on Pearl Harbor and the ensuing war include Pearl Harbor Naval Base, Hickam Air Force Base, Kāne‘ohe Naval Air Station, the *U.S.S. Missouri* battleship, the *U.S.S. Bowfin* submarine, and numerous artillery battery sites.

Much of the Hawaiian royalty occupied palaces and other residences on O‘ahu. These historic royalty sites include ‘Iolani Palace, the Royal Flower Garden of Queen Lili‘uokalani, and Kamehameha III Summer Palace.

3.6.5.3 Molokai

The SIHP identifies seven historic buildings or districts on Molokai. Although Molokai’s historic resources consist of only a few buildings and sites such as the public library, Kaluaaha Church, and the Molokai Light Station, the island is well known for the Kalaupapa settlement for patients with Hansen’s Disease (leprosy), which is an NHL with over 200 contributing historic buildings. The Kalaupapa NHL is located within Kalaupapa National Historical Park, which extends northward on a peninsula from the north-central part of the island. The NHL designation for Kalaupapa includes historic buildings, structures, objects, archeological resources, and the vernacular cultural landscape. Under NHPA Section 106 regulations, NHLs receive special consideration to resolve any adverse effects.

3.6.5.4 Lāna‘i

Although the SIHP lists eight historic buildings or structures on Lāna‘i, none is listed on the HRHP or NRHP; however, all eight are categorized as eligible for listing in either register.

Lāna‘i City has been designated a potential historic district, and in April 2009 the National Trust for Historic Preservation included Lāna‘i City on its list of the 11 most endangered historic places in the United States. The National Trust considers Lāna‘i City to be “the last remaining intact plantation town in Hawai‘i.” The island rose to prominence with the arrival of James Drummond Dole, whose pineapple empire once stretched over 20,000 acres and employed thousands of workers. In the 1920s, Dole, who owned the entire island, created a thriving company town, complete with hundreds of plantation-style homes, a laundromat, jail, courthouse and police station, all centered on a tree-lined park named in his honor ([NTHP 2009](#)).

3.6.5.5 Maui

The SIHP identifies 125 historic buildings or districts on Maui. Some of the resources include 18 historic districts and complexes, 10 residences, seven schools, nine churches and temples, and 10 commercial properties. Three of the several historic districts present on Maui include, Wailuku Civic Center, Lahaina, and Kipahulu.

The Wailuku Civic Center Historic District includes Circuit Courthouse, County Office Building, Police Station, Wailuku Library, and District Courthouse. A source of civic pride for the community, the entire district represents tangible links to the events that have shaped the island community. The district dates back into pre-contact times, to an era when Wailuku was the center of power for Maui ([MHS 2010](#)).

The Lahaina Historic District was declared a National Historic Landmark in 1962 and is located on the west side of the island. Long the residence of Maui kings and chiefs, Lahaina preserves the atmosphere of a mid-19th century Hawaiian seaport, when it was a favorite port of call for American whalers. It was also the center of missionary activities ([NPS 2008](#)).

Kipahulu is a remote farming district on Maui located about 10 miles from Hana. Kipahulu is an isolated coastal valley characterized by acres of lush vegetation in their native and undisturbed states. Once heavily populated, Kipahulu was farmed by native Polynesians about 1,200 years ago. Farm sites and terraces abound in the area. A former sugar town, Kipahulu was turned into a ranch-style village when the mill closed in 1923. During the 1900s, Kipahulu served as a port for an inter-island steamship company. Other highlights of the town include the nearby burial place of the American aviator Charles Lindbergh ([To-hawaii.com 2013f](#)).

3.6.5.6 Hawai'i Island

The SIHP identifies 497 historic buildings or districts on the Big Island. Some of the resources that are specifically listed on the HRHP and/or NRHP include 75 buildings including schools, six roads, various bridges, and Kīlauea Volcano-related sites. Some of the historic roads on the Big Island are Mauna Loa Road, Crater Rim Drive, and Hilina Pali Drive all associated with and in close proximity to the Big Island's volcanic activity. Two notable trails include Ala Loa Foot Trail and Kīholo-Puako Trail.

3.6.6 COMMON CONSTRUCTION AND OPERATION IMPACTS

Potential adverse impacts could occur to cultural, historical, and related natural resources during construction and operational phases of a relatively small, distributed to utility-scale renewable energy project if effective conservation and BMPs are not implemented. In many locations on the Hawaiian Islands it can reasonably be expected that there will be significant surface and subsurface archaeological and historic features present, as well as ongoing traditional and customary Native Hawaiian practices like taro farming, fishing, fisheries cultivation and limu (seaweed) gathering. Quite often these features are likely connected to each other through past and possible current practices and should be evaluated not only as discrete features but as integral parts of a larger cultural landscape. Cultural traditions and practices may also be evaluated as environmental justice concerns if impacts to minority or low-income populations (especially Native Hawaiians) might occur. Given the potential scale of some renewable energy projects and the rural nature of the areas for which they may be sited, it is anticipated that direct and indirect impacts would occur to cultural and historic resources.

Significant cultural resources, including historic properties listed or eligible for listing in the HRHP and/or NRHP, could be affected by a renewable energy power project. The potential for impacts on cultural resources, including the ancillary facilities, such as access roads and transmission lines, is directly related to the amount of land disturbance and the location of the project. Indirect effects, such as impacts on the cultural landscape resulting from the erosion of disturbed land surfaces and from increased human access to possible site locations, should also be considered. Viewsheds of renewable energy developments from historic properties may have an effect to the overall integrity, setting, feeling, and association to the historic properties.

During construction, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. The amount of land area for siting of the project could destroy or permanently alter the cultural landscape and resources present in the area. If the project were constructed on previously disturbed land in support of an existing facility, impacts to cultural resources might be minimized; however, this is not always the case and archaeological surveying of previously disturbed land is necessary at times depending on the situation. For renewable energy technology projects sited near the coast or transitioning between onshore and offshore, cultural and historic impacts could occur from construction activities in beach, nearshore, and offshore locations.

Degradation and/or destruction of archaeological and historic properties could result from the alteration of topography, alteration of hydrologic patterns, removal of soils, erosion of soils, run-off into and sedimentation of adjacent areas, and contaminant spills if sites are located on or near the project area. Such degradation could occur both within the project footprint and in areas downslope or downstream. While the erosion of soils could negatively affect cultural resources downstream of the project by potentially eroding materials and portions of the downstream archaeological sites, erosion can also destabilize historic structures.

Increases of human access and subsequent disturbance of cultural resources could result from the establishment of corridors or facilities in otherwise intact and inaccessible areas. Increased human access exposes archaeological sites and historic structures and features to a greater probability of impacts. The collection of artifacts by workers or amateur collectors accessing areas that may have been previously inaccessible would be another possible impact. Increased access might also increase the potential for vandalism. Also, access by Native Hawaiians to traditional and customary cultural and natural resources for gathering rights, including religious practices, during construction can be limited or disallowed when areas are closed for safety reasons.

Visual impacts could occur from construction activities where significant cultural resources for which visual integrity is important to a site's significance such as sacred locations (e.g., heiau and burial sites) and landscapes, historic structures, trails, prominent vistas, and other related sites. Large areas of exposed surfaces; the increase of dust and debris; and the presence of construction machinery, equipment, vehicles, and personnel could contribute to an adverse visual impact on specific cultural resources and landscapes.

Noise degradation of culturally sensitive locations and landscapes is possible from construction activities. Noise effects on the pristine nature and sacredness of a place should also be taken into consideration.

Construction within or in close proximity to historical buildings, structures or districts can impact the nature and contextual meaning of the resources present, and may have an impact on Native Hawaiian's and the visiting public's awareness and experiences associated with historic properties.

Although operational impacts to cultural and historic resources of a renewable energy project arguably may be less likely to occur than construction impacts, some adverse effects are still possible. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Cultural and historic resources listed or eligible for listing on the HRHP and NRHP, as well as burial sites, fisheries, ocean ecosystems sustaining limu and sea life (and other sites pending eligibility), are considered sensitive locations or receptors for potential adverse impacts. The SIHP maintained by the Hawai'i SHPD provides a listing of these resources. However, consulting just the SIHP is not adequate to determine whether such resources are present. If proposed projects have not been adequately evaluated or not evaluated at all, then unknown but significant cultural and historic resources may be present. Any such resources will need to be identified and evaluated for their eligibility to the HRHP and the NRHP. It is infrequent that burial sites are listed because identification of burial sites is more unpredictable; thus, archaeological inventory survey work prior to construction is often recommended. Moreover, when survey studies fail to identify burial sites, discoveries of burials during construction triggers another set of regulatory requirements. In addition, artifacts, locations, landscapes, practices, visual corridors, and natural resources considered significant by Native Hawaiians must be addressed for consideration of sensitive locations and receptors.

3.6.7 COMMON BEST MANAGEMENT PRACTICES

Construction and operation BMPs must be implemented to ensure potential impacts to cultural and historic resources from a renewable energy project are addressed. Avoidance of impacts is the primary objective; however, when avoidance is not possible or practicable, then BMPs and/or mitigation would be applied. This also includes identifying and then avoiding or mitigating any potential for restraints to access and adverse impacts on traditional and customary Native Hawaiian practices, including but not limited to subsistence gathering, loi kalo (taro farming), loko ia (fishponds), and loko ia kalo (combined fish and taro farming) located outside of the project footprint or relating to traditional cultural landscapes or properties.

The NHPA Section 106 process would be conducted on individual, site-specific projects where a Federal agency is deciding whether to carry out the project or where the project might receive Federal financial assistance, permits, or approvals. In consultation with the SHPD, a detailed cultural and historic resource literature review, followed by an archaeological inventory survey, if necessary, might be conducted. Depending on the outcome of the reviews and surveys, additional surveys or other field identification studies may be required for other types of resources, such as ethnographic resources (including traditional cultural properties), historic structures, and cultural landscapes. A management plan or memorandum of agreement may also be required to address potential adverse effects to historic properties. Consultation with the NPS is desirable when NHLs are within a study area, or within the direct or indirect impact areas of a proposed project.

[HRS 6E](#) governs the State's historic preservation process, as administered through [HAR 13](#). Approaches to historic and cultural resources should be developed in consultation with the SHPD, NHOs, OHA, Island Burial Councils, lineal and cultural descendants, and other Native Hawaiians that can provide site-specific, traditional, religious, burial, and other culturally important information on any proposed project area. The opinions of kupuna, or elders, are traditionally given greater appreciation and weight pursuant to Native Hawaiian custom. Similarly, Native Hawaiian practitioners who carry on the traditional and customary practices and knowledge provide invaluable insights. In accordance with State law, if a historic property or structure listed or eligible for listing on the HRHP and/or NRHP is proposed for modification, the project proponent must complete and submit a Historic Preservation Review Form in compliance with [HRS 6E](#) such that the modifications may be reviewed prior to project implementation. Consultation with the SHPD and Native Hawaiians should occur early in the process and often enough to allow the maximum time possible to adequately address cultural issues.

For either the Federal or State processes, other options beyond literature reviews, surveys, and consultations include excavation, collection, and site monitoring activities. Although data recovery of

cultural resources is an option for addressing adverse effects, it does not eliminate the potential impacts. Monitoring and surveillance of a site to protect resources *in situ*, cultural education and training, and funding of historic preservation efforts have proven to be effective in mitigating adverse impacts. Mitigation for the demolition or modification of historic buildings, structures, and other resources may require architectural and historic documentation using processes such as the Historic American Engineering Record program (see <http://www.nps.gov/history/hdp/>).

There are several construction and operations practices that can be employed, where applicable, to minimize adverse effects from a renewable energy project. BMPs include the following:

- Identify all NHOs with cultural and religious ties to the land and resources in the proposed project vicinity and begin an early dialogue of information sharing.
- Conduct a study to determine the specific locations of low-income and minority populations, specifically Native Hawaiians, as it relates to potential siting of renewable energy projects.
- Conduct archaeological and historic resources survey and inventory of potential project areas to facilitate the avoidance, minimization, or mitigation of impacts to resources and to provide input to consultation and review processes.
- Use Native Hawaiian monitors during pre-construction archaeological survey and inventory studies to ensure a culturally sensitive approach and to provide a native perspective to the studies.
- Avoid culturally significant natural resources such as fresh water springs, fishponds, and near shore resources whenever possible.
- Maximize the use of previously disturbed land, existing access roads, utilities, and other infrastructure.
- Conduct viewshed consultations and analyses and minimize siting of renewable energy facilities where viewshed incompatibilities could occur to historic properties and cultural landscapes.
- Develop monitoring plans for use during construction with provisions for addressing burial treatment in consultation with NHOs, OHA, SHPD, and potential lineal and cultural descendants, if applicable.
- Ensure compliance of inadvertent discovery of artifacts, shipwrecks, and historic sites, including burial remains during construction, with applicable laws including the *Abandoned Shipwreck Act*, NHPA, NAGPRA and State Burial laws, as applicable.
- Halt work immediately as a result of inadvertent cultural discoveries until consultation and compliance in accordance with applicable requirements occur and mitigation measures are developed.
- Use archaeological and Native Hawaiian monitors during construction to monitor ground- and seafloor-disturbing activities, and to provide additional culturally sensitive perspectives and assurances to communities if resources are encountered.
- Avoid culturally important landscapes (e.g., pohaku quarries, coral reefs, and fishponds), wildlife (animals and fisheries), and plant (e.g., limu) species and their habitats.
- Conduct cultural worker training, orientations, and educational programs.

3.7 Coastal Zone Management

Coastal zone management (CZM) has a long history in Hawai‘i, predating the formal passage of the national *Coastal Zone Management Act of 1972* (16 U.S.C. §§ 1451–1464; CZMA) (Hawai‘i 1990, 2011). The coastal zone is an extremely important resource to the State of Hawai‘i because it is the primary location of human residences, business, tourism, and industry and the resources on which they depend. The formal development of the Hawai‘i Coastal Zone Management Program (CZMP) is rooted in the passage of the *Land Use Law* (HRS 205) in 1961 and passage of the *State Shoreline Setback Law* (Act 136, SLH 1970) in 1970 (Hawai‘i 1990, 2011). The Shoreline Setback Law prohibited development of any structure within the shoreline area without a variance and eventually led to the development of a comprehensive coastal zone policy. As defined in HRS 205A and consistent with 15 CFR 923.31, which specify areas surrounded by water on all sides such as the Hawaiian Island chain must be included in their entirety as the coastal zone, Hawai‘i’s coastal zone management area includes all lands of the State and the area extending seaward from the shoreline to the limit of the State’s police power and management authority, including the United States territorial sea.

The CZMA is a Federal law whose goal, among other things, is to advance a national policy to preserve, protect, develop, and where possible restore or enhance the resources of the Nation’s coastal zone [16 U.S.C. § 1452(1)]. Under the CZMA, the coastal zone means coastal waters and adjacent shorelands [16 U.S.C. § 1453(1)]. The CZMA creates a framework for planning and approving coastal projects that turns on a complex network of relationships between the Federal, State, and local governments. While the full details of these relationships and the framework are not useful for the purpose of this PEIS, the key point is that Hawai‘i, as a coastal State, has to develop and adopt a management program that guides the public and private uses of lands and waters in the coastal zone [16 U.S.C. § 1453(12), § 1454, § 1455(d)]. The management program must be approved by the U.S. Secretary of Commerce [16 U.S.C. § 1455(d)]. Federal activities, including Federally permitted activities, that impact a coastal State’s coastal zone must be consistent to the maximum extent practicable with the enforceable policies of the State management program [16 U.S.C. § 1456(c)].

In compliance with the CZMA, Hawai‘i prepared the Statewide CZMP that conforms to the national CZMA, which culminated in the enactment of the 1977 *Hawai‘i Coastal Zone Management Act* (HRS 205A) and was subsequently approved by the U.S. Department of Commerce in 1978 (Hawai‘i 1990, 2011). For more information about the CZMP and how Hawai‘i generally regulates the coastal zone under the CZMP, see http://files.hawaii.gov/dbedt/op/czm/program/doc/czm_program_description_2011.pdf and http://files.hawaii.gov/dbedt/op/czm/program/doc/1990_czm_program_doc.pdf, (respectively).

3.7.1 ENERGY FACILITY SITING

The 1976 amendments to the CZMA required that the planning process for siting of energy facilities and identifying their impact be included in State coastal zone management programs [16 U.S.C. § 1455(d)(2)(h)]. HRS 226-18 presents objectives and policies for energy facility systems in Hawai‘i.

The CZMP is administered by the State of Hawai‘i Office of Planning attached to DBEDT, which collaborates with other State agencies in energy planning and conservation. Most energy facility siting decisions trigger various State and county planning and zoning regulations and compliance with other resource protection regulations.

3.7.2 FEDERAL CONSISTENCY REVIEW

Hawai‘i’s CZMP administers the Federal consistency review program (<http://planning.hawaii.gov/czm/Federal-consistency/>). Federal consistency requirements apply to Federal

agency activities (including Federal development projects), Federal license or permit activities, and Federal financial assistance activities [[16 U.S.C. § 1456\(c\)\(1\)-\(3\)](#)]. Typically, Federal agencies make consistency determinations for their activities but Hawai‘i’s concurrence would be required before the agencies could engage in the activities ([15 CFR 930.41](#), [930.54](#), [930.90–930.101](#)).

The Federal consistency review process starts with a review of the proposed activity and determination of the type of review required. The Hawai‘i CZMP encourages early pre-application consultation. Public notices of CZM Federal consistency reviews are published in *The Environmental Notice*, which is distributed by direct mail and posted on the Hawai‘i Office of Environmental Quality Control Website (<http://www.state.hi.us/health/oeqc/notice/index.html>).

For more details on the Federal consistency review process and how developers or applicants for permits or funding can secure a Federal consistency determination and State concurrence, refer to [15 CFR Part 930](#) and <http://planning.hawaii.gov/czm/Federal-consistency/>.

The Federal consistency review process starts with a review of the proposed activity and determination of the type of review required. The Hawai‘i CZMP encourages early pre-application consultation.

3.7.3 COMMON CONSTRUCTION AND OPERATION IMPACTS

Two major elements of the CZMP could be potentially impacted by development of renewable energy technologies: special management areas and shorefront access. Construction projects along the coastline such as power cable or pipeline crossings from offshore projects could disturb designated special management areas that have been designated by counties throughout the islands to avoid loss of coastal resources and ensure access to beaches, recreation areas, and natural reserves. Construction of energy facilities or ancillary components such as power cables and pipelines along the shoreline could limit access to shorefront areas depending on the particular location. Locating power cable crossings and any facilities in areas previously developed or outside designated special management areas would minimize potential impacts.

3.7.4 COMMON BEST MANAGEMENT PRACTICES

BMPs that would prevent, minimize, or mitigate potential impacts to coastal zone management include the following:

- Developers should coordinate with CZMP office early in the project planning phase to identify potential coastal areas that should be avoided. Locating energy facilities or facility components outside of special management areas and avoiding undeveloped coastal areas that have high resource value would reduce potential impacts.
- Use horizontal directional drilling technology when technically feasible to install any power cabling or pipelines that cross the shoreline underground to avoid any aboveground impacts.

3.8 Scenic and Visual Resources

The Hawaiian Islands are world famous for their beautiful, scenic resources. These resources are diverse and include developed and undeveloped sections of shoreline, tropical rainforests, rugged valleys, cliffs, jagged peaks, active and inactive volcanoes, vast open spaces, historic towns and villages surrounded by productive agricultural land, and panoramic ocean views. On clear days, one can look across the ocean and see neighboring islands. Many of these scenic resources are accessed via Hawai‘i’s State and county roadways and State, county, and national parks.

Scenic resources are defined as the visual quality or character of an area, consisting of both the landscape features and the social environment from which they are viewed. The landscape features that define an area of high visual quality may be natural (e.g., mountain views) or manmade (e.g., a city's skyline). Visual resources more specifically include places of cultural importance, such as traditional cultural properties, and areas and structures of historical importance (see [Section 3.6](#) of this PEIS for a discussion on cultural and historic resources).

The physical character of an area is defined in terms of four primary components: water, landform, vegetation, and cultural modifications. Visual components also may be described as being distinct (unique or special), average (common or not unique), or minimal (a liability). Elements of the visual field can be characterized in terms of the degree to which they are visible to surrounding viewers, i.e., foreground, middle ground, and background. Scenic resources often include:

- Areas of high scenic quality (i.e., scenic hiking trails, designated scenic byways or locations);
- Recreation areas characterized by high numbers of users with sensitivity to visual quality (i.e., parks, preserves, and land- water- and commercial- based recreation areas);
- Important historic, cultural, and archaeological locations;
- Dark night skies that promote tourism and scientific research at astronomical observatories; and
- The natural beauty of the Hawaiian Islands, which include tropical rainforests, waterfalls, beaches, ocean views, sea cliffs, canyons and gorges, valleys, active and dormant volcanoes, and mountains.

Hawai'i's beauty enriches the quality of life for residents and serves as a primary visitor attraction. However, the growth of the visitor industry, and subsequent urbanization to support it, has dramatically impacted the State's scenic resources. Over the past two decades, new development has blocked views of the ocean shoreline, changed the viewshed along State and county roadways, and produced urban conditions on agricultural land that once separated distinct communities ([Hart 2006](#)).

3.8.1 MANAGEMENT OF SCENIC AND VISUAL RESOURCES

Scenic resources, like other valuable natural resources, require a management strategy to protect the resource from unnecessary depletion. Lands rich in scenic resources are often the same lands that are in high demand for recreational, resort, and residential uses ([Hart 2006](#)).

Current Federal, State, and county laws and programs have established the regulatory authority and responsibility to protect scenic resources from development. In addition to the Federal CZMA, the Hawai'i *Coastal Zone Management Act* ([HRS Chapter 205A](#)) incorporated the existing county special management areas as geographical areas subject to Federal and State coastal zone management policies and objectives. One objective of the CZMA is to "protect, preserve, and, where desirable, restore or improve the quality of coastal scenic and open space resources." Within the special management areas, this translates into the requirement that all development be scrutinized for impact on scenic and open space resources ([Hart 2006](#)). See [Section 3.7](#) of this PEIS for a discussion of coastal zone management.

County zoning permits also take into account a proposed project's visual impacts to the community and may require mitigation measures as a condition to a zoning permit. The Hawai'i Environmental Impact Statement Rules ([HAR 11-200](#)) require all that environmental impact statements describe the potential impacts of a proposed project to resources with aesthetic significance and consider mitigation measures to

avoid, minimize, rectify, or reduce impacts to these resources. This often requires accurate models or visual simulations in the impact statement, showing the project site before and after construction from key viewpoints (e.g., nearby residences, towns, and vantage points). Project proponents must also provide accurate day and night visuals of the project to local community leaders (neighborhood boards) to adequately inform the community of what can be expected. In Hawai‘i, visual impacts can also be cultural impacts where line-of-sight is key to a particular area’s cultural significance. [HAR 11-200](#) requires extensive outreach with the community surrounding the project to identify and effectively mitigate all potential visual impacts. Visual impacts can also be caused by light pollution. For example, the night sky over the Big Island, where Mauna Kea Observatories is located, is protected by a strong lighting ordinance to preserve the dark night sky.

The State maintains a Hawai‘i Scenic Byways Program. Currently there are four designated scenic byways: three on the island of Hawai‘i, the fourth on the island of Kaua‘i. Information regarding the Scenic Byways Program can be found at <http://hawaiiscenicbyways.org>.

Six of the eight main islands have a general land use plan and associated implementation tools such as zoning ordinances and development standards. Some of the counties’ plans include more detail than others, but all include objectives related to protecting and maintaining open space and scenic resources consistent with the State’s land use designations. For example, the *Maui County General Plan 2030* includes an inventory of scenic resources ([Hart 2006](#)).

Counties can participate in funding the acquisition of public lands through a Public Access, Open Space, and Natural Resources Preservation Fund. A commission in each county oversees the Fund. By ordinance, a percentage of the county’s revenues go to the Fund. In some cases, State and Federal agencies, such as NOAA (via its Coastal and Estuarine Lands Conservation Program), DLNR (via its Legacy Lands Fund), and USFWS provide dollar-for-dollar matching funds ([Hecht 2012](#)). To qualify for a property acquisition using the Fund, a proposed site must meet at least one of nine criteria, including “conserving land for open space and scenic values.” Additional information can be obtained from each county’s website (www.Kauai.gov, www.co.maui.hi.us, www.honolulu.gov, and www.HawaiiCounty.gov).

Hawai‘i has more than 50 State parks spread among five islands, and eight National parks, historical parks, landmarks, historical trails, and historic sites on five islands. In 1970, the Hawai‘i State Legislature expressed the need to protect and preserve unique natural assets for the enjoyment of future generations ([DLNR 2009a](#)). To accomplish these purposes, the legislature established the Statewide Natural Area Reserves System to preserve in perpetuity specific land and water areas that support communities, as relatively unmodified as possible, of the natural flora and fauna, as well as geological sites of Hawai‘i. The system presently consists of 20 reserves on five islands. The reserves range from marine and coastal environments to lava flows, tropical rainforests, and alpine desert ([DLNR 2014](#)).

3.8.2 SCENIC RESOURCES BY ISLAND

The following sections provide representative scenic resources by island and region for each island. This PEIS does not attempt to present all of the vast scenic resources of the islands; only to provide a perspective of the scenic beauty that can be found and protected during future development. Collectively, these sections demonstrate the range of scenic resources in Hawai‘i and the State’s diversity and character. Information in the following section overlaps with other sections of this PEIS, particularly [Sections 3.4.4](#), [3.6](#), and [3.9](#). The following sections were prepared with material available at <http://gohawaii.com/regions>.

3.8.2.1 Kaua‘i

Kaua‘i has five regions with much diversity in terms of scenic resources and island character ([Table 3-41](#)). The Napali Coast has soaring sea cliffs more than 3,000 feet above the ocean, while Waimea Canyon is often called the “Grand Canyon of the Pacific.” This island has approximately 50 miles of beaches from Poipu Beach to Hanalei Bay (on the North Shore). Historical small towns include Hanapepe (on the West Side) and Koloa (on the South Shore). Scenic diversity includes valleys, mountain spires, cliffs, tropical rainforests, rivers, and waterfalls. The Koloa Heritage Trail on the South Shore covers 19 miles through an area mixed with pre-contact and post-contact cultural sites. Some parts of Kaua‘i are accessible only by sea or air.

Table 3-41. Kaua‘i Scenic Resources

Region	Feature	Attributes	Location
	<p>Na Pali Coast</p> <p>Natural beauty (sea cliffs, ocean views, mountains)</p>	<p>Iconic, mountainous shoreline 17 miles long</p> <p>Offers panoramic views of the ocean</p> <p>Lumahai Beach is where portions of the movie <i>South Pacific</i> were filmed</p>	North of Lihue
	<p>Nounou Mountain (Sleeping Giant)</p> <p>Recreation area (hiking trail)</p>	<p>The Sleeping Giant looks like a human figure lying on his back</p> <p>There is a scenic hiking trail to the top of the Sleeping Giant</p>	On Kaua‘i’s East Side between Wailua and Kapa‘a
	<p>Alekoko, Menehune Fishpond</p> <p>Important historic, cultural location</p>	<p>Built nearly 1,000 years ago, the pond has been on the National Register of Historic Places since 1973</p> <p>The fishpond is located near the Huleia National Wildlife Refuge</p>	Lihue

Region	Feature	Attributes	Location
 <p>A topographic map of the island of Kauai, with the southern coastal region highlighted in green and labeled 'South Shore'.</p>	<p>Spouting Horn</p> <p>Natural beauty (ocean views)</p> <p>Important cultural location</p>	<p>Scenic blowhole of Hawaiian legend</p> <p>The Poipu surf channels into a natural lava tube and releases a huge spout of water during large swells</p>	<p>On Kaua'i's South Shore near Poipu</p>
 <p>A topographic map of the island of Kauai, with the western interior region highlighted in green and labeled 'West Side'.</p>	<p>Waimea Canyon</p> <p>Natural beauty (canyon, gorges)</p>	<p>Scenic canyon nicknamed the Grand Canyon of the Pacific</p> <p>Stretches 14-miles long, one mile wide and more than 3,600 feet deep</p> <p>Provides panoramic views of crested buttes, rugged crags and deep valley gorges</p>	<p>On the southwest side of Kaua'i in Waimea</p>

3.8.2.2 O'ahu

O'ahu hosts the City and County of Honolulu, the State capital. O'ahu has five regions ([Table 3-42](#)). Honolulu and vicinity is an urban and resort center and comprises most of the State's population. Diamond Head offers tremendous scenic panoramas within an urban setting. In contrast, the Nu'uauu Pali Lookout offers dramatic mountain views. The North Shore is famous for world-class surfing, with its endless horizon and waves cresting 30 feet or more in the winter months. Pearl Harbor is a National Historic Landmark with five memorials to recognize its role in the beginning of World War II. The *O'ahu General Plan: Proposed 2013 Edition (Parts 1 and 2)*, establishes a planning goal to preserve and enhance the natural landmarks and scenic views of O'ahu ([City and County of Honolulu 2012a](#), [2012b](#)).

Table 3-42. O‘ahu Scenic Resources

Region	Feature	Attributes	Location
 <p>Honolulu</p>	<p>Lē‘ahi (Diamond Head)</p> <p>Area of high scenic quality (National Landmark)</p>	<p>Iconic State monument with panoramic views of Honolulu, Waikīkī, and O‘ahu’s South Shore</p> <p>760-foot tuff crater</p> <p>Named a National Landmark in 1968</p>	<p>East of Waikīkī</p>
 <p>Windward Coast</p>	<p>Nu‘uanu Pali Lookout</p> <p>Natural beauty (cliffs, mountains, valleys, ocean views)</p> <p>Important historical, cultural location</p>	<p>Historic landmark and scenic spot with panoramic views of the sheer Ko‘olau cliffs and the Windward Coast</p> <p>1,000 feet above O‘ahu’s coastline amid mountain peaks</p>	<p>Pali Highway between Honolulu and Kailua</p>
 <p>North Shore</p>	<p>Haleiwa</p> <p>Important cultural location</p> <p>Natural beauty (ocean views)</p>	<p>Historic surf town that is the cultural hub of the North Shore</p> <p>The town is on Waimea Bay, home of the Banzai Pipeline and Sunset Beach</p>	<p>North Shore about 1 hour from Waikīkī</p>
 <p>Leeward Coast</p>	<p>Ka‘ena Point</p> <p>Recreation (scenic hiking trail)</p> <p>Natural beauty (ocean views)</p> <p>Important cultural location</p>	<p>State park with trails to scenic vista points</p> <p>Dramatic lava shoreline</p> <p>Scenic views of the Waianae coast to the south, Mokolē‘ia to the</p>	<p>Western tip of O‘ahu</p>

Region	Feature	Attributes	Location
		north, and the Pacific The site is deemed sacred	
	Pearl Harbor Important historic site (National Landmark)	Five historic sites honoring events occurring at this National Historic Landmark at the beginning of World War II	Center of the South Shore

3.8.2.3 Molokai

Molokai has three regions ([Table 3-43](#)), with no manmade structures taller than a single story or traffic lights. Molokai is home to the highest sea cliffs in the world (up to 4,000 feet) along the northeastern coast and Hawai‘i’s longest continuous fringing reef (28 miles) on the southern coast. The tallest mountain on Molokai is Kamakou (4,961 feet). The Nature Conservancy has a preserve on the mountain’s slopes with a 3-mile boardwalk through tropical rainforest. With a high percentage of its population of Native Hawaiian ancestry, Molokai’s town of Kaunakakai is strong in traditional culture, as is the sacred Hālawā Valley.

Table 3-43. Molokai Scenic Resources

Region	Feature	Attributes	Location
	Hālawā Valley Natural beauty (valley, waterfalls) North Shore Sea Cliffs Natural beauty (sea cliffs, ocean views)	The valley is about a half-mile wide and three to four miles long and offers vistas of towering waterfalls Moo‘ula Falls has a 250-foot drop	Molokai East End

Region	Feature	Attributes	Location
 <p>Central Molokai</p>	<p>Kaunakakai</p> <p>Important historic and cultural location</p> <p>North Shore Sea Cliffs</p> <p>Natural beauty (sea cliffs, ocean views)</p> <p>Kalaupapa National Park</p> <p>Important historic site</p>	<p>Central Molokai is a town that is virtually unchanged since the early 1900s</p> <p>Has the State's longest pier, which extends well past the reef</p> <p>The last Royal coconut grove is in town</p> <p>Preserves the setting and memories of isolation settlements established in 1866 to control Hansen's Disease (leprosy)</p>	<p>Southeast of Molokai Airport</p> <p>Northern tip of Molokai</p>
 <p>West End</p>	<p>Mauna Loa</p> <p>Important historic location</p>	<p>This small plantation village is set in the hills above the coast and is the only town in the West End.</p> <p>The town is near Papohaku Beach, which is one of the largest white sand beaches in Hawai'i, 3 miles long and 100 yards wide</p>	<p>West of Molokai Airport</p>

3.8.2.4 Lāna'i

Lāna'i has three regions (Table 3-44). The island has just 30 miles of paved roads and about 400 miles of dirt roads. Many of the scenic sights require access by four-wheel drive vehicles. The Munro Trail offers stunning views from atop the pine-lined trail. Spinner dolphins and humpback whales can be watched at Hulopoe Bay in South Lāna'i. Other features of interest include the lunar-like landscape of the Garden of the Gods (in North Lāna'i) and Sweetheart Rock (in South Lāna'i).

Table 3-44. Lāna‘i Scenic Resources

Region	Feature	Attributes	Location
	<p>Kaumalapau Harbor</p> <p>Natural beauty (ocean views)</p>	<p>Located on the southwestern coast, Kaumalapau is the main commercial seaport for Lāna‘i</p> <p>The unobstructed views from the harbor are great for sunsets</p> <p>Whales are sometime spotted during the winter months, and also spinner dolphins</p>	<p>Kaumalapau Highway southwest to the sea</p>
	<p>Munro Trail</p> <p>Recreation (scenic hiking trail)</p> <p>Natural beauty (tropical rainforest, canyon, gorges, ocean views)</p>	<p>Trail with scenic views; driving and biking</p> <p>The trail offers spectacular views, and at the 1,600 foot elevation there is a tropical rainforest</p> <p>A lookout provides canyon views of Maunalei gulch, as well as the islands of Maui, Molokai, Kaho‘olawe, the Big Island, and O‘ahu far in the distance</p>	<p>Begins north of Lāna‘i City and ends in the Palawai Basin</p>

Region	Feature	Attributes	Location
 <p>North Lanai</p>	<p>Kaiolohia (Shipwreck Beach)</p> <p>Important historic site</p> <p>Natural beauty (ocean views)</p>	<p>Shipwreck Beach is 8-miles long and has had a number of shipwrecks along its shallow and rocky shore over the years</p> <p>In fact, the hull of a 1940s oil tanker is still beached on Kaiolohia Bay's coral reef</p> <p>The beach offers excellent views of Molokai and Maui</p>	<p>North of Lānaʻi City</p>

3.8.2.5 Maui

The Island of Maui has five regions (Table 3-44). Hana has a small-town atmosphere with protected beaches, a rugged shoreline, and towering waterfalls. To the west of Hana in Upcountry Maui is the Haleakalā National Park, home to Haleakalā, the world's largest dormant volcano. Wailea, in South Maui, is a surfing and resort center.

Table 3-44. Maui Scenic Resources

Region	Feature	Attributes	Location
 <p>West Maui</p>	<p>Lahaina</p> <p>Important historic, cultural location</p>	<p>Lahaina is a historic town. Once the capital of the Hawaiian Kingdom in the early 19th century</p> <p>Lahaina was also a historic whaling village during the mid-1800s</p> <p>Lahaina is on the National Register of Historic Places</p> <p>Also a center for whale watching</p>	<p>West Side of Maui about 45 minutes from Kahului Airport</p>

Region	Feature	Attributes	Location
 <p>A topographic map of Maui with a label 'South Maui' pointing to the southwestern coast area.</p>	<p>Molokini</p> <p>Recreation area (preserve)</p>	<p>Small crescent - shaped island about 160-feet above the ocean</p> <p>It is a State Marine Life and Bird Conservation District</p> <p>Good spot for whale watching</p>	<p>Off Maui's southwestern coast</p>
 <p>A topographic map of Maui with a label 'Central Maui' pointing to the central valley area.</p>	<p>'Iao Valley State Park</p> <p>Important historic and cultural area</p> <p>Recreation (park)</p>	<p>Historic State park, home to iconic 1,200 foot 'Iao Needle, which is a green-mantled rock outcropping</p> <p>'Iao Valley also has sacred significance</p>	<p>Just West of Wailuku</p>
 <p>A topographic map of Maui with a label 'Upcountry Maui' pointing to the central and eastern mountainous areas.</p>	<p>Haleakalā National Park</p> <p>Area of high scenic quality</p> <p>Natural beauty (mountains)</p> <p>Recreation (park)</p>	<p>A scenic national park known as the "House of the Sun"</p> <p>The park is the home to Maui's highest mountain, which rises more than 10,000 feet above sea level</p> <p>The park has a wide diversity of environments, including desert</p> <p>The Haleakalā visitor center, at the 9,740 foot point, is a popular location to watch sunrises</p>	<p>Upcountry Maui to the southeastern coast</p>

Region	Feature	Attributes	Location
	<p>Hana</p> <p>Area of high scenic quality (scenic byway)</p>	<p>Small town connected to central Maui by legendary scenic highway from Kahului (52 miles)</p> <p>The Hānā highway has 360 curves and 59 bridges. The highway travels through tropical rainforests, waterfalls, plunging pools, and seascapes</p>	<p>Maui's eastern coast line</p>

3.8.2.6 Hawai'i

Hawai'i, the Big Island, has seven regions (Table 3-45). Because of its size, it hosts a vast range of environments: it is home to the world's most active volcano (Kīlauea), the tallest sea mountain in the world (Mauna Kea), at more than 31,000 feet, the most massive mountain in the world (Mauna Loa), and the largest park in the State (Hawai'i Volcanoes National Park). All but two of the world's climate zones can be found on Hawai'i; from a rainforest (Hāmākua Coast) to volcanic deserts, from snow-capped mountains to black sand beaches.

Table 3-45. Hawai'i island Scenic Resources

Region	Feature	Attributes	Location
	<p>Wailuku River State Park</p> <p>Natural beauty (waterfalls)</p> <p>Recreation (park)</p>	<p>Wailuku (Rainbow Falls), has an 80-foot drop and is known for the rainbows that are formed in the surrounding mist</p> <p>Further upland are the Boiling Pots, terraced pools with bubbling water, as if boiling, connected by a series of cascading water flows.</p>	<p>West of downtown Hilo</p>

Region	Feature	Attributes	Location
 <p>Hamakua</p>	<p>The Hāmākua Heritage Corridor</p> <p>Area of high scenic quality (scenic byway)</p> <p>Natural beauty (ocean views, waterfalls, valleys)</p>	<p>The corridor, a Hawai‘i Scenic Byway, begins in Hilo and ends at the Waipio Valley Lookout</p> <p>In between the start and finish are ocean views, old plantation towns, and views of Mauna Kea, and an overlook for Umauma Falls.</p>	<p>Starts at Hilo, ends at the Waipio Valley</p>
 <p>North Kohala</p>	<p>Pololu Valley Lookout</p> <p>Natural beauty (sea cliffs, ocean views, valley)</p>	<p>The lookout offers panoramic views of the northeastern coastline, sea cliffs, and the Pololu Valley</p>	<p>North Kohala at the end of Highway 270</p>
 <p>Kohala Coast</p>	<p>Pu‘ukoholā Heiau National Historic Site</p> <p>Important cultural location</p>	<p>The Park is the home of the largest restored heiau (temple) in Hawai‘i and is considered to be a historic sacred site</p> <p>The site is also a location to watch humpback whales during the winter months</p>	<p>On the Kohala Coast, south of Kawaihae Harbor</p>
 <p>Kona</p>	<p>Keauhou Bay and State Park</p> <p>Recreation area (preserve, park)</p>	<p>The Bay is a Marine Life Conservation District with coral and large numbers of tropical fish species</p> <p>Spinner Dolphins can sometimes be seen</p>	<p>South of Kailua-Kona</p>

Region	Feature	Attributes	Location
		<p>The park marks the location where Captain James Cook first landed in Hawai‘i and was also killed there a year later</p>	
	<p>Kalapana</p> <p>Important historic location</p>	<p>In 1990, lava from the Kīlauea Volcano engulfed the town of Kalapana</p> <p>In 2009, Federal, State, and county leaders officially opened the Kalapana viewing area to provide for the safe viewing of the lava flows</p> <p>Kalapana is a historic fishing village</p>	<p>At the end of Highway 130 in Puna</p>
	<p>Hawai‘i Volcanoes National Park</p> <p>Recreation area (park, hiking trails, lava viewing)</p>	<p>The park has two active volcanoes, Kīlauea and Mauna Loa</p> <p>The park has trails into very diverse environments</p> <p>Visitors can travel to the rim of the caldera</p>	<p>Southwest of Hilo</p>

3.8.3 COMMON CONSTRUCTION AND OPERATION IMPACTS

Typical impacts to visual resources from construction activities include ground disturbance; the presence of workers, vehicles, and equipment; and the generation of dust and vehicle exhaust. Lighting during nighttime construction activities could impact dark night skies. These impacts would be short term and intermittent and would depend on the project. Construction projects may require clearing, grading, and leveling of the construction site and extra workspaces, such as construction laydown yards and storage/preparation areas. Once construction is complete, the reclamation of disturbed areas would remove these visual impacts.

Common operational-related impacts to visual resources would depend on how the permanent or long-term structures associated with the specific technologies matched the nature and character of the surrounding environment. Similarly, the operational-related impacts to dark skies would also depend on the final design of the permanent lighting for the facilities or structures.

3.8.4 COMMON BEST MANAGEMENT PRACTICES

BMPs to minimize impacts to visual resources include:

- Consider potential impacts on visual resources in the project planning and siting phase, for example, when siting structures, consider landscape characteristics, lighting and glare from facility components, minimizing structure profiles, views from key observation points and nearby recreation lands, and integration of project components with natural land contours and colors.
- Consider potential visual impacts on the nature and character of nearby culturally sensitive and historic structures.
- Consider visual effects of project location and components on nearby units of the National Park System and other areas under NPS management, including effects of light pollution.
- Consider visual effects of project components on local infrastructure facilities such as schools, hospitals, and housing developments in urban and rural communities.
- Consider the importance of dark night skies in the short term during construction and in the long term. Use low lumen lighting, on demand lighting, and well-directed lighting. Use the minimum amount of light necessary; select lamps using long-wavelength light [greater than 560 nm (in vacuum)]; and select the most energy efficient lamps and fixtures.
- Limit the hours of construction at night, limit total lumen output of artificial lighting, and direct lighting downward and shield fixtures to reduce impacts from construction lighting.
- Provide accurate day and night visual simulations of the proposed project to local community and regulatory stakeholders (e.g. neighborhood boards) to adequately inform the community of what can be expected.

3.9 Recreation Resources

Hawai‘i’s unique environment and mild climate provide an ideal backdrop for a myriad of outdoor recreation activities supported by National Parks and Historic Sites, National Wildlife Refuges, State Forest Reserves, State Parks, State Harbors and Boating Facilities, and County Parks and Recreation departments. In addition to public lands, each island has commercial resort/hotel facilities and vendors that support outdoor recreation activities.

Many different Federal, State, and county governmental agencies and commercial, private, and non-profit entities provide recreation opportunities in Hawai‘i. The more directly involved Federal agencies include the NPS, the USFWS, NOAA’s Office of Ocean and Coastal Resource Management, and the DoD, which administers the Morale, Welfare, and Recreation Facilities program. The DoD program provides a wide variety of recreational opportunities for active duty and retired military personnel and their dependents. At the State level, the most directly involved agency is DLNR and its divisions of Forestry and Wildlife and State Parks. The Division of Forestry and Wildlife administers the “Na Ala Hele” program, the Statewide trails and access program established by Act 236, SLH 1998. All four counties in Hawai‘i have

parks and recreation departments, which are responsible for providing community recreation programs. Private agencies and organizations that provide organized sporting and camping opportunities to children and adults include the Boy and Girl Scouts of America and the Young Men's and Women's Christian Associations.

Hawai'i's recreational environment is often divided into mauka (inland or land-based) and makai (seaward or water-based). Land-based recreation activities, often in forest and park settings, include land and nature-based activities such as hiking, camping, picnicking, and hunting. Water-based recreation activities, along the shorelines and in the ocean, include surfing, swimming, snorkeling, scuba diving, fishing, and boating.

Various factors influence outdoor recreation in Hawai'i. The *State Comprehensive Outdoor Recreation Plan* (SCORP), a 5-year planning document for Statewide outdoor recreation, provides detailed descriptions of the influencing factors, which include ([DLNR 2009b](#)):

- Population growth
- Aging population
- Military
- Visitors
- Public health
- Tourism
- Ecotourism
- Sports tourism

Appendix A of the SCORP provides detailed matrixes of all recreation areas on each island and the recreational activities that are pursued at each area. Appendix A also provides detailed maps showing recreation areas on each island by the recreation planning district defined to in the Plan to concentrate survey and planning efforts.

State-managed public areas used for recreation include 23,000 acres of inland surface waters, 3 million acres of State ocean waters, and 410,000 acres of coral reef around the main Hawaiian Islands. In addition, there are 2 million acres of conservation land and 1.2 million acres of State-owned lands ([Hawai'i 2013a](#)). In total, the islands have 55 State parks, 8 national parks and historic areas, 10 national wildlife refuges, 20 State small boat harbors and 25 boat ramps or landings, and hundreds of county parks and recreation areas ([DLNR 2009b](#)). The national park lands total about 379,000 acres. Also, The Nature Conservancy operates 11 nature preserves on six islands, eight of which are jointly administered with the U.S. Forest Service ([DLNR 2009b](#)).

From 2011 to 2012, the Outdoor Industry Association estimated that outdoor recreation in Hawai'i represented \$6.5 billion in consumer spending, 65,000 direct jobs, \$2.1 billion in wages and salaries, and \$478 billion in State and county revenue ([OIA 2014](#)). These estimates are based on the resident population and visitors. In 2012, the number of visitors to O'ahu was 4.9 million; Maui, 2.3 million visitors; Hawai'i, 1.4 million visitors; Kaua'i, 1.1 million visitors; Lāna'i, 73,000; and Molokai, 53,000 visitors ([Hawai'i Tourism Authority 2013](#)).

3.9.1 RESORT-BASED OUTDOOR RECREATION

Resorts commonly include a range of amenities including restaurants, pools, spas, access to golf, tennis, and other activities such as horseback riding. Most resorts in Hawai'i are considered seacoast resorts, which typically offer beach access, ocean-oriented recreational activities such as whale and dolphin

watching tours, and other water-based outdoor activities (see [Section 3.9.3](#)). [Table 3-46](#) shows a distribution of seaside resort areas within the Hawaiian Islands.

Table 3-46. Distribution of Resorts in Hawai‘i

Island	Resorts	Locations
Kaua‘i	21	<ul style="list-style-type: none"> • North Shore (Princeville) • East Side (Coconut Grove) • Lihue (Kalapaki) • South Shore (Poipu) • West Side (Waimea)
O‘ahu	30	<ul style="list-style-type: none"> • Waikīkī • East Honolulu • North Shore • Leeward Coast
Maui	31	<ul style="list-style-type: none"> • West Maui • Kapalua • Kaanapali • Kihei • Wailea
Molokai	7	Bed and breakfast, smaller hotel, cottage-type establishments
Lāna‘i	2	<ul style="list-style-type: none"> • Manele Bay • Central Lāna‘i (uplands area)
Hawai‘i	14	<ul style="list-style-type: none"> • Kohala Coast • Kailua Village at Kailua-Kona • Keauhou

3.9.2 LAND-BASED OUTDOOR RECREATION

Land-based resident and visitor outdoor recreation surveys conducted for the SCORP included a wide range of activities including those related to nature and sports. The surveys also included interpretive activities and activities that require use of manmade facilities. [Table 3-47](#) lists the land-based activities.

Based on the SCORP 2008 surveys, the most popular (that is, more than 50 percent of the respondents stated they participated in at least once a year) land-based recreation activities Statewide are as follows:

- Picnicking/BBQ (86 percent)
- Visiting a scenic lookout (83 percent)
- Hiking (80 percent)
- Visiting a historic site (77 percent)
- Camping (69 percent)
- Visiting a botanical garden (65 percent)
- Visiting a nature center (65 percent)
- Bicycling on a roadway or path (60 percent)

Table 3-47. Land-Based Activities in Hawai‘i

Nature-Based Activities	
Nature-based land activities are recreation activities in undeveloped land settings. Limited developed facilities such as comfort stations or campsites may be used in conjunction with these activities. The purpose of a typical nature-based land activity is to experience natural surroundings. These activities include:	
<ul style="list-style-type: none"> • Camping • Hiking • Horseback riding 	<ul style="list-style-type: none"> • Hunting (Mammals and Birds) • Mountain (Off-Road) • Off-Road or all-terrain vehicles
Sports Activities	
Sports activities involve some form of competition and require a built setting. Sports activities include:	
<ul style="list-style-type: none"> • Baseball/Softball • Soccer • Football • Basketball 	<ul style="list-style-type: none"> • Tennis • Handball • Volleyball • Archery, rifle, or pistol shooting
Interpretive Facilities	
Interpretive activities generally involve viewing and learning about nature. Interpretive activities may also include cultural resources. Interpretive activities may not require a large degree of physical activity, although it often is a complementary component. Interpretive facilities include:	
<ul style="list-style-type: none"> • Nature parks • Botanical gardens • Scenic lookouts 	<ul style="list-style-type: none"> • Historic/Cultural sites • Trailhead kiosks and interpretative trails
Activities in Developed Facilities	
Developed land setting activities include outdoor recreational activities that use some form of manmade development (such as roads or sidewalks), or involve a high level of social interaction. These activities include:	
<ul style="list-style-type: none"> • Bicycling • Picnicking/BBQ • Playground use 	<ul style="list-style-type: none"> • Skateboarding/Rollerskating • Visiting a dog park • Walking/jogging on paths

Source: [DLNR 2009b](#).

3.9.3 WATER-BASED OUTDOOR RECREATION

Beach parks and ocean-based activities are a major factor in the quality of life for residents and attracting visitors to Hawai‘i. Based on SCORP surveys of both residents and visitors, the top two activities are visiting a beach and swimming. Other popular water-based recreation activities include snorkeling, pool swimming, bodysurfing, surfing/bodyboarding, and stand-up paddling. In addition, respondents indicated they also participate in sunbathing, scuba diving, boat rides, and whale watching ([Table 3-48](#)) ([DLNR 2009b](#)).

Table 3-48. Water-Based Activities in Hawai‘i

Water-Based Activities	
Water-based activities are popular recreational activities in Hawai‘i. Abundant water resources Statewide offer a wide variety of recreation opportunities from motorized boating in the open ocean to bodysurfing the shorebreak, to sunbathing on the beach. Water-based facilities accommodate the following water-based activities.	
<ul style="list-style-type: none"> • Boating (motorized) • Boating (Sailing/non-motorized) • Fishing (deep sea) • Fishing (shore) • Kayaking • Paddling, Outrigger Canoe • Personal Watercraft (jet-ski) 	<ul style="list-style-type: none"> • Scuba diving • Snorkeling • Surfing/Bodyboarding/Bodysurfing • Swimming (Ocean) • Swimming (Pool) • Visiting a beach • Windsurfing/Kitesurfing

Source: [DLNR 2009b](#).

Based on SCORP 2008 surveys, the most popular (that is, more than 50 percent of the respondents stated they participated in at least once a year) water-based recreation activities Statewide include the following:

- Visiting a Beach (90 percent)
- Ocean Swimming (86 percent)
- Snorkeling (68 percent)
- Pool swimming (66 percent)
- Bodysurfing (57 percent)
- Surfing/bodyboarding (51 percent)

3.9.4 COMMON CONSTRUCTION AND OPERATION IMPACTS

Short-term impacts to recreation resources are caused by visual and noise impacts from construction activities. Impacts could result from ground disturbance; the presence of workers, vehicles, and equipment; and the generation of noise, dust, and vehicle exhaust during construction of new facilities if located near existing recreation areas. In addition, access restrictions to recreation areas may occur if construction is located near the recreation areas. Because utility-scale energy projects typically occupy larger land or marine areas, potential impacts to recreational access could occur during project operation. Depending on location and project layout, access roads (e.g., non-paved and two-track roads) that have traditionally been used to access areas for hunting, fishing, hiking, mountain biking, birdwatching, and other types of outdoor recreation may be blocked or disturbed, prohibiting or restricting access. Utility-scale energy projects also could displace or eliminate use of lands or marine areas currently used for recreation activities.

3.9.5 COMMON BEST MANAGEMENT PRACTICES

BMPs to minimize impacts to recreation resources include:

- Consider potential impacts on visual resources in the project planning and siting phase, for example, when siting structures, consider landscape characteristics, lighting and glare from facility components, minimizing structure profiles, views from key observation points and nearby recreation lands, and integration of project components with natural land contours and colors.
- Consider visual effects of project location and components on nearby units of the National Park System and other areas under NPS management
- Consider the importance of dark night skies to recreation areas, for example areas popular for camping and stargazing. Use low lumen lighting, on demand lighting, and well-directed lighting. Use the minimum amount of light necessary; select lamps using long-wavelength light [greater than 560 nm (in vacuum)]; and select the most energy efficient lamps and fixtures.
- Identify and consult with key local recreational clubs (canoe clubs, fishing/diving clubs, hiking clubs) to get an accurate sense of the outdoor activities occurring within and near the proposed project area.
- Implement BMPs to limit impacts to visual resources (see [Section 3.8.4](#)) and noise impacts (see [Section 3.12.6](#))

3.10 Land and Marine Transportation

The Hawai‘i transportation network differs from other states in that it relies entirely on marine and air (see [Section 3.11](#)) transport for imports and exports both at the State (overseas) and interisland levels. While land transportation planning is guided by a long range Statewide land transportation plan, implementation of land transportation projects is on an island-by-island basis ([HDOT 2011a](#)).

3.10.1 LAND TRANSPORTATION

The Hawai‘i land transportation system consists of roads, freeways, bike paths, and multi-modal transportation including cars, trucks, mass transit (buses), bicycles, and mopeds. The HDOT Highways Division is primarily responsible for the maintenance, development, and support of land transportation facilities within the State ([HDOT 2013a](#)). However, the Highways Division of HDOT partners with the counties and municipalities in planning, managing, and maintaining the land transportation system.

3.10.1.1 Highway and Road Systems

There are approximately 4,200 miles of paved streets and highways in the State of Hawai‘i (Table 3-49). O‘ahu, the most populous island, has nearly 40 percent of the paved road and highway system including the only freeway system in the State. The O‘ahu freeway system comprises three roads primarily in the southern part of the island. Highway 1 extends from Diamond Head through the Honolulu metropolitan area, around Pearl Harbor to the Barbers Point region. Highway 2 extends north from Pearl Harbor to the Wahiawa region in the central valley between the Ko‘olau and Wai‘anae Mountains. Highway 3 connects the Honolulu area near Pearl Harbor with the Kāne‘ohe Bay area on the east side of the Ko‘olau Mountains.

Table 3-49. Length of Streets and Highways in Hawai‘i by Island

Island	Total Mileage	Paved		Unpaved
		Freeway	Other	
Kaua‘i	439	(a)	417	22
O‘ahu	1,663	89	1,566	8
Maui	636	(a)	579	57
Lāna‘i	48	(a)	34	14
Molokai	136	(a)	124	12
Hawai‘i	1,495	(a)	1,435	59
STATE TOTALS	4,417	89	4,155	172

Source: [DBEDT 2013a](#).

a. O‘ahu is the only island in Hawai‘i with freeways.

Hawai‘i island has 35 percent of the paved roads and highways in the State. The HDOT Highways Division manages approximately half of the paved freeways, highways, and roadways in the State ([HDOT 2011a](#)). Counties and municipalities manage the remaining public roadways. In 2012, Hawai‘i had 1,310,286 registered vehicles ([DBEDT 2013b](#)). Approximately two-thirds of those registered vehicles were on the island of O‘ahu. The Honolulu metropolitan region has the highest motor vehicle density within the State.

3.10.1.2 Public Transit

Each county has a public transit system, which are operated by the respective county governments. Each county has developed transit plans ([HDOT 2011a](#)). Mass transit is more developed in the City and County of Honolulu because of the large urban and tourist population base. In 2011, the City and County of

Honolulu bus system operated 515 buses with an estimated 76.3 million passengers ([DBEDT 2013b](#)). The City and County of Honolulu is currently developing plans for a 20-mile elevated rail line that will connect West O‘ahu with downtown Honolulu and the Ala Moana Center. Transit systems in the other counties were developed for and have adapted to the particular needs of each island ([HDOT 2011a](#)).

3.10.1.3 Non-Motorized Transportation

HDOT has recognized the importance of bicycles as a means to move people. The first Hawai‘i bike plan was developed in 1977, updated in 1994, and again in 2003. The plan serves as roadmap for improving existing conditions for biking and encouraging new users ([HDOT 2003](#)). A separate Honolulu Bicycle Master Plan was prepared in 1999 ([City and County of Honolulu 1999](#)). The goal of both plans is to establish bicycling as a safe and convenient mode of transportation for residents and visitors throughout the State. The State of Hawai‘i requires that bicycles with a wheel diameter of 20 inches or greater be registered. In 2001 the Statewide registration of bicycles and mopeds was 32,110 ([HDOT 2003](#)). In 2011, one decade later, bicycle and moped registration increased by over 300,000, for a total of 359,378. Bicycle facilities are developed on an island-by-island basis.

3.10.2 MARINE TRANSPORTATION

The geography of the Hawaiian Islands dictates that marine transportation is a critical part of the economy of the State. The majority of imported and exported goods is transported through the marine transportation system ([DBEDT 2013b](#)). The primary components of the marine transportation system are the harbors, docks or piers, near-shore shipping lanes, and navigation aids. Navigation aids are largely the responsibility of the U.S. Coast Guard. The Coast Guard develops, establishes, operates, and maintains Aids to Navigation systems to assist mariners in determining position and a safe course, warning of dangers and obstructions, and promoting safe and economic movement of commercial vessel traffic ([USCG 2013](#)).

The following sections discuss marine transportation in terms of use and users.

3.10.2.1 Harbor Systems

The Statewide commercial harbors system consists of ten commercial harbors located at Honolulu, Kalaehoa Barbers Point, Hilo, Kawaihae, Kahului, Hana, Kaunakakai, Kaunapau, Nāwiliwili, and Port Allen on the six major islands ([Table 3-50](#)). These harbors are used for cargo and bulk shipping, passenger cruises, commercial fishing, and excursions. Some harbors also handle military shipping. The military has a large maritime presence in Hawai‘i and is discussed separately below. The harbor system is operated under the Harbors Division of HDOT. One of the main objectives of the harbor system is to provide adequate maritime facilities to accommodate the needs of the commercial shipping industry and the public.

The major activities of the Harbors Division are to maintain, repair, and operate the ten commercial harbors that comprise the Statewide harbors system; plan, design, and construct harbor facilities; provide program planning and administrative support; manage vessel traffic into, within, and out of harbor facilities; provide for and manage the efficient utilization of harbor facilities and lands; and maintain offices and facilities for the conduct of maritime business with the public ([HDOT 2013c](#)).

Table 3-50. Size of Hawai‘i’s Commercial Harbor Facilities

Harbor Name	Island	Number of Piers	Total Berth Length (feet)	2010 Vessel Arrivals ^a
Honolulu	O‘ahu	53	31,087	3,408
Kalaeloa Barbers Point	O‘ahu	6	3,255	899
Nāwiliwili	Kaua‘i	3	1,860	579
Port Allen	Kaua‘i	1	1,200	25
Kahului	Maui	3	3,052	987
Hana	Maui	1	337	(b)
Kaunanakai	Molokai	1	689	211
Kaumalapau	Lāna‘i	1	400	(b)
Hilo	Hawai‘i	3	2,605	737
Kawaihae	Hawai‘i	2	1,562	644

Sources: [HDOT 2013b](#); [DBEDT 2012b](#).

a. Excluding domestic fishing vessels.

b. No data available.

The Harbors Division interacts with other public and private sectors that are essential to the effective operation of the marine transportation system. The Federal Government agencies include the following:

- USACE, which administers and participates in the planning, construction, and maintenance of harbor navigational improvements;
- Federal Maritime Commission, which regulates ports and marine terminal operators and receives and reviews tariff filings;
- USCG, which oversees maritime security at the commercial harbors and is also involved in the enforcement of safety and oil pollution regulations within harbor complexes of the State;
- U.S. Treasury Department, which inspects foreign goods to ensure a proper assessment of duty.
- U.S. Department of Agriculture, which also inspects goods to safeguard the State against the introduction of biological pests and invasive species;
- U.S. Customs and Border Protection, which monitors the flow of foreign people and goods through State ports; and
- EPA, which is involved with water quality standards.

State agencies are involved in the management of coastal zone areas, land and water use, economic development, and implementation of environmental regulations and safety regulations. The counties are involved in matters involving zoning. The private sector provides a variety of services, including shipping services, stevedoring, warehousing, tug services, maintenance, ship chandlery and repair, and distribution.

3.10.2.1.1 O‘ahu

The island of O‘ahu has two commercial harbors: Honolulu Harbor and Kalaeloa Barbers Point Harbor. Pearl Harbor is used for military operations and discussed separately below. The Honolulu Harbor is the largest and most active harbor in the State. It is located on the south shore of O‘ahu, adjacent to downtown Honolulu and east of Honolulu International Airport. The majority of marine transported goods to Hawai‘i flows through this harbor. It also is the primary distribution point for interisland marine

transportation. Honolulu Harbor handles all types of marine shipping: bulk goods, cruise ships, commercial fishing vessels, water taxis, bunkering (i.e., supplying ships with fuel), and petroleum products.

Kalaeloa Barbers Point Harbor is located along the southwestern shore of O‘ahu, approximately 20 miles west of Honolulu. Barbers Point Harbor is the second busiest port in Hawai‘i and contains specialized cargo handling facilities not available at Honolulu Harbor, such as a coal bulk unloading system and a pneumatic cement pump system. It handles liquid-bulk (e.g., petroleum products) and dry-bulk (e.g., coal, cement, and scrap metal) cargos and has space for ship maintenance and repair facilities. Approximately a mile-and-a-half off of Barbers Point are berths (moorings anchored in 100 feet of water) where large oil tankers (up to 1 million barrel capacity) are docked to unload. The crude oil is pumped to the mooring where the crude oil is transferred to underwater pipes that deliver it to shore.

3.10.2.1.2 Kaua‘i

The primary port on Kaua‘i is Nāwiliwili Harbor. It is located on the southeastern coast near the county seat of Lihue about 96 nautical miles from Honolulu Harbor. Facilities include piers for handling both overseas and interisland containerized and general cargo. A second commercial harbor, Port Allen, is located on Kaua‘i’s leeward south coast. Port Allen Harbor has facilities for liquid-bulk cargo. Military and excursion/charter vessels also use this harbor.

3.10.2.1.3 Maui

The island of Maui has two commercial harbors. Kahului Harbor is located on the north shore of Maui, within Kahului Bay and is approximately 89 nautical miles southeast of Honolulu Harbor. The harbor provides a full range of maritime services and facilities. It is a regular stop for passenger cruise ships. Maui’s second commercial harbor is located at Hana Harbor on the east side of the island. Administrative authority for Hana Harbor was transferred in 2010 from the Hawai‘i DLNR to HDOT Division of Harbors. Hana Harbor currently is being improved to provide better commercial service to the Hana region that currently is accessible only by the narrow and winding 50-mile Hāna Highway.

3.10.2.1.4 Molokai

The island of Molokai has one commercial port facility located on the south (leeward) central shore at Kaunakakai Harbor. The port is 52 nautical miles from the Honolulu Harbor. It has facilities for interisland barge cargo operations, a passenger ferry terminal, and liquid-bulk cargo.

3.10.2.1.5 Lāna‘i

Kaumalapau Harbor is located on the southern shore of Lāna‘i, approximately 1 mile from Lāna‘i City. It has facilities for interisland barge cargo operations and liquid-bulk cargo.

3.10.2.1.6 Hawai‘i

The island of Hawai‘i has two commercial harbors, Hilo Harbor and Kawaihae Harbor. Hilo Harbor provides a range of maritime facilities and services and is the major distribution center for the island. Hilo Harbor is located on the northeastern coast of Hawai‘i, 194 nautical miles from Honolulu Harbor. The harbor is at Kuhio Bay, which is a small extension of the larger Hilo Bay. Hilo Harbor handles overseas containers, cruise ships, interisland liquid- and dry-bulk cargo, and dry cargo.

Kawaihae Harbor is located on the northwestern coast of Hawai‘i, approximately 132 nautical miles from Honolulu Harbor. The Kawaihae Harbor handles barges, overseas containers, interisland cargo, and dry- and liquid-bulk cargos and serves west Hawai‘i island.

3.10.2.2 Cargo and Bulk Shipping

Honolulu Harbor is the primary cargo shipping port for the State. Much of the maritime cargo for the other islands passes through Honolulu Harbor and is then distributed by interisland marine transport ([Figure 3-68](#)). In 2012, the latest year for which statistics are available for Honolulu Harbor, 976 overseas vessels passed through the harbor carrying nearly 6.8 million short tons of cargo ([DBEDT 2013b](#)). The harbor had 2,705 interisland vessel arrivals carrying 3.2 million short tons of cargo during the same period ([DBEDT 2013b](#)). Kalaheo Barbers Point Harbor is the primary bulk shipping port. In 2011, approximately 9.8 million short tons passed through Kalaheo Barbers Point Harbor; most of which was petroleum and petroleum products. Most of the cargo and bulk shipping is done with large open or closed barges, container cargo ships, and liquid-bulk barges or ships.

Figure 3-68. Primary Marine Transportation Routes (2008-2009 data)

As shown in [Table 3-51](#), petroleum and petroleum products account for over one third of all marine transported cargo (35 percent in 2011). Of the 10.4 million short tons of petroleum transported in 2011, 79 percent was handled at the Kalaheo Barbers Point Harbor on the southwestern shore of O‘ahu.

Manufactured equipment, machinery, and products account for about 55 percent of marine transported products, while food and farm products account for 7 percent) based on 2011 statistics ([DBEDT 2013b](#)).

Table 3-51. Amount of Cargo Handled at Six of the Ten Commercial Harbors in Hawai‘i, 2011

Commodity	Weight (in 1,000 short tons)	Percent of Total
Petroleum and Petroleum Products	10,367	35
Primary Manufactured Goods	821	3
Food and Farm Products	2007	7
Manufactured Equipment, Machinery and Products	16,261	55
TOTAL	29,456	

Source: [DBEDT 2013b](#).

Note: The six harbors include Honolulu, Barbers Point, Nāwiliwili, Kahului, Hilo, and Kawaihae.

3.10.2.3 Passenger and Tourism Excursions

Tourism is a primary industry of Hawai‘i’s economy. Passenger cruise lines, smaller excursion vessels, and recreational boating are important components of the marine transportation system. In 2011, over 420,000 cruise ship passengers arrived in Honolulu Harbor and 778,000 cruise ship passengers departed from the harbor. These numbers include both out-of-state and home-ported cruise ships. The larger harbor ports on Kaua‘i, Maui, and Hawai‘i can also handle large cruise ships. There were over 14,000 registered vessels in the State in 2011. In addition to the larger harbors, Hawai‘i has many small-craft facilities throughout the islands ([Hawai‘i 2013d](#)). The DLNR Division of Boating and Outdoor Recreation manages many of these facilities although some are Federal, county, or private. Small-craft facilities include small boat harbors, launch ramps, anchorages, and piers.

3.10.2.4 Recreational and Commercial Fishing Vessels

Fishing is an important recreational and commercial industry in Hawai‘i. Fishing vessels ranging from the smaller-sized sport fishing and charter boats to the large longline commercial vessels comprise a significant part of the marine transportation system. The smaller fishing boats typically operate within 25 miles of the islands with trips lasting one day ([WPRFMC 2009b](#)). The larger longline commercial fishing vessels are mostly steel-hulled ships that largely target tuna (e.g., bigeye and yellowfin) and billfish (e.g., marlins and swordfish). The larger longline vessels typically operate from 500 to 700 nautical miles from the islands but some larger tuna vessels travel out to 1,000 nautical miles ([WPRFMC 2009b](#)). Based on the amount of commercial sea landings, 86 percent of the commercial fish catch in Hawai‘i passed through O‘ahu in 2011. The majority of that catch, approximately 27.2 million pounds, passed through Honolulu Harbor ([DBEDT 2012b](#)). Hawai‘i island had the second highest commercial sea landings, with approximately 2.7 million pounds.

3.10.2.5 Military and Homeland Security Operations

Pearl Harbor, located 7 miles west of downtown Honolulu, is naval headquarters for the U.S. Pacific Fleet Command. The Navy maintains submarine, surface, and air defense capabilities in Hawai‘i. Naval operations and training missions are an integral part of the marine transportation system, as the Navy uses waters in and around the islands. The Command for the Submarine Force, U.S. Pacific Fleet is based at Pearl Harbor and several submarine squadrons use Pearl Harbor as their homeport and are supported by the Pearl Harbor Naval Submarine Support Command. The U.S. Pacific Fleet, Naval Surface Force is based in San Diego, California. However, Pearl Harbor is the homeport for naval surface ships in the Pacific Fleet with two support commands, Commander for the Destroyer Squadron 31 and Commander Naval Surface Group Middle Pacific.

The U.S. military conducts training exercises (including gunnery and flare activities) throughout the year in specific areas ([USCG 2013](#)). Marine open water exercises are conducted in sea-space that coincides with Warning Areas (see [Section 3.11.2](#)). To facilitate the safe operation of military operations and training in the marine regions around the Hawaiian Islands, the military notifies the respective U.S. Coast Guard Sector Office (and Federal Aviation Administration) to issue a Broadcast Notice to Mariners or NOTMAR (as well as Flight Information Publications or Notice to Airmen or NOTAM). In addition, a visual and radar search of the area is conducted. During these exercises, small craft which may not be readily visible are advised to remain clear of these areas during these exercises. Individuals are requested to direct their inquiries concerning the times of the exercises to the U.S. Coast Guard Sector, and Federal Aviation Administration offices covering these areas. Other types of restricted areas may be established in marine areas to ensure the safety of the general public and any commercial marine activity such as shipping and fishing ([USCG 2013](#)). A Safety Zone is a water area, shore area, or both to which access is limited to authorized persons, vehicles, or vessels for safety or environmental purposes. It may be stationary and described by fixed limits or it may be described as a zone around a vessel in motion. A security zone is an area of land, water, or land and water which is so designated by the Captain of the Port or District Commander (U.S. Coast Guard) for such time as is necessary to prevent damage or injury to any vessel or waterfront facility, to safeguard ports, harbors, territories, or [waters of the United States](#). Information on active Safety or Security Zones may be obtained from the U.S. Coast Guard.

In addition to the general Safety and Security Zones, special marine restricted areas have been designated. The Special Operating Areas Four was established in 1995 as a permanent “Hot Area” named KAPU south of O‘ahu bounded by the coordinates: 20-46N/158-16W, 20-42 N/158-04W, 20-13N/158-36W, and 20-04N/158-11W ([USCG 2013](#)). Activities include intermittent naval gunnery exercises and airborne ordnance drops.

Intermittent missile firing operations are conducted by the Pacific Missile Range Facility (PMRF), Barking Sands, located on the southwest coast of Kaua‘i. PMRF conducts intermittent missile firing operations in the Warning Area 188 (W-188) operating area west of Kaua‘i. Approximate coordinates of the safety zone are provided in [U.S. Coast Guard \(2013\)](#). The safety zone is activated during launch operations at PMRF and is closed to all vessels except those specially authorized.

The Keahi Point Danger Zone is located in ocean waters southwest of Pearl Harbor as described by the coordinates 21-18-21N/157-59-14W, 21-18-11N/158-00-17W, 21-17-11N/158-00-06W, and 21-17-22N/157-59-03W. The Keahi Point Danger Zone is closed at all times to surface craft, swimmers, and divers, with the exception of authorized personnel. The Coast Guard provides notice of hazardous operations through published weekly Local Notice to Mariners.

The Ulupau Crater Weapons Training Range Danger Zone encompasses a sector extending seaward for 3.8 nautical miles between radial lines bearing 001 and 129 degrees true, from the Marine Corps Base on Mokuapu Peninsula along the northeast coast of O‘ahu from coordinate point 21-27-12N/157-43-54W ([74 FR 58846, November 16, 2009](#)).

Many marine surface operations by the U.S. military and Homeland Security also require airspace control because the operation involves aerial fire and joint aviation operations. Airspace management and control is discussed in [Section 3.11.2](#). However, airspace and marine navigation are often managed jointly because of links between surface and air operations.

3.10.3 COMMON CONSTRUCTION AND OPERATION IMPACTS

3.10.3.1 Land Transportation

Construction and operation of most renewable energy projects would have minimal impacts on land transportation systems. Traffic could temporarily increase in the vicinity of project sites during construction. Local traffic may be disrupted from temporary road restrictions or closures if installation of utility services for energy projects requires road crossings.

3.10.3.2 Marine Transportation

Development of renewable energy projects in the marine environment would normally involve the installation of structures in the ocean including power cables, water pipes, floating platforms with cable tethered anchors, or submerged energy devices on the ocean floor. During construction, all of these types of energy projects could have the potential in cause temporary disruption of marine transportation including commercial, recreational, and military (both surface and sub-surface). These impacts would be temporary and be localized to the vicinity of the project location.

Placement of energy projects in the marine environment could have longer term impacts to marine transportation. Energy facility structures placed in the ocean become potential obstacles to all types of marine transportation depending on the location of the project. Ocean-based energy facilities would require coordination with the U.S. Coast Guard and possible marking through their Aids to Navigation program. Underwater structures, particularly anchor cabling for floating platforms, would be a hazard to submarine navigation. Locating ocean-based energy facilities away from highly used routes between islands would reduce potential impacts on commercial marine transportation.

3.10.4 COMMON BEST MANAGEMENT PRACTICES

- Coordinate early with State and county transportation agencies and local emergency response organizations if construction of a renewable energy project is expected to require road crossings or impact local transportation.
- Approvals from the appropriate agencies (e.g., HDOT, Highways Division) would be needed in order to transport oversized loads on public roadways.
- Coordinate with the U.S. Coast Guard and HDOT early in the planning phase for any ocean-based energy project to evaluate potential project locations, issues with marine transportation, and any specific requirements such as safety marking. The Department of Defense should also be included in these early planning discussions because their organizations of have extensive surface and submarine transportation operations in the vicinity of the islands.

3.11 Airspace Management

Air transportation is an important component of the Hawai'i transportation system, connecting the State with the world and the islands with each other; air is the primary mode of transportation for people traveling to and among the Hawaiian Islands. Tourism contributes significantly to air transportation in Hawai'i. In addition to commercial transport of tourists to the islands, local tour operations including helicopters and airplanes use Hawai'i airspace. Because of its location in the central Pacific Ocean, the islands are also a strategic military defense base for the United States and contain air defense operations for several branches of the U.S. military.

3.11.1 AIRPORT SYSTEMS

The HDOT Airports Division manages the public airport system in Hawai‘i. In addition, the U.S. Department of Defense operates airfields and training areas on the islands as part of its national defense mission. Refer to the *Hawai‘i Airports and Flying Safety Guide* ([HDOT 2013d](#)) for a description of airports and the air transportation system in Hawai‘i. All Hawai‘i airports and air transportation systems, including military operations, operate in accordance with rules and regulations established by the Federal Aviation Administration (FAA) ([FAA 2012](#)). FAA regulations address both the management and control of airspace and obstructions to airspace navigation.

3.11.1.1 Airspace

The FAA has developed a system of airspace designations to control and manage use of airspace. Airspace is a finite resource that is defined both vertically and horizontally and is classified into four types: controlled, uncontrolled, special use, and other airspace ([FAA 2012](#)). *Controlled airspace* is defined as airspace where air traffic control service is provided to both instrument and visual flights in accordance with the airspace classification. Controlled airspace in the United States is designated as Class A, B, C, D, or E. Class A airspace is above 18,000 feet above mean sea level, overlying land and the sea out to 12 nautical miles. For the purposes of this PEIS, Class A airspace is not a concern. Classes B through E are classified in descending order based on the amount of air traffic and air traffic control service. Class B airspace is the airspace from the ground surface to 10,000 feet mean sea level, surrounding the busiest airports. Class B airspace also contains two additional air layers defined at 2,900 and 5,500 feet above ground level and is designed to contain all published instrument procedures. Class C airspace generally is the airspace from the ground surface to 4,000 feet above ground level, surrounding airports that have an operational control tower, serviced by a radar control approach, and have a certain number of instrument flight rule operations. Class C airspace typically has a 5-nautical-mile radius at the surface and a 10-nautical-mile radius from 1,200 to 4,000 above ground level. Class D airspace generally is from the ground surface to 2,500 feet above ground level, surrounding airports with an operational control tower. Class D requires two-way communication with the air traffic control tower prior to entering the airspace. No separation services for visual flight rule aircraft are provided. Class E airspace is any controlled airspace not classified as A through D and includes a variety of different types such as transition airspace, surface area extensions, and Federal airways ([FAA 2012](#)).

Uncontrolled airspace is classified as Class G where no air traffic control services are provided. The primary purpose of special use airspace is to establish and designate airspace in the interest of national defense and security where activities must be confined or limits may be imposed on aircraft operating in the area. Special use airspace categories include Prohibited Areas, Restricted Areas, Warning Areas, Military Operation Areas, Alert Areas, Controlled Firing Areas, and National Security Areas ([FAA 2012](#)). [Section 3.11.1.2](#) of this PEIS discusses special use airspace by island. Other airspace is airspace that does not fit into the other categories and includes categories such as En Route Domestic Airspace Areas and Offshore/Control Airspace Areas (in international airspace) ([FAA 2012](#)). Neither category is applicable to energy technologies being evaluated in this PEIS.

The FAA established regulations regarding obstructions to navigable airspace based on airport zoning ([FAA 2012](#); [HAR Chapter 19-12](#)). Airport zoning is designed to prevent hazards to air traffic by establishing imaginary three-dimensional surfaces for both airports and heliports through which no obstruction may penetrate. Construction of structures of more than 200 feet above ground level or in a particular location relative to an airport as defined in 14 CFR 77.9 require an FAA obstruction analysis. Developers of any project that may affect airspace should file a Form 7460-1 (Notice of Proposed Construction or Alteration) with the FAA Office of Obstruction Evaluation/Airport Airspace Analysis (OE/AAA) to request an evaluation and determination of potential hazard to navigable airspace

(<https://oeaaa.faa.gov/oeaaa/external/portal.jsp>). OE/AAA coordinates the FAA review of potential hazards to air navigation and issues a determination.

3.11.1.2 Airports

There are 16 public airports in Hawai‘i; 15 operated by the HDOT Airports Division, and 1 privately operated airport in Princeville, Kaua‘i. Honolulu International Airport is the only airport in the State that operates in Class B airspace and handled 263,340 operations in Calendar Year 2011 (arrivals and departures) (Table 3-52). Kalaeloa Airport in west O‘ahu, formerly the Naval Air Station Barbers Point, is the second busiest airport but mostly serves general aviation and military aircraft. Kahului Airport on Maui operates in Class C airspace while all other airports on the islands operate in Class D, E, or G airspace. Large air carriers primarily use Honolulu International while the other islands are served by a larger proportion of air taxi aircraft (60 seats or less) (Table 3-52).

Table 3-52. Airspace Classification of Hawai‘i Airports and Number of Flight Operations in 2012

Island/Airport	Airspace Class ^a	Total Operations ^b	Air Carrier	Air Taxi ^c	General Aviation	Military
Kaua‘i						
Lihue	D/E	118,431	28,522	62,482	23,746	3,681
Port Allen Airport	G	(d)	(d)	(d)	(d)	(d)

Waimea-Kohala Airport (Kamuela)	E/G	(d)	(d)	(d)	(d)	(d)
Upolu Airport	G	(d)	(d)	(d)	(d)	(d)

Source: [DBEDT 2013b](#), Table 18.29.

Note: Statistics available for select airports and are for Calendar Year 2012.

- Some airports have multiple airspace classifications based on time of available air traffic control services.
- An operation is either an arrival or departure.
- Air taxi is an aircraft with 60 seats or less.
- No data available.

3.11.1.3 Commercial Air Passenger and Cargo

In 2011, 11.8 million overseas passengers arrived and departed through Honolulu International Airport, nearly 70 percent of the State's total overseas passenger arrivals and departures. Kahului Airport in Maui handled 18 percent of the State's total of overseas passenger arrivals and departures. On the other main islands, interisland passengers outnumbered overseas passengers. In 2011, ninety-four percent of overseas air cargo flew through Honolulu International Airport ([DBEDT 2012b](#)).

3.11.1.4 Air Tour Operators

Air tours, helicopter and airplanes, are a large industry in Hawai'i due to tourism. To support this industry and promote air safety, the FAA Honolulu Flight Standards District Office has published the *Hawai'i Air Tour Common Procedures Manual* ([FAA 2008](#)). All commercial air tour operators authorized to conduct operations below 1,500 feet above ground level within the State of Hawai'i must comply with the requirements and limitations set forth in this manual. The manual contains island-specific instructions, procedures, and requirements.

3.11.2 MILITARY AIR BASES AND OPERATIONS

The State of Hawai'i is a strategic location for the U.S. Departments of Defense and Homeland Security. Aviation operations are an important component of military and homeland security operations and training missions throughout the State and in the Pacific region. The military operates several air bases and training areas throughout the Hawaiian Islands. Airspace classification and special use airspace in Hawai'i associated with military and homeland security activities are described in two environmental impact statements ([Navy 2008](#); [Army 2004](#)). The following types of special use airspace exist in the main Hawaiian Islands and are discussed by island in this PEIS: Alert Area, Restricted Area, Warning Area, and National Security Area. An Alert Area is an area that contains a high volume of pilot training or other unusual type of aerial activity. No special clearances are required. A Restricted Area contains activities that create hazards to aircraft such as artillery firing or aerial gunnery. Restricted Areas usually have specific hours of operation and require permission to enter the airspace. Warning Areas in the State of Hawai'i are located in off-shore waters. These open water areas may periodically be reserved for military use to protect the general public from safety hazards. The public is notified of activation of a Warning Area through notices from the USCG and FAA (i.e. NOTMAR, NOTAM and Flight Information Publication). A National Security Area is airspace where additional security is needed. Pilots are requested to voluntarily avoid flying through these areas. Airspace designations and locations are illustrated at http://aeronav.faa.gov/index.asp?xml=aeronav/applications/VFR/chartlist_sect (select Hawaiian islands). Special use airspace and marine surface areas are often linked because operations could affect both airspace and marine surface space. Activation of special use airspace also may require activation of a marine special use area. Marine navigation areas with respect to military and homeland security operations are discussed in [Section 3.10.2.5](#).

3.11.2.1 Kaua'i Military Airspace

The Department of the Navy operates the Pacific Missile Range Facility (PMRF) on the southwestern coast of Kaua'i. The facility serves as a missile testing and training range and has a 6,000-foot airfield. Airspace surrounding the airfield is Class D with a 2,500-foot ceiling. The Class D airspace is surrounded to the north, south, and east by Class E airspace with a floor 700 feet above the ground surface. A Restricted Area R-3101 air space (surface to unlimited) lies immediately above the PMRF main base and extends offshore to the west approximately 5 nautical miles ([Navy 2008](#)). Two airspace Warning Areas, W-186 and W-188, lie approximately 5 nautical miles off of and outward from Kaua'i's southwestern, western, and northern coasts into international waters.

3.11.2.2 O'ahu Military Airspace

The island of O'ahu contains the largest military presence in the State. The Naval Station Pearl Harbor is located on the southern shore of the island and is home to Naval Command for the U.S. Pacific Fleet. The U.S. Navy and U.S. Air Force share the Joint Base Pearl Harbor-Hickam (JBPHH) air base at Pearl Harbor. Aircraft that use JBPHH include fixed wing, rotary, and airships. JBPHH and adjacent Honolulu International Airport constitute a single large airport complex and share airspace. Class B airspace lies above JBPHH, surrounded by several layers of floor altitudes ([Navy 2008](#)). Below the Class B layers are Class E airspace with a floor 700 feet above the ground surface. Special use airspace includes the Pali Air Traffic Control Assigned Airspace, which is in effect above the entire O'ahu area from 25,000 feet up to unlimited. National Security Area airspace has been assigned above portions of the Naval Station Pearl Harbor, where pilots are requested not to fly below 5,000 feet.

The U.S. Army operates combat training centers on O'ahu including Wheeler Army Airfield located in central O'ahu adjacent to the Schofield Barracks between the Ko'olau and Wai'anae Mountains. Helicopter support to Army training exercises and helicopter training comprises much of the air traffic at Wheeler Army Airfield and over the Army training areas in the central and northern part of the island ([Army Garrison 2010a](#)). Wheeler Army Airfield also is home to the Air Force 6010th Aerospace Defense Group, the Hawai'i Army National Guard Aviation Support Facility, and the 25th Infantry Division (Light) Aviation Brigade ([Navy 2008](#)). The airspace above Wheeler Army Airfield includes Class D airspace from the ground surface to 3,300 feet and Class E airspace with a floor 700 feet above the surface ([Navy 2008](#); [Army 2004](#)). Intermittent Restricted Area airspace (3109 A, B, C and 3110 A, B, C) is located immediately to the northwest of the Wheeler Army Airfield Class D airspace. These Restricted Areas are associated with several military training areas and are activated as needed. To the north of Wheeler Airfield over the East Range training areas is an Alert Area (A-311) airspace associated with an area of pilot training activity ([Army 2004](#)).

Dillingham Airfield is on the northwestern coast of O'ahu and is a general aviation joint-use facility located on Dillingham Military Reservation. Dillingham has a State-operated air traffic advisory facility, several hangars, and a tie-down area for recreation aircraft, but no other facilities. Air traffic is limited to daytime operation, visual operating rules by small single-engine and light twin-engine aircraft, sailplanes, ultra-light aircraft, and helicopters. Airspace above Dillingham is classified as Class G (uncontrolled) from the ground surface to 1,200 feet and Class E (controlled) above 1,200 feet ([Army 2004](#)).

The U.S. Coast Guard Air Station Barbers Point is on the southwestern coast of O'ahu, at Kalaeloa Airport, which formerly was the active airfield portion of Naval Air Station Barbers Point. Kalaeloa Airport is a general aviation facility that uses 750 acres of the former Navy facility. The State operates the three runways at the airport, the control tower, and support facilities. Aircraft Support Operations are associated with U.S. Coast Guard Air Station Barbers Point. The airspace above Kalaeloa Airport includes Class D, surface Class E, and Class E airspace with a 700-foot floor above the ground surface ([Navy 2008](#)). Class B airspace from Honolulu International Airport also is located within and above Kalaeloa Airport airspace.

The U.S. Marine Corps operates the Marine Corps Base Hawai'i on the northeastern coast of O'ahu on the Mokapu Peninsula bounded by Kāne'ōhe Bay, the Pacific Ocean, and Kailua Bay. The Marine Aviation Group 24 and Marine Aviation Logistics Squadron 24 are based at the Kāne'ōhe Bay Marine Corps Airfield ([Navy 2012](#)). Airspace above the Marine Corps Base Hawai'i includes both Class D (4.3-nautical-mile radius up to 2,500 feet) and E ([Navy 2008](#), [2012](#)).

3.11.2.3 Maui, Molokai, and Lānaʻi Military Airspace

There is no special use airspace on Maui or Lānaʻi associated with any military activity. The Pali Air Traffic Control Assigned Airspace that is in effect above the entire Oʻahu area from 25,000 feet up to unlimited overlaps the western part of the island of Molokai.

3.11.2.4 Hawaiʻi Military Airspace

The Pohakuloa Training Area in the center of Hawaiʻi island is a sub-installation of the Schofield Barracks on Oʻahu. Its primary mission is to provide training of full-scale, live fire exercises for the 25th Infantry Division (Light), U.S. Army Garrison, Hawaiʻi. Bradshaw Army Airfield serves the Pohakuloa Training Area and is used for deploying, redeploying, and resupplying military units. Army personnel deploy to Pohakuloa from JBPHH or Wheeler Army Airfield using C-17 or C-130 aircraft. The area is used extensively for helicopter training with an average of 900 aircraft movements per month, 99 percent involving helicopters ([Navy 2008](#)). The U.S. Air Force and Navy train tactical aviation aircraft bombing and strafing, and the U.S. Navy uses the area for air-to-surface missile training and for high altitude, laser-guided, inert bombing of targets in the southern part of the Pohakuloa Training Area ([Army Garrison 2010b](#)).

Airspace above the Pohakuloa Training Area includes uncontrolled Class G airspace, which extends from the ground surface to a 1,200-foot ceiling, and controlled Class E airspace above 1,200 feet. Bradshaw Army Airfield is surrounded by Class D airspace, extending from the ground surface to a ceiling of 8,700 feet ([Army 2004](#)). However, the same airspace has the special use airspace classification of Restricted Area ([Army 2004](#); [Army Garrison 2010b](#); [Navy 2008](#)) that is intermittently activated. This restricted airspace, R-3103, extends from the ground surface up to 30,000 feet above mean sea level. Flight corridors are established for this airspace to control aircraft without interfering with ground-firing weapons systems and to prevent over-flight of active firing points. This airspace is under the control of the Range Office at Pohakuloa when activated and released back to the Honolulu Control Facility when deactivated. There is also one Air Traffic Control Assigned Airspace area (Pele) extending west and southwest of Pohakuloa that provides additional controlled airspace between R-3103 and Warning Area W-194, which is approximately 25 nautical miles from the coast. The Pele assigned airspace lies between 16,000 and 29,000 feet above mean sea level.

3.11.3 COMMON CONSTRUCTION AND OPERATION IMPACTS

There are no common impacts to airspace management from construction and operation of renewable energy projects. The most obvious impact would be potential aviation obstruction from tall structures. Those and other potential impacts to airspace management are discussed in Chapters 4 through 8 under the appropriate energy technology.

3.11.4 COMMON BEST MANAGEMENT PRACTICES

The developer should coordinate with the FAA early in the planning phase if the energy project includes tall structures, reflective surfaces, or is located near an airfield. These discussions may include other State (e.g., HDOT) and Federal (e.g., Department of Defense) agencies as appropriate to identify potential impacts and issues early in project planning.

3.12 Noise and Vibration

This section describes techniques used to analyze noise and vibration, and characterizes the affected environment for potential locations of future projects in the State of Hawaiʻi.

3.12.1 NOISE

Noise is defined as unwanted sound and is a common environmental concern to the general public. Sound is defined as a varying pressure wave travelling through a media (such as air or water). People experience sound as a result of the pressure variations through such mediums. Sensitive receptors to noise include nearby residences, religious institutions, day care centers, libraries, schools, hospitals, nursing home facilities, and recreational areas. In the marine environment, sensitive noise receptors include species that depend on sound to navigate, feed, and socialize. A number of factors affect how noise is perceived by the listener. These include the noise's frequency and loudness; the type and number of sources; distance away from the source; duration; and the time of day.

Two important characteristics of noise are frequency (perceived as pitch) and amplitude (perceived as loudness). The frequency of sound is the number of pressure variations per second (also referred to as cycles per second), and is measured in Hertz. Humans hear frequencies ranging from approximately 20 Hertz to 20,000 Hertz, and are most sensitive to sounds in the middle frequencies (1,000 to 8,000 Hertz) and less sensitive to sounds in the low and high frequencies. The higher the frequency, the more high-pitched a sound would be perceived. For example, sounds from drums have lower frequencies and sounds from whistles have higher frequencies. A loud sound has larger pressure variation and a weak sound has smaller pressure variation. Loudness of sound is measured in terms of decibels (dB), which uses a logarithmic scale.

Since people are less sensitive to low and high frequencies, the decibel scale is adjusted (A-weighted, or dBA) to reflect the normal hearing sensitivity range for humans. In general, people do not typically notice changes in a community noise level of less than 3.0 dBA; changes from 3.0 to 5.0 dBA may be noticed by extremely sensitive individuals; an increase greater than 5.0 dBA is readily noticeable; and most people perceive a 10.0 dBA increase in sound level to be a doubling of sound volume (FHWA 1980). Noise levels in dBA from typical sources are provided in [Figure 3-69](#). The noise level for a quiet residential neighborhood is 40.0 dBA, while the noise level from heavy surf at 3 feet is 107 dBA (NPS 2010).

Sources for noise are grouped into two types: point and line noise sources. Point noise sources have fixed locations, such as stationary equipment used for normal operations. Line noise sources, such as roadways or railways, include a large number of point sources such as motor vehicles. In general, highway traffic noise levels depend on traffic volumes, speeds, number of trucks, as well as other factors such as terrain and vegetation.

Ambient noise, also known as background noise, is a combination of unwanted sounds from various sources heard simultaneously. Because the decibel scale is logarithmic and not linear, the combined noise level of two sounds occurring at the same time cannot just be added together. For example, a garbage truck with a noise level of 100 dBA combined with a lawn mower with a noise level of 95 dBA results in a noise level of 101.2 dBA, not 195 dBA.

Noise levels decrease, or attenuate, with distance from the source of noise. The decrease in noise level is inversely proportional to the square distance from the noise source. Noise levels from point sources typically attenuate at a rate of 6 dBA each time the distance from the noise source is doubled at acoustically "hard" sites (locations that do not provide excess ground-effect attenuation) and 7.5 dBA at acoustically "soft" sites (locations that absorb noise through ground-effect attenuation, such as normal earth and most ground with vegetation) (FHWA 1980). Noise levels from line sources attenuate at a rate of 3 to 4.5 dBA each time the distance from the source is doubled. Noise levels may be further reduced by natural factors such as temperature and climate and are reduced by barriers, both manmade (e.g., sound walls) and natural (e.g., forested areas and hills) (FTA 2006).

As an example of this relationship, if point source emitted noise on the order of 50 dBA at 50 feet from a specific location, you would expect that the noise measured at 100 feet from that same noise source to be reduced by 6 dBA, or to 44 dBA. This would continue to reduce as the distance increased (i.e., 38 dBA at 200 feet).

Noises that occur over a longer duration are more likely to be an annoyance or cause direct physical damage or environmental stress. The noise metric that considers both duration and noise level is the equivalent noise level (Leq). Leq is the average A-weighted noise level measured over a given time interval (1-minute, 15-minute, or 1-hour periods). Leq is also expressed in dBA.

Figure 3-69. A-Weighted Noise Levels (Cowan 1993)

The time of day in which noise occurs is also important since noise that occurs at night tends to disturb people more than noise that occurs during the day. People perceive noise occurring in the evening (7 p.m. to 10 p.m.) as if the noise were 5 dBA higher than if it occurred during the day (7 a.m. to 7 p.m.), and at nighttime (10 p.m. to 7 a.m.) the same noise is perceived as 10 dBA higher. Two commonly used noise metrics are the Day-Night average level (Ldn) and the Community Noise Equivalent Level, which weight hourly Leqs over a 24-hour period. Ldn adds 10 dB to nighttime noise levels, and Community Noise Equivalent Level is identical to the Ldn except 5 dBA is added for noise occurring during the evening.

Sound intensity in water is not directly comparable to the same sound intensity in air, and sound travels about five times faster underwater than it does in air. Current knowledge of marine species hearing frequencies and sound detection is limited. The amount of pressure and the duration of the exposure determine whether marine species might be harassed, injured or killed by an underwater noise. Due to the sensitivity of marine species to sound intensity, the root-mean-square pressure is the most widely used metric to characterize noise levels underwater ([BOEM 2012](#)). The root-mean-square is the square root of the average of the square of the pressures of a sound signal over a given duration. Underwater noise levels are typically expressed in the notation “dB re 1 μ Pa-m,” which is the pressure level that would be measured at a reference distance of 1 meter from a source.

3.12.2 VIBRATION

Vibration is defined as the oscillations or rapid linear motion of parts of a fluid or elastic solid whose equilibrium has been disturbed. The pressure waves that generate sound are created by vibrations (such as sound created by vibrating vocal cords), and pressure waves can also induce vibration (such as an ear drum vibrating in response to sound). Traffic, construction machinery and ground breaking activities such as drilling or excavation are common causes of vibration. Sources of vibration can be transient (a single isolated event), or continuous, frequent, or intermittent. Ground-borne vibration is transmitted from a source into the ground, and then transmitted through the ground to nearby buildings. Subsurface geological conditions affect vibration levels, and vibration levels decrease with increasing distance. Similar to noise, the sensitive receptors for vibration include nearby residences, religious institutions, day care centers, libraries, schools, hospitals, nursing home facilities, and recreational areas. Other sensitive receptors could also include scientific laboratories that use sensitive equipment. In the marine environment, sensitive vibration receptors include species that depend on sound to navigate, feed, and socialize. Vibration is measured in terms of the peak particle velocity in inches per second.

3.12.3 REGULATORY FRAMEWORK

The regulatory framework for noise and vibration includes Federal guidance and State regulatory standards that range from levels that cause annoyance up through levels that are hazardous.

In 1974, the EPA provided information suggesting that continuous and long-term noise levels in excess of Ldn 65 dBA are normally unacceptable for noise-sensitive land uses such as residences, schools, churches, and hospitals ([EPA 1974](#)). Similarly, the U.S. Department of Housing and Urban Development (HUD) established 65 dBA as a threshold for unacceptable noise levels for residential areas ([HUD 1985](#)). HUD’s guidelines categorize noise level impacts on residential properties as acceptable, normally unacceptable, and unacceptable, as shown in [Table 3-53](#). The HUD noise levels shown in [Table 3-53](#) serve as guidance, not requirements.

Table 3-53. Guidelines for Evaluating Noise Level Impacts on Residential Properties

Acceptability for Residential Use	Guideline Levels (Ldn)
Acceptable	< 65 dB
Normally Unacceptable	> 65 dBA to < 75 dBA
Unacceptable	> 75 dBA

Source: [HUD 1985](#).

dB = decibel; dBA = A-weighted decibel; Ldn = day-night average level.

The HDOH Indoor and Radiological Health Branch enforces, monitors, and issues permits and variances related to public noise issues. The regulations are found in [HRS 342F](#), “Noise Pollution,” and [HAR 11-46](#), “Community Noise Control.” HDOH issues noise permits when excessive noise levels are anticipated and issues variances when noise levels may exceed the maximum permissible amounts. Noise abatement measures may also be conditions of certain county zoning permits.

Maximum daytime permissible noise levels for stationary sources are based on the primary land use zoning classification and are shown in [Table 3-54](#). Land use zoning classifications are shown on General Plans (see [Section 3.5](#)). The HDOH Community Noise Control rule does not address moving sources, such as vehicular, rail, and air traffic noise, but does regulate agricultural, construction, and industrial activities that may not be stationary. A permit or variance would be required for construction activities that exceed the maximum permissible sound levels for more than 10 percent of the time within any twenty minute period. Additionally, permits do not allow any construction activities which emit noise in excess of the maximum permissible noise levels during the following hours:

- Before 7 a.m. and after 6 p.m. of the same day, Monday through Friday
- Before 9 a.m. and after 6 p.m. on Saturdays
- Any time on Sundays or holidays

Table 3-54. Maximum Daytime Permissible Noise Levels in dBA

Zoning Class	Zoning Classification	Daytime (7 a.m. – 10 p.m.)	Nighttime (10 p.m. – 7 a.m.)
Class A	All areas equivalent to lands zoned residential, conservation, preservation, public space, open space, or similar type	55	45
Class B	All areas equivalent to lands zoned for multi-family dwellings, apartment, business, commercial, hotel, resort, or similar type	60	50
Class C	All areas equivalent to lands zoned agriculture, country, industrial, or similar type	70	70

Source: [HAR 11-46](#).

dBA = A-weighted sound level in decibels.

The Federal Highway Administration (FHWA) uses the Leq 1-hour descriptor to estimate the degree of nuisance or annoyance arising from changes in traffic noise. The FHWA established noise abatement criteria that provide a benchmark to assess the level at which noise becomes a source of annoyance for various land uses. HDOT adopted these criteria (see [Table 3-55](#)), and according to the HDOT guidelines, a noise impact occurs when the predicted traffic noise levels approach the criteria by 1 dBA or exceed existing noise levels by at least 15 dBA ([HDOT 2011b](#)).

Table 3-55. HDOT Traffic Noise Abatement Criteria

TABLE 1 TO PART 772—NOISE ABATEMENT CRITERIA [Hourly A-Weighted Sound Level_decibels (dB(A)) ¹]				
Activity category	Activity Leq(h)	Criteria ² L10(h)	Evaluation location	Activity description
A	57	60	Exterior	Lands on which serenity and quiet are of extraordinary significance and serve an important public need and where the preservation of those qualities is essential if the area is to continue to serve its intended purpose.
B ³	67	70	Exterior	Residential.
C ³	67	70	Exterior	Active sport areas, amphitheatres, auditoriums, campgrounds, cemeteries, day care centers, hospitals, libraries, medical facilities, parks, picnic areas, places of worship, playgrounds, public meeting rooms, public or nonprofit institutional structures, radio studios, recording studios, recreation areas, Section 4(f) sites, schools, television studios, trails, and trail crossings.
D	52	55	Interior	Auditoriums, day care centers, hospitals, libraries, medical facilities, places of worship, public meeting rooms, public or nonprofit institutional structures, radio studios, recording studios, schools, and television studios.
E ³	72	75	Exterior	Hotels, motels, offices, restaurants/bars, and other developed lands, properties or activities not included in A–D or F.
F				Agriculture, airports, bus yards, emergency services, industrial, logging, maintenance facilities, manufacturing, mining, rail yards, retail facilities, ship-yards, utilities (water resources, water treatment, electrical), and warehousing.
G				Undeveloped lands that are not permitted.

¹ Either Leq(h) or L10(h) (but not both) may be used on a project.
² The Leq(h) and L10(h) Activity Criteria values are for impact determination only, and are not design standards for noise abatement measures.
³ Includes undeveloped lands permitted for this activity category.

Source: [HDOT 2011b](#).

Leq(h) = equivalent sound level over one hour.

The FAA issues guidelines for land uses around airports based on yearly Ldn noise contour maps due to aircraft operations. HDOT Airports Division adopted noise restrictions similar to but stricter than the FAA’s. In most cases, HDOT maximum noise limits are 5 dB lower than the FAA restrictions (see [Table 3-56](#)). The HDOT also limits Ldn noise levels for noise sensitive receptors to Ldn 60 without noise level reduction measures.

Under provisions of the Federal [Occupational Safety and Health Act of 1970](#) (Public Law 91-596), a hearing conservation program must be implemented when employees are exposed to 85 dB or more in an 8-hour day and engineering or administrative noise controls are required when exposure exceeds 90 dB. The State of Hawai‘i, under an agreement with the Occupational Safety and Health Administration (OSHA), operates an occupational safety and health program in accordance with the Federal Act. The Occupational Safety and Health Division of the Hawai‘i Department of Labor and Industrial Relations is responsible for both enforcement and consultation programs under provisions of HAR 12-200.1, “Occupational Noise Exposure.” OSHA permissible noise exposures in the workplace are shown in [Table 3-57](#).

Table 3-56. HDOT Recommendations for Airport Land Use Compatibility

LAND USE	YEARLY DAY-NIGHT AVERAGE SOUND LEVEL (DNL) IN DECIBELS					
	BELOW 65	65-70	70-75	75-80	80-85	OVER 85
RESIDENTIAL						
Residential, other than mobile homes and transient lodgings	Y	N ¹	N ¹	N	N	N
Mobile home parks	Y	N	N	N	N	N
Transient lodgings	Y	N ¹	N ¹	N ¹	N	N

Golf courses, riding stables, and water recreation	Y	Y	25	30	N	N

The designations contained in this table do not constitute a Federal determination that any use of land covered by the program is acceptable under Federal, state, or local law. The responsibility for determining the acceptable and permissible land uses and the relationship between specific properties and specific noise contours rests with the local authorities. FAA determinations under Part 150 are not intended to substitute Federally determined land uses for those determined to be appropriate by local authorities in response to locally determined needs and values in achieving noise compatible land uses.

Key To Table A-2

Y (Yes) Land use and related structures compatible without restrictions.

N (No) Land use and related structures are not compatible and should be prohibited.

NLR Noise Level Reduction (outdoor to indoor) to be achieved through incorporation of noise attenuation into the design and construction of the structure.

25, 30, 35 Land use and related structures generally compatible; measures to achieve a NLR of 25, 30, or 35 dB must be incorporated into design and construction of structure.

Notes for Table A-2

1. Where the community determines that residential or school uses must be allowed, measures to achieve outdoor-to-indoor Noise Level Reduction (NLR) of at least 25 dB and 30 dB should be incorporated into building codes and be considered in individual approvals. Normal residential construction can be expected to provide a NLR of 20 dB, thus, the reduction requirements are often stated as five, ten, or 15 dB over standard construction and normally assume mechanical ventilation and closed windows year round. However, the use of NLR criteria will not eliminate outdoor noise problems.
2. Measures to achieve NLR of 25 dB must be incorporated into the design and construction of portions of these buildings where the public is received, office areas, noise-sensitive areas, or where the normal noise level is low.
3. Measures to achieve NLR of 30 dB must be incorporated into the design and construction of portions of these buildings where the public is received, office areas, noise-sensitive areas, or where the normal noise level is low.
4. Measures to achieve NLR of 35 dB must be incorporated into the design and construction of portions of these buildings where the public is received, office areas, noise-sensitive areas, or where the normal noise level is low.
5. Land use compatible provided special sound reinforcement systems are installed.
6. Residential buildings require a NLR of 25 dB.
7. Residential buildings require a NLR of 30 dB.
8. Residential buildings not permitted.

 dBA = A-weighted decibel.

Kaua‘i, Honolulu, Hawai‘i, and Maui counties have established local noise control programs. Kaua‘i County Code Chapter 22, Article 14, outlines unlawful use of noise reproduction devices and excessive noise in public areas. Chapter 41, Article 5 of the Honolulu County Code prohibits conducting noisy activities from workshop, factory, trade, manufacture, industry or business within 500 feet of a hospital. Maui County Code, Title 9, Chapter 9.36 addresses amplification systems in vehicles, which cannot be heard outside of fifty feet from the vehicle. The noise ordinance in Hawai‘i County Code, Chapter 14, Article 3, is almost identical to Kaua‘i’s. Maui County includes Maui, Lāna‘i, and Molokai, except for Kalawao County. Kalawao County is a county and a National Park; HDOH administers Kalawao County and Kalaupapa National Park is subject to National Park Service regulations ([NPS 2010](#)).

Currently there are no Federal, State, or county standards for underwater noise and vibration. NOAA is developing acoustic guidelines for assessing the effects of anthropogenic sound on marine mammal species ([NOAA 2013c](#)). Recent discussions have also highlighted the need for additional study on the emission of electromagnetic waves from undersea power cables, and potential impacts on nearby marine life. The acoustic guidelines will provide past criteria as well as updated assessment procedures for authorizations, permits, consultations, and exemptions under various environmental statutes (such as the [Marine Mammal Protection Act](#), the ESA, and the [National Marine Sanctuaries Act](#)).

Guidelines have been published for land-based vibration. [Table 3-58](#) presents guidelines for human perception and annoyance, and [Table 3-59](#) presents guidelines for potential building damage.

Table 3-58. Guidelines for Potential Vibration Annoyance

Human Response	Maximum Peak Particle Velocity (inches per second)	
	Transient Sources	Continuous/Frequent/ Intermittent Sources
Barely Perceptible	0.04	0.01
Distinctly Perceptible	0.25	0.04
Strongly Perceptible	0.9	0.10
Severe	2.0	0.4

Table 3-59. Thresholds for Potential Vibration Damage

Structure and Condition	Maximum Peak Particle Velocity (inches per second)	
	Transient Sources	Continuous/Frequent/ Intermittent Sources
Extremely fragile historic buildings, ruins, ancient monuments	0.12	0.08
Fragile buildings	0.2	0.4
Historic and some old buildings	0.5	0.25

3.12.4 REGION OF INFLUENCE

The ROI for the noise and vibration affected environment is based on the potential magnitudes of noise and vibration generated for the particular project being evaluated and baseline noise and vibration levels, which would affect how far away the noise might be heard or vibration might be felt. The ROI for this programmatic analysis is identified by addressing existing night and day ambient (background) noise and vibration sources and estimated levels in general for the State of Hawai‘i.

Baseline Noise and Vibration Levels

Estimated baseline project-related noise and vibration levels would be site-specific. Maximum daytime permissible noise levels for potential future clean energy projects in the State of Hawai‘i are based on the primary land use zoning classification at the proposed project location (see Tables [3-54](#), [3-55](#), [3-56](#), and [Section 3.5](#)). Existing land use zoning classifications and sensitive noise and vibration receptors vary by location. General locations for noise abatement areas recommended by the HDOT are shown for the islands of Kaua‘i ([Figure 3-70](#)), Oah‘u ([Figure 3-71](#)), Maui ([Figure 3-72](#)), and Hawai‘i ([Figure 3-73](#)) ([HDOT 2013d](#)).

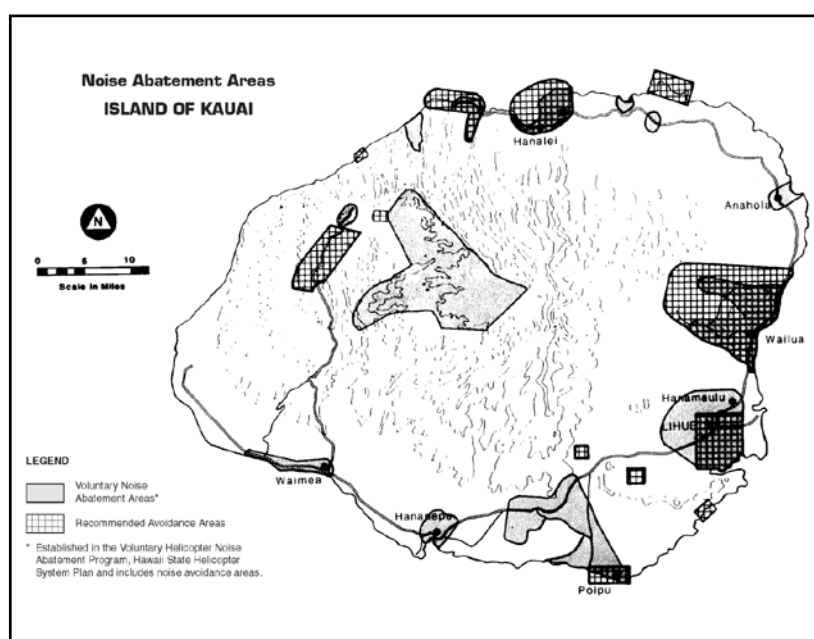

Figure 3-70. Noise Abatement Areas on the Island of Kaua‘i

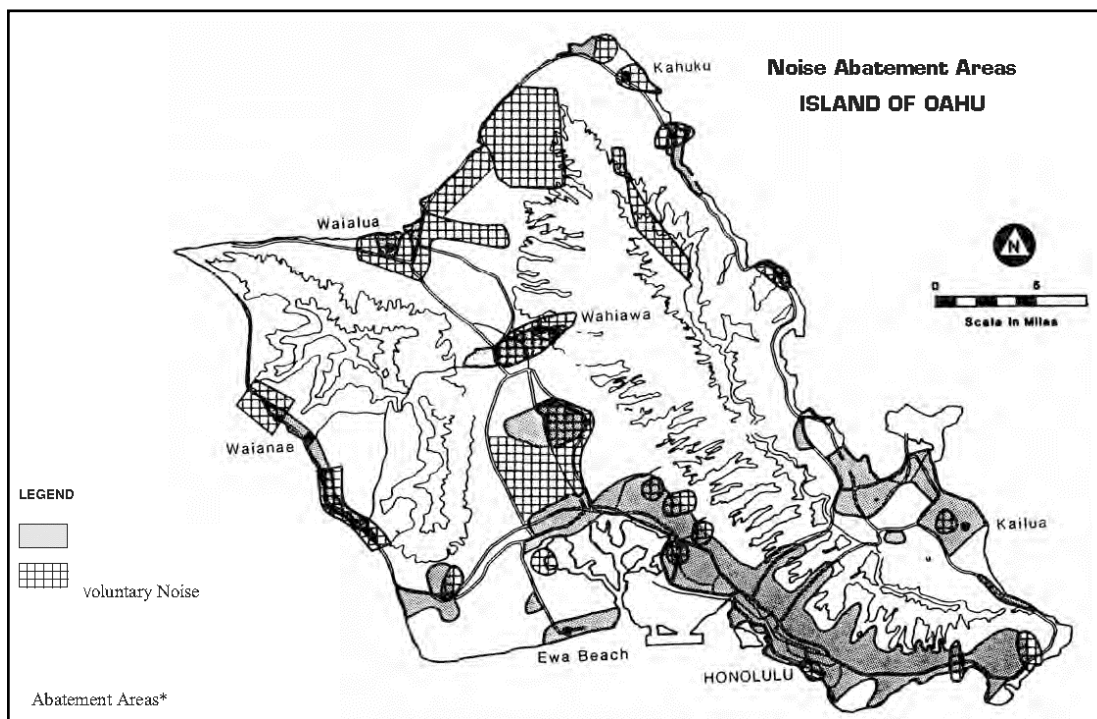

Figure 3-71. Noise Abatement Areas on the Island of O‘ahu

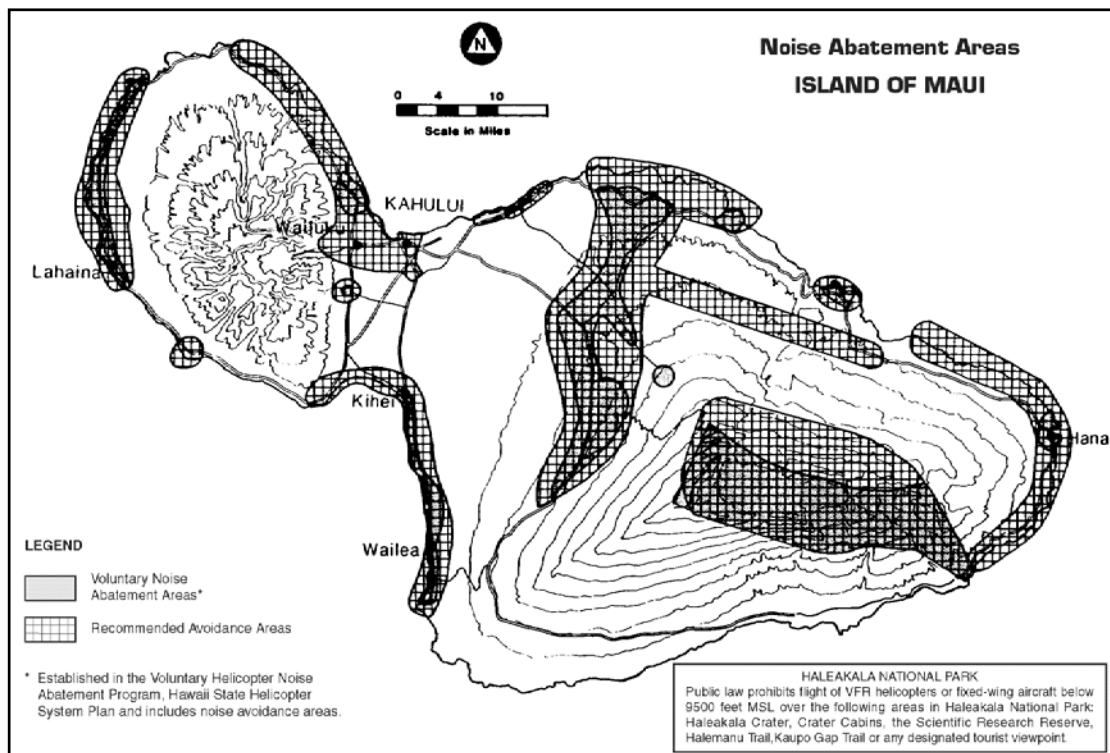

Figure 3-72. Noise Abatement Areas on the Island of Maui

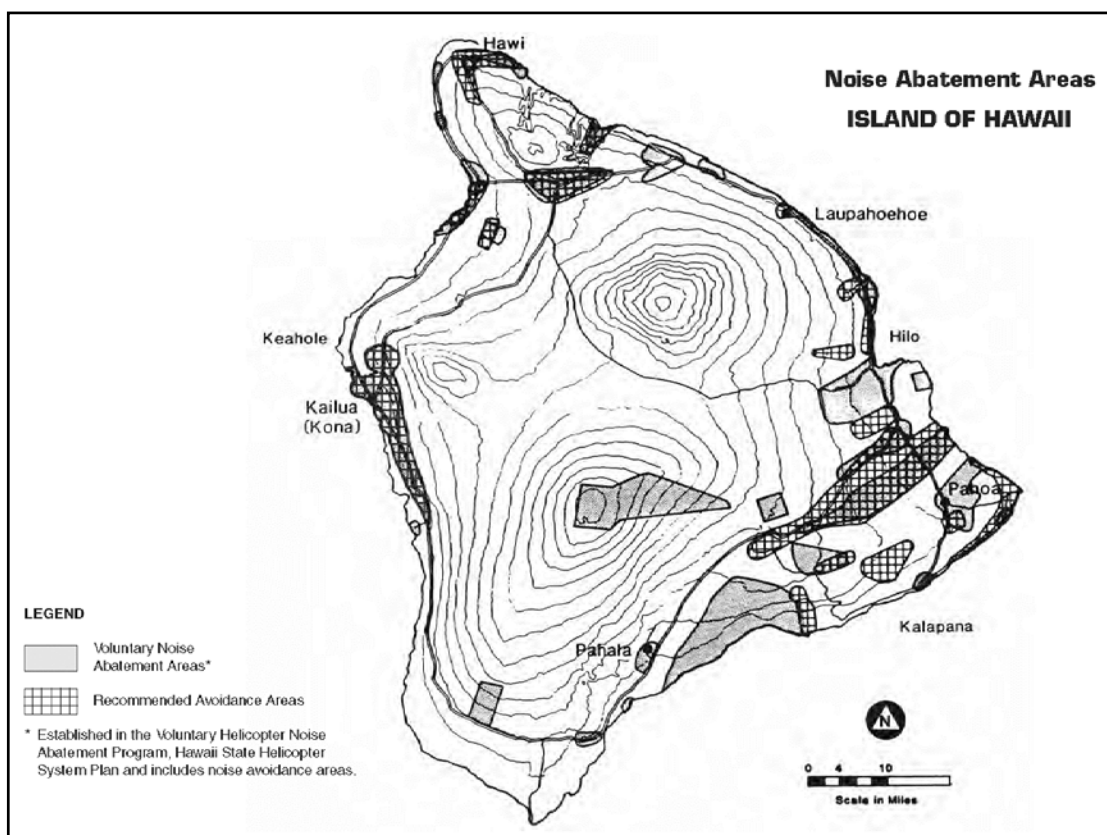

Figure 3-73. Noise Abatement Areas on the Island of Hawai‘i

3.12.5 COMMON CONSTRUCTION AND OPERATION IMPACTS

Construction activities inherently produce sound levels or sound characteristics that result in short-term noise and vibration impacts. Noise and vibration levels from common construction activities (which exclude pile-driving) are not anticipated to exceed regulatory levels, and a construction noise permit would be obtained if regulatory noise limits are temporarily exceeded. If common BMPs are applied (see [Section 3.12.6](#)), noise and vibration impacts from typical construction would be short-term and minor.

Sounds generated by operation of proposed facilities may be perceived as noise depending on land use surrounding the facilities, whether or not those noise levels exceed regulatory levels. If regulatory noise levels would be exceeded an operational noise permit would be required. When areas adjoining proposed facilities contain sensitive noise and vibration receptors, potential noise and vibration impacts are more likely to be a matter of concern. Potential noise and vibration impacts from operation would depend on operational noise and vibration levels, the proposed site location, and the proposed project.

3.12.6 COMMON BEST MANAGEMENT PRACTICES

Common BMPs for noise and vibration refer to actions that will be taken to avoid or reduce the effects of or levels of noise and vibration on a receptor. Common noise and vibration BMPs include:

- Avoid sensitive noise and vibration receptors. Typical sensitive receptors for noise and vibration include nearby residences, religious institutions, day care centers, libraries, schools, hospitals, nursing home facilities, recreational areas, and scientific laboratories that use sensitive equipment.

- Reduce adverse noise effects at the point of generation thereby diminishing the effects of the noise and vibration at the point of reception. Alternative construction or operational methods, equipment maintenance, selection of alternative equipment, physical barriers, siting of activities, setbacks, and established hours of construction or operation, are among the techniques that can successfully reduce adverse noise effects ([State of New York 2001](#)).
- Noise permits would be required if noise levels exceed regulatory limits. A noise permit variance would be necessary when permitted noise limits would be exceeded. Noise avoidance and mitigation measures may be imposed directly as conditions of permit issuance.
- Conduct site-specific and project-specific noise and vibration evaluations for proposed construction and operational-related activities.

3.13 Utilities and Infrastructure

Utilities and infrastructure are an important part of the daily life throughout Hawai‘i. Considered in this section are the existing electric utilities and electrical transmission and distribution services. The public sewer systems are discussed in [Section 3.14](#) and public safety (e.g. police, fire, and medical) services are discussed in [Section 3.17](#). The affected environment is described overall for the State of Hawai‘i. The depth of discussion is based upon the overall importance of each area for impacts development. Additional information is provided for each island of Kaua‘i, O‘ahu, Molokai, Lāna‘i, Maui, and Hawai‘i where important differences maybe noted.

3.13.1 ELECTRIC UTILITIES AND DISTRIBUTION

Electric power for the six Hawaiian Islands of Kaua‘i, O‘ahu, Molokai, Lāna‘i, Maui, and Hawai‘i is supplied by Hawaiian Electric Company (HECO), Hawai‘i Electric Light Company (HELCO), Maui Electric Company (MECO), and Kaua‘i Island Utility Cooperative (KIUC). HELCO and MECO are subsidiaries of HECO and those three companies supply power to about 95 percent of the population of Hawai‘i. HECO serves O‘ahu; MECO serves Maui, Lāna‘i, and Molokai; HELCO serves the island of Hawai‘i (Big Island); and KIUC serves Kaua‘i. See [Table 3-60](#) for the electricity demand and supply of Hawai‘i utilities.

Table 3-60. Electricity Demand and Supply for Hawaiian Utilities

2012 Demand (rounded)	HECO (O‘ahu)	MECO			HELCO (Hawai‘i Island)	HECO Companies	KIUC	State Total
		Maui	Lāna‘i	Molokai			(Kaua‘i)	
System Peak (net MW)	1,141	199	4	5	189	N/A	65	N/A
Net firm utility and IPP capacity (MW)	1,783	262	10	12	292	2,359	125	2,456
Annual Utility Sales of Electricity (GWh)	6,976	1,090	24	30	1,085	9,206	433	9,639

Source: [HECO 2013a](#).

GWh = gigawatt-hour; IPP = independent power producers; MW = megawatt; N/A = not applicable.

On-island transmission of electricity includes connections from the power generation source, transmission over a short or long distance, and connection to the power user. This system is often referred as the island electrical grid or simply power grid (or grid) (Figure 3-74). The power grid is how the majority of people and companies get their electricity. The generating station shown on the left in the figure may be current fossil fuel-fired power plants, auxiliary generators to help regulate power throughout the power grid, or any of the various renewable power generation sources (e.g., sun, wind, biomass, hydropower, geothermal).

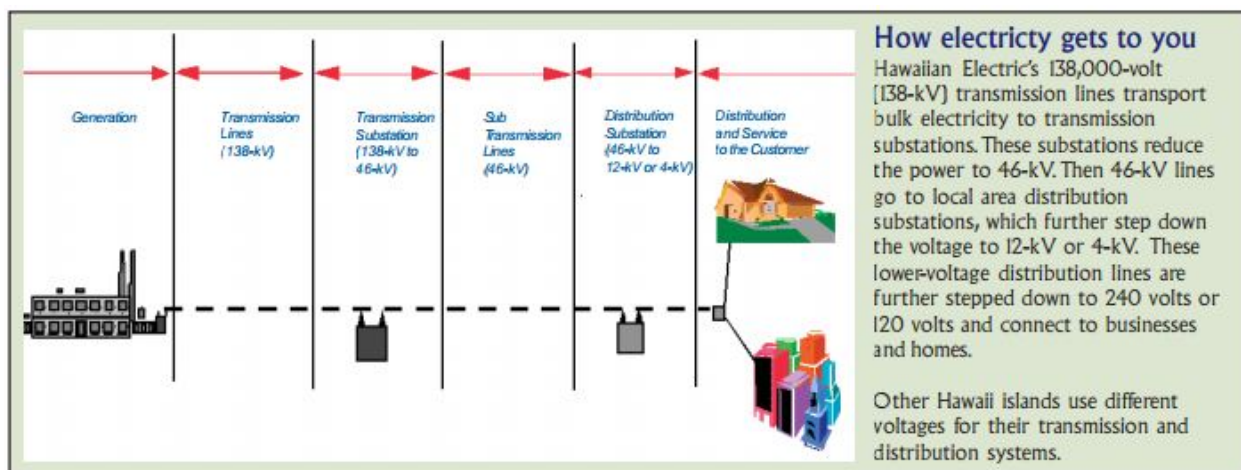

Figure 3-74. Electricity Transmitted from the Power Plant to the Consumer (HECO 2014a)

The power source connection may include meters, switch gear, circuit breakers, inverters, transformers, and connection to transmission lines. The transmission line may be above ground or buried to distribute the power to customers. At the power user, connections would also include switchgear, circuit breakers, inverters, transformers, meters and connection to customer facilities. Some customers with renewable power generation capability may be both users and/or suppliers of power to the grid. Each island has a stand-alone power-generating system, rather than a system of interconnected transmission lines between the islands. These self-contained power grids must be more reliable and self-reliant than comparable utilities in continental United States to maintain customer service.

Table 3-61 summarizes some of the key characteristics of the Hawai‘i power grids. For transmitting power long distances, *transmission lines* are typically used at voltages of 138 kilovolts. From 138 kilovolts to 34.5 kilovolts is considered to be subtransmission. Substations are facilities where the power electronics and transformers are located to change between voltage levels. Below 34.5 kilovolts is called *distribution*, and voltages are reduced in steps through a series of transformers all the way down to 220/110 volts in a neighborhood.

Table 3-61. Hawai‘i Transmission and Distribution Lines

	Hawai‘i ^{a, b}	Maui ^{b, a}	Molokai ^{b, a}	Lāna‘i ^{b, a}	O‘ahua	Kaua‘i ^{c, b}
Provider	HELCO	MECO	MECO	MECO	HECO	KIUC
Residential Customers	69,700	54,500	2,600	1,400	264,200	28,200
Commercial Customers	12,400	9,000	500	200	33,100	4,700
Transmission Lines (miles)	623	240	N/A	N/A	746	161
Transmission Lines (voltage)	69 kV/ 34.5 kV	69 kV/ 23 kV	N/A	N/A	138 kV/ 46 kV	69 kV
Distribution Lines (miles)	3,141	1,475	No data	No data	2,249	1,226
Distribution Lines (voltage)	No data	No data	34.5 kV	12 kV	12 kV/ 4 kV	12 kV

HECO = Hawaiian Electric Company; HELCO = Hawai‘i Electric Light Company; kV = kilovolt; MECO = Maui Electric Company; N/A = not applicable.

The electric utilities are undergoing major changes driven by the need to meet the 2030 goals of the State of Hawai‘i to be a less fossil fuel dependent and more renewable energy based State. These changes are contributing to the decline in electricity consumption ([Figure 3-75](#)). Hawai‘i electrical energy consumption has decreased by 7 percent (770 gigawatt-hours) since the peak in 2004. Energy conservation and other programs being planned and implemented under the Hawai‘i Clean Energy Initiative may continue this downward trend. To be less oil dependent, utilities will be ([HECO 2013a](#)):

Figure 3-75. Electricity Use Decrease since 2004 Peak

- Accelerating the deactivation decommissioning of older, oil-fired steam generators.
- Procuring or developing low-cost, fast track utility-scale renewable energy sources,
- Converting existing generating units to cost effective renewable and low carbon fuels, including biomass, biofuels, and liquefied natural gas.

While assuring a stable electric power grid and minimizing disruption to service quality and reliability, the electric power grids on all islands are being modified to accommodate new renewable power generation and to compensate for the variations in power output from those sources (e.g., wind power varies with the wind flow; solar varies with the day/night cycle, clouds, and shading). These modifications include:

- Initiation of local connections of renewable sources to the power grid (e.g., residential or commercial customers);

- Construction of new transmission lines from new power sources to the existing power grid (e.g., connection of a solar power plant via transmission line) or replacement of older transmission lines and structures that are reaching the end of their service life; and
- Implementation of smart grid technologies (e.g., energy storage and load control/shifting).

Currently, the power grid on each of the six islands is connected to most of the residents and businesses on that island. For those already connected to the utility's electric grid, adding local residential or commercial renewable energy sources may be possible through the Net Energy Metering (NEM) program. NEM is currently available to customers of HECO, HELCO, MECO, and KIUC, while the programs differ slightly by island. In the HECO, HELCO, and MECO service territories, the maximum system size is 100 kilowatts, and as the program has grown rapidly in recent years, aggregate system caps were replaced by a screening process at the distribution circuit level.

In the KIUC service territory, the NEM Pilot Program has set the maximum system size at 50 kilowatts, and the aggregate capacity is capped at 1 percent of Kaua'i's system peak demand ([PUC 2014](#)). It is worth noting that interconnection policies are rapidly evolving and subject to change as more variable renewable energy comes online.

The Feed-In-Tariff Program had been another avenue for adding residential and commercial renewable energy sources. However, on August 27, 2013, the PUC issued Order No. 31424 to re-examine the Program. As part of this re-examination, HECO and the Independent Observer Accion Group submitted a Joint Plan to the PUC to maintain the continued administration of the current active projects in the Feed-In-Tariff Program. The joint plan was accepted by the PUC on December 5, 2014, and the feed-in-tariff queue was closed pursuant to Docket No. 2013-0194, Order No. 32499. Future revisions or modifications to the Feed-In-Tariff Program will be addressed in Docket No. 2014-0192 or 2014-0183.

Larger utility-scale power sources such as solar farms, wind farms, large biomass generators, hydropower facilities, or geothermal plants are being added to the power grids across the islands. Current information on new generation may be found at the Hawaiian Electric Website (see [HECO 2013b](#)). Each of these projects is required to comply with the Public Utilities Commission requirements, especially those for Transmission Line Approval and Power Purchase Agreements. Those requirements include interfacing with the appropriate utility (i.e., HECO, MECO, HELCO, or KIUC). During early development of a project, interface with the utilities helps the developer find feasible solutions to interconnections with the grid and allows the utilities to join planning for the additional power generation capabilities.

3.13.2 COMMON CONSTRUCTION AND OPERATION IMPACTS

On all islands, transmission line modifications may be needed to connect the generating facility to the power grid (see Section 8.1 in Chapter 8 for impacts related to on-island transmission lines). The utility connection to the power grid would be required to comply with the Public Utilities Commission requirements for Transmission Line Approval and Power Purchase Agreements. Those requirements include interfacing with the appropriate island utility.

The representative projects presented throughout Chapters 4, 5, 6, 7, and 8 highlight renewable energy changes that are described at HECO and KIUC websites. The IRP Report outlines extensive changes to adapt the utility system to meet the IRP goals and to match the various non-utility renewable energy initiatives ([HECO 2013a](#)). This PEIS outlines a few of the changes that would be necessary to handle intermittent power sources such as photovoltaic and wind power. The PEIS also identifies some changes to modify the existing utility generators and transmissions systems. Further changes to the utilities are noted in the sections on smart grids and energy storage, Sections 2.3.5.3 and 2.3.5.4, respectively. As

more renewable sources come on line to meet IRP goals, the utilities will need to continue to adapt. the projects presented in this PEIS are examples of actions to meet the IRP goal of 4,300 gigawatt-hours per year for 2030.

3.13.3 COMMON BEST MANAGEMENT PRACTICES

BMPs applicable to utilities and infrastructure are as follows:

- Engineer, construct, and install projects so as to make them compatible with the continued operation and maintenance of co-located infrastructure (e.g., aboveground, below ground, and submerged electric, telecommunications, water, and wastewater infrastructure), and affected transportation systems.
- Consult with existing utility infrastructure operators prior to beginning any preconstruction activities and throughout any project's design process.
- Develop and adhere to protection measures and specifications for existing and planned utility infrastructure and upgrades.

3.14 Hazardous Materials and Waste Management

3.14.1 HAZARDOUS MATERIALS

Hazardous materials include any item or agent (biological, chemical, physical) that has the potential to cause harm to humans, animals, or the environment, either by itself or through interaction with other factors ([IHMM 2014](#)). According to the EPA, *hazardous waste* is a hazardous material that can be characterized by ignitability, corrosiveness, reactivity, and toxicity. Those *solid wastes* that exhibit one or more of these characteristics are classified as hazardous wastes [pursuant to RCRA ([40 CFR 262.11](#))], including discarded military munitions. Exposure to such waste may cause or contribute to an increase in mortality rates or cause serious, irreversible, or incapacitating illness ([EPA 2012](#)). Issues associated with hazardous materials and waste typically center around under- and aboveground storage tanks; and the storage, transport, and use of pesticides, fuels, petroleum, oils, paints, and lubricants. When such resources are improperly treated, stored, transported, disposed of, or managed, the resources can threaten the health and well-being of wildlife species, botanical habitats, air, soil, water resources, and humans. This section discusses how hazardous materials are managed in Hawai'i and includes an identification of significant quantities hazardous material in each island that may require further site assessment and remediation planning.

3.14.1.1 Regulatory Setting

Different hazardous materials (including hazardous substances and hazardous wastes) are regulated in a variety of ways. Hazardous materials are defined and regulated in the United States primarily by laws and regulations administered by the EPA, OSHA, USDOT, the U.S. Nuclear Regulatory Commission, and state governments. Each agency incorporates hazardous substance safeguards according to its unique Congressional mandate.

- EPA regulations focus on the protection of human health and the environment (see [Section 3.17](#)).
- OSHA regulations primarily protect employee and workplace health and safety (see [Section 3.17](#)).

- USDOT regulations promote the safe transportation of hazardous substances used in commerce.
- The Nuclear Regulatory Commission regulations govern the safe transportation and disposal of radioactive and hazardous materials.

At the State level, the HDOH Solid and Hazardous Waste Branch regulates the generation, transportation, treatment, storage, and disposal of hazardous wastes. This agency also administers EPA permits, procedures, and regulations for the State. Proper identification of hazardous materials is required for compliance with applicable regulations to ensure human and environmental health and safety and to support the design and implementation of mitigation measures (see [Section 3.17](#)). Where hazardous materials have already been identified, cleanup efforts are often underway by a wide range of State and Federal agencies and stakeholders. However, hazardous materials may be encountered during future site development, which would require handling and disposal safely and in compliance with county, State, and Federal regulations.

This section describes the regulatory setting for hazardous waste materials that commonly impact site development activities, including [Resource Conservation and Recovery Act \(RCRA\)](#), [Comprehensive Environmental Response Compensation and Liability Act \(CERCLA\)](#), and those related to under- and aboveground storage tanks, pesticides, asbestos, lead based paint, polychlorinated biphenyls (PCBs), and arsenic.

3.14.1.1.1 Resource Conservation and Recovery Act

RCRA is a Federal law that provides, in broad terms, the general guidelines for the Federal waste management program. RCRA's primary goals are to protect human health and the environment from the potential hazards of waste disposal, to conserve energy and natural resources, to reduce the amount of waste generated, and to ensure that wastes are managed in an environmentally sound manner. RCRA regulates the management of solid waste (e.g., garbage), hazardous waste, and underground storage tanks holding petroleum products or certain chemicals. It includes a Congressional mandate directing EPA to develop a comprehensive set of regulations to implement the law. The hazardous waste program, under RCRA Subtitle C, establishes a system for controlling hazardous waste from cradle to grave; that is, from the time it is generated, during transport and treatment, to ultimate disposal. In any given state, EPA or the state hazardous waste regulatory agency enforces hazardous waste laws. EPA encourages states to assume primary responsibility for implementing a hazardous waste program through state adoption, authorization, and implementation of the regulations.

On November 13, 2001, the Federal Government authorized HDOH to administer the Hawai'i Hazardous Waste Program. As part of the delegation process, HDOH adopted amendments to the State's hazardous waste rules (found in the HAR), some of which are more stringent than Federal Government regulations including procedures required by the State for Federally approved variances and exclusions by the EPA, and those concerning permits. For example, the State must separately approve any exclusion, variance, or alternative treatment method approved by the EPA under [40 CFR 268.5](#), [268.6](#), [268.42\(b\)](#), and [268.44](#); the State limits hazardous waste permits to five years (the Federal limit is 10 years) and landfill permits to three years (the Federal limit is five years). The State did not adopt [40 CFR 261.4\(b\)\(5\)](#) and therefore does not exclude drilling fluids, produced waters, and other wastes associated with the exploration, development, or production of crude oil, natural gas, or geothermal energy from regulation as a hazardous material. In addition, Hawai'i requires permits from HDOH for used oil transporters, marketers, and recyclers as well as an annual report of transporters, processors, re-refiners, and marketers in addition to the biennial RCRA reports. The State also requires additional information from foreign importers of hazardous waste, which is broader than Federal hazardous waste requirements ([66 FR 55119, November 1, 2001](#)).

3.14.1.1.2 Comprehensive Environmental Response Compensation and Liability Act

CERCLA, as amended by the [Superfund Amendments and Reauthorization Act](#) in 1986 ([Public Law 99-499](#)), authorized the EPA to create a list of polluted locations requiring a long-term response to clean up hazardous material contaminations. These locations are known as [Superfund sites](#) and are placed on the [National Priorities List](#) (NPL). The NPL guides EPA in “determining which sites warrant further investigation” for environmental remediation. There are presently three Superfund sites on the NPL in Hawai‘i. One additional site has been cleaned up and removed from the NPL. No sites are currently proposed for addition. All of these sites are on the island of O‘ahu ([Figure 3-71](#)).

3.14.1.1.3 Occupational Safety and Health Administration

The OSHA requirements are designed to protect workers and prevent workplace accidents, injuries, or illnesses (see [Section 3.17](#)). One such requirement is the Hazard Communication Regulation ([29 CFR 1910.1200](#)), which defines a hazardous chemical as one that poses a physical or health hazard and requires that workers are trained and notified of specific hazards associated with hazardous workplace substances. The definition of a hazardous chemical also includes:

- Carcinogens, toxins, toxic agents, irritants, corrosives, and sensitizers;
- Agents that act on the hematopoietic system (bodily system of organs and tissues);
- Agents that damage the lungs, skin, eyes, or mucous membranes;
- Chemicals that are combustible, explosive, flammable, unstable (reactive), or water reactive;
- Oxidizers;
- Pyrophorics (materials that can spontaneously ignite);
- Chemicals that in the course of normal handling, use, or storage may produce or release dusts, gases, fumes, vapors, mists, or smoke that may have any of the previously mentioned characteristics; and
- Workplace exposure to approximately 400 substances¹, including dusts, mixtures, and common materials such as paints, fuels, and solvents, currently regulated by OSHA.

3.14.1.1.4 U.S. Department of Transportation Regulations

USDOT Hazardous Materials Regulation at [49 CFR Part 171](#) defines a hazardous material as a substance capable of posing an unreasonable risk to health, safety, and property when transported in commerce. The USDOT definition includes hazardous substances, hazardous wastes, and marine pollutants. The hazardous materials are classified into different classes including explosives, gases, flammable liquid, flammable solids, oxidizing substances/organic peroxides, poisonous (toxic) and infectious substances, radioactive material, corrosives, and miscellaneous dangerous goods. USDOT regulations require the

¹ The OSHA Chemical Sampling Information file contains listings for approximately 1,500 substances; EPA’s *Toxic Substance Control Act* Chemical Substances Inventory lists information on more than 62,000 chemicals or chemical substances.

implementation of various protective and preventative measures designed to promote the safe transport of hazardous materials in commerce.

3.14.1.1.5 Right-to-Know Compliance

In 1993, the State of Hawai‘i enacted the Hawai‘i [Emergency Planning and Community Right-to-Know Act \(HRS 128E\)](#) which is modeled after the Federal [Emergency Planning and Community Right-to-Know Act](#). Hawai‘i Administrative Rules ([HAR 11-453](#)) for implementing the Community Right-to-Know regulations became effective in November 2010 and established requirements for State, county, and industry regarding emergency planning and reporting on hazardous and toxic chemicals. The Community Right-to-Know provisions help increase the public’s awareness of the potential chemical hazards present in the community in order to improve chemical safety and protect human health and the environment. Under this regulation, facilities (both large and small) are required to plan for possible emergencies and report chemical information to the Hawai‘i State Emergency Response Commission, county emergency planning committees, and the local fire department. [HRS 128E](#) has four major provisions, including Emergency Response Planning, Emergency Release Reporting, Hazardous Chemical Storage and Tier II Reporting, and Toxic Release Inventory Reporting. A facility may be subject to more than one of these provisions depending on the types of chemicals stored, the quantities of stored chemicals, and the facility’s activities. Additional information on each provision can be found at [http://eha-web.doh.hawaii.gov/eha-cma/Leaders/HEER/right-to-know-\(hepcra\)-compliance](http://eha-web.doh.hawaii.gov/eha-cma/Leaders/HEER/right-to-know-(hepcra)-compliance).

3.14.1.1.6 Under- and Aboveground Storage Tanks

Title [40 CFR Parts 280](#), promulgated under RCRA, and [281](#) contain Federal regulations concerning underground storage tanks, including information regarding general operating requirements, release detection, out of service tank systems and closure, purpose, general requirements and scope, and general provisions. The Hawai‘i State underground storage tank regulations require owners and operators to take specific steps to respond to confirmed releases from such tanks. These requirements are specified in HAR Title 11 for underground storage tanks ([HAR 11-281-07](#)) and [HRS 342L](#). A map and list of known leaking underground storage tanks can be found online using the HDOH Environmental Health Warehouse database and Map Viewer at <http://eha-web.doh.hawaii.gov/ehw/>.

States primarily regulate aboveground storage tanks. However, Hawai‘i does not have any specific requirements. The Hawai‘i Water Pollution Control Law does prohibit the discharge of any pollutant into State waters without a permit. In addition, the Hawai‘i Environmental Response Law requires immediate reporting of any hazardous substance release. Hawai‘i also requires that the owner or operator of a tank control [air pollutant](#) emissions from each tank.

3.14.1.1.7 Pesticides

The Federal *Insecticide, Fungicide and Rodenticide Act of 1972* (as amended by [7 U.S.C. §§ 136–136y](#)) regulate registration and use of pesticides. Pesticide management activities are subject to Federal regulations contained in [40 CFR Parts 162, 166, 170, and 171](#) and the Hawai‘i Pesticides Law. [Hawai‘i Code Division 1 Title 11 Chapter 149A](#) is the State of Hawai‘i’s law that authorizes the Hawai‘i Department of Agriculture to make and enforce pesticide rules for Hawai‘i.

3.14.1.1.8 Asbestos

Asbestos is a mineral fiber that can cause cancer or asbestosis when inhaled; it has the potential to pollute air and water. The EPA regulates asbestos with the authority promulgated by OSHA ([29 U.S.C. § 669](#)). Emissions of asbestos fibers to ambient air are regulated under Section 112 of the CAA. EPA has banned

the use of asbestos in manufacturing or construction; however, asbestos-containing materials may be present in buildings constructed before 1973 based on the type of insulation materials that were used at the time. [HAR 11-501.7](#) provides standards for demolition and renovation work in Hawai‘i with regard to asbestos, and requires surveys and notices to document work in which asbestos-containing building materials may be a concern. Asbestos abatement is frequently an issue of concern when remodeling older buildings to make them more energy efficient.

3.14.1.1.9 Lead-Based Paint

On October 28, 1992, Congress passed the *Residential Lead-Based Paint Hazard Reduction Act of 1992* ([42 U.S.C. §§ 4851–4856](#), commonly called Title X). This Act along with associated EPA rules provide for lead-based paint hazard reduction and worker and resident notification and protection. Lead-based paint may be present in buildings constructed before 1992 based on the type of building materials that were used at the time. Lead-based paint can sometimes be an issue of concern when remodeling older buildings to make them more energy efficient.

3.14.1.1.10 Polychlorinated Biphenyls

The *Toxic Substances Control Act* ([15 U.S.C. § 2601](#)) became law in 1976. This Act authorizes EPA to secure information on all new and existing chemical substances, as well as to control any substances that were determined to cause unreasonable risk to public health or the environment. Current PCB regulations can be found at [40 CFR Part 761](#). PCBs have been used in a wide variety of materials, including electrical equipment such as transformers and caulking around doors and windows.

3.14.1.1.11 Arsenic

Arsenic is a naturally occurring element in the earth’s crust. In Hawai‘i, low levels of arsenic are found naturally in native soils and are also naturally present in most produce. However, elevated levels of arsenic have been identified in soils at former sugar cane fields, former pesticide mixing areas, former sugar cane plantation camps, a former cane production plant, wood-treatment plants, and at least one former golf course. The State has also indicated that arsenic may be present in canec building materials, which were manufactured in Hawai‘i from the early 1930s to the early 1960s. Canec is the common name for a fiberboard building material that was made from sugar cane bagasse, the residual fiber that remained after the juice was extracted from the sugarcane. Canec was treated with inorganic arsenic compounds as an anti-termite agent. Canec was used for interior ceilings and walls in many residential and commercial structures throughout the State of Hawai‘i. As such, the HDOH published technical guidance for soils and for safe management practices during the handling, demolition, and disposal of soils or materials with arsenic. In addition, the HDOH published maps of sugar cane lands from 1920 to 1937 that indicate sugar plantations that could have used arsenic herbicides. It is important to note that while a plantation may be included on the maps, it is not positively identified as having used arsenic. HDOH generally advises to test these areas soil for arsenic residues, prior to redeveloping the land. This map can be found online at <http://eha-web.doh.hawaii.gov/eha-cma/Leaders/HEER/soil-arsenic-guidance-and-information>.

3.14.1.2 Munitions and Explosives of Concern

As a result of the large military presence in Hawai‘i over the past hundred years, the potential exists for encountering munitions and explosives of concern (MEC) on both land and in the ocean. MECs are military munitions that pose an explosive safety risk and include unexploded ordnance (UXO) and discarded military munitions (DMM). Until 1972, munitions disposal included burning, burial, on-land or disposal at sea, with sea disposal considered one of the safest alternatives until Congress prohibited the practice by passing the *Marine Protection, Research, and Sanctuaries Act*. Today, MEC is considered a

threat to public health since it may detonate if disturbed, and may also threaten soil, surface water, and groundwater.

MECs are regulated by the *Federal Facility Compliance Act*, which requires that the EPA, in consultation with DoD and the states, publish regulations [known as the Military Munitions Rule ([62 FR 6622, February 12, 1997](#))] that identify when conventional and chemical military munitions (waste military munitions) become hazardous waste (and subject to Subtitle C of RCRA), and provide for the safe storage and transportation of such waste. There are many policies and guidelines that govern most aspects of military munitions and military munitions siting; cleanup operations and standards; and transport of UXO, UXO workers, and property transfers under the Military Munitions Rule. These include DoD and service-specific directives, policies, and guidelines. The service-specific policies usually reiterate the DoD policies and directives but may also provide additional details and requirements pertinent to that service. Specific services include the U.S. Army, U.S. Navy, and the U.S. Air Force. U.S. Marine Corps ranges tend to follow U.S. Navy guidelines while Army National Guard Ranges tend to follow U.S. Army policies. Most munitions-related investigations and cleanup are performed by or in conjunction with various DoD agencies. DoD is responsible for all military munitions.

The WMM is managed to minimize health hazards and environmental damage caused by the use or misuse of hazardous material. Under RCRA, MECs are considered hazardous waste when such munitions are used, fired or disposed of. In order to improve public safety and reduce the risk that munitions pose to present and future generations, the DoD developed the Military Munitions Response Program (MMRP), which addresses potentially hazardous military munitions located in former on- and offshore disposal sites around the nation. Those properties known or suspected to contain MECs, UXO, or DMM are referred to as Munition Response Sites.

3.14.1.3 Affected Environment

The biggest location-specific hazardous materials concerns are associated with the presence of contaminated soil and/or groundwater. To evaluate areas where these hazardous materials may be present, two main sources of information were queried: the EPA Superfund Information System (<http://cumulis.epa.gov/supercpad/cursites/srchsites.cfm>) and the HDOH Office of Hazard Evaluation and Emergency Response lookup spreadsheets ([HDOH 2012c](#)). The Superfund database contains information on hazardous waste sites, potentially hazardous waste sites, and remedial activities across the nation, including sites that are on the NPL or being considered for listing. The database was frozen on November 12, 2013, to allow EPA to develop and deploy the new Superfund Enterprise Management System (expected in early 2014). The HDOH spreadsheets list environmental interests that Hazard Evaluation and Emergency Response Office has investigated or may investigate. The Emergency Preparedness and Response or Site Discovery, Assessment and Remediation sections within that Office manage environmental interests. These databases are updated by the EPA and the State, respectively. Readers are directed to the following websites for additional information: <http://cumulis.epa.gov/supercpad/cursites/srchsites.cfm> and <http://eha-web.doh.hawaii.gov/eha-cma/Leaders/HEER/public-records>.

In the event any of the identified areas should be chosen for development, it would be necessary to perform detailed investigations including a site-specific environmental assessment in conformance with ASTM Method E 1527 05 ([ASTM 2005](#)), which would provide for detailed review of accessible public records and require site inspections to confirm the presence of affected sites at or near the project-specific location.

Additional location-specific hazardous material concerns are associated with the presence of munition and explosives of concern sites, which are designated as Munitions Response Sites by the military. To evaluate areas where these hazardous materials may be present, the Munitions Response Sites Inventory was queried ([DENIX 2014a](#)). A total of 55 munitions response sites were identified within the State, including one in American Samoa, and six offshore sites or sea disposal military munition sites as shown in [Figure 3-76](#). Four sites did not have maps to show exact locations. Information regarding these munitions response sites, particularly MECs are listed below.

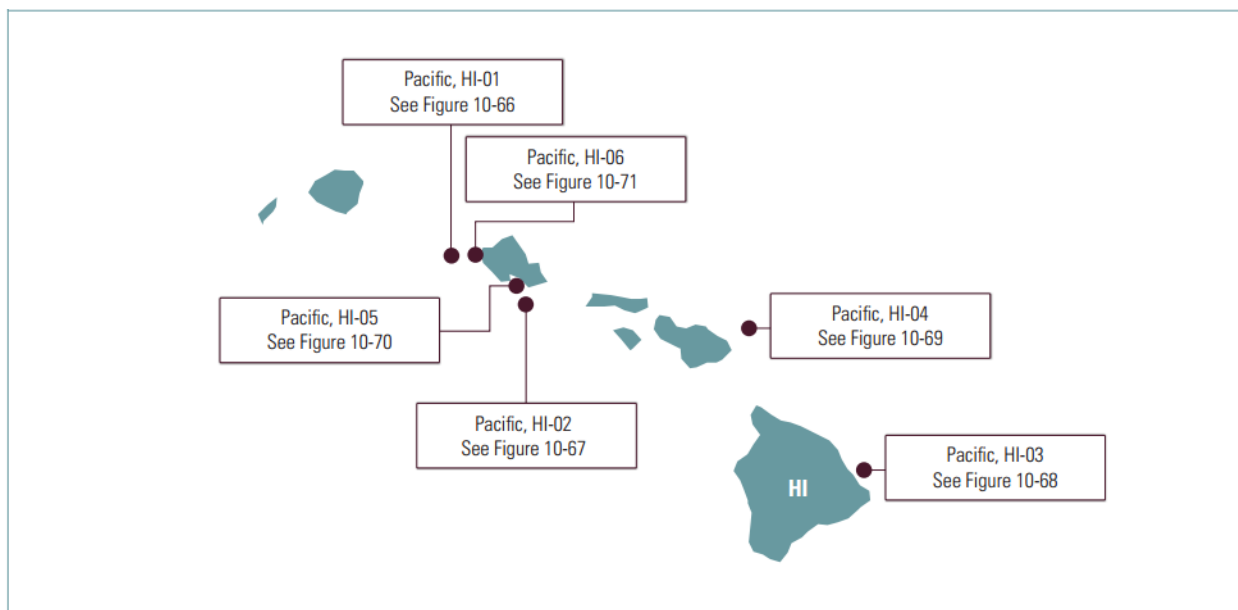

Figure 3-76. Approximate Locations of Munitions Disposals in Hawai‘i (Source: [DENIX 2014b](#))

Once the locations of a project are determined, it would be necessary to perform detailed investigations including a site-specific Environmental Site Assessment in conformance with the ASTM Method E 1527-05 ([ASTM 2005](#)) including an evaluation of the presence of MEC at the project-specific locations and along possible project location alignments as the presence of dumped materials could impact project alignment, construction, and maintenance.

3.14.1.3.1 Kaua‘i

A review of the EPA Database for Kaua‘i identified five Superfund sites, as shown in [Table 3-62](#); none is on the NPL.

A total of 389 Emergency Preparedness and Response and 85 Site Discovery, Assessment and Remediation sites are listed on the Lookup Spreadsheets for Kaua‘i. Two 290 Site Discovery, Assessment and Remediation sites were identified as a State High Priority Contamination Site: the Grace Pacific Corporation - Hanamaulu Facility and the Lihue Plantation Combined Sites Facility.

Table 3-62. Superfund Sites on Kaua‘i

Site Name	City	County
Brewer Chemical Corp	Lihue	Kaua‘i
Kaua‘i Agricultural Research Center	Wailua	Kaua‘i

3.14.1.3.2 O‘ahu

A review of the EPA Database for O‘ahu identified 70 Superfund sites (see [Table 3-64](#)); three of which are on the Final NPL (NPL Status Code “F”): the Del Monte Corporation (O‘ahu Plantation) site, the Naval Computer and Telecommunications Area Master Station Eastern Pacific site, and the Pearl Harbor Naval Complex site; 13 of which are a part of a NPL site (NPL Status Code “A”); two of which were removed from the proposed NPL (NPL Status Code “R”); and one that was deleted from the Final NPL (NPL Status Code “D”). [Figure 3-77](#) shows the location of the three sites that are on the Final NPL (listed in bold in the table below).

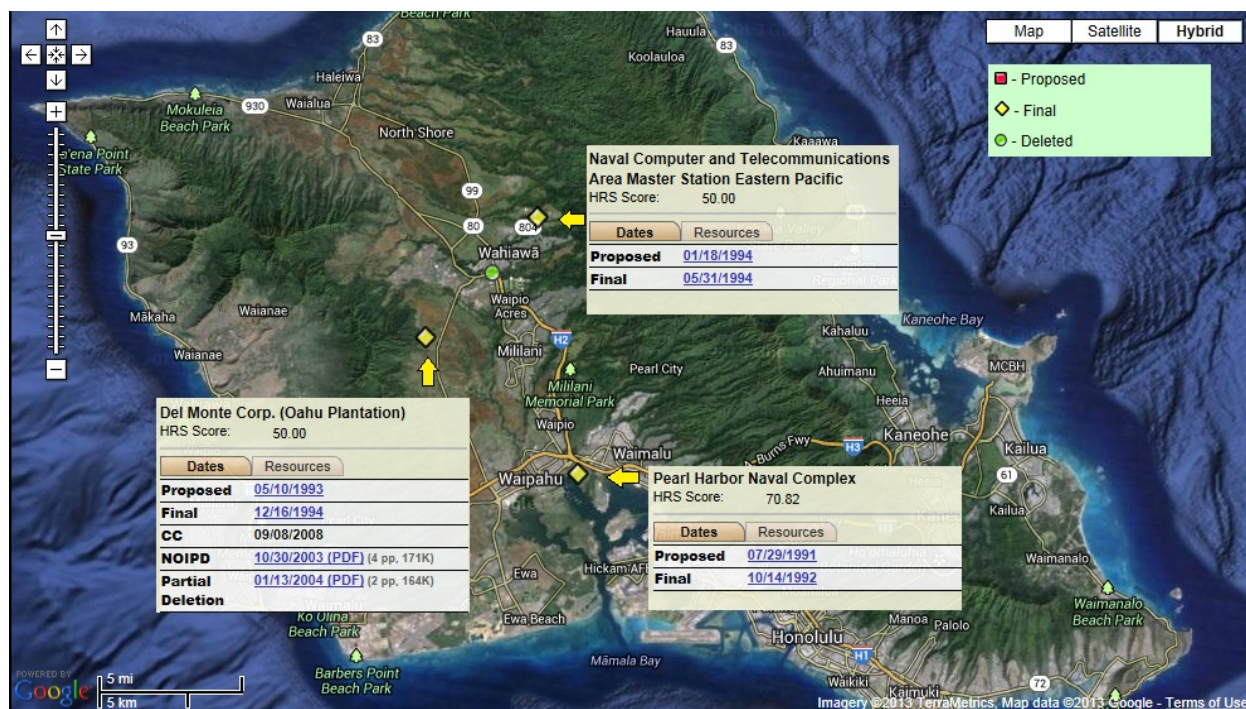

Figure 3-77. Final NPL Sites on Island of O’ahu (Source: [EPA 2013b](#))

A total of 8,400 Emergency Preparedness and Response and 1,290 Site Discovery, Assessment and Remediation sites were listed on the Lookup Spreadsheets for the island of O’ahu. Ninety-four are identified as a State High Priority Contamination Site; approximately half of which are owned by the U.S. Air Force and associated with multi-family housing at Hickam Air Force Base, the rest of the sites are spread out across the island.

A total of 25 munitions response sites were identified on or around the island of O’ahu as shown in [Table 3-65](#). Among the 25, four were identified as sea munition disposal sites as shown in [Table 3-66](#).

3.14.1.3.3 Molokai

A review of the EPA Database for Molokai identified one Superfund site: the Kīlauea Pesticides site, which is not on the NPL. This site is being addressed only by the Federal Superfund removal program and not by the Site assessment program; therefore, no site assessment work is required.

A total of 64 Emergency Preparedness and Response and 28 Site Discovery, Assessment and Remediation sites were listed on the Lookup Spreadsheets on Molokai. None are identified as a State High Priority Contamination site. One munitions response site was identified on or around the island of Molokai as shown in [Table 3-67](#).

Table 3-67. Munitions Response Site Inventory Search Results/MEC Sites – Molokai

MEC = Munitions and Explosives of Concern.

3.14.1.3.4 Lāna‘i

A review of the EPA Database for Lana‘i identified no Superfund sites.

A total of 29 Emergency Preparedness and Response sites were listed in the Lookup Spreadsheets. None was listed as a Site Discovery, Assessment and Remediation site. None was identified as a State High Priority Contamination site. One munitions response site was identified on around the island of Lāna‘i as shown in [Table 3-68](#).

Table 3-68. Munitions Response Site Inventory Search Results/MEC Sites – Lāna‘i

3.14.2 WASTE MANAGEMENT

Waste management involves the collection, handling, storage, and disposal of various waste streams including residential, commercial, industrial, and special waste. In an island state like Hawai‘i, waste management options are severely limited by the shortage and expense of available land. Burying wastes in island landfills is not a sustainable strategy for the long term. As such, new waste management approaches and technologies are continuously being identified, including harnessing waste streams as potential sources of biomass energy. This section includes a discussion of the quantities and types of waste generated and current management practices (treatment, storage, and disposal) by island. The following sections also discuss the status of existing recycling and zero waste programs on each island. This PEIS provides a separate discussion on hazardous waste in [Section 3.14.1](#).

3.14.2.1 Regulatory Setting

3.14.2.1.1 Resource Conservation and Recovery Act

In addition to its regulation of hazardous materials, RCRA also includes waste management provisions. Subtitle D of the RCRA encourages environmentally sound solid waste management practices that maximize the reuse of recoverable materials and foster resource recovery. Additional regulations governing solid waste management are often adopted by states and tribes.

3.14.2.1.2 State of Hawai‘i

[HRS 342G](#), “Integrated Solid Waste Management,” [HRS 342H](#), “Solid Waste Pollution,” [HRS 342I](#), “Special Waste Management,” and [HRS 342J](#), “Hazardous Waste,” regulate waste management in the State. In addition, [HAR 11-58-01](#), “Solid Waste Management Control,” governs the design, construction, installation, operation, and maintenance of solid waste disposal, recycling, reclamation, and transfer systems, as well as of special waste in the State. The Solid Waste Management section within the HDOH Solid and Hazardous Waste Branch enforces these rules and regulations.

3.14.2.1.3 Hawai‘i Revised Statutes on Integrated Solid Waste Management

[HRS 342G](#), “Integrated Solid Waste Management,” requires each county to develop an integrated solid waste management plan and revise the Plan once every five years. Beyond the State of Hawai‘i’s solid waste management planning requirement, the City and County of Honolulu adopted legislation that requires the development of a 25-year plan, which is updated every five years.

3.14.2.1.4 Kaua‘i County Code

Kaua‘i County Code Chapter 21, “Integrated Solid Waste Management,” establishes the minimum standards governing the refuse collection services for the county, and the handling, proper disposal processing, disposal, recycling, reuse, and salvage of solid waste at refuse transfer stations, debris recycling stations, temporary emergency debris receiving sites, residential drop-off recycling centers, and landfills the County of Kaua‘i owns or operates.

In August 2010, the County of Kaua‘i adopted Ordinance 902, banning the landfill disposal of commercially generated loads exceeding 10-percent corrugated cardboard, 10-percent ferrous and non-ferrous metal, or 10-percent greenwaste by volume. Businesses and garbage haulers that exceed the 10-percent limit by volume are subject to load rejection and penalties. In addition, businesses and haulers are required to collect and store cardboard separately from waste to keep it clean and dry and to prevent contamination.

3.14.2.1.5 The City and County of Honolulu Revised Ordinances

Waste disposal services and recycling is governed on O‘ahu by the City and County of Honolulu’s Revised Ordinances of Honolulu: Chapter 9, “Collection and Disposal of Refuse” ([City and County of Honolulu 2013b](#)). The Ordinance includes general provisions regarding the collection and disposal of refuse, licensing regulations to collect refuse, regulations applicable to businesses, private dwellings, and government facilities, collection and disposal charges, enforcement provisions and arrest, the recycling of glass containers, asphalt paving, and the regulation of bags provided to customers.

3.14.2.1.6 Maui County Code

Maui County Code Chapter 8.04, “Refuse Collection and Landfills,” establishes the means by which all solid waste in the County of Maui is collected, disposed of, and/or recycled. The Code includes regulations on collection arrangements, private disposal dumps, collection charges, disposal permits and charges, the rulemaking authority, and the penalties that would be imposed for violations. Rules for refuse collection for the island of Lāna‘i are authorized by the existing director of the Maui County Department of Environmental Management. There are no specific regulations in the Maui County Code for refuse collection and landfills for the island of Molokai.

3.14.2.1.7 Hawai‘i County Code

County laws and regulations associated with waste management in Hawai‘i County include Hawai‘i County Code, Chapter 20, “Refuse,” and the County of Hawai‘i Administrative Rules for Solid Waste Refuse Control and Disposal Fees. In addition, in 2007, the Hawai‘i County Council adopted resolution 356-07 on a mission to reduce the county’s ecological footprint. In February 2009, the County of Hawai‘i revised the *Draft Zero Waste Implementation Plan*, which promotes the reduction, reuse, and recycling of waste in the county ([County of Hawai‘i 2009](#)).

3.14.2.2 Affected Environment

All solid waste generated across the Hawaiian Island chain is managed within each island. Across the islands, various city and county landfills, transfer stations, and privately owned solid waste operations exist to manage the ever-growing production of solid waste. Due to the scarcity of land, the State is continuously looking to reduce overall waste through recycling and recovery for both its environmental and economic benefits. However, recycling does have some limitations in island states like Hawai‘i. While there are environmental benefits to reducing, reusing, and recycling waste, some materials cannot economically be recycled or processed in the State, in such case the recyclables must be exported. Where available, recycling facilities are discussed below.

3.14.2.2.1 Kaua‘i

For the fiscal year 2010–2011, the island of Kaua‘i generated approximately 93,000 tons of waste ([HDOH 2011b](#)). This was projected to increase to more than 157,000 tons through 2013 ([R.W. Beck 2009](#)). The Kaua‘i County integrated solid waste management plan did not include projections beyond 2013. Of the 93,000 tons of waste that was generated in Kaua‘i, approximately 23.8 percent (22,000 tons) was diverted from Kaua‘i’s landfills for reuse and recycling activities. The County of Kaua‘i Department of Public Works, Solid Waste Division is responsible for the collection and disposal of garbage and refuse. [Figure 3-78](#) shows a map of the solid waste facilities including the landfills that serve the County of Kaua‘i.

Figure 3-78. County of Kaua‘i Solid Waste Management Facilities (Source: [R.W. Beck 2009](#))

Kaua‘i is served by the Kekaha Phase II Landfill, which accepts residential and RCRA Subtitle D commercial solid waste. Subtitle D includes *nonhazardous* solid wastes and certain hazardous wastes that are exempt from the Subtitle C regulations, such as hazardous wastes from households and from conditionally exempt small quantity generators. Subtitle D also includes garbage (e.g., food containers, coffee grounds); non-recycled household appliances; residue from incinerated automobile tires; refuse such as metal scrap and construction materials; and sludge from industrial and municipal wastewater facilities and drinking water treatment plants.

The landfill is projected to reach capacity in mid-2014. Therefore, the County of Kaua‘i currently is in the process of designing and permitting a vertical expansion to increase the landfill’s permitted height to 120 feet, which would provide an additional estimated 317,000 cubic yards of airspace ([County of Kaua‘i](#)

[2013a](#), [2013b](#)). The vertical expansion is projected to allow landfill operations for up to 5 years, or when the county anticipates having a new landfill in operation.

The new landfill project would involve the construction and operation of a new municipal solid waste landfill and a resource recovery park, intended to provide a comprehensive and integrated set of waste management programs and facilities to help maximize the diversion of waste from the landfill via reuse, recycling, and recovery. In July 2012, a new landfill siting study evaluated the suitability of eight sites for the proposed landfill. At the time of preparation of this PEIS, Kaua‘i County was preparing an environmental impact statement for the new landfill, which will include a preliminary design of the proposed resource recovery park. More information on the new landfill is online at <http://www.Kauai.gov/Government/Departments/PublicWorks/SolidWaste/NewLandfillSite/tabid/71/Default.aspx>.

Refuse Transfer Stations

Waste transfer stations are facilities where municipal solid waste is unloaded from collection vehicles and briefly held while it is reloaded onto larger transport vehicles for shipment to landfills or other treatment or disposal facilities. The island is served by four refuse transfer stations: Hanalei, Kapa‘a, Hanapepe, and Lihue stations. Collection crews deliver refuse to the refuse transfer stations, where it is loaded into high cube (65 to 75 cubic yard capacity) trailers and delivered to the Kekaha Landfill.

Recycling

As part of Kaua‘i County’s Recycling and Waste Management Program, the following are implemented: (1) Source reduction, reuse, and recycling programs; (2) Special waste management programs including junk vehicle, appliance, tire, lead-acid battery, used oil, and household hazardous waste disposal; and (3) A public education/awareness program. The Kaua‘i Resource Center will accept prohibited materials as long as they are first cleaned. The Garden Isle Disposal facility in Lihue accepts larger loads. Ferrous metal is accepted for recycling at Puhī Metals Recycling in Puhī. Non-ferrous metal is accepted for recycling at Reynold’s Recycling in Lihue.

Greenwaste Program

The greenwaste program in Kaua‘i was created to divert residential and commercial greenwaste from the Kekaha landfill. The County currently accepts separated greenwaste for diversion at all four transfer stations and at the landfill. There are six collection crews servicing the entire island.

Greenwaste may be deposited at Heart and Soul Organics in Moloaa, and clean loads of greenwaste may be deposited at Kaua‘i Nursery in Puhī.

3.14.2.2.2 O‘ahu

For the fiscal year 2010-2011, the island of O‘ahu generated approximately 1.2 million tons of waste ([City and County of Honolulu 2013c](#)). This is projected to double to approximately 2.4 million by 2030 ([R.W. Beck 2008](#)). Of the 1.2 million tons of waste that was generated on O‘ahu, approximately 37 percent (766,000 tons) was diverted from O‘ahu’s landfills. This amount is even higher (up to 73 percent) when the amount of waste converted for energy is taken into account ([City and County of Honolulu 2013c](#)). Waste on the island is primarily disposed of at two landfills, the Waimanalo Gulch Sanitary Landfill and the Nanakuli Landfill, three transfer stations, 10 public refuse drop-off centers, and six convenience centers. [Figure 3-79](#) shows a map of the solid waste facilities that serve the island of O‘ahu.

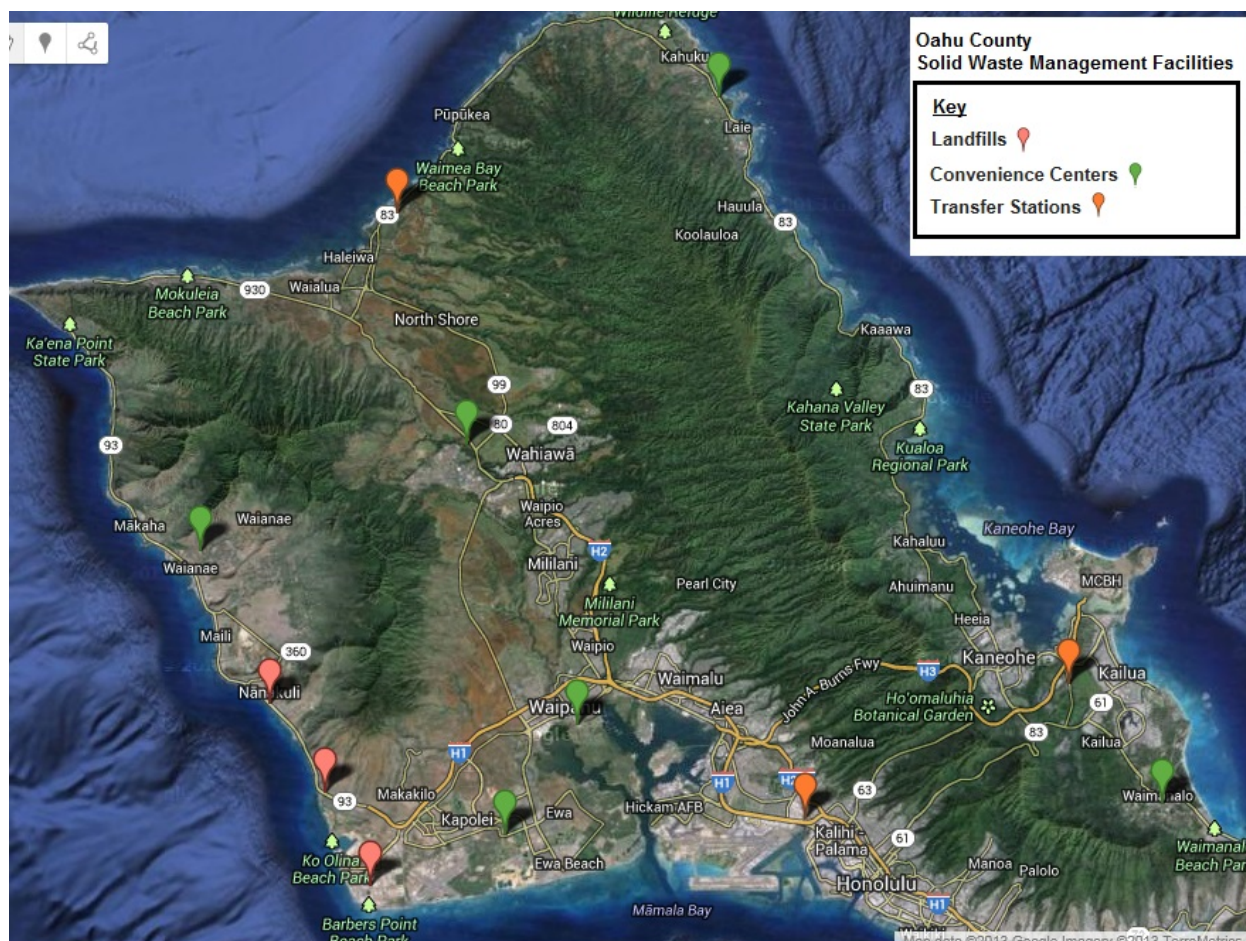

Figure 3-79. Solid Waste Management Facilities on O‘ahu (Source: [City and County of Honolulu 2013d](#))

The City and County of Honolulu owns the Waimanalo Gulch Sanitary Landfill and Waste Management of Hawai‘i operates the landfill. The landfill covers 200 acres and accepted 400,000 tons of municipal solid waste annually. To date, the continued use of the Waimanalo Gulch Sanitary Landfill is being determined. The City and County of Honolulu estimates the physical capacity of the landfill would enable it to continue to receive waste materials for at least the next 15 years. However, in 2009, in response to community opposition to the landfill, the State Land Use Commission (LUC) issued an order requiring the City to begin the process of identifying one or more landfill sites to supplement or replace the landfill by November 2010 (the City’s own integrated solid waste management plan called for the City to identify a new municipal solid waste landfill by 2012). The LUC order acknowledged that it would take the City at least seven years to construct and open a new landfill, but conditioned that the Waimanalo Gulch Sanitary Landfill stop accepting municipal solid waste as of July 2012. The City litigated the condition with the courts, with the Supreme Court striking down the LUC’s condition imposing the MSW deadline. The action was then remanded to the LUC, who remanded the case to the Planning Commission. At this time, the landfill is continuing operations under the current Special Use Permit, while the deadline for receipt of MSW is resolved by the Planning Commission and the LUC. In addition, the City and County of Honolulu is currently evaluating potential landfill sites to supplement or replace the Waimanalo Gulch Sanitary Landfill. Based on a recent Landfill Site Selection Committee report, the Upland Kahuku 2 site is ranked highest of 11 potential sites for a new landfill ([City and County of Honolulu 2012c](#)).

The Nanakuli Landfill is a privately owned landfill (owned by PVT Land Company, Ltd.) and only accepts construction and demolition waste and petroleum-contaminated soils ([R.W. Beck 2008](#)). Information on the specific annual quantity of materials received at the Nanakuli Landfill is not available; however, it is estimated at approximately 200,000 tons per year. The Nanakuli Landfill reportedly had approximately 18 years of remaining permitted capacity (as of 2008) at its existing fill rate ([R.W. Beck 2008](#)). Therefore, it is anticipated that the Nanakuli Landfill has capacity until 2026.

Recycling and Waste-to-Energy

In addition to landfills, O‘ahu employs Covanta Honolulu, known as H-POWER², a waste-to-energy facility located in the Campbell Industrial Park, to discard solid waste. According to the City and County of Honolulu, the majority of residential and commercial municipal solid waste discarded on O‘ahu is delivered to H-POWER. Approximately 90 percent of the volume and 70 to 75 percent of the weight of the solid waste processed at H-POWER is diverted from the Waimanalo Gulch Sanitary Landfill to generate electricity. The ash and residue from H-POWER is delivered to the landfill for disposal. In fiscal year 2006, over 600,000 tons of waste were recycled for energy at H-POWER ([R.W. Beck 2008](#)). The facility currently processes up to 3,000 tons per day of municipal solid waste and generates up to 90 megawatts of energy for HECO, enough to meet approximately 8 percent of O‘ahu’s energy needs. In 2012, the facility completed a 900-ton-per-day expansion, which is expected to increase H-POWER’s annual processing capacity by at least 300,000 tons ([Covanta 2013](#)). Section 2.3.3.8 of this PEIS discusses the H-POWER facility.

Transfer Stations

The City and County of Honolulu operates three transfer stations in Kapa‘a, Keehi, and Kawailoa that consolidate waste from municipal solid waste collection trucks into large transfer trailers for more efficient and economical transport to H-POWER or the Waimanalo Gulch Sanitary Landfill. In addition to the three municipal transfer stations, two additional private transfer stations operate on O‘ahu: the Honolulu Disposal Transfer Station and the Island Demo Transfer Station. The Honolulu Disposal Transfer Station accepts municipal solid waste from its own company’s trucks. The Island Demo facility receives construction and demolition waste, sorts materials for recycling, and transfers the non-recyclable portion to H-POWER or the Nanakuli Landfill ([R.W. Beck 2008](#)).

3.14.2.2.3 Molokai

The County of Maui’s Molokai-Laiwa Landfill and Recycling Center serves the island of Molokai. It accepts municipal solid waste and recycling wastes from commercial and residential customers. The landfill accepts 17.6 tons of trash per day ([County of Maui 2009](#)). Annually, 6,570 tons of trash is disposed of at the landfill ([County of Maui 2009](#)). The Molokai Landfill has a design capacity of 387,000 cubic yards with approximately 166,400 cubic yards of capacity currently remaining ([County of Maui 2009](#)). This capacity is projected to be filled in 2015 ([County of Maui 2009](#)).

The island includes the Molokai Metals Facility located on Mauna Loa Highway at the Molokai-Naiwa Landfill. The Molokai Metals Facility accepts vehicles, motorcycles, appliances, vehicle tires and batteries, metal items such as roofing, gutters, tubs, sinks, faucets, pipes, metal furniture, bicycles, mowers, engine parts, tools, fencing, propane tanks, and ferrous and non-ferrous scrap metals ([County of Maui 2013b](#)).

² H-POWER stands for the Honolulu Program of Waste Energy Recovery.

3.14.2.2.4 Lānaʻi

The County of Maui's Lānaʻi Landfill, located 4 miles west of Lānaʻi City, serves the island of Lānaʻi. Lānaʻi Landfill accepts commercial and residential waste. The landfill has a disposal capacity of 178,000 cubic yards ([County of Maui 2009](#)). Annually, the landfill has a capacity usage of 13,400 cubic yards, and disposes of 5,127 tons of waste. Per operating day, 19.7 tons of waste is disposed of at the landfill. Lānaʻi Landfill has 178,000 cubic yards of remaining capacity and is projected to reach capacity in 2020 ([County of Maui 2009](#)).

3.14.2.2.5 Maui

Maui County comprises the islands of Maui, Molokai, and Lānaʻi. For the fiscal year 2010–2011, the islands of Maui County generated approximately 244,000 tons of waste ([HDOH 2011b](#)). This is projected to increase to 250,000 tons by 2015 and to approximately 306,000 by 2030 ([County of Maui 2009](#)). Of the 244,000 tons of waste generated in Maui County, approximately 36.6 percent (89,000 tons) was diverted from Maui's landfills. The County of Maui owns and operates two municipal solid waste landfills on Maui, one landfill on Lānaʻi, and one landfill on Molokai. The County Solid Waste Division within the Maui County Department of Environmental Management plans, operates, and maintains the county landfills. [Figure 3-80](#) shows a map of the solid waste facilities including the landfills and recycling centers that serve the County of Maui.

Figure 3-80. Maui County Solid Waste Management Facilities ([County of Maui 2013c](#))

- **Central Maui Landfill** – The County owns and operates this landfill. It accepts municipal solid waste and serves the entire island of Maui. It is located approximately 3 miles from Kahului Airport. Central Maui Landfill accepts an average of 500 tons of waste per day ([County of Maui 2012b, Chapter 6](#)). Its existing capacity is 11.6 million cubic yards ([County of Maui 2012b, Chapter 6](#)). The projected demand of 2030 is 12.4 million cubic yards. Therefore, a shortage of 0.8 million cubic yard will occur if additional space is not created ([County of Maui 2012b, Chapter 6](#)). Central Maui Landfill is projected to reach capacity in 2026.

- Hana Landfill – This landfill is a 35-acre facility that serves the Hana Community Plan area. The Hana Landfill accepts residential, commercial, and greenwaste.
- Olowalu Recycling and Refuse Convenience Center – This center accepts self-hauled residential waste and is then transferred to the Central Maui landfill.
- Maui Construction and Demolition Landfill – This landfill is the only operating facility in the county that currently accepts construction and demolition debris for recycling. It is privately owned and located near Ma‘alaea. The Maui Construction and Demolition Landfill has a capacity of 872,000 cubic yards of waste. Currently, it accepts approximately 3,000 to 5,000 tons of waste per month ([Hart 2007](#)). The facility may cease operations in the near future; however, there are plans for another construction and demolition recovery facility to open on Maui.

Greenwaste and Food Waste

Commercial and residential greenwaste is accepted at the Central Maui Landfill, EKO Compost, Hana Landfill, Maui Earth Compost Company, the Molokai Landfill, and the Olowalu Recycling and Refuse Convenience Center. EKO Compost has the current contract to process greenwaste collected through the County of Maui curbside collection program. Following co-composting with biosolids, the facility sells the compost to contractors and residents on Maui.

Food waste generated at resorts is recycled by Puaa Food Waste. The company uses the food waste at pig farms. The pigs are in turn sold to resorts to be used in luau.

Recycling

There are currently 17 Hawai‘i Deposit Beverage Container Program (HI-5) redemption centers in Maui County. Following collection of HI-5 beverage containers, the materials are transported to either of two materials recycling facilities on Maui, operated by Aloha Recycling and Maui Disposal. The materials recycling facilities bale the HI-5 materials and broker them in out-of-state markets.

The majority of metals recycling on Maui is provided by the Hammerhead Metals Recycling Facility and Maui Tow and Transport. Hammerhead Metals has the current contract with Maui County to process large appliances and disposed-of vehicles from residential sources. Hammerhead Metals also buys valuable metals, such as copper and brass, from the general public. Maui Tow and Transport processes scrap metal, mainly from commercial sources. Several other facilities on Maui accept scrap metal for recycling, including the Central Maui Landfill and Maui Tire Recycling LLC. Following collection, the materials are shipped to various end recyclers.

3.14.2.2.6 Hawai‘i

For the fiscal year 2010–2011, the island of Hawai‘i generated approximately 234,000 tons of waste. This is projected to increase to 316,000 tons by the end of fiscal year 2012–2013 and to approximately 452,000 by fiscal year 2027–2028 ([CH2MHill 2009](#)). Of the 234,000 million tons of waste generated in the County of Hawai‘i, approximately 28.9 percent (68,000 tons) was diverted from the county’s landfills. Waste on the island is served by two County-owned and operated landfills: the South Hilo Sanitary Landfill and the West Hawai‘i Sanitary Landfill, located in Puuanahulu. For residents, the common forms of residual materials sent to either landfill is household refuse, municipal solid waste, and do-it-yourself construction and demolition waste. Businesses and institutions send a wide range of different nonhazardous residual materials from their daily operations ([CH2MHill 2009](#)). Commercial disposal of residual waste generally requires a landfill disposal permit through the Hawai‘i County Department of Environmental Management. [Figure 3-81](#) shows a map of the solid waste facilities including the landfills and transfer stations that serve the County of Hawai‘i.

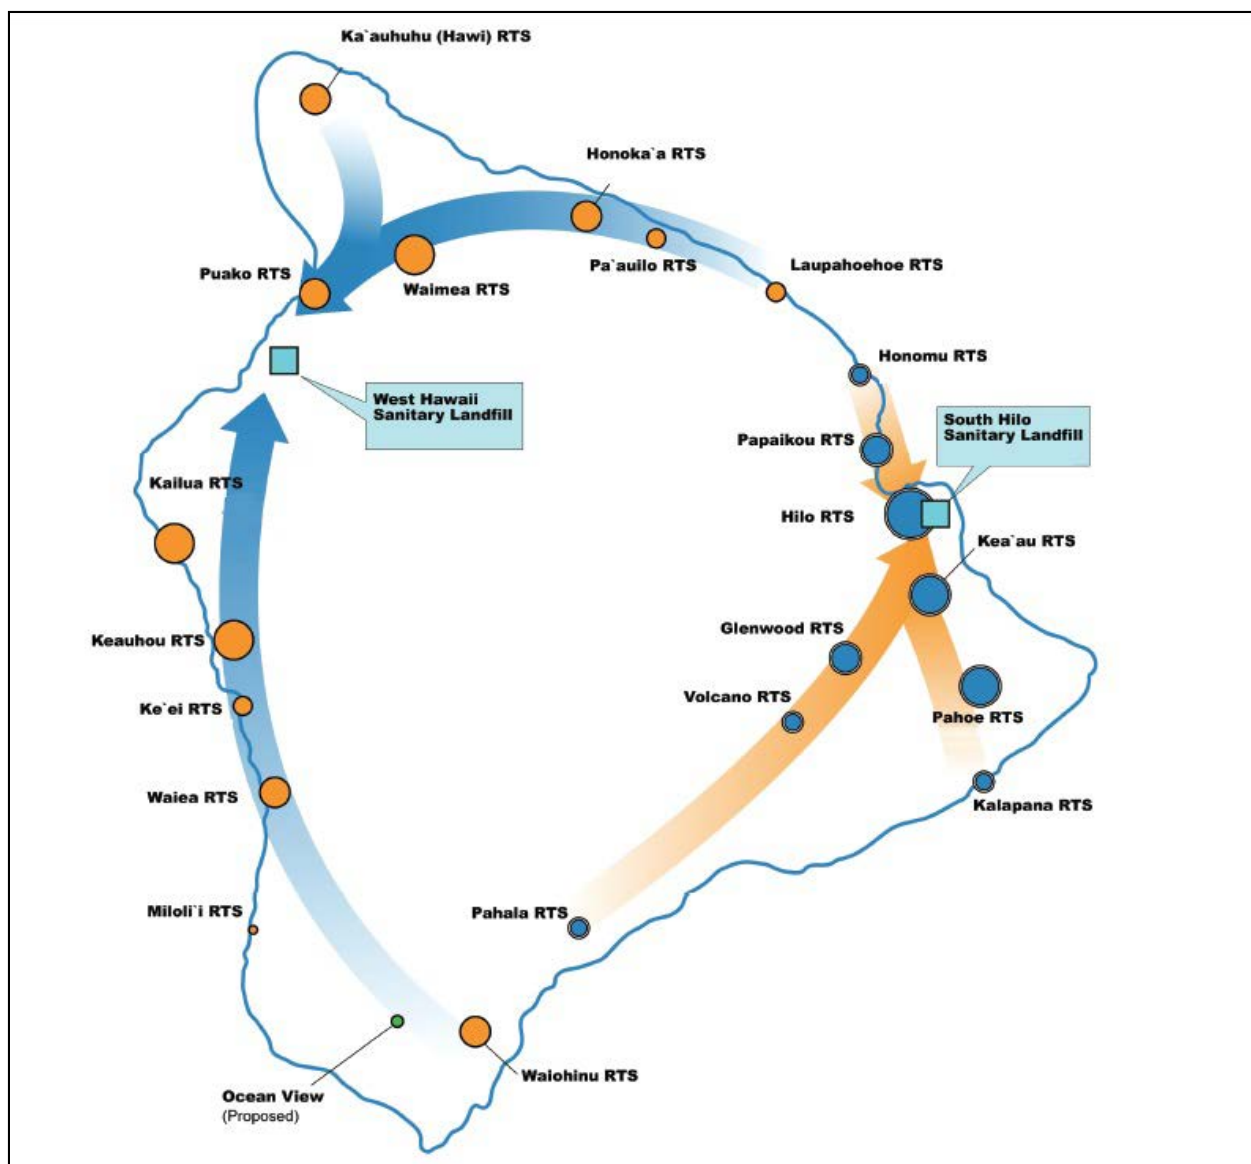

Figure 3-81. Hawai'i County Landfills and Transfer Stations (Source: [CH2MHill 2009](#))

The South Hilo Sanitary Landfill is located on approximately 40 acres of land in Hilo. Owned and operated by the County of Hawai'i, the landfill currently accepts waste from the eastern part of the county. The Department of Environment Management estimates that the landfill has been in operation since the 1970s, and was established on a former quarry (currently unlined). In 2003, Hawai'i County began a focused evaluation of potential options for future disposal of residual waste on the east side of the island because the South Hilo Sanitary Landfill was near its permitted capacity and planned closure date (2006). Unfortunately, the costs of a waste recovery/treatment process proved too costly and the proposed project was abandoned. As such, the capacity of the landfill has been extended by implementing a "sliver fill." Based on current disposal and recycling rates, the South Hilo Sanitary Landfill is estimated to have capacity through 2015 ([R.W. Beck 2012](#)). The 2009 integrated solid waste management plan ([County of Maui 2009](#)) recommended building a new landfill within the quarry, adjacent to the landfill (if cost-effective) or to transport waste to the West Hawai'i Sanitary Landfill, another island, or the mainland. The County is currently exploring potential projects that will provide additional recycling or reuse programs that will divert waste from disposal in the South Hilo Sanitary Landfill, including diversion of

organics from the waste stream. Therefore, until further information is gained, it is difficult to accurately estimate the year capacity would be reached and how any diversion program would lengthen the life of the landfill ([R.W. Beck 2012](#)).

The West Hawai'i Sanitary Landfill is located southwest of Waikoloa at Puuanahulu in the North Kona District, and accepts waste from the western part of the county. Waste Management of Hawai'i operates the landfill under a contract with Hawai'i County, and is currently responsible for construction and development of new landfill cells, environmental monitoring, and closure and post-closure activities. The landfill has been in operation since its construction in 1993, and is located on approximately 300 acres of land, of which 149 acres are currently permitted for landfill activities. The West Hawai'i Sanitary Landfill is a RCRA Subtitle-D landfill, lined with a geomembrane and has an engineered leachate collection system. A landfill gas collection and control system was installed in 2006. The landfill accepts approximately 12,000 tons of waste per month, approximately 140,000 tons per year. The landfill has 23 cells currently permitted, of which seven have been filled and two are active. According to the County of Hawai'i's *Integrated Solid Waste Management Plan* prepared in 2009, the West Hawai'i Sanitary Landfill has an estimated 38 years of life remaining at current recycling rates ([R.W. Beck 2012](#)).

Special Waste

Some types of special waste (such as hazardous waste) are not allowed to be disposed of in either landfill and require transport to separate recycling, processing, or disposal facilities. The County manages many types of special wastes by establishing drop-off or collection points, and then transporting the waste materials to either the landfill or other recycling or disposal facilities.

Recycling Transfer Stations

Residential residual waste is accepted (at no charge) at 21 transfer stations and transported by County Solid Waste Division staff for disposal at both landfills. These 21 residential recycling transfer stations include Glenwood, Hawaiian Ocean View Estates, Hawi, Hilo, Honoka'a, Honomu, Kailua-Kona, Kalapana, Keeau, Keauhou, Keei, Laupahoehoe, Milolii, Paauilo, Pahala, Pahoa, Papaikou, Puako, Volcano, Waiea, Waimea, and Waiohinu. No commercial or farm waste is allowed.

Scrap Metal Recycling Facilities

The County operates two scrap metal and recycling facilities: the Hilo and Kealakehe/Kailua-Kona Scrap Metal facilities. However, as of March 28, 2013, the facilities accept only self-hauled residential loads.

Greenwaste Recycling Facilities

Several greenwaste recycling facilities serve Hawai'i County, including the East Hawai'i Organics Facility, the West Hawai'i Organics Facility, and the Kealakehe Greenwaste Facility. The greenwaste facility accepts materials from both households and commercial businesses.

3.14.3 WASTEWATER

Wastewater (sewage) is generated from many daily activities such as washing clothes and dishes, preparing food, taking a bath or shower, washing our hands, and using the bathroom. Management of the wastewater stream is important to help safeguard the water supply from contamination, protects the environment, and also aids in water conservation by allowing reclaimed water to be used for non-potable water purposes. Proper disposal of the millions of gallons of wastewater produced protects the drinking water supply, coastal water quality, and other important environmental resources.

Most wastewater in the State (approximately 62 percent) is managed via collection and conveyance of wastewater facilities by each county's public sewer system. The county typically treats the collected wastewater in a centralized facility and either beneficially reuses the effluent or disposes of it in

subsurface soil systems or ocean outfalls. County staff manages, operates, and maintains the collection, treatment, and disposal systems year-round ([WRRC 2008](#)). In some locations, however, there are no public sewers, and homeowners or developers assume the responsibility of wastewater management. The tasks involved include selecting, designing, constructing, operating, and maintaining the appropriate treatment and disposal systems including onsite wastewater treatment systems or individual wastewater treatment systems. An individual wastewater treatment system is a decentralized system that receives and disposes of domestic wastewater from one or multiple buildings that are not connected to a centralized wastewater treatment plant. Some systems treat wastewater by removing pollutants such as solids, organic matter, nutrients and bacteria. Not all systems provide equal levels of treatment. Suspended growth aerobic treatment systems provide secondary levels of treatment, for example, while others (such as septic tanks) only provide primary treatment of wastewater. Other systems only dispose of wastewater (e.g., cesspools). With an individual wastewater treatment system, wastewater is dispersed or reused very close to where it was generated. If several adjacent parcels are serviced by a single system, the treatment and water dispersal system can also be referred to as a cluster system.

3.14.3.1 Regulatory Setting

3.14.3.1.1 Federal

Clean Water Act of 1977 as Amended (Public Law 95-217, Title 33 U.S.C. § 1251 et seq.)

The *Clean Water Act* ([33 U.S.C. § 1251 et seq.](#); CWA) is the major Federal legislation concerning improvement of the nation's water resources. The Act was amended in 1987 to strengthen enforcement mechanisms and to regulate storm water runoff. The CWA provides for the development of municipal and industrial wastewater treatment standards and a permitting system to control wastewater discharges to surface waters. Through Part 503, "Rules of the Federal Clean Water Act," the EPA regulates the Underground Injection Control (UIC) Program (Part C of the [Safe Drinking Water Act](#)) involving injection wells, large capacity cesspools, and the management, reuse, and/or disposal of wastewater sludge or biosolids; i.e., areas that impact onsite wastewater treatment systems.

NPDES Permit Compliance

NPDES permits are issued by the EPA or an authorized tribal government. The permit establishes effluent limits, including type and quantity restrictions, and pollutant monitoring, record keeping, and reporting requirements. Each publicly owned treatment work (or other dischargers into surface water) that intends to discharge into the nation's waters must obtain an NPDES permit prior to initiating discharge. State NPDES requirements are discussed below.

3.14.3.1.2 State of Hawai'i

The EPA has relinquished authority to the State of Hawai'i Department of Health (HDOH) for the regulation, oversight, and enforcement of onsite wastewater treatment system planning, design, construction, inspection, and maintenance in Hawai'i. The HDOH Wastewater Branch formulates and enforces all wastewater rules and regulations in Hawai'i including the review and approval of all new waste systems including septic tanks and wastewater works through [HAR 11-62](#), "Wastewater Systems" ([HDOH 2013b](#)), as well as through [HAR 11-55](#), "National Pollutant Discharge Elimination System Permitting," [HAR 11-23](#), "Underground Injection Control," and [HAR 11-54](#), "Water Quality Standards."

[HAR 11-62](#) codifies these regulations and covers all public wastewater treatment and disposal systems as well as private wastewater treatment plants and onsite wastewater treatment systems throughout the State (from individual cesspools to major municipal wastewater treatment plants).

[HAR 11-55](#) regulates the permitting of minor and major wastewater treatment facilities including the following provisions for onsite wastewater treatment systems:

- Selection of appropriate, conventional wastewater treatment and disposal systems is outlined in the regulations. No effluent requirements are specified. However, National Sanitation Foundation class certification is required for aerobic treatment units. There are provisions in the rules allowing approval for innovative and alternative technologies based on testing and monitoring on a case-by-case basis.
- The State of Hawai‘i does not require permits for onsite wastewater systems. Hawai‘i rules require that new onsite wastewater treatment system plans be reviewed and approved by the HDOH prior to construction. Once constructed, written authorization for use must also be obtained from the HDOH. The actual construction permits are integral to the individual county building permit processes. It is important to note that the design of onsite wastewater treatment systems must be carried out by a State-licensed professional engineer, and the system must be installed by a licensed contractor.
- Routine inspections of onsite wastewater treatment systems are not required following construction. However, HDOH requires the engineer-of-record to submit a final inspection report, certifying the onsite wastewater treatment system was constructed in accordance with approved plans. HDOH also requires an operation and maintenance manual and owner certification that they will follow the manual. HDOH then issues a written approval for use of the onsite wastewater treatment system.

[HAR 11-62](#) also designates on all six islands critical wastewater disposal areas, which are areas where the disposal of wastewater has or may cause adverse effects on human health or the environment due to existing hydrogeological conditions (e.g., high water table, impermeable soil, steep terrain, flood zone, protected coastal water, high rate of cesspool failure, and/or protected groundwater resource). Identification of critical wastewater disposal areas for each of the islands is a critical component for any new development without convenient access to public sewer systems as onsite wastewater treatment systems may be constructed in these areas. In the event onsite wastewater treatment systems are to be constructed in these areas, more stringent requirements may be required than those for other onsite wastewater treatment systems located outside of these areas. Critical wastewater disposal area maps are included in [HAR 11-62](#) as Appendix E, Pages E-1 through E-6 and show the boundaries of the critical wastewater disposal areas. Current, more detailed, and user friendly maps are available through the HDOH Wastewater Branch, which should be contacted whenever planning a new project. The HDOH maps may be more up to date versus the maps in the HAR.

3.14.3.1.3 County

In 1985, the State Legislature enacted Act 282, “Relating to Environmental Quality,” which reassigns the County of Hawai‘i, effective July 1, 1987 (or upon receipt of State funds), to assume complete administration and implementation for the regulation of sewerage and wastewater treatment system programs

3.14.3.2 Affected Environment

3.14.3.2.1 Kaua‘i

The Kaua‘i Department of Public Works Division of Wastewater Management Wastewater Treatment Facilities Program is responsible for the operation, maintenance and repair of all County wastewater

collection, treatment and disposal facilities in order to provide consistent and reliable level of performance necessary to protect health and the environment. Activities include preventive maintenance, treatment process control, wastewater effluent reuse, solids management, safety and training, laboratory monitoring for regulatory compliance. The County manages four sanitary sewerage facilities: Wailua, Lihue, Eleele, and Waimea (design capacity 0.30 million gallons per day) currently operating at 0.25 million gallons per day ([County of Kaua'i 2000b](#); [Pruder 2013](#)), and operates approximately 5,500 service connections via 19 sewage pump stations, 43 miles of gravity sewer lines, 7 miles of force main pipelines, and 1,200 manholes ([County of Kaua'i 2009](#)). [Figure 3-82](#) shows the location of the Kaua'i County's wastewater treatment systems.

Other locations in Kaua'i are served by private sewage treatment plants that serve small and large developments. However, according to the County of Kaua'i, most residential areas and some commercial areas are not sewered and rely instead on individual wastewater systems, administered by the State. Most individual wastewater systems were historically constructed as cesspools. However, HDOH changed the regulations so that septic tank systems are now required. There are no communities with cesspool problems threatening public health, but some areas with poor subsurface conditions experience overflow problems.

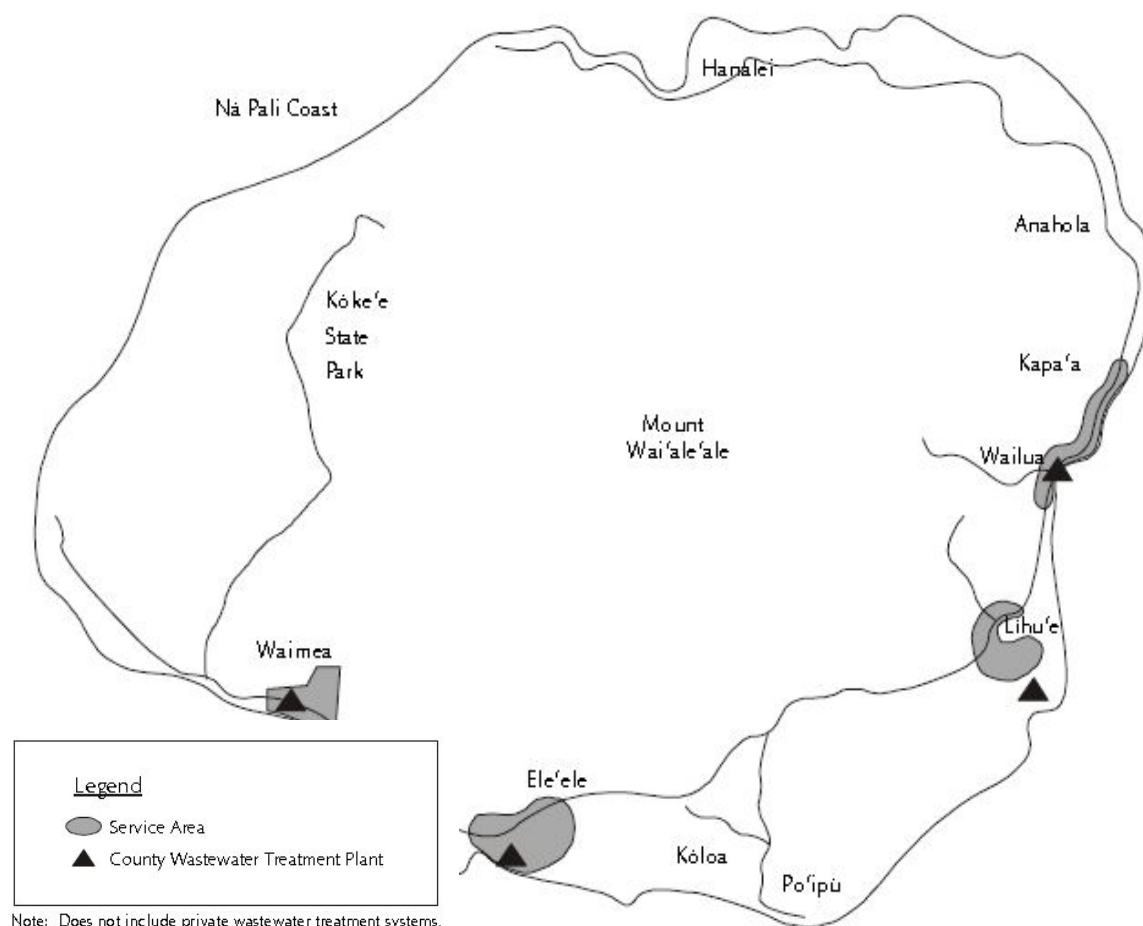

Figure 3-82. Wastewater Systems in the County of Kaua'i

[Table 3-73](#) shows the existing wastewater flows and treatment capacity for all four Kaua‘i County wastewater facilities. As shown, the County of Kaua‘i has approximately 3.3 million gallons per day of estimated remaining capacity ([R.W. Beck 2010](#)).

Table 3-73. Kaua‘i County Wastewater Treatment Plant Capacity, 2010 to 2013

Wastewater Facility	Design Flow (gpd)	Actual Flow (gpd)	Estimated Remaining Capacity (gpd)
Wailua	1,500,000	370,000	1,130,000
Lihue	2,500,000	1,100,000	1,400,000
Eleele	800,000	300,000	500,000
Waimea	300,000	200,000	300,000
TOTALS	5,100,000	1,970,000	3,330,000

Source: [Pruder 2013](#).

3.14.3.2.2 O‘ahu

The City and County of Honolulu Environmental Services Division manages 9 wastewater treatment plants: Honouliuli, Kahuku, Kailua, Laie, Paalaa Kai, Sand Island, Wahiawa, Waianawe, and the Waimanolo; a 2,100-mile collection system, and 70 pump stations ([City and County of Honolulu 2013e, 2013f](#)). In addition, the City and County of Honolulu provides cesspool services to those residential properties where municipal sewers are not available or accessible. [Figure 3-83](#) shows the locations of the City and County’s wastewater treatment plants and infrastructure. [Table 3-74](#) shows the existing wastewater flows and treatment capacity for all the City and County’s wastewater facilities. As shown, the City and County has an estimated remaining capacity of 56 million gallons per day.

The City and County of Honolulu is currently undertaking long-range sewer rehabilitation to improve the sewer system to meet the City’s goals for environmental improvement. More than 165 projects have been identified which needed to start between 2000 and 2019 and additional projects are occurring as a result of several consent decrees agreed to the by the City and County with the EPA. Approximately 43 percent of the projects have been started ([City and County of Honolulu 2013g](#)). A list of the current sewer construction projects can be found online at <http://www1.honolulu.gov/env/wwm/sewerconstructionprojects.htm>.

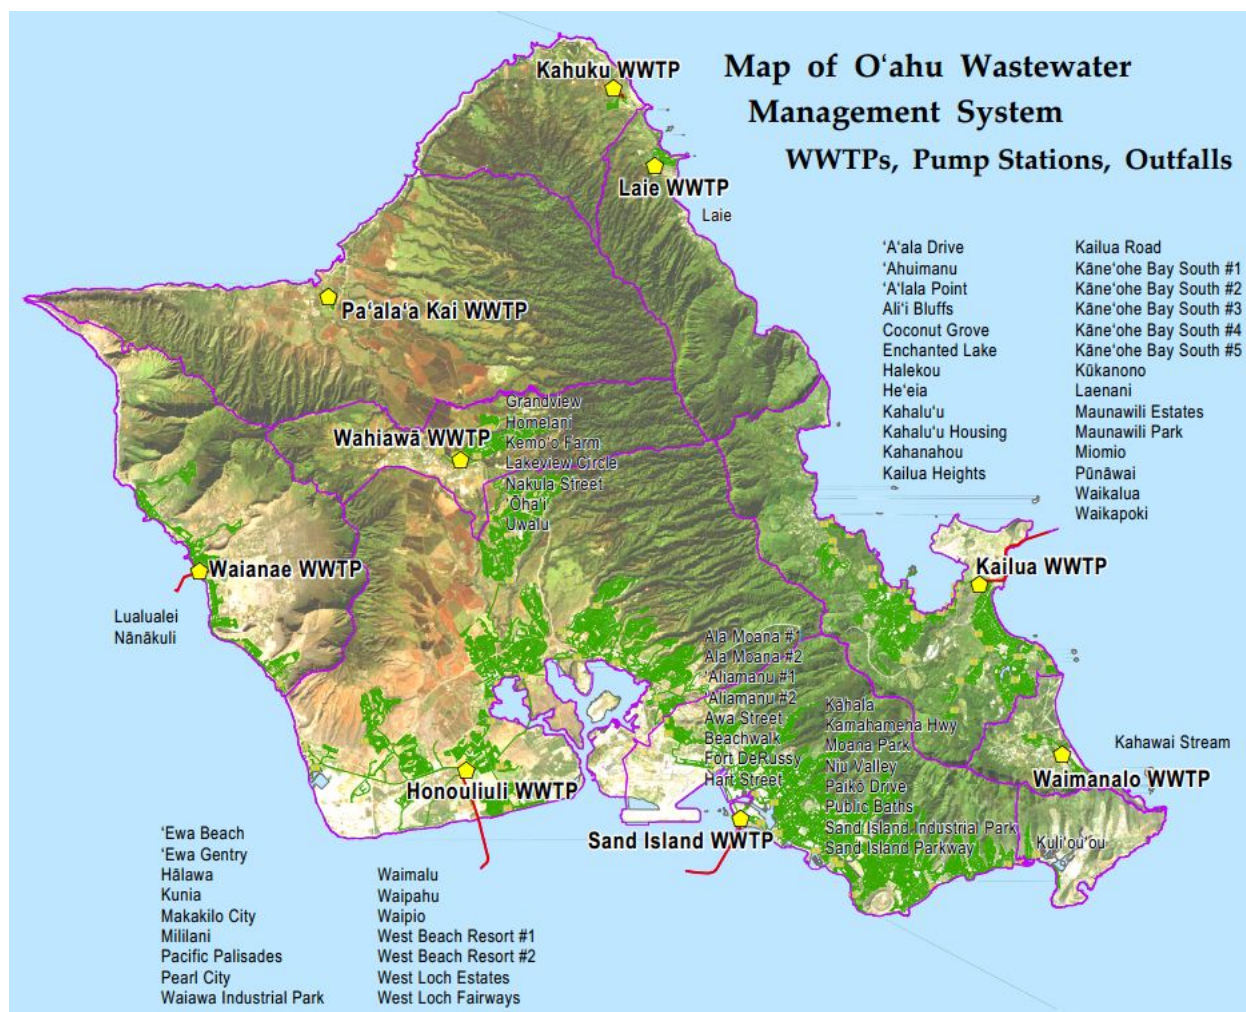

Figure 3-83. O'ahu Island Wastewater Management System ([City and County of Honolulu 2013h](#))

Table 3-74. Island of O'ahu Wastewater Treatment Plant Capacities, 2010 to 2013

Wastewater Facility	Design Flow (gpd)	Actual Flow (gpd)	Estimated Remaining Capacity (gpd)
Honouliuli	38,000,000	26,900,000	11,100,000
Kahuku	400,000	189,000	211,000
Kailua	15,250,000	6,930,000	8,320,000
Laie	900,000	600,000	300,000
Paalaa Kai	144,000	82,000	62,000
Sand Island	90,000,000	56,500,000	33,500,000
Wahiawa	2,500,000	1,970,000	530,000
Wai'anae	5,200,000	3,250,000	1,950,000
Waimanalo	1,100,000	540,000	560,000
TOTALS	153,494,000	96,961,000	56,533,000

Source: [Pruder 2013](#).
 gpd = gallons per day.

3.14.3.2.3 Molokai

Wastewater services to the island of Molokai are provided by the County of Maui. Molokai includes one wastewater reclamation facility, Kaunakakai, which is a secondary treatment plant with effluent disposal by underground injection. Two injection wells are located on the treatment plant site, but are no longer in use. A third injection well, located approximately one-half mile northeast of the treatment plant, currently provides disposal for plant effluent ([County of Maui 1990](#)).

3.14.3.2.4 Lānaʻi

Wastewater collection and treatment services to the island of Lānaʻi are provided by the County of Maui. A discussion of these services is discussed below.

3.14.3.2.5 Maui

The County of Maui Wastewater Facilities Program is responsible for the management, operation, maintenance, and repair of all County wastewater and pumping facilities in order to provide the consistent and reliable level of performance necessary to protect public health and the environment. The Wastewater Facilities Program includes preventative maintenance, wastewater reuse/reclamation, safety and training, solids management, regulatory compliance, and other services for Maui County.

The island of Maui has three wastewater reclamation facilities: Lahaina, Wailuku-Kahului, and Kihei ([Freitas 2011](#)). The three wastewater management systems operating on the island of Maui roughly correspond to the island's Community Plan Districts. Two of the Community Plan Districts are mainly served by Maui County's wastewater management system. The third district, the Makawao-Pukalani-Kula Community Plan area, is served by individual cesspools and septic tanks, with the exception of a portion of Pukalani that is served by a privately owned wastewater reclamation facility.

In addition to the three wastewater reclamation facilities on the island of Maui, the County of Maui manages all wastewater treatment facilities and conveyance systems in Molokai and Lānaʻi. Altogether, the County manages 5 reclamation facilities, 42 pump stations, 222 miles of gravity transmission lines, and 25 miles of County-owned force main pipelines. [Figure 3-84](#) shows a map of the county's wastewater facilities. [Table 3-75](#) shows the capacity of the County of Maui's wastewater management system. As shown, the County of Maui has approximately 14.6 million gallons per day of estimated remaining capacity.

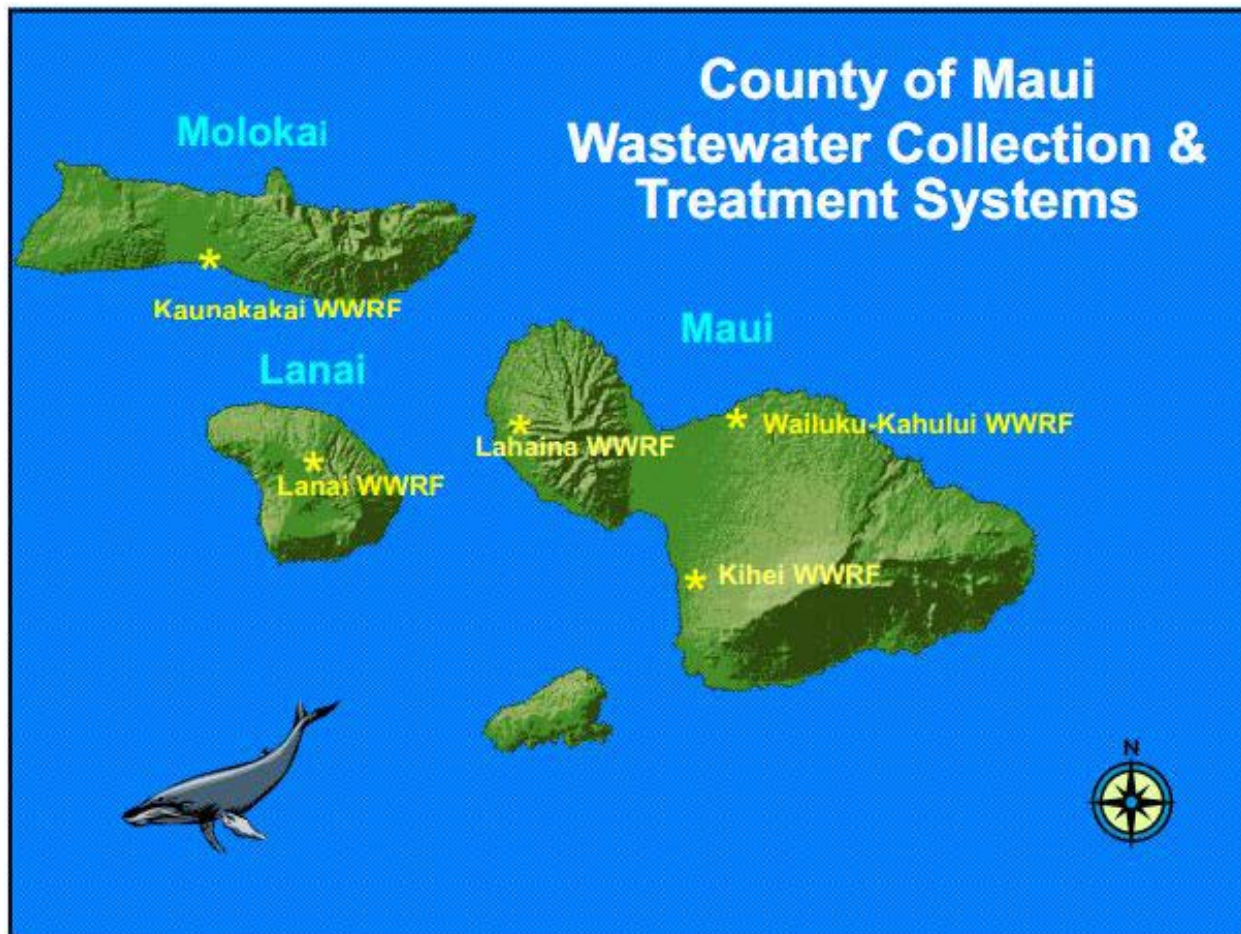

Figure 3-84. County of Maui Wastewater Collection and Treatment Systems

Table 3-75. Maui County Wastewater Treatment Plant Capacity, 2010 to 2013

Wastewater Facility	Design Flow (gpd)	Actual Flow (gpd)	Estimated Remaining Capacity (gpd)
Kaunakakai	300,000	220,000	80,000
Lāna‘i	540,000	310,000	230,000
Lahaina ^a	9,000,000	4,230,000	4,770,000
Wailuku Kahului ^b	7,900,000	3,950,000	3,950,000
Kihei ^c	9,000,000	3,440,000	5,560,000
TOTALS	26,740,000	12,150,000	14,590,000

a. If regulatory constraints and requirements remain unchanged, adequate treatment capacity should be available to serve the projected population growth through the 2030 planning horizon.

b. Based on population growth to 2030, the capacity of the treatment facility will not be reached by the end of the planning horizon.

c. Based on projected population growth between 2005 and 2030, the capacity of the treatment facility will be sufficient to meet projected demand over the planning period. According to WWRD, there are no near-term concerns with the capacity of the Kihei Wastewater Reclamation Facility. However, should larger projected developments connect to the County of Maui system they will have a long-term impact on plant capacity.

Sources: Pruder 2013; Maui 2012b.

gpd = gallons per day.

The County also manages 15 injection wells on Maui: 8 in Kahului, 4 in Lahaina, and 3 in Kihei. In addition to the publicly maintained wells, there are numerous privately owned and operated injection wells in the county. Many privately owned condominiums and businesses in areas that were built outside of existing county sewer service have their own injection well(s). These privately owned and operated facilities can treat wastewater to a level of quality that meets Federal, State, and county requirements ([County of Maui 2012b, Chapter 6](#)).

According to the *Maui Island Plan: General Plan 2030*, adopted in December 2012, the County-operated wastewater treatment facilities and collection systems are aging and will require increased maintenance through the 2030 planning horizon ([County of Maui 2012b, Chapter 6](#)). In order to meet the projected wastewater treatment demand, the island's wastewater facilities will require upgrade and maintenance.

Repeated raw sewage spill incidents on Maui prompted the State to issue administrative orders to the County to reduce spills since 1992. Due to repeated spills, the EPA and HDOH filed two lawsuits against the County of Maui. The County of Maui entered into a Consent Decree in 1999 with the EPA and HDOH. As a requirement under the Consent Decree, the County is required to submit to EPA and the HDOH quarterly compliance reports. The quarterly reports includes steps taken by the County to develop and implement the various goals, plans, programs, procedures, schedules and budgets required pursuant to the Consent Decree including a spill reduction plan, a sewer rehabilitation program, a fats, oil, and grease (FOG) control program, preventative maintenance, and an information management system (automated reporting software GIS application) to monitor and access sewer collection data. Although Maui County has reduced its sewage spills, spills have continued to occur.

There has also been a growing public concern that wastewater may be leaching from injection wells into the ocean. As such, the County is planning upgrading the wastewater reclamation reuse systems, improving the current level of water treatment, or phasing out injection wells entirely; albeit these upgrades and improvements require significant financial investment to implement. Over the last several years, in order to reduce wastewater flows, water saving projects were implemented throughout the County. More recently, the County's mayor set a goal of 100 percent recycling of Maui's wastewater. The water saving projects have alleviated some of the County's overflows. However, some of the County's facilities currently require upgrades. Additional information on the reach of the Mayor's goal is currently not available.

3.14.3.2.6 Hawai'i

The Department of Environmental Management currently operates and is responsible for the operation and maintenance of 5 sewer systems: Hilo, 5 million gallons per day; Papaikou, 0.35 million gallons per day; Kulaimano, 0.5 million gallons per day; Kapehu, 0.016 million gallons per day; and Kealakehe, 5.3 million gallons per day; 17 pump stations; 90 miles of gravity mains; and 11 miles of force main pipelines ([D. Beck 2009](#)). Those residents or commercial entities located in the vicinity of one of the five existing wastewater treatment facilities are served by these sewer systems; however, those areas not served by these sewer systems are served by private wastewater treatment facilities or individual facilities such as cesspools or septic tanks. It is estimated that less than 16 percent of housing units are served by the Hawai'i County wastewater systems and are operating well below their theoretical capacity. [Table 3-76](#) shows the capacity of the County of Hawai'i wastewater management system. As shown, the County has approximately 5.9 million gallons per day of estimated remaining capacity.

In 2005, the County estimated that approximately 77 percent of the County's population was served by cesspools ([County of Hawai'i 2005](#)). However, as most soil on the island is volcanic and permeable (with widespread underground lava tubes), seepage from cesspools have been known to contribute to the pollution of coastal waters and pose a threat to underground drinking water sources.

In addition, the EPA required that all cesspools be eliminated by April 5, 2005. Thus, in response to the EPA regulation, the County of Hawai‘i entered into consent agreement and final order with the EPA to complete and prepare a preliminary engineering report and environmental assessment that identified alternatives to cesspools or recommended solutions to satisfy the EPA regulation.

Table 3-76. Hawai‘i Wastewater Treatment Capacity, 2010 to 2013

Wastewater Treatment Facility	Design Flow (gpd)	Actual Flow (gpd)	Estimated Remaining Capacity (gpd)
Hilo	5,000,000	3,400,000	1,600,000
Kealahou	5,310,000	1,670,000	3,640,000
Kapehu	16,000	7,000	6,000

3.14.4 COMMON CONSTRUCTION AND OPERATION IMPACTS

3.14.4.1 Hazardous Materials

The siting of a project would likely require new construction which could result in potential hazardous material impacts. To minimize impacts, it is recommended that proposed project locations be investigated via the review of public records and the performance of site inspections to identify possible hazardous materials that may be present at the proposed development locations. Once the project location is determined, it will be necessary to perform detailed investigations including a site-specific Environmental Site Assessment in conformance with ASTM Method E 1527 05 ([ASTM 2005](#)), which would provide a detailed review of accessible public records and require site inspection to identify the classes of land uses and/or hazardous materials that may be present at these sites. In the event that the project location is sited in a contaminated site, abatement and remediation activities by trained and certified professionals would be required before construction can occur.

Potential impacts could also result if project construction were proposed in an area with munitions response sites, however, BMPs have been provided below to ensure that munitions response sites are avoided and that no hazardous wastes are encountered.

Potential hazardous material impacts could result from those projects that were proposed in an existing structure or facility. To minimize impacts, such projects would be required to perform site surveys to identify any areas within the structure or facility containing asbestos materials, lead-based paint, polychlorinated biphenyls, and/or arsenic. If a structure or facility is found to be contaminated, proper abatement procedures and activities would be required to comply with State and Federal OSHA, and the county air quality district requirements. Only personnel trained and certified in abatement and remediation would be allowed to perform these activities; and materials would be handled and disposed of appropriately.

Construction activities could also involve the use of hazardous materials such as fuels, oils, solvents, and adhesives. In addition, inadvertent spills could occur during onsite fueling of equipment or by accident (e.g., puncture of a fuel tank through operator error or slope instability). Therefore, the use of hazardous materials onsite would be required to comply with developed site-specific BMPs related to fueling, vehicle washing and handling, use, and storage of chemicals to minimize any risk to workers or the public.

3.14.4.2 Waste Management

Project construction could require land clearing, the possible demolition of existing structures, excavation, drilling, and other related construction activities. These activities would generate construction and demolition waste consisting of wooden beams, asphalt, concrete, glass, brick, metal, soil, vegetation, and other miscellaneous building and landscaping materials. Potential impacts to landfills accepting these wastes can be minimized through recycling efforts and resultant diversion of generated wastes. During design and construction phases, consideration should be given to development and implementation of a recycling plan. In addition, a recycling program would effectively recover building materials that could contain potentially hazardous substances (e.g., liquid wastes, paints, oil, solvents). Proper handling, transport, and disposal of hazardous materials or substances would be required to comply with State and Federal OSHA, and county requirements. This would include proper handling and transport for disposal at the appropriate hazardous material facility to ensure that no hazardous materials were disposed of at landfills and that hazardous materials do not enter the waste stream.

It is noted that several landfills in the islands of O‘ahu and Hawai‘i are currently at capacity. As such, depending on the proposed project location, the disposal of non-recyclable materials may add to existing landfill capacity constraints. The resolution of landfill siting and expansion on several islands are pending or are in the process. Therefore, additional waste produced in the islands of O‘ahu and Hawai‘i may result in potentially significant impacts, pending the resolution of existing landfill capacity constraints.

3.14.4.3 Wastewater

During construction, wastewater generation from construction activities would result in a nominal increase in wastewater flows as construction activities and staff would generate a small amount of wastewater. It is anticipated that portable toilets would be provided by a private company and the associated waste disposed of off-site. As such, during construction, the project would not constrain the existing wastewater infrastructure or treatment plants.

Primary wastewater impacts could occur as result of project operations that require conveyance and or treatment at the appropriate wastewater treatment plant or on-site. Therefore, each project would be required to ensure that that wastewater connections and treatment systems, as well as maintenance of pipes and screens (including potential manual cleaning) are performed regularly to prevent clogging and ensure that proper discharge and wastewater conveyance or treatment occurs. All wastewater discharge would be required to comply with Federal, State, and county requirements, including the NPDES permit requirements. In addition, it is anticipated that projects would incorporate BMPs to ensure that proper treatment and discharge of effluent meet general water quality and toxic contaminant parameter requirements.

3.14.5 COMMON BEST MANAGEMENT PRACTICES

3.14.5.1 Hazardous Materials

The following general mitigation measures would be applicable to all construction and operation activities associated with a clean energy project, regardless of location.

A comprehensive Phase I Environmental Site Assessment should be conducted prior to acquiring a property for development. The site assessment will assess the property for any environmental contamination. This will reduce the possibility that construction project footprints would encounter sites contaminated with hazardous materials, substances, or waste including military munitions. If MECs are discovered during site activities, the following procedures will be followed:

- Visually identify the item discovered without disturbance.
- Establish its location at the site and retreat from the location.
- Contact local authorities to address the item of concern.

If development were to occur in active military facilities, all work would need to be coordinated with proper base authorities.

Military munitions could also be present on the seafloor throughout the State. Therefore, additional consideration should be given to areas of dense concentrations where it may be difficult for workers to completely avoid munitions. As such, construction and mitigation measures for MEC areas would be avoidance to ensure that personnel and equipment would not be adversely impacted and safety hazards are avoided.

For those areas where it has not been determined whether previous marine dumping sites as identified in NOAA nautical charts contain non-MEC hazardous materials. The presence of dumped materials could impact offshore construction projects. Therefore, construction in those marine dumping sites should be avoided to ensure no safety hazards occur.

Construction activities could involve use of hazardous materials such as fuels, oils, solvents, and adhesives during construction. Inadvertent spills could occur during on-site fueling of equipment or by accident (e.g., puncture of a fuel tank through operator error or slope instability). Use of hazardous materials on-site would be required to comply with developed site-specific BMPs related to fueling, vehicle washing and handling, use, and storage of chemicals, which would minimize any risk to either workers or the public.

Site construction and demolition should be performed in accordance with a site-specific safety and health plan. The plan would identify safe working conditions for construction areas. Safety measures would include proper techniques for personal protective equipment, use of allowable tools, and mechanical measures as appropriate. Potential adverse impacts to construction personnel include possible exposure to both known and unknown hazardous materials and wastes present in existing structures or surrounding environment.

3.14.5.2 Waste Management

Proposed project locations could require land clearing, possible demolition of existing structures, excavation, drilling, and other related construction activities. These activities would generate construction and demolition waste consisting of wooden beams, asphalt, concrete glass, brick, metal soil, vegetation, and other miscellaneous building and landscaping materials. Potential impacts to landfills accepting these wastes could be minimized through recycling efforts and resultant diversion of generated wastes. During design and construction phases of the proposed project, consideration should be given to development and implementation of a recycling plan. A recycling program would minimize wastes requiring permanent disposal.

3.14.5.3 Wastewater

The project proponent should establish a program to provide beneficial reuse of wastewater.

For those locations without wastewater treatment conveyance systems, project proponents should install septic tank systems or on-site wastewater treatment facilities.

3.15 Socioeconomics

The socioeconomic environment potentially affected by the development of any of the analyzed technologies encompasses the State of Hawai‘i generally, and potentially each of the four State-

NOTE ABOUT DATA COLLECTION

Numbers for the same demographic variable (e.g., population, employment, jobs), year, and geographic area presented in this section of the PEIS may vary because they were generated by differing reference sources.

recognized counties. Data for a fifth county, Kalawao, generally is not independently cited in this analysis but is occasionally included in data presented for Maui County (as noted herein). The 2012 population in Kalawao County was 90 people ([USCB 2012](#)).

Some variables in the socioeconomic environment potentially affected include resident population; employment and the related unemployment rate and employment-specific sectors; housing; and personal

income, the resulting income and sales tax consequences, and the expenditure of those revenues by State government. Electricity consumption and prices could also be affected. A profile of these variables is presented to establish a baseline from which changes associated with the implementation of analyzed technologies could be described and analyzed.

3.15.1 POPULATION

The total population in the State was about 1,364,000 in 2010, estimated at 1,392,000 in 2012, projected to be 1.5 million in 2020 and 1.6 million by 2030 ([Table 3-77](#)). Approximately 70 percent of the 2012 State population was reportedly concentrated in the City and County of Honolulu, and approximately 14 percent of the population was a resident of Hawai‘i County. Population projections to 2020 and 2030 indicate a more rapidly growing population in Hawai‘i County than the other three counties, with a markedly slower population growth in the City and County of Honolulu.

3.15.2 EMPLOYMENT

Most jobs in Hawai‘i are in the civilian sector. Approximately 7 percent of the jobs in the State are military positions ([BEA 2013](#)). Approximately 71 percent of the civilian jobs within the State are in the City and County of Honolulu, and about 12 percent are in Hawai‘i County and Maui County each. Kaua‘i County has approximately five percent of the civilian jobs. Kalawao County has about 43 agricultural positions. The number of civilian jobs is expected to grow at approximately the same rate as the population is projected to increase in the periods from 2010 to 2020 and from 2020 to 2030. The projected growth rate of jobs in Hawai‘i County is almost twice that of the State’s most populated county and is almost twice that of the State’s projected growth rate. [Table 3-78](#) summarizes historical and projected civilian jobs in the State and each county.

Table 3-77. State and County Population, 1990 to 2030

Year	State of Hawai'i	Hawai'i County	City and County of Honolulu	Kaua'i County	Maui County

3.15.3 UNEMPLOYMENT

Unemployment rates in the State and in all counties were higher in January 2013 than the annual average rate from 2003 to 2008 ([Table 3-79](#)). Unemployment rates in the State and counties peaked in 2009 and 2010 and have been steadily declining. Each county's and the State's unemployment rates were lower each year, including January 2013, than the comparable national unemployment rates ([BLS 2013c](#)).

Table 3-79. State and County Unemployment Rates, 2003 to January 2013

e. Preliminary.

3.15.4 STATE AND COUNTY GOVERNMENT EMPLOYMENT

Jobs classified as "State and Local Government" in the National Association of Industrial Classification industrial sector represent approximately 10 percent of the State's and each county's total employment. Employment in the State and county government sector in each county is approximately equal to the county's proportion of the State's population (see [Table 3-77](#)). With the exception of the Maui/Kalawao area, growth in the number of State and local jobs has been markedly slower than the growth in the number of jobs during the 2003 to 2011 era. Historical information about employment in the State and county government sector is displayed in [Table 3-80](#).

Table 3-80. State and County Total Employment and State/County Government Employment, 2003 to 2011^a

Area	Description	2003	2008	2010	2011	Average Annual Growth 2003 to 2011 (percent)	2011 State and County Government Jobs of Total Area Jobs

Source: [BEA 2013](#).

a. The estimates of employment for 2001-2006 are based on the 2002 North American Industry Classification System (NAICS). The estimates for 2007 to 2010 are based on the 2007 NAICS. The estimates for 2011 forward are based on the 2012 NAICS.

3.15.5 VACANT RENTAL HOUSING

[Table 3-81](#) presents select housing characteristics for Hawai‘i and the Hawai‘i counties. Growth in the size of an area’s labor force, when the change is attributed to in-migration of workers associated with new energy initiatives, for example, can impact a community’s rental housing market. In 2011, the City and County of Honolulu with approximately 70 percent of the State population, had less than 65 percent of the total housing units. Vacancy rates among rental housing units varied among the counties. For comparison purposes, the 2011 national rental housing vacancy rate was 7.4 percent ([USCB 2013a](#)).

Table 3-81. State and County Housing Characteristics, 2011

Area	State of Hawai‘i	Hawai‘i County	City and County of Honolulu	Kaua‘i County	Maui County
Total Housing Units	522,314	83,183	337,528	30,273	71,213
Occupied Housing Units	448,563	64,605	308,495	22,874	52,549
Vacant Housing Units	73,751	18,578	29,033	7,399	18,664
Rental Vacancy Rates (percent)	8.4	9.2	4.9	16	22.5

Source: [USCB 2013b](#).

3.15.6 PERSONAL INCOME

In 2011, Hawai‘i residents generated about \$59.0 billion in personal income. Residents of the City and County of Honolulu, with approximately 70 percent of the State population, contributed about 76 percent of the total personal income. Hawai‘i County, with approximately 14 percent of the State population, accounted for 10 percent of the total personal income generated in 2011. Historical annual growth in personal income was nearly evenly distributed among the counties. Per capita personal income varies widely: the State per capita personal income was \$42,925 in 2011; Hawai‘i County’s was \$31,749; the City and County of Honolulu was \$46,624; Kaua‘i County was \$36,520; and Maui and Kalawao Counties was \$36,272 ([BEA 2012](#)). [Table 3-82](#) summarizes historical personal income by county.

Table 3-82. Aggregate State and County Personal Income, 2003 to 2011^a

Area	2003	2008	2010	2011	Average Annual Growth 2003 to 2011 (percent)
State of Hawai‘i	39,032,023	55,313,744	55,832,057	59,014,071	5.3
Hawai‘i County	3,869,362	5,899,236	5,682,107	5,928,662	5.5
City and County of Honolulu	29,704,539	41,474,816	42,397,145	44,926,809	5.3

Source: [BEA 2012](#).

a. In thousands of dollars.

3.15.7 INDIVIDUAL INCOME TAX REVENUES

The State of Hawai‘i collects tax from several sources of individuals’ income. Generally, the State’s tax laws reflect income tax laws of the Federal Government, but the State does not tax social security benefits, many pension distributions, and several other sources of income. The State does tax wages and salaries. Wages and salaries, and hence individual income tax revenues, could be impacted if a community experienced a change in economic activity associated with new energy initiatives. Net

revenues collected from individual income tax declarations grew at varying rates among the counties between 2003 and 2010. The City and County of Honolulu accounted for more than 90 percent of the income tax collected within the State in 2010. In 2012, individual income tax revenues comprised 31.4 percent of the general funds distributed to the State ([DBEDT 2013d](#)). [Table 3-83](#) summarizes historical collections of individual income tax revenues by county.

Table 3-83. State and County Net Individual Income Tax Revenues, in thousands of dollars, 2003 to 2012

Year	State of Hawai'i	Hawai'i County	City and County of Honolulu	Kaua'i County	Maui County
2003 ¹	1,071,360	53,650	952,227	17,473	48,011
2008 ¹	1,564,708	84,829	1,367,113	37,467	75,299
2010 ¹	1,375,120	60,884	1,244,011	20,068	50,157
2011 ²	1,460,621	63,086	1,314,949	22,548	60,037

Average Annual Growth Rate (percent)					
2003 to 2010	3.6	1.8	3.9	2.0	0.6
2010 to 2012	9.6	NA	NA	NA	NA

a. [DBEDT 2013e](#), Table C-13.

b. [DBEDT 2013d](#), Table C-4.

NA = not available.

3.15.8 GENERAL EXCISE AND USE TAX REVENUES

Hawai'i does not have a sales tax. It does have a gross receipts tax, known as general excise tax, which applies to almost all sales of goods and services. The general excise tax is charged to the business rather than the customer, but the business may pass some or all of the tax on to its customers similar to a traditional sales tax. The State general excise tax rate is 4 percent and county entities may impose additional taxes. In addition, Hawai'i strictly imposes a use tax on products and services that are purchased from other states but used in Hawai'i. This includes nontangible products or services such as engineering services ([Tax-Rates.org 2013](#)). [Table 3-84](#) summarizes historical general excise and use tax revenues for the State by county.

Table 3-84. State and County General Excise and Use Tax Revenues, in thousands of dollars, 2003 to 2010

Year	State of Hawai'i	Hawai'i County	City and County of Honolulu	Kaua'i County	Maui County
2003	1,820,498	137,257	1,478,293	55,011	149,937
2008	2,567,818	161,024	2,141,374	69,723	195,696
2010	2,379,942	133,627	2,019,244	60,950	166,122

Source: [DBEDT 2013e](#), Table C-10.

Generally, annual growth rate in revenues collected from the general excise and use taxes and from the individual income tax have paralleled the State's annual growth in personal income (see [Table 3-81](#)). Collections of corporate income taxes have been volatile. [Table 3-85](#) presents information about major revenues components collected by the State.

Table 3-85. State General Fund Tax Revenues, by Component, 2003 to 2012

Year	General Use and Excise Tax	Net Individual Income Tax	Net Corporate Income Tax
2003	1,820,498	1,071,360	5,189

a. In thousands of dollars.

3.15.9 STATE GOVERNMENT EXPENDITURES

Expenditures to support education represent about one-third of the State's general fund obligations. Expenses associated with public welfare represent about 20 percent of the annual budget, and insurance trust expenditures comprise about 15 percent of the general fund. [Table 3-86](#) summarizes the 2010 State general fund budget by function.

Table 3-86. State Government Expenditures^a by Function, 2010

General Expenditures	9,710,283
Education	3,254,387
Public welfare	1,960,542
Hospitals	609,893
Health	545,908
Highways	468,922

Other and unallowable	1,712,126
Direct expenditure	9,553,402

Source: [DBEDT 2012b](#), Table 9.12.

a. Thousands of dollars.

3.15.10 UTILITIES

Energy is a major component of the State's gross domestic product. Energy expenditures accounted for almost 9 percent of the gross domestic product in 2010. Petroleum accounted for almost 97 percent of Hawai'i's primary energy expenditures in 2010. Heavy fuel oil for electrical generation, jet fuel, and gasoline remain the primary fuels in the State demand profile ([DBEDT 2012d](#)).

[Table 3-76](#) reflects energy consumption by source. In 2010, renewable energy represented about 7.6 percent of the total energy consumption. In 2010, about 37 percent of the State's total energy was used to generate electricity. Fossil fuels accounted for about 95 percent of the total energy consumption, while renewable energy sources provided about 4.9 percent of the total electric power energy consumption.

In 2010, Hawai'i had the third lowest per capita energy use in the nation. Hawai'i's military presence and tourism industry's consumption of aviation fuel resulted in the transportation sector leading the demand

for energy. Energy production is derived from imported petroleum. Petroleum-fired plants supply more than three-fourths of Hawai‘i’s electricity generation. Due to the mild climate, most households do not use any electricity for home heating, a major source of energy consumption nationwide. Yet in 2010, Hawai‘i led the nation in electricity costs. The residential cost per million Btu, \$101.64, was almost three times more than the average national cost of \$34.34. In 2010, the average household in Hawai‘i spent \$1,969 annually for energy, \$1,805 of which was for electricity ([DBEDT 2012d](#)).

Historical analysis indicates that Hawai‘i energy consumers do not alter consumption habits as the price of electricity and gasoline fluctuate. Historically, energy consumption in Hawai‘i has not changed in tandem with changes in income. Price elasticity (changes in quantity demanded of a product as a result of changes in its price) of energy tends to be low because there is little room for substitution; that is, there is no real substitute yet for electricity or gasoline ([DBEDT 2011](#)).

[Table 3-87](#) demonstrates that electricity consumption is evenly distributed over the residential, commercial, and industrial sectors. [Table 3-88](#) displays information about selected renewable energy sources. The increased share of renewable source electricity since 2000 is attributable to additional wind generation.

Fuel costs for operating transportation vehicles, other than airplanes, are relatively high in Hawai‘i. On May 27, 2013, the average price for regular, unleaded gasoline in the nation was \$3.645 a gallon, while the average price for the same in Honolulu was \$4.24 a gallon.

Table 3-87. Hawai‘i’s Electricity Consumption by Sector, 1990 to 2010

Year	Electricity Consumption by Sector				Percent of Total		
	Residential Million (kWh)	Commercial Million (kWh)	Industrial Million (kWh)	Total Million (kWh)	Residential	Commercial	Industrial
1990	2,324	2,253	3,734	8,311	28.0	27.1	44.9
2000	2,765	3,092	3,834	9,691	28.5	31.9	39.6
2010	2,989	3,355	3,672	10,016	29.8	33.5	36.7

Source: [DBEDT 2012d](#), Table 2.7.

Table 3-88. Hawai‘i’s Primary Energy Consumption by Source, 1990 to 2010

Year	Total Energy Consumption Billions (Btu)	Energy Consumption by Source % of Total			
		Petroleum	Coal	Natural Gas	Renewable
1990	321,434	91.1	0.2	0.0	8.7
2000	273,488	86.0	6.5	0.0	7.5
2010	272,156	86.1	6.3	0.1	7.6
Year	Renewable Energy % of Total				
	Biomass	Geothermal	Hydro	Solar	Wind
1990	8.1	0.0	0.3	0.3	0.1
2000	5.6	1.0	0.4	0.5	0.3
2010	4.4	0.7	0.3	1.3	0.9

Source: [DBEDT 2012d](#), Table 2.1.

Readers interested in detailed historical and current information about Hawai‘i’s energy consumption are encouraged to access the Energy Resources Coordinator’s Annual Reports, available from the “All Energy” tab of the following web page: <http://energy.hawaii.gov/resources/hawaii-state-energy-office-publications>.

3.15.11 COMMON CONSTRUCTION AND OPERATION IMPACTS

In general, socioeconomic impacts that could result from the construction and operation of any specific clean energy project would be minimal. At a Statewide level, and within each county jurisdiction, project related impacts to the key socioeconomic variables, population, employment, and housing would be very small. However, modest employment opportunities are common impacts that could be recognized at the local community level.

3.15.12 COMMON BEST MANAGEMENT PRACTICES

The existing labor force in the State would be likely to provide the required workers to construct, install, operate, and maintain any clean energy project represented in this PEIS. Best management practices dictate that project management personnel anticipate needs for unskilled, skilled and professional workers and then co-ordinate with public and private employment agencies and with organizations responsible for post-secondary education and training to fill those needs.

3.16 Environmental Justice

Executive Order 12898, “Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations,” directs Federal agencies to incorporate environmental justice as part of their missions (59 FR 7629, February 16, 1994) by identifying and addressing, as appropriate, any disproportionately high and adverse human health or environmental effects of their actions, programs, or policies on [minority](#) and [low-income](#) populations.

ENVIRONMENTAL JUSTICE TERMS

Minority: Persons are included in the minority category if they identify themselves as belonging to any of the following groups (1) Hispanic or Latino, (2) Black (not of Hispanic origin) or African American, (3) American Indian or Alaska Native, (4) Asian, or (5) Native Hawaiian or other Pacific Islander. In addition, individuals who categorize themselves as being of multiple racial or ethnic origins are minorities.

Low-income: Individuals who fall below the poverty line are categorized as low-income. The poverty line takes into account family size and the age of individuals in the family. For any given family below the poverty line, all family members are considered to be below the poverty line for analysis. In 2013, for example, the poverty line for a family of four in Hawai‘i is \$27,090. For comparison, the poverty line in the contiguous United States for the same period is \$23,550 ([HHS 2013](#)).

The racial composition of the population of Hawai‘i, where no single group represents a majority, differs markedly from the population of the continental United States (not including the District of Columbia or any U.S. Territories), where whites constitute a clear majority (nearly 80 percent) (USCB 2014). In 2011, for example, the largest racial group was Asians who compromised approximately 38 percent of the State’s population.

In recognizing the unique racial characteristic of Hawai‘i’s population, where minority racial groups collectively represent a majority of the population, the State enacted legislation, Act 294, that in turn resulted in *The Hawai‘i Environmental Justice Initiative*. The Act determined that analysis of Federally defined environmental justice populations (minority and low-income populations) will include a special emphasis on the Native Hawaiian population ([HEC 2008](#)).

[Table 3-90](#) shows the racial and ethnic composition of the total population and the percent of low-income persons in Hawai‘i and each of its counties based on the United States Census Bureau’s 2011 American Community Survey one-year estimates (hence, numbers presented in this section may vary from numbers for the same year, same geographical area, generated by other referenced sources). Race and ethnicity is a self-reported variable. Individuals identifying themselves as Hispanic or Latino are listed in the table as a single entry. However, because Hispanics can be of any race, this number could include individuals also identifying themselves as part of another minority population groups listed in the table.

Table 3-90. State and County Minority and Low-Income Populations, 2011

Category	State of Hawai‘i	Hawai‘i County	City and County of Honolulu	Kaua‘i County	Maui County
Total population	1,374,810	186,738	963,607	67,701	156,693
Hispanic or Latino (any race)	126,419	21,991	81,570	6,557	16,301
Non-Hispanic or Latino	1,248,391	164,747	882,037	61,144	140,392
One race					
White	314,810	57,853	186,667	20,570	49,703
Black or African American	24,969	1,415	22,138	366	1,050
American Indian and Alaska Native	2,875	667	2,108	13	87
Asian	512,081	39,140	410,487	24,156	38,289
Native Hawaiian or Other Pacific Islander	121,824	18,554	85,436	6,001	11,788
Some other race	1,071	66	1,005	0	0
Two or more races	270,761	47,052	174,196	10,038	39,475
Total minority	1,060,000	128,885	776,940	47,131	106,990
Percent minorities	77.1	69.0	80.6	69.6	68.3
Percent total population low-income	12.0	21.5	10.1	12.3	12.3

The Council on Environmental Quality guidelines ([CEQ 1997](#)) propose that minority populations should be identified where either (1) the minority population exceeds 50 percent or (2) the minority population percentage of the potentially affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographical analysis; that is, a “geographic comparison area” (generally the State as a whole). Hawai‘i’s minority population in 2011 was 77.1 percent of the total State population. It is the only state in the nation with an aggregate minority population greater than 50 percent and the only state where each county’s aggregate minority population exceeds 50 percent. For purposes of analysis, this PEIS uses the State of Hawai‘i as the comparison geographical unit. The general population of Hawai‘i is a minority and each county’s population is minority.

[Table 3-91](#) presents specific data about the Native Hawaiian and other Pacific Island population in the State and in each county. Native Hawaiians represent about 7.5 to 9.9 percent of the population in the State and each county. Of the aggregate minority population, Native Hawaiians comprise 11 to 14.4 percent of the population.

In 2011, Hawai‘i County had a much higher proportion of residents living below the poverty line, 21.5 percent, than the other three counties. In the City and County of Honolulu, with approximately 70 percent of the State’s population, 10.1 percent of the residents were reported as living below the poverty line. For comparison, the national rate of low-income persons was 15.9 percent for the same period ([USCB 2013c](#)).

Table 3-91. State and County Native Hawaiian or Other Pacific Islander Population, 2011

	State of Hawai‘i	Hawai‘i County	City and County of Honolulu	Kaua‘i County	Maui County
Native Hawaiian or Other Pacific Islander as a percentage of area population	8.9	9.9	8.9	8.9	7.5
Native Hawaiian or Other Pacific Islander as a percentage of area minority population	11.5	14.4	11.0	12.7	11.0

Source: [USCB 2013d](#).

Any site selection process for any technology must recognize that there could be environmental justice impacts; namely, disproportionately high and adverse environmental or human health effects on minority and low-income populations. Future documents evaluating proposed clean energy projects in Hawai‘i must be mindful during the site selection process and in the analysis of impacts once a site has been selected of the potential disproportionately high and adverse effects on human health on minority and low-income populations, specifically Native Hawaiians. A careful analysis would be warranted for four reasons:

- There are pockets of low-income populations throughout the State (Hawai‘i County, in particular, has a rate of poverty almost twice that of the State);
- Approximately 77.1 percent of the residents of the State are racial or ethnic minorities, hence any location would likely be populated by minorities;
- Cultural traditions suggests that many locations could host populations dependent on subsistence hunting and fishing; and
- It is the law ([Executive Order 12898](#) and State of Hawai‘i Act 294).

Depending on type, location, and extent, Native Hawaiian cultural resources, sacred sites, burials, practices, and beliefs can also be considered environmental justice issues requiring analysis as they relate to the potential siting of renewable energy projects. Environmental justice analyses can include cultural resource evaluations to ensure impacts are addressed. [Section 3.6](#) presents more detailed Native Hawaiian cultural resource and traditional practices information.

3.16.1 COMMON CONSTRUCTION AND OPERATION IMPACTS

Construction and operation of any of the clean energy technologies in the State could have environmental justice impacts (including cultural traditions and practices) if it results in disproportionately high and adverse human health or environmental effects on minority or low-income populations. Utility-scale renewable energy projects, however, would tend to result in a higher potential for environmental justice impacts due to the larger-scale aspect of the facilities. In order to evaluate the potential environmental justice-related impacts, potential renewable energy projects would require an understanding of location and scale of facilities, the proximity to minority and low-income populations, and range of potential impacts expected. The various resource areas in Chapter 3 address typical environment-related impacts to the general population; potentially high and adverse effects to the general population are identified separately in respective sections Chapters 4 through 8. Typically, the construction-related impacts for clean energy projects have not been shown in previous sections of Chapter 3 to be high and adverse; however, the specific project location would need to be evaluated to make the final determination.

3.16.2 COMMON BEST MANAGEMENT PRACTICES

The primary BMP associated with environmental justice impacts would be for the project proponent to design the project to minimize or prevent environmental impacts such that it would not result in any high or adverse impacts to the general population.

3.17 Health and Safety

This section describes existing public and occupational safety conditions in Hawai‘i, including information on health and safety regulations, toxicity characteristics for relevant gases, worker safety and injury data, and data on populations that could potentially be affected by accidents and/or intentional destructive acts.

3.17.1 REGULATORY SETTING

3.17.1.1 Occupational Safety and Health

Occupational safety and health are regulated under the *Federal Occupational Safety and Health Act* ([29 U.S.C. § 651 et seq.](#)) and enforced by OSHA through the implementing regulations under 29 CFR. OSHA regulations are intended to assure that employers maintain safe and healthful workplaces by setting and enforcing standards, and by providing training, outreach, education and assistance. Employers must comply with all applicable OSHA standards and must also comply with the General Duty Clause of the OSH Act, which requires employers to keep their workplace free of serious recognized hazards. The regulations, accessible at the U.S. Department of Labor Website (<https://www.osha.gov/law-regs.html>), establish standards that are applicable to potential projects for the HCEI, including standards applicable to general industry ([29 CFR Part 1910](#)), construction ([29 CFR Part 1926](#)), and recordkeeping ([29 CFR Part 1904](#)).

In Hawai‘i, OSHA regulations are implemented by the Hawai‘i Occupational Safety and Health Division of the Department of Labor and Industrial Relations through the Hawai‘i State Plan (<https://www.osha.gov/dcsp/osp/stateprogs/hawaii.html>). Hawai‘i has adopted the majority of the OSHA regulations verbatim; although some standards differ and some have no Federal counterpart, such as requirements for safety and health programs and for certification of hoisting equipment operators not found in standard OSHA rules. The Hawai‘i Occupational Safety and Health standards are online at <http://labor.hawaii.gov/hiosh/standards/>.

3.17.1.2 Public Health and Safety

Numerous Federal and State laws and regulations, as well as local ordinances, have been established to protect public health and safety. Many of these are also intended to protect environmental quality associated with resources discussed throughout this chapter and are described in respective sections. For example, regulations under the CAA described in [Section 3.2](#) establish standards for maintaining public health with respect to air emissions; regulations under the CWA discussed in [Section 3.3](#) are intended to protect water sources and public water supplies; traffic regulations discussed in [Section 3.10](#) enforce traffic safety; noise ordinances discussed in [Section 3.12](#) protect the public from harmful noise impacts; and hazardous materials and waste regulations discussed in [Section 3.14](#) implement standards to protect the public from harmful exposures. Ultimately, the maintenance of public health and safety is an objective of most environmental laws and regulations discussed in this PEIS.

3.17.2 AFFECTED ENVIRONMENT

3.17.2.1 Occupational Safety and Health

The U.S. Department of Labor, Bureau of Labor Statistics collects and maintains statistics on workplace injuries, illnesses, and fatalities. [Table 3-92](#) summarizes the occupational injury and fatality statistics for the United States in 2012 for selected industries based on the North American Industry Classification System (NAICS). Industries in this table were selected to represent occupational injury and fatality statistics during construction and operation, both in industries associated with energy systems, as well as with other comparable industries. The table presents the total numbers of recordable injuries or illnesses per 100 workers, the numbers of injury or illness cases involving days lost (away from work) per 100 workers, and the total numbers of fatalities in the year for each NAICS industry considered. The table also provides the rates of fatalities in all construction industries and all utility industries per 100 full-time equivalent workers (based on 2,000 hours each) for the year.

Table 3-92. Occupational Injury and Fatality Data for Selected Industries in United States, 2012

Industry	NAICS Code ^a	Total Recordable Injury Cases per 100 Workers	Injury Cases with Lost Days per 100 Workers	Total Fatal Injuries	Fatal Injury Rate per 100 Full-time Equivalent Workers
Construction	23	3.7	1.4	775	0.0095
Construction of buildings	236	3.4	1.4	133	-
Heavy and civil engineering construction	237	3.2	1.1	169	-
Utility system construction	2371	2.8	1.0	68	-
Power and communication line and related structures construction	23713	3.1	1.1	26	-
Highway, street, and bridge construction	2372	4.2	1.3	84	-
Utilities	22	2.8	0.8	11	0.0025
Electric power generation, transmission and distribution	2211	2.5	0.7	3	-
Electric power generation	22111	1.7	0.4	0	-
Fossil fuel electric power generation	221112	2.1	0.5	0	-
Nuclear electric power generation	221113	0.3	0.1	0	-
Other electric power generation	221119	4.4	1.3	0	-
Electric power transmission, control, and distribution	22112	3.1	0.9	3	-
Natural gas distribution	2212	2.9	0.9	0	-
Water, sewage, and other systems	2213	4.9	1.8	8	-

a. Industry data are based on the North American Industry Classification System.

Sources: [BLS 2013d](#), [2013e](#), [2013f](#).

Occupational data related to the construction and operation of renewable energy facilities would include a combination of many of these table entries. The project-specific evaluation of potential health and safety impacts to workers could be developed using these data once the specific work activities, and projected staffing were known.

3.17.2.2 Public Health and Safety

Hawai'i recorded the lowest age-adjusted mortality rate of any state in the nation in 2010, with 589.6 deaths per 100,000 population compared with 747 deaths per 100,000 population in the United States as a whole ([Murphy et al. 2013](#)). Hawai'i's mortality rate also declined from 620.8 deaths per 100,000 population in 2009. The age-adjusted mortality rates from accidents and motor vehicle accidents in Hawai'i (29.6 and 9.1 per 100,000 population, respectively) were lower than the national rates (38 and 11.3) in 2010. Hawai'i's age-adjusted mortality rate from chronic lower respiratory diseases, 18 deaths per 100,000 population, was also substantially lower than the national rate of 42.2 in 2010.

3.17.2.3 Public Health and Safety Services

3.17.2.3.1 Police

In aggregate, Hawai'i has seven State and local law enforcement agencies with 4,097 total employees, including 3,234 sworn officers for a ratio of 2.51 officers per 1,000 population (in 2008). Hawai'i's ratio ranked 19th in the United States and equaled the national average ratio in 2008 ([Reaves 2011](#)). The Hawai'i Department of Public Safety is a State agency headquartered in Honolulu with divisions responsible for administration, correctional facilities, and law enforcement. The two law enforcement divisions include the sheriff division and narcotics enforcement division.

Separate county police departments serve the islands of Hawai'i. The Honolulu Police Department, serving the island of O'ahu, is the largest with 1,933 officers and 463 civilians in 29 divisions. The department was ranked 20th in the number of full-time sworn officers among all State and local law enforcement agencies in the United States in 2008 ([Reaves 2011](#)). The department has approximately 2.1 officers per 1,000 population ([City and County of Honolulu 2014a](#)). The Kaua'i Police Department operates three district stations serving Lihue, Waimea, and Hanalei, plus a traffic safety unit ([County of Kaua'i 2014a](#)). The Maui Police Department operates six district stations serving Hana, Kihei, Lahaina, Lāna'i, Molokai, and Wailuku ([County of Maui 2014a](#)). The Hawai'i County Police Department serves the island of Hawai'i and includes two areas of operation bureaus. Area I includes the South Hilo Patrol, the North Hilo District, Hāmākua District, Puna District, and investigative, traffic, and community units. Area II includes the Kona Patrol, South Kohala District, North Kohala District, Kau District, and investigative and community units ([County of Hawai'i 2014a](#)).

3.17.2.3.2 Fire and Rescue

The City and County of Honolulu Fire Department, serving O'ahu, is the largest fire protection service in the State, with more than 1,100 firefighters. The department has 45 fire stations in 5 battalions and operates 43 engine companies, 13 ladder companies, 2 rescue companies, 2 hazardous materials companies, 2 tower companies, 1 fireboat company, 6 tankers, 2 helicopters, and 3 rescue boats. The department provides response for fire and rescue, emergency medical service (EMS), and first response to hazardous materials incidents. The Honolulu Fire Department has been accredited by the Commission on Fire Accreditation International ([City and County of Honolulu 2014b](#)). The Kaua'i Fire Department has eight stations serving the island and provides fire protection and suppression, rescue (ocean and land), hazardous materials response and EMS ([County of Kaua'i 2014b](#)). The Maui Fire Department has 14 stations serving the islands of Maui, Lāna'i, and Molokai. The department provides response for fire and rescue, EMS, and hazardous materials incidents with 279 personnel and operates 14 engine companies, 2 ladder companies, 1 rescue company, 1 hazardous materials company, 4 tankers, 3 mini-pumpers, 1 helicopter, 3 rescue boats, and 11 utility vehicles ([County of Maui 2014b](#)). The Hawai'i County Fire Department provides fire protection and suppression, pre-hospital EMS, land and sea search and rescue, hazardous materials response, ocean safety, and fire prevention and public education for the County of

Hawai'i ([County of Hawai'i 2014b](#)). The U. S. Fire Administration did not include Hawai'i in its computation of the relative risk of death by fire among states nationwide in 2010 because of the small number of fire deaths in the State ([USFA 2014](#)).

3.17.2.3.3 Medical

In addition to the EMS response provided by the respective county fire departments, medical facilities in Hawai'i include more than 20 acute care hospitals, as well as numerous clinics and non-acute facilities. Most hospitals are located on the island of O'ahu, but Kaua'i, Maui, and Hawai'i have at least three hospitals each ([USA Hospitals 2014](#)).

3.17.3 COMMON CONSTRUCTION AND OPERATION IMPACTS

3.17.3.1 Occupational Safety and Health

Potential activities and technologies evaluated in this PEIS range from measures that would require limited new construction or facilities, as in the case of energy efficiency alternatives, to measures that may change existing construction and operational practices, as in the case of distributed renewable energy sources or alternative transportation fuels and modes, to measures that may involve substantial new construction and operation of facilities, as in the case of utility-scale renewable energy and electrical transmission and distribution systems. Therefore, the potential effects of these technologies on occupational health and safety would relate directly to the size of the workforce needed for particular projects and activities. Projects having associated major construction activities, such as site preparation and installation of components and equipment, and resulting in the need for operation of complex utility systems would pose the greatest risks to occupational health and safety. Construction and operation workers at any facility are subject to risks of injuries and fatalities from physical hazards. While such occupational hazards can be minimized when workers adhere to safety standards and use appropriate protective equipment, fatalities and injuries from on-the-job accidents can still occur.

Many of the occupational hazards associated with the analyzed technologies are similar to those of the heavy construction and electric power industries (i.e., working at heights, exposure to weather extremes and high winds, exposure to dangerous animals and plants, working around energized systems, working around lifting equipment and large moving vehicles, and working in proximity to rotating/spinning equipment). Therefore, the potential occupational safety and health impacts of specific projects can be estimated using the statistics for the power and communication line and related structures construction NAICS code in [Table 3-91](#). The statistics for worker injuries and fatalities in this industry do not indicate risks greater than those for construction of buildings, highways, or bridges.

The operation of the most complex of facilities for the analyzed technologies would involve activities comparable to those performed in electric power generation, transmission, and distribution utilities (i.e., working around energized systems, working around heavy equipment and large moving vehicles, working in proximity to rotating/spinning equipment, and potentially working on exposed towers or with hazardous materials). These activities would involve risks to workers comparable to those summarized for respective NAICS codes in [Table 3-91](#) and can be used to predict occupational safety and health impacts of specific projects. The statistics for worker injuries and fatalities in this industry do not indicate risks greater than those for water, sewage, and other utilities. Operational requirements for some analyzed technologies, such as energy efficiency alternatives or alternative transportation fuels or modes, would likely require substantially fewer workers than for utility-scale projects and facilities and thus would have fewer predicted injuries or fatalities.

3.17.3.2 Public Health and Safety

With the expected establishment of adequate access controls that would prevent entry to hazardous areas by unauthorized individuals, the great majority of adverse impacts during construction, operation, and future decommissioning of the analyzed technologies would be limited to the respective workforces involved. However, both beneficial and adverse impacts to public health and safety may result from specific projects. Beneficial impacts may result from the displacement of older and less-efficient, conventional oil-fueled electric generation facilities that emit higher amounts of pollutants to air and water. Such benefits are diffuse and may or may not be realized within the areas immediately adjacent to specific projects. Conversely, adverse impacts from operation of facilities the analyzed technologies may be experienced by individuals living within the immediate vicinity of a project, such as a wind farm, photovoltaic array, thermal facility, biomass facility, or geothermal facility. Therefore, potential adverse impacts on public health and safety are addressed for specific technologies in the impacts chapters (Chapters 4 through 8).

Accidents or incidents may occur during construction or operation of facilities that would require police, fire, or EMS response. Demands on these services by particular projects could affect service capacities and their ability to respond to concurrent needs of the community. Such adverse impacts on public health and safety may have greater potential to occur in cases where a project would be located distant from a service provider and, because of the emergency needs of the project, the capacity of the provider to serve the needs of residents may be impaired. For example, in rural locations, competing demands on service providers may result in increased time for emergency units to respond to serious events, such as a heart attack. Projects in remote, rural locations could also create situations where it may not be feasible for emergency units to respond using standard procedures, such as use of fire trucks to fight an onsite grass fire.

Effects on the public health and safety services of each island from the addition of construction workers for typical potential projects would generally be small, as the workers needed to construct most projects are expected to be drawn from the island's existing workforce (see [Section 3.15.12](#)). Police, fire, and medical services would not be adversely affected by small changes in local populations.

Additional concerns may be caused by inadequate infrastructure or roads that are unpaved or undersized for fire and rescue vehicles. Also, there may not be sufficient manpower and equipment available from a single station to respond to an emergency during project construction or operation. Other fire stations may provide support, but distance and travel time may impair efficiency. Also, limited medical facilities in remote locations could adversely affect public health and safety in the event of a major accident or emergency during construction or operation of a specific project.

3.17.4 ACCIDENTS AND INTENTIONAL DESTRUCTIVE ACTS

Owners and operators of critical infrastructure are responsible for ensuring the operability and reliability of their systems. To do so, they must evaluate the impacts on their system from all credible events, including natural disasters as well as mechanical failure, human error, or deliberate destructive acts of both domestic and international origin, recognizing intrinsic system vulnerabilities, the realistic potential for each event/threat, and the consequences.

3.17.4.1 Regulatory Setting

Various regulations promulgated by Federal and State agencies confirm project developers' responsibilities for protecting critical infrastructure through a variety of prescribed actions and system performance requirements designed to protect the public and/or the environment from adverse

consequences of disruptions or failures, and to provide for system reliability and resiliency. Regulations and directives promulgated by the Federal Energy Regulatory Commission are an example of such a regulatory program. Special system designs, construction techniques, advanced communication and system-monitoring capabilities, and other preemptive protective measures have been developed to meet the requirements of those regulations. BMPs that have also been developed are designed to further ensure system reliability and to minimize interruptions in service (e.g., security measures, fencing, personnel policies). Future projects associated with the analyzed technologies would be expected to conform to all applicable regulations and best industry practices.

Homeland Security Presidential Directive 7 (HSPD-7), signed on December 21, 2003, establishes a national policy that affirms the responsibility of Federal departments and agencies to identify and prioritize U.S. critical infrastructure and key resources and to protect them from terrorist attacks ([DHS 2003](#)). Under that Directive, “Federal departments and agencies will identify, prioritize, and coordinate the protection of critical infrastructure and key resources in order to prevent, deter, and mitigate the effects of deliberate efforts to destroy, incapacitate, or exploit them. Federal departments and agencies will work with State and local governments and the private sector to accomplish this objective.”

HSPD-7 resulted in the June 2006 publication of the *National Infrastructure Protection Plan* ([DHS 2006](#)), the development of which was coordinated by the U.S. Department of Homeland Security. The current *National Infrastructure Protection Plan* ([DHS 2009](#)) comprises 18 sector-specific plans, each addressing a category of critical infrastructure and key resources. The DOE Office of Energy Efficiency and Electricity Reliability serves as the sector-specific agency for energy and is primarily responsible for the development and implementation of the energy plan. The Transportation Security Administration of the Department of Homeland Security serves a similar function for the transportation plan.

The energy sector-specific plan addresses the production, refining, storage, and distribution of oil and gas and electricity. The transportation sector-specific plan addresses the movement of people and the transport of goods by all modes of transportation, and especially addresses the transport of hazardous materials (including crude oil, natural gas, and refined petroleum products) by all modes of transport, including pipelines. Pipelines are addressed in the transportation sector-specific plan as a mode of transportation; however, pipelines are also an integral part of the energy sector. As a result, unique partnerships have been struck between private-sector representatives and representatives of both sector-specific agencies to ensure coordinated implementation of both plans. The energy and transportation plans establish appropriate risk management frameworks to meet their respective goals and objectives. Although the DOE and the Transportation Security Administration are the agencies explicitly directed to develop and implement the plans that most directly address critical infrastructure and key resources for utility-scale facilities, HSPD-7 obligates all Federal agencies to cooperate with those efforts. Utility-scale project developers for the HCEI would also be full participants in the implementation of applicable plan objectives and programs.

Although it is important for the public to be informed as to the commitment and basic structural approach of the national integrated effort to address terrorism, the specific strategies and tactics that emerge cannot be shared. Thus, while some protective measures and activities are obvious (e.g., fencing around electric substations and switchyards, routine surveillance and inspections), other measures must remain under cover to maintain their effectiveness.

3.17.4.2 Credible Events

3.17.4.2.1 Natural Occurrences

There is a potential for natural events to affect human health and the environment during all phases of development of projects and facilities. Such events include severe storms, fires, volcanic activity, earthquakes, and tsunamis. Depending on the severity of the event, fixed components of a facility could be damaged or destroyed, resulting in economic, safety, and environmental consequences. The probability of a natural event occurring is location-specific and differs among the locations for potential projects in Hawaii. Such differences should be taken into account during project-specific studies and reviews.

The consequences of natural events could include injuries, loss of life, and the release of hazardous materials to the environment. The likelihood of injuries and loss of life may be decreased by emergency planning (e.g., fire drills) and onsite first-aid capabilities. For hazardous materials releases, the potential types and quantities of materials that would be present at a facility and that potentially could be released to the environment during a natural event are discussed in the Hazardous Materials and Waste Management sections of Chapters 4 through 8 for the various technologies.

3.17.4.2.2 Intentional Destructive Acts

In addition to the natural events described above, there is a potential for intentional destructive acts to affect human health and the environment. In contrast to natural events, for which it is possible to estimate event probabilities based on historical data and information, it is not possible to accurately estimate the probability of sabotage or terrorism. Consequently, discussion of the risks from sabotage or terrorist events generally focuses on the measures taken to prevent occurrence and the potential consequences of such events.

The consequences of a sabotage or terrorist attack on a facility could be comparable to those discussed above for natural events. Additionally, a cyber-attack on computerized control and communications systems could have similar effects by causing equipment failures or overloads. Depending on the severity of the event, fixed components of a facility could be damaged or destroyed, and releases of hazardous materials or toxic substances may occur, resulting in economic, safety, and environmental harm. The population at most risk in any such event would consist primarily of the operational staff at the facility. The potential consequences of such events should be evaluated on a project- and site-specific basis.

3.17.5 COMMON BEST MANAGEMENT PRACTICES

3.17.5.1 Occupational Health and Safety

The degree to which best management practices for occupational health and safety are implemented would depend on the potential hazards involved in the specific project. The following best management practices to protect project workers are recommended for implementation during all phases associated with a large-scale project. Many of these practices may not be necessary for specific projects with lower risks.

- Conduct site characterization, construction, operation, and decommissioning activities in compliance with applicable Federal and State occupational safety and health standards (e.g., Occupational Health and Safety Standards, [29 CFR Parts 1910](#) and [1926](#), and the Hawai'i State Plan).

- Conduct a safety assessment to describe potential safety issues and the means that would be taken to mitigate them, covering issues such as site access, construction, safe work practices, security, heavy equipment transportation, traffic management, emergency procedures, and fire control.
- Develop a health and safety program to protect workers during site characterization, construction, operation, and decommissioning of a project. The program would identify all applicable Federal and State occupational safety standards and establish safe work practices addressing all hazards, including requirements for developing the following plans: general injury prevention; personal protection equipment requirements and training; respiratory protection; hearing conservation; electrical safety; hazardous materials safety and communication; housekeeping and material handling; confined space entry; hand and portable power tool use; gas-filled equipment use; and rescue response and emergency medical support, including onsite first-aid capability.

The health and safety program would address OSHA standard practices for the safe use of explosives and blasting agents where applicable; measures for reducing occupational EMF exposures; the establishment of fire safety evacuation procedures; and required safety performance standards (e.g., electrical system standards and lighting protection standards). The program would include training requirements for applicable tasks for workers and establish procedures for providing required training to all workers. Documentation of training and a mechanism for reporting serious accidents to appropriate agencies would be established.

- Prepare a health risk assessment to evaluate potential cancer and non-cancer risks to workers from exposure to facility emission sources during construction and operations. If potential risks are found to exceed applicable threshold levels, measures should be taken to decrease emissions from the source.
- Design electrical systems to meet all applicable safety standards (e.g., National Electrical Code) and should comply with the interconnection requirements of the transmission system operator.
- In the event of an accidental release of hazardous substances to the environment, project developers should document the event, including a root cause analysis, a description of appropriate corrective actions taken, and a characterization of the resulting environmental or health and safety impacts. Documentation of the event should be provided to the permitting agencies and other Federal and State agencies within 30 days, as required.
- For the mitigation of explosive hazards where applicable, workers should be required to comply with the OSHA standard ([29 CFR 1910.109](#)) for the safe use of explosives and blasting agents.
- Consider measures to reduce occupational EMF exposures, such as backing electrical generators with iron to block the EMF, shutting down generators when work is being done near them, and otherwise limiting exposure time and proximity while generators are running.
- During construction and operation, proposed sites should have an emergency response plan and be equipped with onsite emergency first aid and fire-fighting equipment.

3.17.5.2 Public Health and Safety

Similar to occupational health and safety, the degree to which BMPs for public health and safety are implemented would depend on the potential hazards involved in the specific project. The following BMPs for the protection of public health and safety are recommended for implementation during all phases

associated with a large-scale project. Many of these practices may not be necessary for specific projects with lower risks.

- Ensure the project health and safety program addresses protection of public health and safety during site characterization, construction, operation, and decommissioning for a project. The program would establish a safety zone or setback for project facilities and associated transmission lines from residences and occupied buildings, roads, rights-of-way, and other public access areas that is sufficient to prevent accidents resulting from various hazards during all phases of development. It would identify requirements for temporary fencing around staging areas, storage yards, and excavations during construction or decommissioning activities. It would also identify measures to be taken during the operations phase to limit public access to facilities (e.g., equipment with access doors should be locked to prevent public access, and permanent fencing should be installed around sensitive or potentially dangerous equipment).
- Prepare a traffic management plan for the site access roads to control hazards that could result from increased truck traffic (most likely during construction or decommissioning), to ensure that traffic flow would not be adversely affected and that specific issues of concern (e.g., the locations of school bus routes and stops) are identified and addressed. This plan should incorporate measures such as informational signs, flaggers (when equipment may result in blocked throughways), and traffic cones to identify any necessary changes in temporary lane configurations. The plan should be developed in coordination with local planning authorities.
- Prepare a health risk assessment to evaluate potential cancer and non-cancer risks to the general public from exposure to facility emission sources during construction and operations. If potential risks are found to exceed applicable threshold levels, measures should be taken to decrease emissions from the source.
- Use proper signage and or engineered barriers (e.g., fencing) to limit access to electrically energized equipment and conductors in order to prevent access to electrical hazards by unauthorized individuals or wildlife.
- Project developers should work with appropriate agencies (e.g., DOE and the Transportation Security Administration) to address critical infrastructure and identify key resource vulnerabilities at utility-scale facilities to minimize and plan for potential risks from natural events, sabotage, and terrorism.

3.19 Glossary

Affected Environment: In accordance with CEQ NEPA regulations, the affected environment is “interpreted comprehensively to include the natural and physical environment and the relationship of people with the environment.” The descriptions of the affected environment serve as a baseline – or description of existing environmental conditions – against which the impacts of potential future actions may be evaluated and compared.

Air Pollutant: Generally an airborne substance that could, in high enough concentrations, harm living things or cause damage to materials. From a regulatory perspective, an air pollutant is a substance for which emissions or atmospheric concentrations are regulated or for which maximum guideline levels have been established due to potential harmful effects on human health and welfare. In Hawai‘i, under [HRS Chapter 342B](#), the term “air pollutant” has the same meaning as under the Clean Air Act. *Related terms: air pollution, ambient air.*

Air Pollution: Under Hawai‘i law ([HRS Chapter 342B](#)), refers to the presence in the outdoor air of substances in quantities and for durations which may endanger human health or welfare, plant or animal life, or property or which may unreasonably interfere with the comfortable enjoyment of life and property throughout the State and in such areas of the State as are affected thereby, but excludes all aspects of employer-employee relationships as to health and safety hazards. *Related terms: air pollutant, ambient air.*

Air Quality: The cleanliness of the air as measured by the levels of air pollutants relative to standards or guideline levels established to protect human health and welfare. Air quality is often expressed in terms of the pollutant for which concentrations are the highest percentage of a standard (e.g., air quality may be unacceptable if the level of one pollutant is 150% of its standard, even if levels of other pollutants are well below their respective standards). *Related terms: air pollutant, air pollution.*

Alien (Introduced) Species: Organisms that were not brought to that location naturally but by man. *Related terms: Endemic species, indigenous species, native species.*

Ambient Air: The surrounding atmosphere, usually the outside air, as it exists around people, plants, and structures. It is not the air in immediate proximity to an emission source. Under Hawai‘i Administrative Rules (HAR) Title 11 Chapter 59, ambient air is defined as the general outdoor atmosphere to which the public has access. *Related terms: air pollutant, air pollution, criteria pollutant, National Ambient Air Quality Standards (NAAQS).*

Anchialine Pond: This term, pronounced “AN-key-ah-lin,” comes from a Greek word meaning “near the sea.” These typically small pools, which form in limestone or volcanic rock, are located throughout the world but are most common in the Hawaiian Islands where over half the world’s known anchialine pools are found. They are often found in underground cave systems. Anchialine pools have their own unique ecosystems populated by tiny and often rare species of crustaceans, fish, and eels. Water levels in the pools can fluctuate in response to ocean tides. Due to their subterranean connection to the ocean, anchialine surface waters are often brackish and become more saline (salty) with increasing depth.

Aquifer: Water-bearing geologic formation(s) with sufficient saturated, permeable material to yield significant quantities of water to wells or springs.

Best Management Practices (BMPs): Policies, practices, and measures that reduce the environmental impacts of designated activities, functions, or processes. BMPs are distinguished from mitigation

measures because mitigation measures are required as a result of the NEPA/HEPA environmental review process.

Brackish: Water that has more [salinity](#) than [fresh water](#), but not as much as [seawater](#).

Carbon Dioxide Equivalent (CO₂Eq): A metric measure used to compare the emissions from various greenhouse gases based upon their global warming potential (GWP). Carbon dioxide equivalents are commonly expressed as “million metric tons of carbon dioxide equivalents (MMTCO₂Eq).” The carbon dioxide equivalent for a greenhouse gas is derived by multiplying the tons of the gas by the associated global warming potential (GWP):

$$\text{MMTCO}_2\text{Eq} = (\text{million metric tons of a gas}) * (\text{GWP of the greenhouse gas})$$

Related terms: global warming potential, greenhouse gases.

CEQ (Council on Environmental Quality): A division within the Executive Office of the President that coordinates Federal environmental efforts and works closely with agencies and other White House offices in the development of environmental policies and initiatives. Established under the National Environmental Policy Act (NEPA) of 1969, CEQ is tasked with ensuring that Federal agencies meet their obligations under NEPA by overseeing Federal agency implementation of the environmental impact assessment process and to act as a referee during agency disagreements.

Climate Change: (1) Climate change refers to any significant change in the measures of climate lasting for an extended period of time. In other words, climate change includes major changes in temperature, precipitation, or wind patterns, among others, that occur over several decades or longer. (2) A change of climate which is attributed directly or indirectly to human activity that alters the composition of the global atmosphere and which is in addition to natural climate variability observed over comparable time periods. Among these human activities are burning fossil fuels as oil, coal, and natural gas (for electricity and transportation); farming (agriculture); deforestation; and other land use changes that result in the release of substantial amounts of greenhouse gases into the atmosphere that most climate scientists believe is contributing to human-induced climate change. The term “global warming” is often used in public discourse when referring to this human-induced climate change. *Related terms: carbon dioxide equivalent, greenhouse gases, global warming potential.*

Controlled Airspace: is defined as airspace where air traffic control service is provided to both instrument and visual flights in accordance with the airspace classification.

Convection: Generally, transport of heat and moisture by the movement of a fluid. In meteorology, the term is used specifically to describe vertical transport of heat and moisture in the atmosphere, especially by updrafts and downdrafts in an unstable atmosphere. The terms "convection" and "thunderstorms" often are used interchangeably, although thunderstorms are only one form of convection. However, convection is not always made visible by clouds. Convection which occurs without cloud formation is called dry convection, while the visible convection processes referred to above are forms of moist convection.

In the case of the Hawaiian Islands, trade winds interact with the mountainous terrain, resulting in convection as the air cools and the moisture in it condenses to form clouds and rain. This convective rainfall is most pronounced on the windward sides of the more mountainous islands at elevations between 2,000 and 3,000 feet where annual amounts are as much as 15 times the statewide sea level average of 25 to 30 inches. There are places in the Hawaiian Islands where annual rainfall top 450 inches (37-1/2 feet) per year such as Mount Wai‘ale‘ale on Kaua‘i and Big Bog on Maui where at least 450 inches of rain a year fall on average.

Covered Source: In the State of Hawai‘i under [HRS Chapter 342B](#), this refers to any sources of air pollution that includes is any major source, any source subject to a standard or other requirements under Section 111, “Standards of performance for new stationary sources,” of the Clean Air Act, or any source subject to an emissions standard or other requirements for hazardous air pollutants under Section 112, “Hazardous air pollutants”, of the Clean Air Act (with specified exceptions). [HRS Chapter 342B](#) defines five different meanings of covered sources. *Related terms: air pollutant, air pollution, hazardous air pollutant, major source, stationary source, non-covered source.*

Criteria Pollutant: An air pollutant that is regulated by the Environmental Protection Agency (EPA) under the Clean Air Act through the National Ambient Air Quality Standards (NAAQS) on the basis of specific criteria of human health-based and/or environmentally-based criteria. EPA has set NAAQS standards for six criteria air pollutants: sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and two size classes of particulate matter, less than 10 micrometers (0.0004 inch) in diameter, and less than 2.5 micrometers (0.0001 inch) in diameter. *Related terms: air pollutant, air pollution, ambient air, hazardous air pollutant, National Ambient Air Quality Standards (NAAQS).*

Critical Habitat: Areas deemed necessary to a species’ conservation and officially designated under the Endangered Species Act; provided that the species is legally protected. *Related terms: endangered species, threatened species.*

Cultural Landscape: Cultural properties that represent the combined works of nature and of man. They can be sites associated with a significant event, activity, person or group of people; can range in size from thousands of acres of rural land to historic homesteads; can be grand estates, farmlands, public gardens and parks, college campuses, cemeteries, scenic highways, and industrial sites; and can be works of art, narratives of cultures, and expressions of regional identity. *Related terms: Hawai‘i Register of Historic Places (HRHP), National Register of Historic Places (NRHP).*

Distinct Population Segment: A vertebrate population or group of populations that is discrete from other populations of the species and significant in relation to the entire species.

Distribution: With respect to electric power distribution, refers to the transfer of electrical energy from the local wiring between high-voltage substations and customers.

Emperor Seamounts: A chain of submerged mountains (primarily guyots) that rise from the Pacific Ocean floor but do not reach the sea surface that run on a north-northwesterly direction toward, terminating near the Kamchatka Peninsula in a subduction trench off the western Aleutian Islands. It is believed the Emperor Seamounts were formed approximately 80 million years ago as the Pacific plate moved over the same hotspot that formed the Hawaiian Archipelago. In this way, these submerged mountains are the oldest portion of the combined Emperor Seamounts – Hawaiian Archipelago (sometimes called the “Hawaiian Ridge – Emperor Chain”). *Related terms: See hotspots, guyot, Hawaiian Archipelago.*

Emperor Seamounts – Hawaiian Archipelago (also called the Hawaiian Ridge – Emperor Chain): The entire chain of approximately 130 volcanic mountains including submerged seamounts that spans about 3,800 miles from the Island of Hawai‘i (the Big Island) to near the Kamchatka Peninsula where they terminate in a subduction trench off the western Aleutian Islands. The complex consists of the older submerged Emperor Seamounts and the younger Hawaiian Archipelago that make up the Hawaiian Islands including the six that are the focus of this PEIS – Hawai‘i (“Big Island”), Maui, O‘ahu, Kaua‘i, Molokai, and Lāna‘i – as well as Ni‘ihau and Kaho‘olawe, and the smaller Northwestern Hawaiian Islands.

The entire complex was formed by the motion of the Pacific Plate over a relatively fixed hotspot that is presently under Hawai‘i Island (i.e., “Big Island”). There is a sharp bend in the chain with the Emperor Seamounts aligned south-southeast to north-northwest while the Hawaiian Archipelago is aligned east-southeast to west-northwest. *Related terms: Emperor Seamounts, Hawaiian Archipelago, hotspots.*

Endangered Species: Any species in danger of extinction throughout all or a significant portion of its range. *Related terms: listed species, proposed species, threatened species, and taking.*

Endemic Species: Organisms that are native and can be found only in that location. Examples of organisms that are endemic to Hawai‘i are the spectacled parrotfish and Hawaiian Monk Seal. *Related terms: Alien (or introduced) species, indigenous species, native species.*

Essential Fish Habitat (EFH): Those waters and substrate necessary to fish for spawning, breeding, or growth to maturity.

Euphotic Zone: The uppermost layer of the ocean; on average, extending to a depth of about 600 feet, although in murky water it can only be 50 feet deep. Because plants require sunlight for photosynthesis, the euphotic zone is the only ocean zone where plants can grow.

Evapotranspiration: Loss of water to the atmosphere by a combination of transpiration of plants and direct evaporation.

Floodplain: The lowlands and relatively flat areas adjoining inland and coastal waters and the flood prone areas of offshore islands. Floodplains include, at a minimum, that area with at least a 1.0 percent chance of being inundated by a flood in any given year (that is, experiencing a 100-year flood). Floodplains include the base floodplain (those areas subject to 100-year floods) and the critical action floodplain (those areas with at least a 0.2 percent chance of being flooded in any given year, also known as a 500-year flood). *Related term: National Flood Insurance Program.*

General Conformity Rule: Under the General Conformity Rule, federal agencies must work with State, Tribal and local governments in a air quality nonattainment or maintenance areas to ensure that federal actions conform to the initiatives established in the applicable state implementation plan or tribal implementation plan.

Global Warming Potential (GWP): A measure of the total energy that a gas absorbs over a particular period of time (usually 100 years), compared to carbon dioxide. In this way, GWP of a gas provides a relative basis for calculating the equivalent warming it produces as carbon dioxide. For reference carbon dioxide has a GWP of 1, and is therefore the standard by which all other greenhouse gases are measured. The term “global warming” is synonymous with climate change (see climate change). *Related terms: carbon dioxide equivalent, climate change, greenhouse gases.*

Greenhouse Gases: Those natural or manmade gaseous constituents of the atmosphere that absorb and re-emit infrared radiation. Such gases allow sunlight to enter the atmosphere freely but absorb the resulting infrared or thermal radiation (heat) that is reradiated by the ground, objects on it, or even the air itself. In this way, such gases “trap” the heat in the atmosphere, causing the air warm. There are many greenhouse gases in nature including water vapor, carbon dioxide, methane, and nitrous oxide, as well certain manmade ones such as aerosols and chlorofluorocarbons (CFCs). Each gas had a specific ability to warm the air that is measured versus the warming potential of carbon dioxide. *Related terms: Carbon dioxide equivalent, climate change, global warming potential.*

Groundwater: Water below the ground surface in a zone of saturation. *Related terms: streams (classifications), waters of the United States, watershed, wetlands.*

Groundwater Hydrologic Unit: Ground-water hydrologic units have been established by the Commission on Water Resource Management to provide a consistent basis for managing ground water resources. The units are primarily determined by subsurface conditions. In general, each island is divided into regions that reflect broad hydrogeological similarities while maintaining hydrographic, topographic, and historical boundaries where possible. Smaller sub-regions are then delineated based on hydraulic continuity and related characteristics. In general, these units allow for optimized spreading of island-wide pumpage on an aquifer-system-area scale.

Groundwater Management Area: A way to manage water resources in a defined area. The objective is to delineate areas considered suitable for management of groundwater resources. A groundwater management area should ideally coincide with the boundaries of a groundwater reservoir or a subdivision of a groundwater reservoir, but it may also be defined by other factors, including the boundaries of political subdivisions.

Guyot: An underwater, flat-topped, coral-capped volcanic mountain (seamount). Nearly all the volcanoes in the Hawaiian-Emperor seamount chain older than 30 million years old are guyots, although some never actually reached the sea surface. *Related terms: Hawaiian Archipelago (Hawaiian Ridge), Emperor Seamounts.*

Hawai'i Register of Historic Places (HRHP): A list officially maintained by the State Historic Preservation Division of the State of Hawai'i. The list formally recognizes districts, sites, structures, buildings, and objects and their significance in Hawai'i's history, architecture, archaeology, engineering, and culture. *Related terms: Cultural landscape, National Register of Historic Places (NRHP).*

Hawaiian Archipelago (Hawaiian Ridge): Refers to the principal islands of the State of Hawai'i including the six that are the focus of this PEIS – Hawai'i ("Big Island"), Maui, O'ahu, Kaua'i, Molokai, and Lāna'i – as well as Ni'ihau and Kaho'olawe, and also the various lesser islands, atolls, reefs, and submerged volcanic seamounts of the Northwestern Hawaiian Islands. The former are sometimes referred to as the Hawaiian Windward Islands, and the latter is sometimes called the Hawaiian Leeward Islands. The Hawaiian Archipelago rises off the Pacific Ocean floor and was created by the west-northwesterly motion of the Pacific plate over a relatively stationary hotspot with the oldest portions approximately 30 million years old. The Hawaiian Archipelago terminates at the Emperor Seamounts, a chain of submerged volcanoes that terminates off the western Aleutian Islands. Together the two features are known as the Emperor Seamounts – Hawaiian Archipelago. *Related terms: Emperor Seamounts, Emperor Seamounts – Hawaiian Archipelago, hotspots, guyot.*

Hazardous Air Pollutant: Also known as toxic air pollutants or air toxics, these are pollutants that cause or may cause cancer or other serious health effects, such as reproductive effects or birth defects, or adverse environmental and ecological effects. Section 112 of the Clean Air Act addresses the emissions of hazardous air pollutants. Under the Clean Air Act Amendments of 1990, EPA is required to control 187 hazardous air pollutants. Through appropriate rulemaking, the pollutants on the list can be modified. A current list of modifications is available on the EPA website along with clarifications on certain pollutant aggregation. Additional information is available at <http://www.epa.gov/ttn/atw/pollsour.html>. The State of Hawai'i defines hazardous air pollutant to include those listed in Section 112 of the Clean Air Act Amendments of 1990. *Related terms: hazardous material, hazardous waste.*

Hazardous Material: Any item or agent (biological, chemical, physical) that has the potential to cause harm to humans, animals, or the environment, either by itself or through interaction with other factors.

Related terms: Hazardous air pollutant, hazardous waste, nonhazardous waste, solid waste.

Hazardous Waste: (1) As defined in this PEIS, a hazardous waste refers to any *hazardous material* that can be characterized by ignitability, corrosiveness, reactivity, and toxicity. Those solid wastes that exhibit one or more of these characteristics is are classified as a hazardous wastes, and/or as a hazardous substances, including discarded military munitions. (2) As defined by EPA, a hazardous waste is any waste that is dangerous or potentially harmful to our health or the environment. Hazardous wastes can be liquids, solids, gases, or sludges. *Related terms: Hazardous air pollutant, hazardous material, nonhazardous waste, solid waste.*

Hotspots: Locations where massive plumes of hot rock have risen through Earth’s mantle toward the lithosphere, where the lower pressures at the base of the lithosphere cause the rock to melt along its upper margins. The resulting molten rock can rise into Earth’s crust and generate active volcanism.

In the case of the Hawaiian Islands, the entire island Hawaiian Archipelago as well as the older Emperor Seamounts were formed by the motion of the Pacific plate over a hotspot that has been more or less stationary hotspot for the past 40 million years. The hotspot is currently under the Big Island of Hawai‘i, which is the youngest of the islands along with the nearby submerged volcano (seamount) called Lō‘ihi. The northwestern part of the Hawaiian chain is the oldest part at roughly 30 million years ago. *Related terms: Emperor Seamounts, Emperor Seamounts – Hawaiian Archipelago, Hawaiian Archipelago (Hawaiian Ridge), lithosphere, Lō‘ihi, seamount.*

Indigenous Species: Organisms that are native but can be found elsewhere. An example of this is the Hawaiian Green Sea Turtle. *Related terms: Alien (introduced) species, endemic species, native species.*

Intergovernmental Panel on Climate Change (IPCC): The leading international body for the assessment of climate change. It was established by the United Nations Environment Programme (UNEP) and the World Meteorological Organization (WMO) in 1988 to provide the world with a clear scientific view on the current state of knowledge in climate change and its potential environmental and socio-economic impacts. See <http://ipcc.ch/organization/organization.shtml>

Listed Species: Any species of fish, wildlife, or plant determined to be endangered or threatened under Section 4 of the Endangered Species Act. *Related terms: Critical habitat, endangered species, threatened species.*

Lithosphere: The outer layer of the Earth consisting of the crust and the rigid, upper part of the mantle. It is 25 to 125 miles thick under the continents and 30 to 60 miles thick under the oceans. The lithosphere is divided into tectonic plates consisting of continents and ocean basins (with the two types consisting of distinct types of rocky materials). The Hawaiian Islands exist as a result of a hotspot underneath the Pacific plate. *Related term: hotspots.*

Lō‘ihi: An active submerged volcanic seamount located approximately 16 miles off the southeast coast of the Big Island of Hawai‘i. The top of the volcano is approximately 3,200 feet below sea level. It is not expected to break the sea surface for possibly 200,000 years. Together with the Big Island, Lō‘ihi is the youngest islands in the Hawaiian Archipelago and sits atop the stationary hotspot above which the Pacific plate is slowly moving. *Related terms: hotspots, Hawaiian Archipelago (Hawaiian Ridge).*

Low-Income: Individuals who fall below the poverty line are categorized as low-income. The poverty line takes into account family size and the age of individuals in the family. For any given family below

the poverty line, all family members are considered to be below the poverty line for analysis. *Related term: minority.*

Major Source: In the State of Hawai‘i under [HRS Chapter 342B](#), this refers to a source of air pollution or a group of stationary sources of air pollution located on one or more contiguous or adjacent properties that is under common control of the same person or persons and that emits or has the potential to emit:

- 10 tons or more per year of any single hazardous air pollutant or 25 tons or more per year of any combination of hazardous air pollutants;
- 100 tons or more per year of any other air pollutant; and
- Any amount specified by the Hawai‘i Department of Health for radionuclides.

Related terms: air pollutant, covered source, hazardous air pollutant, stationary source, non-covered source.

Minority: Persons are included in the minority category if they identify themselves as belonging to any of the following groups (1) Hispanic or Latino, (2) Black (not of Hispanic origin) or African American, (3) American Indian or Alaska Native, (4) Asian, or (5) Native Hawaiian or other Pacific Islander. In addition, individuals who categorize themselves as being of multiple racial or ethnic origins are minorities. *Related term: low-income.*

Mitigation: As defined by the Council on Environmental Quality (CEQ) in 40 CFR 1508.20, this refers to (1) avoiding an impact altogether by not taking a certain action or parts of an action; (2) minimizing impacts by limiting the degree or magnitude of an action and its implementation; (3) rectifying an impact by repairing, rehabilitating, or restoring the affected environment; (4) reducing or eliminating the impact over time by preservation and maintenance operations during the life of an action; or (5) compensating for an impact by replacing or providing substitute resources or environments.

Mitigation Measures: Refers to any required plan or course of action (i.e., a measure) for purposes of mitigation. Such measures are required as a result of the National Environmental Policy Act / Hawai‘i Environmental Policy Act (NEPA/HEPA) environmental review process for future proposed actions to support the State of Hawai‘i in achieving the goals established in the HCEI.

National Ambient Air Quality Standards (NAAQS): Refers to the standards established under the Clean Air Act (42 U.S.C. § 7401 *et seq.*) and implementing Environmental Protection Agency (EPA) regulations (40 CFR Part 50) defining the highest allowable levels of certain pollutants in the ambient air (i.e., the outdoor air to which the public has access). Primary standards are established to protect public health; secondary standards are established to protect public welfare (for example, visibility, crops, animals, buildings). EPA is required to establish the criteria for setting these standards, and therefore the regulated pollutants are called criteria pollutants. EPA has set standards for six principal criteria pollutants include sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and two size classes of particulate matter, less than 10 micrometers (0.0004 inch) in diameter, and less than 2.5 micrometers (0.0001 inch) in diameter. *Related terms: air pollutant, air pollution, ambient air, criteria pollutant.*

National Flood Insurance Program (NFIP): Created by Congress originally in 1968, this is a flood insurance program administered by the Federal Emergency Management Agency (FEMA). NFIP provides flood insurance to homeowners, renters, and business owners to participating communities that agree to adopt and enforce ordinances that meet or exceed FEMA requirements to reduce the risk of flooding (refer to 44 CFR Parts 1 - 399). The basis of the insurance coverage is the Flood Insurance Rate Map (FIRM), the official map that delineates both the Special Flood Hazard Area (SFHA) and the risk premium zones applicable to the community. The maps show areas prone to inundation by 100-year

floods. The NFIP also includes a voluntary Community Rating System (CRS) that is intended to provide incentives in the form of premium discounts for communities to go beyond the minimum floodplain management requirements to develop extra measures to provide protection from flooding. In the Hawaiian Islands, the Department of Land and Natural Resources (DLNR) has been designated as the State Coordinating Agency responsible for assisting the coordination of the program between the Federal and County agencies in Hawaii.

National Pollutant Discharge Elimination System (NPDES): A provision of the Clean Water Act which prohibits discharge of pollutants into waters of the United States unless a special permit is issued by the Environmental Protection Agency, a state, or, where delegated, a tribal government on an Indian reservation. The NPDES permit lists either permissible discharges, the level of cleanup technology required for wastewater, or both.

National Priorities List (NPL): The list of national priorities among the known releases or threatened releases of hazardous substances, pollutants, or contaminants throughout the United States and its territories. The NPL is intended primarily to guide the EPA in determining which sites warrant further investigation. The Superfund law (CERCLA) enabled revisions to the existing National Oil and Hazardous Substances Pollution Contingency Plan (40 CFR 300), commonly known as the National Contingency Plan (NCP). It is the NCP that is established the NPL. *Related terms: Superfund, Superfund site.*

National Register of Historic Places (NRHP): The official list of the Nation's cultural resources that are worthy of preservation. The National Park Service maintains the list under direction of the Secretary of the Interior. Buildings, structures, objects, sites, and districts are included in the National Register for their importance in American history, architecture, archeology, culture, or engineering. Properties included on the National Register range from large-scale, monumentally proportioned buildings to smaller scale, regionally distinctive buildings. The listed properties are not just of nationwide importance; most are significant primarily at the state or local level. Procedures for listing properties on the National Register are found in 36 CFR 60. *Related terms: Cultural landscape, Hawai'i Register of Historic Places.*

Native Species: Organisms brought to a location without the help of man, such as by wind, wave and or birds. Hawai'i's state bird, the nēnē or Hawaiian goose, is an example. *Related terms: Alien (or introduced) species, endemic, indigenous.*

Non-covered source: Any stationary source of air pollution constructed, modified, or relocated after March 20, 1972, that is not a covered source. *Related terms: air pollutant, air pollution, covered source, hazardous air pollutant, major source, stationary source.*

Nonhazardous Waste: Wastes that do not meet the EPA definition of hazardous waste. In general, it includes certain kinds of municipal solid waste and industrial waste. The nonhazardous secondary material regulations under the Resource Conservation and Recovery Act (RCRA) identifies which nonhazardous secondary materials are, or are not, solid wastes when burned in combustion units. *Related terms: Hazardous waste, solid waste.*

Prevention of Significant Deterioration (PSD): A permitting program pursuant to the Clean Air Act for new and modified major sources of air pollution such as power plants, manufacturing facilities, and other facilities that emit air pollution. PSD applies to all pollutants that do not exceed the National Ambient Air Quality Standards (NAAQS) in an area. PSD also applies to other pollutants that do not have a NAAQS. These non-criteria pollutants are listed in EPA's regulations and include fluorides, sulfuric acid mist, hydrogen sulfide, total reduced sulfur, and certain contaminants from municipal solid waste plants. *Related terms: NAAQS, criteria pollutant.*

Proposed Species: Any species of fish, wildlife or plant proposed in the *Federal Register* to be listed under Section 4 of the Endangered Species Act. *Related terms: endangered species, listed species, threatened species, take (taking).*

Solid Waste: As defined by the U.S. Environmental Protection Agency (EPA), any garbage or refuse, sludge from a wastewater treatment plant, water supply treatment plant, or air pollution control facility and other discarded material, including solid, liquid, semi-solid, or contained gaseous material resulting from industrial, commercial, mining, and agricultural operations, and from community activities. Solid waste includes both hazardous waste and nonhazardous waste. EPA regulations at 40 CFR §261.2 provide the conditions for whether the discarded material meets the “Definition of Solid Waste” (DSW) under RCRA Subtitle C Hazardous Waste. *Related term: hazardous waste.*

Stationary Source: In the State of Hawai‘i under [HRS Chapter 342B](#), this refers to any piece of equipment or any activity at a building, structure, facility, or installation that emits or may emit any air pollutant. *Related terms: air pollutant, air pollution, covered source, major source, non-covered source.*

Streams (Classifications): There are three distinct classifications of streams including perennial stream, intermittent stream, and ephemeral stream.

Perennial Stream: A stream that flows continuously throughout the year over at least a portion of its course. In Hawaii, perennial streams are continuous if they normally flow all the way to the sea, but often they are termed interrupted because they flow year-round in upper portions and intermittently at lower elevation under normal conditions. Interruptions may be natural or manmade. A perennial stream is also called a year-round stream.

Intermittent Stream: A stream, or part of a stream, that flows only at certain times of year, generally for several weeks or months in response to seasonal precipitation and subsequent groundwater discharge. An intermittent stream is also called a seasonal stream.

Ephemeral Stream: A stream with little or no groundwater influence that flows only a few hours or days in direct response to rainfall. These streams typically are manifest by dry gulches and in Hawai‘i are generally found on the leeward side of mountainous areas. An ephemeral stream is also called a rain-dependent stream.

Superfund: The common name of the Federal Government’s program to clean up the nation's uncontrolled hazardous waste sites. The Superfund program was enacted under the Comprehensive Environmental Response Compensation and Liability Act (CERCLA) of 1980. *Related term: Superfund site.*

Superfund Site: An uncontrolled or abandoned place where hazardous waste is located, possibly affecting local ecosystems or people. The Environmental Protection Agency lists Superfund sites on the National Priorities List (NPL) upon completion of Hazard Ranking System screening, public solicitation of comments about the proposed site, and after all comments have been addressed.

There are presently three Superfund sites on the NPL in Hawai‘i. One additional site has been cleaned up and removed from the NPL. No sites are currently proposed for addition. All of these sites are on the island of O‘ahu. *Related terms: National Priorities List, Superfund site.*

Sustainable Yield: The maximum rate at which water may be withdrawn from a water source without impairing the utility or quality of the water source as determined by the Hawai‘i Commission on Water Resource Management ([HRS 174C-3](#)).

Take (Taking): As defined under the Endangered Species Act in relation to threatened or endangered species, to “take” means to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect or attempt to engage in any such contact. *Related terms: Endangered species, listed species, threatened species.*

Thermocline: (1) A zone of water in the ocean where temperature decreases rapidly with depth. (2) A region in a thermally stratified body of water which separates warmer surface water from cold deep water and in which temperature decreases rapidly with depth.

Threatened Species: Any species likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range. *Related terms: Endangered species, Listed species, Proposed species, Take (taking).*

Total Maximum Daily Loads (TMDLs): Refers to the maximum amount of a pollutant that a water body can receive and still meet water quality standards.

Transmission: With respect to electric power transmission, refers to the transfer of electrical energy from generating power plants to electrical substations located near demand centers. *Related term: distribution.*

Tropic of Cancer: The imaginary dividing line between tropical and temperate climates, at 23.5° north latitude, marking the degree of the earth’s tilt from the plane of its revolution around the sun.

Twilight Zone: The middle layer of the ocean; appears deep blue to black in color. The depth of this zone depends on the clarity or murkiness of the water. In clear water, the twilight zone can begin at depths up to 600 feet; in murky water, it can start at only 50 feet deep. It extends to about 3,300 feet deep.

Vog: Vog is volcanic smog, and its sulfuric acid and other toxic compounds can create health hazards for people with respiratory conditions. Vog can produce headaches, breathing difficulties, and irritation to the lungs and eyes. HDOH monitors vog, and emergency health advisories and evacuations can occur due to a high vog index.

Waters of the United States: A legal term from the Clean Water Act and defined in 40 CFR 122.2 that includes “navigable waters of the United States” (see Chapter 2 glossary definition); interstate waters including interstate wetlands; other waters used for interstate travel, commercial, or recreational purposes; impoundment waters; associated tributaries; territorial seas, and wetlands adjacent to these waters. Excluded from this definition are waste treatment systems including treatment ponds or lagoons designed to meet the requirements of the Clean water Act. See <http://www.epa.gov/earth1r6/6en/w/watersus.htm>. *Related terms: groundwater, streams (classifications), watershed, wetlands.*

Watershed: An area that drains into a body of water, such as a river, lake, reservoir, estuary, sea, or ocean. It includes the rivers, streams, and lakes that convey the water, as well as the land surfaces from which water runs off. In the Hawaiian Islands, the primary inland surface water features are streams that drain watersheds. By contrast, there are very few natural lakes in the Hawaiian Islands. *Related terms: groundwater, streams (classifications), wetlands.*

Wetlands: For regulatory purposes under the Clean Water Act, the term wetlands means “those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs and similar areas” [40 CFR 230.3(t)]. In the case of Hawai‘i, there are four distinct types of wetlands:

Riverine wetlands – These are the surface water systems found along the edges of rivers and streams.

Palustrine wetlands – These include marshes and bogs and generally are found in depressions where rain and groundwater collect. Hawai‘i’s rare montane bogs, which take millions of years to form, are in this group.

Estuarine wetlands – These include swamps and mudflats that occur on coasts where streams empty to the ocean. These areas typically are influenced by tides, are brackish, and provide habitat for fish, shellfish, and water birds.

Marine wetlands – These include intertidal shorelines, seagrass beds, and tide pools. They are saltwater systems that often provide habitat for many species harvested by humans for food.

Related terms: groundwater, waters of the United States, watershed.

4 ENVIRONMENTAL IMPACTS FROM ENERGY EFFICIENCY

This chapter presents the potential environmental impacts that could be expected from the energy efficiency activities and technologies presented in Chapter 2, Section 2.3.1. This chapter includes discussion of only those energy efficiency activities and technologies with the potential for environmental impacts, as presented in Sections 2.3.1.2, 2.3.1.3, and 2.3.1.4: Energy Efficient Buildings, Sea Water Air Conditioning, and Solar Water Heating, respectively. The representative projects described in Section 2.3.1 were used to estimate the potential environmental impacts for each activity and technology. Each of the sections below includes a summary table of the potential environmental impacts and best management practices (BMPs) for that activity or technology. The potential impacts are presented for each environmental resource area. As was described in Chapter 3, many of the activities and technologies could result in environmental impacts that would be common of typical construction projects and may not be unique to the specific activity or technology. In these cases, the presentation of potential impacts in this chapter refers the reader to the appropriate section in Chapter 3 that presents these common impacts for that resource area. Therefore, the details in this chapter deal primarily with those impacts that would be unique to the specific activity or technology being evaluated. Not all activities and technologies have the potential to impact all environmental resource areas analyzed in this document. Therefore, the summary table also identifies and screens those resources areas that are not expected to be impacted by the activity/technology.

4.1 Energy Efficient Buildings

The energy efficient buildings representative project would retrofit all existing homes in the City and County of Honolulu (as of 2015) to bring them into compliance with the 2009 IECC. The representative project also involves the replacement of incandescent light bulbs inside homes with energy efficient lighting (i.e., LED lamps) beyond what is required to comply with the 2009 IECC.

[Table 4-1](#) presents a summary of the potential environmental impacts for energy efficient buildings, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of a retrofit activity and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 4-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Energy Efficient Buildings

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	None; retrofitting buildings, would not cause any additional land disturbance that could result in impacts to geology and soils.	N/A
Climate and Air Quality		
Air Quality	Minor impacts during construction. Reductions in criteria pollutants as a result of reduction of electricity generation using fossil fuels.	None.

Table 4-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Energy Efficient Buildings (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Climate Change	Minor impacts during construction. Reductions in GHG emissions as a result of reduction of electricity generation using fossil fuels.	None.
Water Resources		
	None; retrofitting buildings would not cause any additional land disturbance or increased water demand that could result in impacts to water resources, including surface water, groundwater, floodplains, and wetlands.	N/A
Biological Resources		
	None; retrofitting buildings would not cause any additional land disturbance that could result in impacts to biological resources.	N/A
Land and Submerged Land Use		
	None; retrofitting buildings would not cause any changes to land or submerged land use.	N/A
Cultural and Historic Resources		
	Potentially adverse visual or architectural context impact to historic properties.	<p>Prior to construction, evaluate all potential resources for eligibility to the HRHP and the NRHP. In accordance with State law, if a historic property or structure that is listed or eligible for listing on the HRHP and/or NRHP is proposed for building retrofits, the project proponent must complete and submit a Historic Preservation Review Form to the State Historic Preservation Office (SHPO) in compliance with Hawai'i Revised Statutes (HRS) Chapter 6E such that the modifications may be reviewed and approved prior to project implementation. Such measures would avoid impacts to an affected property.</p> <p>Review the State Inventory of Historic Properties (SIHP) prior to project startup to determine whether a property is historic. While the SIHP identifies 143 historic buildings or districts on O'ahu, simply relying on this database alone is not adequate to determine whether a prospective property is historic.</p>

Table 4-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Energy Efficient Buildings (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
		Comply with <i>The Secretary of the Interior's Standards for the Treatment of Historic Properties with Guidelines for Preserving, Rehabilitating, Restoring and Reconstructing Historic Buildings</i> (DOI 2011).
Coastal Zone Management		
	None; retrofitting buildings would not cause any changes that would have to be reviewed for coastal zone management.	N/A
Scenic and Visual Resources		
	Potential short-term effects due to visibility of construction activities and personnel. Potential long-term visual impacts (project-specific).	Design the installation of energy retrofits to limit visibility and reduce potential visual impacts.
Recreation Resources		
	None; retrofitting buildings, would not cause any additional land disturbance or impacts to recreation resources.	N/A
Land and Marine Transportation		
	None; retrofitting buildings would not cause any changes or impacts to land or marine transportation.	N/A
Airspace Management		
	None; retrofitting buildings would not result in any tall structures or other potential impacts to airspace.	N/A
Noise and Vibration		
	Typical construction noise, as identified in Section 3.12.5.	Same as those common across construction projects (see Section 3.12.6).
Utilities and Infrastructure		
	Potential reduction in energy consumption. See Section 2.3.5.	None.
Hazardous Materials and Waste Management		
Hazardous Materials	Potential impact from exposure to hazardous materials including: asbestos materials, lead-based paint, polychlorinated biphenyls, arsenic; and/or mercury (site-specific).	Prior to renovation, perform surveys to identify any areas in homes containing asbestos materials, lead-based paint, polychlorinated biphenyls, and/or arsenic. The EPA recommends proper cleanup and disposal to ensure best practices for mercury handling during building retrofitting.

Table 4-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Energy Efficient Buildings (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Waste Management	<p>Potential impacts to waste management services could occur during project construction/retrofitting, as special handling and disposal of building materials and retrofits may be required.</p> <p>Retrofit work to bring buildings up to code with the 2009 IECC may result in the discovery of asbestos, lead-based paint, polychlorinated biphenyls, and arsenic.</p> <p>The replacement of incandescent light bulbs and/or compact fluorescent bulbs with LED lamps would require special handling and disposal requirements, as certain fluorescent bulbs contain a small amount of mercury.</p> <p>Potential landfill impacts.</p> <p>After completion, building retrofits would not result in waste management impacts.</p>	<p>Consideration should be given to development and implementation of a recycling plan. A recycling program would effectively recover building materials that could contain potentially hazardous substances (e.g., liquid wastes, paints, oil, and solvents).</p>
Wastewater	<p>Common impacts from typical construction activities are identified in Section 3.14.4.</p>	<p>None.</p>
Socioeconomics		
	<p>Beneficial – few jobs created.</p>	<p>None.</p>
Environmental Justice		
	<p>None; no disproportionately high and adverse human health or environmental effects on minority and low-income populations.</p>	<p>N/A</p>
Health and Safety		
	<p>During building retrofits, workers may encounter asbestos, lead-based paint, polychlorinated biphenyls, and arsenic. Exposure to such hazardous materials could result in harmful health effects, the severity of which would depend on the level of exposure.</p>	<p>Retrofit projects should begin with an audit performed by a licensed and experienced contractor. The audit involves inspecting, evaluating, and analyzing the building. This evaluates for the presence of potentially hazardous materials.</p>

4.1.1 GEOLOGY AND SOILS

As identified in [Table 4-1](#), there would be no potential impacts to geology and soils from the representative energy efficient building.

4.1.2 CLIMATE AND AIR QUALITY

4.1.2.1 Potential Impacts

Energy retrofits for all existing homes in the City and County of Honolulu would produce beneficial impacts in the form of substantial energy savings. Retrofitting homes to bring them into compliance with the 2009 IECC would reduce energy consumption by 15 percent per year, or about 1,200 kilowatt-hours per home per year. In addition, replacing the remaining 50 percent of the 50-watt incandescent light bulbs with LEDs would reduce energy consumption by about 400 kilowatt-hours per home per year, respectively. Applying these savings to the projected 400,000 residential units in the City and County of Honolulu would produce annual energy savings of about 620,000 megawatt-hours. This reduction in electricity would reduce oil consumption from electricity generation by about 41 million gallons [assuming 66.7 gallons of oil per megawatt-hour of electricity (calculated from [DBEDT 2013](#))]. On O‘ahu, this would correspond with an annual reduction in greenhouse gas emissions of about 0.45 million metric tons carbon dioxide equivalent based on EPA eGrid2012 emission factors (<http://www.epa.gov/egrid>).

No adverse impacts to air quality would be expected from the representative energy efficient building.

4.1.2.2 Best Management Practices and Mitigation Measures

None noted.

4.1.3 WATER RESOURCES

As identified in [Table 4-1](#), there would be no potential impacts to water resources, including surface water, groundwater, and floodplains and wetlands, from the representative energy efficient building.

4.1.4 BIOLOGICAL RESOURCES

As identified in [Table 4-1](#), there would be no potential impacts to biological resources from the representative energy efficient building.

4.1.5 LAND AND SUBMERGED LAND USE

As identified in [Table 4-1](#) there would be no potential impacts to land or submerged land use from the representative energy efficient building.

4.1.6 CULTURAL AND HISTORIC RESOURCES

4.1.6.1 Potential Impacts

The representative project involves energy retrofits to existing residences, so no impacts to archaeological sites would be expected. There would be no reason for land disturbance during retrofit actions, so there would be no site grading or excavations that could increase the potential for encountering buried cultural resources. There is the possibility that building retrofits (e.g., window replacement) to existing buildings

or residences that are listed or eligible for listing on the *Hawai'i Register of Historic Places* (HRHP) or the *National Register of Historic Places* (NRHP), and/or are located in a historic district, would change the characteristics of the property such that the historic nature of the property would be altered. The alterations may have an adverse visual or architectural context impact to the historic property. When modifying historic buildings to retrofit for energy sustainability, the Department of Interior provides standards and guidelines to help guide project proponents ([DOI 2011](#)). Additionally, energy retrofits could affect residences and other buildings that not only qualify as historic properties but also as cultural resources whose alterations may require coordination with the OHA's Native Hawaiian Historic Preservation Council in accordance with applicable regulatory consultation requirements.

4.1.6.2 Best Management Practices and Mitigation Measures

The following BMPs could prevent or reduce the above-discussed impacts:

- Prior to construction, evaluate all potential resources for eligibility to the HRHP and the NRHP. In accordance with State law, if a historic property or structure that is listed or eligible for listing on the HRHP and/or NRHP is proposed for building retrofits, the project proponent must complete and submit a Historic Preservation Review Form to the State Historic Preservation Office (SHPO) in compliance with [Hawai'i Revised Statutes \(HRS\) Chapter 6E](#) such that the modifications may be reviewed and approved prior to project implementation. Such measures would avoid impacts to an affected property.
- Review the State Inventory of Historic Properties (SIHP) prior to project startup to determine whether a property is historic. While the SIHP identifies 143 historic buildings or districts on O'ahu, simply relying on this database alone is not adequate to determine whether a prospective property is historic.
- Comply with *The Secretary of the Interior's Standards for the Treatment of Historic Properties with Guidelines for Preserving, Rehabilitating, Restoring and Reconstructing Historic Buildings* ([DOI 2011](#)), which allow for changes such as energy retrofits and installation of water heaters and photovoltaic panels while ensuring retention of historic characteristics.

4.1.7 COASTAL ZONE MANAGEMENT

As identified in [Table 4-1](#), there would be no potential impacts to coastal zone management from the representative energy efficient building.

4.1.8 SCENIC AND VISUAL RESOURCES

4.1.8.1 Potential Impacts

Construction, including installation of light bulbs and associated construction activities, may be visible during such activities. Visual impacts from building retrofits, such as installation of incandescent light bulbs and associated construction activities, would be short term and minimal.

Long-term visual impacts from the building retrofits could be unlikely; however, potential visual impacts from retrofits such as lighting and window replacement would need to be evaluated on a site-specific basis, as changes in building appearances could be visible.

4.1.8.2 Best Management Practices and Mitigation Measures

Install building retrofits to limit visibility to reduce potential visual impacts. Homeowners could install tall vegetation or use screening to hide retrofits.

4.1.9 RECREATION RESOURCES

As identified in [Table 4-1](#), there would be no potential impacts to recreation resources from the representative energy efficient building.

4.1.10 LAND AND MARINE TRANSPORTATION

As identified in [Table 4-1](#), there would be no potential impacts to land or marine transportation from the representative energy efficient building.

4.1.11 AIRSPACE MANAGEMENT

As identified in [Table 4-1](#), there would be no potential impacts to airspace management from the representative energy efficient building.

4.1.12 NOISE AND VIBRATION

4.1.12.1 Potential Impacts

The representative energy efficient buildings project would involve retrofitting existing buildings and could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

4.1.12.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across construction projects (see Section 3.12.6).

4.1.13 UTILITIES AND INFRASTRUCTURE

4.1.13.1 Potential Impacts

If all residents in the City and County of Honolulu implemented the energy efficiency measures by 2030, then approximately 620,000 megawatt-hours per year of energy would be saved. For O‘ahu, with an annual consumption of 7 million megawatt-hours in 2012 (see Section 3.13.1), the change would represent a 9-percent decrease in power demand. The other islands (i.e., Kaua‘i, Molokai, Lāna‘i, Maui, and Hawai‘i) would have similar impacts if energy efficient measures were implemented. These changes would contribute to meeting about 14 percent of HCEI’s goal of 4,300 gigawatt-hours per year by 2030. This decrease in annual electricity consumption would result in an impact to the utilities and infrastructure as described in Section 2.3.5. On all islands, such changes would contribute to the need to modify the overall utility structure to meet the Renewable Portfolio Standard (RPS) ([HECO 2013](#)).

4.1.13.2 Best Management Practices and Mitigation Measures

None noted.

4.1.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

4.1.14.1 Potential Impacts

4.1.14.1.1 Hazardous Materials

The replacement of incandescent light bulbs and or compact fluorescent bulbs with LED lamps would require special handling and disposal requirements, as certain fluorescent bulbs contain a small amount of mercury, a hazardous substance. After completion, building retrofits would not result in hazardous material exposure impacts.

4.1.14.1.2 Waste Management

Potential impacts to waste management services could occur during project construction/retrofitting, as special handling and disposal of building materials and retrofits may be required. Retrofit work to bring buildings up to code with the 2009 IECC may result in the discovery of asbestos, lead-based paint, polychlorinated biphenyls, and arsenic. In addition, the replacement of incandescent light bulbs and/or compact fluorescent bulbs with LED lamps would require special handling and disposal requirements, as certain fluorescent bulbs contain a small amount of mercury.

After completion, building retrofits would not result in waste management impacts.

4.1.14.1.3 Wastewater

Minimal wastewater would be produced during retrofits of buildings. Therefore, wastewater impacts would be minimal.

4.1.14.2 Best Management Practices and Mitigation Measures

4.1.14.2.1 Hazardous Waste

Prior to renovation, perform surveys to identify any areas in homes containing asbestos materials, lead-based paint, polychlorinated biphenyls, and/or arsenic. To minimize exposure to mercury vapor, the EPA recommends that proper cleanup and disposal steps be taken to ensure best practices during building retrofitting occurs (see http://www.epa.gov/hg/mgmt_options.html; EPA 2013).

4.1.14.2.2 Waste Management

Follow proper handling, abatement, and disposal procedures and activities to comply with State and Federal OSHA regulations and county air quality district requirements. This includes proper handling and transport for disposal at the appropriate waste facility to ensure no hazardous wastes were disposed of in landfills. If feasible, building material waste would be recycled in accordance with construction and demolition waste guidelines.

4.1.14.2.3 Wastewater

None noted.

4.1.15 SOCIOECONOMICS

4.1.15.1 Potential Impacts

Socioeconomic impacts in Hawai‘i arising from building retrofits in the City and County of Honolulu would be very small. However, with about 400,000 housing units in the county, net new jobs created for electricians, Heating, Ventilation, and Air Conditioning (HVAC) technicians, plumbers, home inspectors, and other related service personnel, would be small in comparison to the existing workforce. In January 2013, the City and County of Honolulu had a labor force of 456,765; of which approximately 22,000 persons were unemployed. Jobs directly associated with the building retrofits likely would be filled by individuals already residing within the region of influence (the City and County of Honolulu) and not by in-migrating workers. While any new jobs created would be considered “green industry” jobs (which meets the HCEI goals), the total new jobs would equal less than 0.1 percent of the existing jobs in the City and County of Honolulu.

4.1.15.2 Best Management Practices and Mitigation Measures

None noted.

4.1.16 ENVIRONMENTAL JUSTICE

4.1.16.1 Potential Impacts

As identified in [Table 4-1](#), there would be no environmental justice impacts from the representative energy efficient buildings project.

4.1.16.2 Best Management Practices and Mitigation Measures

None noted.

4.1.17 HEALTH AND SAFETY

4.1.17.1 Potential Impacts

Common potential impacts from typical construction activities are identified in Section 3.17.3. New building energy efficiency designs and construction are governed by national and county building codes, which are protective of human health and safety. Retrofits fall under the same codes but require additional evaluation to assist in developing designs and the associated retrofit installations that are protective of human health and safety.

During building retrofits, workers may encounter asbestos, lead-based paint, polychlorinated biphenyls, and arsenic. Exposure to such hazardous materials could result in harmful health effects, the severity of which would depend on the level of exposure. For example, if a bulb were to break, some of the mercury would release as mercury vapor. Exposure to high levels of mercury can result in harmful health effects to both humans and the environment.

The representative project could result in minor health effects from exposure to hazardous materials and substances. Retrofitting buildings would not introduce any unique accident scenarios.

4.1.17.2 Best Management Practices and Mitigation Measures

Common BMPs for typical construction activities are identified in Section 3.17.5. The following best management practice could prevent or reduce the above-discussed impacts:

- Any retrofit project should begin with an audit performed by a licensed and experienced contractor to inspect, evaluate, and analyze the building. Such audit would identify the presence of potentially hazardous materials such as asbestos, lead-based paint, polychlorinated biphenyls, and/or arsenic; the potential for pressure imbalances that can result in the back drafting of pollutants into the building; and appropriate ventilation to prevent moisture build-up and potential mold and/or mildew issues.
- The retrofit contractor should incorporate the audit results into the design, processes, and procedures of the building-specific retrofit work plan.
- The contractor should also conduct a close-out audit once the retrofit is completed to ensure that the actual retrofit met the design goals.
- Homeowners and otherwise non-construction personnel should remain away from the building during all retrofit activities when there is a potential for adverse health and safety impacts.

4.2 Sea Water Air Conditioning

The representative sea water air conditioning project would be a new facility located close to an existing district cooling system that supplies electrically chilled air to a population center or facilities that require significant cooling requirements. The air conditioning system would use a 63-inch-diameter screened pipe, 4 to 5 miles long, with intake at a depth of 1,770 feet to access water at 44° to 45°F. The effluent pipe would be placed where the average water temperature is closest to the temperature of the wastewater exiting the cooling station, approximately 53°F. This depth could be fairly close to the surface, possibly as high as about 150 feet below the surface, or as deep as 650 feet, depending on the actual location ([NREL 2013](#)). Pumping the effluent sea water into the ocean in this manner would avoid altering the local temperature gradient ([Makai 2013](#)).

The cooling station would be close enough to the shoreline to ensure minimal change in the incoming seawater's temperature. Two sets of pumps located in the cooling station would be connected to the electrical grid; each would require between 300 and 450 kilowatts of power.

[Table 4-2](#) presents a summary of the potential environmental impacts for sea water air conditioning, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of this technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 4-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Sea Water Air Conditioning

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
Onshore	Potential soil erosion and contamination during construction (short-term) (see Section 3.1.3).	Same as those common across construction projects (see Section 3.1.4).
Offshore	Potential disturbance of marine sediments during construction (short-term) and operations.	Same as those associated with construction of land-sea transition sites for undersea cables (see Section 8.2.1).
Climate and Air Quality		
Air Quality	<p>General impacts during construction (short-term) (see Section 3.2.4).</p> <p>The use of a sea water air conditioning system would require 75 percent less electricity than a standard cooling system, therefore, there would be a beneficial impact to air quality from a reduction of criteria pollutants resulting from electricity generated by fossil fuels.</p>	Same as those common across construction projects (see Section 3.2.5).
Climate Change	Potential benefits – Greenhouse Gas (GHG) emission reduction.	Same as those common across construction projects (see Section 3.2.5).
Water Resources		
Surface Water – Land-Based	<p>General impacts during construction (short-term) (see Section 3.3.5).</p> <p>No operational impacts.</p>	Same as those common across construction projects (see Section 3.3.6).
Surface Water – Marine-Based	<p>Sediment disturbance/ dispersal and increased turbidity.</p> <p>Potential site-specific impacts may occur to habitats or communities of concern.</p> <p>Potential increase in nutrient levels (nitrate and phosphates).</p> <p>Potential for sea water temperature variability impact.</p>	<p>Devices such a silt curtains could be deployed at the horizontal directional drilling (HDD) breakout point to help reduce potential impacts.</p> <p>Schedule project activities (sea floor disturbance) during seasonal periods when wave, current, and wind is expected to be at a low.</p> <p>Establish a zone of mixing (per HAR 11-54-9) in accordance with permit requirements for the system’s water discharge or if infeasible, treat water (for example, nutrient removal or temperature adjustment) before discharge.</p>

Table 4-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Sea Water Air Conditioning (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Groundwater	<p>General construction impacts (see Section 3.3.5).</p> <p>No adverse operational impacts.</p> <p>Potential fresh water (groundwater) savings if wastewater is used as the cooling medium.</p> <p>Potentially beneficial; fresh water savings with an open cooling system.</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p>
Floodplains and Wetlands	<p>Potential short-term impacts during construction (see Section 3.3.5).</p> <p>Potential effects during operations (site specific; i.e., if project were located in a floodplain/wetland).</p>	<p>Consideration of permitting requirements and building restrictions.</p>
Biological Resources		
	<p>General impacts to terrestrial and marine ecosystems during construction (short-term impacts to benthic communities and marine mammals if construction occurred in the Hawaiian Islands Humpback Whale National Marine Sanctuary).</p> <p>Localized impacts to marine organisms from water discharge temperature.</p> <p>Potential increase in nutrient levels resulting in increased marine productivity and possible creation of unusual algal blooms.</p> <p>Potential localized disturbance impacts to benthic communities at discharge point.</p> <p>Potential entrainment of smaller organisms at the intake pipe.</p>	<p>Direct outflow upward into the water column away from the ocean floor.</p> <p>Establish a zone of mixing (per HAR 11-54-9) in accordance with permit requirements for the system’s water discharge or if infeasible, treat water (for example, nutrient removal or temperature adjustment) before discharge.</p>

Table 4-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Sea Water Air Conditioning (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Land and Submerged Land Use		
	<p>Short-term land disturbance impacts at the cooling station locations and along distribution line routes during construction.</p> <p>Potential land use impacts related to expansions/maintenance of the cooling stations and/or distribution network.</p>	<p>The project may be required to obtain the necessary right-of-ways/easements and approvals to for construction near and around existing subsurface utilities.</p> <p>The project may also require a lease for submerged lands from the Hawai'i Department of Natural Resources.</p>
Cultural and Historic Resources		
	<p>Potential adverse impacts to cultural, historic, and related natural resources during construction and operation (both on and offshore).</p>	<p>Same as those common across construction and operational projects (see Section 3.6.7).</p>
Coastal Zone Management		
	<p>Potential effects to special management areas established to protect specific coastline resources and limit shorefront access (project- and/or site-specific).</p>	<p>During site selection, avoidance of the beach and near offshore areas would minimize impacts to the shoreline.</p> <p>The use of horizontal directional drilling to avoid the beach and near offshore areas would minimize impacts to the shoreline.</p>
Scenic and Visual Resources		
	<p>Short-term impacts to visual resources during construction (see Section 3.8.3).</p> <p>Long-term visual impacts associated with the new cooling station.</p>	<p>Same as those common across construction projects (see Section 3.8.4).</p>
Recreation Resources		
	<p>General impacts during construction (see Section 3.9.5). Potential short-term impacts to offshore recreation during installation of the subsurface piping.</p> <p>The short-term impacts could include: (1) restricted access to recreation areas near the area of installation of the underwater piping and on-shore facility and (2) possible visual impairment from areas near the construction of the facilities that could have a negative effect on the ongoing recreational activities.</p>	<p>Sensitive locations should be considered and avoided when locating a cooling station.</p>

Table 4-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Sea Water Air Conditioning (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	No operational impact.	
Land and Marine Transportation		
	<p>General impacts including localized short term traffic impacts during construction and/or if road crossings are needed.</p> <p>Potential short-term (temporary) impacts on harbor operation, local marine transportation, and military marine operations</p> <p>Potential impacts to military submarine operations.</p>	Coordinate with DOD to ensure military submarine operations to minimize or avoid impacts.
Airspace Management		
	None; construction and operation of sea water air conditioning would not require any tall structures and therefore would not impact airspace management.	N/A
Noise and Vibration		
	<p>Short-term noise and vibration impacts during construction. Noise levels could temporarily exceed regulatory levels. Exposure to elevated noise and vibration levels may result in temporary impacts to marine & mammal behavior and marine mammal prey species.</p> <p>No long-term ambient noise or vibration impacts are expected during operation.</p> <p>A positive benefit could be the elimination of noise currently generated from cooling towers as buildings convert to sea water air conditioning systems.</p>	<p>Avoid sensitive receptors for noise and vibration identified in Section 3.12.</p> <p>Restrict loud activities to daytime hours and use mufflers on gas- or air-powered equipment.</p> <p>To reduce the potential for disturbance from acoustic stimuli associated with construction of the sea water intake and effluent pipelines, the following mitigation and monitoring measures for marine mammals could be implemented:</p> <ul style="list-style-type: none"> • temporal restrictions (such as not conducting vibratory pile driving during peak humpback whale season in Hawai‘i) • establishment of an exclusion zone (a buffer to prevent harassment [injury] of any marine mammal species). • pile driving shutdown and delay procedures (if a marine mammal approaches or enters an exclusion zone); • soft-start procedures (a technique that allows marine mammals to leave the immediate area before sound sources reach maximum noise levels);

Table 4-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Sea Water Air Conditioning (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
		<ul style="list-style-type: none"> • in-situ underwater sound monitoring (sound monitoring during sheet pile and test pile driving); and • visual monitoring (an onsite, biologically trained individual approved in advance to monitor sound during pile driving).
Utilities and Infrastructure		
	Potential reduction in energy consumption (may require modification of the utility structure to meet the RPS).	None
Hazardous Materials and Waste Management		
Hazardous Materials	General impacts from exposure to hazardous materials during construction (see Section 3.14.4). No adverse operational impacts.	Same as those common across construction projects (see Section 3.14.5).
Waste Management	General waste management impacts during construction. See Section 3.14.4. No adverse operational impacts.	
Wastewater	General wastewater impacts during construction. No adverse operational impacts. Potential beneficial impacts may occur if wastewater were utilized in place of sea water. This would minimize the amount of wastewater from other sources that would have to be treated by the local municipality.	
Socioeconomics		
	Because construction and operations of a sea water air conditioning system would require a minimal number of workers, there would be no measurable impacts to socioeconomic variables.	None
Environmental Justice		
	Depending on siting, impacts to visual and scenic resources could have the potential to be disproportionately high and adverse with respect to environmental justice communities.	Conduct an evaluation of potential effects to low-income and minority populations.

Table 4-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Sea Water Air Conditioning (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Health and Safety		
	General construction and operation impacts (see Section 3.17.3).	Same as those common across construction and operation activities (see Section 3.17.5).

4.2.1 GEOLOGY AND SOILS

4.2.1.1 Potential Impacts

4.2.1.1.1 Onshore

Potential effects on geology and soils from construction of a sea water air conditioning project would be the same as those expected for common construction actions as described in Section 3.1.3. Drilling or tunneling actions might not be considered common construction actions, but the potential to impact soils through erosion or contamination would be similar, as would the BMPs (refer to Section 3.1.4) that would be implemented to minimize the potential for adverse impacts.

4.2.1.1.2 Offshore

Offshore impacts to geology and soils primarily would be those associated with the disturbance of marine sediments where the trenchless technology used to bury the pipe or pipes opened into the ocean. Impacts to sediments would be expected to be similar to those described in Section 8.2.1 for construction of the land-sea transition zone for undersea cables.

During operations there would be no activities that would have the potential to affect geology and soils of the area, other than the possible disturbance of sediments from the discharge pipe. However, if the discharge pipe were in a location where sediments could be disturbed, it would be expected to occur for only a short period before all sediments that could be affected were moved and a new equilibrium was reached.

4.2.1.2 Best Management Practices and Mitigation Measures

For onshore elements of the technology, the BMPs would be the same as those common across construction projects (see Section 3.1.4).

For offshore elements, the BMPs would be similar to those recommended for construction of the land-sea transition zone for undersea cables (see Section 8.2.1).

4.2.2 CLIMATE AND AIR QUALITY

4.2.2.1 Potential Impacts

Potential impacts to climate and air quality from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.2.4.

A sea water air conditioning system would use electricity from the existing electrical grid to supply power to its pumps, so it would not directly burn fossil fuel.

The use of a sea water air conditioning system would require 75 percent less electricity than a standard cooling system; therefore, there would be a beneficial impact to air quality from a reduction of criteria pollutants resulting from electricity generated by fossil fuels.

All counties within Hawai‘i are in attainment with all criteria air pollutants. However, air quality within Hawai‘i is subject to a variety of Federal and State regulations pertaining to the construction and operation of air emission sources. Refer to the “Air Quality Permits” section within Section 3.2.

4.2.2.2 Best Management Practices and Mitigation Measures

The BMPs for climate and air quality would be the same as those common across construction projects (see Section 3.2.5).

4.2.3 WATER RESOURCES

4.2.3.1 Potential Impacts

4.2.3.1.1 Surface Water

Land-Based Surface Water

Land disturbing actions during project construction would include construction of a cooling station, installation of water delivery and return lines from the cooling station to a drilling site near the ocean, preparation of equipment staging sites, and disturbances at the tunneling or drilling site. These actions would involve disturbance of more than one acre. As a result, potential impacts on land-based surface water from construction of a sea water air conditioning project would be the same as those expected for common construction actions as described in Section 3.3.5.

During operation, there would be no activities that would have the potential to affect surface waters. Due to the nature of the sea water air conditioning system, such a system would only be feasible in an area already built up with nearby facilities that could make use of the cold water product. Accordingly, it is reasonable to assume that the area would already be one with a heavy percentage of impermeable surfaces and the representative project would not be expected to involve any notable change in the amount of runoff generated from the area. Additionally, because the effluent from the cooling system would be discharged back into the marine environment at an appropriate depth, there would not be any expected discharges to surface water associated with normal operations.

Marine-Based Water

At the locations where the submarine breakout pit would be constructed and drilling or tunneling activities reached the ocean, where pipe anchoring devices would be placed, and, as applicable, where pile driving would be performed, ocean sediments would be disturbed and dispersed to some degree.

Potential impacts to marine waters from these actions would be similar to those described in Section 8.2.3 for construction of the land-sea transition zone for undersea cables.

During operation, the sea water air conditioning system would pull cold water from a depth of almost 1,800 feet below the surface, use it for cooling (via a heat exchanger), and return the warmed water to a depth where the sea water would be of similar temperature, possibly as high as about 150 feet below the surface. Although the process would return ocean water back to the ocean with no additives, there could still be issues with the discharge meeting water quality criteria for coastal waters because the ocean water at 1,800 feet below the surface does not meet the criteria. A primary example would be nutrient levels as indicated by nitrite plus nitrate ($\text{NO}_2 + \text{NO}_3$) values. As shown in Figure 3-36, nitrite plus nitrate values at a depth of 1,800 feet would be about 30 micromoles per kilogram, which converts to about 420 micrograms per liter (as nitrogen). The water quality standard set by State regulation ([HAR 11-54](#)) for nitrite plus nitrate is 5.0 micrograms per liter (as nitrogen) in coastal waters where there are significant contributions from fresh water discharges, and 3.5 micrograms per liter (as nitrogen) in areas without significant fresh water contributions. (The standards also set higher concentrations not to be exceeded for specific percentages of the time.) In either case, the discharge from the sea water air conditioning system would be well over the standard and would be expected to be over the standard on a continuous basis.

As indicated in Section 3.3.4.2, other parameters such as phosphate levels would be expected to have vertical distributions similar to that of nitrite plus nitrate nutrients; that is, there would be depleted or very low concentrations in the upper layers where photosynthesis takes place. The State water quality standards include criteria for total phosphorus, so it could also be an issue. Other parameters would have to be similarly evaluated. Increased nutrient levels at depths where photosynthesis occurs could result in changes such as unusual algal blooms ([Konan and Grau 2012](#)). Although algae is a normal component of marine life, increased density in an area (because of increased nutrients) has the potential to affect the existing balance of the area's ecosystem as well as recreational and other uses of the area. As indicated in Section 2.3.1.5, studies are currently underway by the Center for Microbial Oceanography Research and Education to better understand the effects that might be expected from a high nutrient discharge of this nature. Changes in temperature and chlorine levels, as described below, could also affect existing conditions by other mechanisms (see [Section 4.2.4](#) for potential impacts to biological resources).

Temperature would also be a potential problem for the discharge because the ocean's surface mixing layer can vary from less than 100 to nearly 400 feet in thickness depending on the season (see Section 3.3.4.2). At a temperature of about 53°F, the discharge would have to be targeted to a portion of the thermocline below the mixing layer in order to hit ocean water near the same temperature. The temperature of the mixing layer is in the mid to upper 70s °F or higher, and as the thickness of that layer changes (by roughly 300 feet over the course of the year) the thermocline position and gradient changes accordingly. As a result, it is unlikely that any stationary discharge depth could match the ocean temperature year-around and it definitely could not if the discharge point was ever within the mixing layer. The State's water quality standard for coastal waters is that temperatures not vary by more than one degree Celsius (or about two degrees Fahrenheit) from ambient conditions.

In order to meet the State's water quality standards, a zone of mixing (per [HAR 11-54-9](#)) would have to be established and approved under the permitting process for the system's water discharge (that is, under the State's NPDES program per [HAR 11-55](#)). The zone of mixing is a limited area around the discharge outfall where dilution would be allowed. The permit would then stipulate that applicable standards be met at the boundary of the zone of mixing and generally require some type of monitoring for verification. As part of the permitting process, the action proponent would likely have to design a diffuser system for the discharge outfall in order to minimize the size of the zone of mixing and perform modeling to demonstrate compliance could be achieved (with the specific diffuser design and proposed zone of mixing) under all reasonable conditions. If an acceptable zone of mixing could not be established,

alternatives such as treating the water (for example, nutrient removal or temperature adjustment) before discharge would be a consideration (if economically feasible).

4.2.3.1.2 Groundwater

Potential impacts to groundwater from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.3.5.

During long-term operations of the sea water air conditioning system, impacts to groundwater would be limited to the water needs to operate the freshwater system side of the cooling system. That is, the building in the representative project would have a closed-loop, freshwater cooling system that would transfer its heat to the sea water through a non-contact heat exchanger. Since groundwater is the primary source for municipal water systems on the islands, it is assumed the freshwater needs of the project would ultimately come from groundwater, although a cooling system could potentially use water from another source such as gray water or treated wastewater. The amount of freshwater needed by the system would depend on the number and size of connected buildings. Although the initial water demand could be sizeable, it would basically be a one-time need, since the freshwater system would be designed to be a closed loop. This type of water demand would not adversely impact groundwater resources. Occasional freshwater demands resulting from system repairs or expansions would similarly not be expected to have adverse impacts on water availability. If the facility being modified had an open water cooling system, such as one involving use of a water cooling tower to remove heat, there could be significant fresh water savings during operation of a sea water air conditioning system.

4.2.3.1.3 Floodplains and Wetlands

Land activities associated with the representative project would be expected to take place in areas already heavily developed. There would have to be substantial commercial or industrial facilities nearby in order to make a sea water air conditioning system feasible. As a result, if there were floodplains or wetlands in the area, it is unlikely they would be floodplains or wetlands in natural settings or conditions. With regard to floodplains, the project could easily be within or near a beach flood zone, but potential effects and construction considerations would still be those described for common construction actions in Section 3.3.5.

In the event wetlands were present in the area, it is reasonable to assume they would be avoided if at all possible, but if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

Depending on the specific design of the project, a Section 404 permit from the Corps of Engineers would likely also be required for the placement of the delivery and discharge lines on the ocean side of the system. Activities involving discharges of dredged or fill materials into the waters of the U.S. require a Section 404 permit. Although placement of pipes may not be a traditional dredge or fill action, the breakout point for the lines (from the tunneling or drilling actions) could require placement of fill material to stabilize the location and areas along the ocean floor could require similar actions to ensure the pipes were supported and stable. The project would also have to consider Federal Guidelines promulgated at [40 CFR Part 230](#) under [Section 404\(b\)\(1\)](#) of the Clean Water Act and if a project requires a [Section 404 permit](#), only the Least Environmentally Damaging Practicable Alternative (LEDPA) could be permitted. If there was any question about the applicability of a Section 404 permit, discussion with the Corps of Engineers would be the appropriate course of action.

4.2.3.2 Best Management Practices and Mitigation Measures

4.2.3.2.1 Surface Water

Land-Based Surface Water

BMPs for land-based surface water would be the same as those common across construction projects (see Section 3.3.6).

Marine-Based Water

The following BMPs could prevent or reduce the above-discussed impacts:

- Deploy devices at the horizontal directional drilling (HDD) breakout point, such as silt curtains.
- Schedule project activities (sea floor disturbance) during seasonal periods when wave, current, and wind are expected to be low.
- Establish a zone of mixing (per [HAR 11-54-9](#)) in accordance with permit requirements for the system's water discharge or if infeasible, treat water (for example, nutrient removal or temperature adjustment) before discharge.

4.2.3.2.2 Groundwater

BMPs for groundwater would be the same as those common across construction projects (see Section 3.3.6).

4.2.3.2.3 Floodplains

As identified in [Section 4.2.3.1.1](#), discharges back to the ocean from the representative project would require a discharge permit with a zone of mixing stipulation because the discharge would not meet all water quality standards set for coastal waters. Within the zone of mixing, sufficient dilution (from mixing with surrounding water) would occur to ensure water quality standards were maintained outside the zone. According to State Water Quality Standards ([HAR 11-54](#)), there are limitations on establishing mixing zones within marine waters designated as class AA waters. This is more protective of the marine environment (i.e., biota, designated uses) because, if applicable, permitted discharges must meet water quality standards at the point of discharge. Class AA marine waters are not permitted to have zones of mixing in the following instances:

1. At depths of less than 18 meters (59 feet) where there is a defined reef; or
2. At depths greater than 18 meters (59 feet) out to 1,000 feet offshore if there is no defined reef area.

Each of the primary islands addressed in this PEIS includes coastal water designated as class AA water, some of the islands more than others. For example, all of Lāna'i's coastal water has a class AA designation. By percentage of its shore line, O'ahu has the least amount of class AA coastal water. The class AA waters were discussed in Section 3.3.1 and the individual island discussions (Sections 3.3.1.2 through 3.3.1.7) include figures showing the islands with their coastal water designations.

Offshore areas designated class AA waters and meeting either of the criteria identified above would be considered sensitive locations with regard to sea water air conditioning systems because they would not be allowed by regulation. By definition, marine waters given class AA designations are considered

pristine waters deserving additional protective measures. This also means such waters are generally in areas that have had less development on the adjacent land areas, so they may not be areas ever considered for sea water air conditioning systems.

4.2.4 BIOLOGICAL RESOURCES

4.2.4.1 Potential Impacts

Potential impacts to biological resources from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.4.5.

Operational impacts would include discharge of warmed sea water after the heat exchange process. The warmed sea water would be discharged at a depth where the ocean water is approximately the same temperature as the effluent water to avoid altering the local temperature gradient. However, as described in [Section 4.2.3.1.1](#), the depth of the ocean surface mixing layer can vary by approximately 300 feet and therefore the natural ocean temperature would fluctuate. If a fixed outflow pipe occurred within the mixing layer, it would be difficult to match the water temperature of the discharge water with the ocean water throughout the year. The potential extent of temperature effects would depend on the volume of discharge water, the temperature difference between the ocean and discharge water, and the ocean currents that could help effectively dilute the discharge water. Any impact on marine organisms from differences in temperature between the ocean water and discharge water would likely be localized and small. Warmer water temperatures typically increase physiological and biochemical rate processes.

The quality of the discharge water could also be different than that of the surrounding ocean water, causing localized impacts to marine habitats and organisms. The nutrient level (e.g., nitrogen and phosphorus) of the cold intake water at approximately 1,800 feet would be higher than the nutrient level of ocean water at the shallower discharge level. An influx of nutrient rich discharge water could create an area of increased marine productivity and possibly create an area of unusual algal blooms. How large of an effect nutrient enrichment could have on the marine ecosystem would depend on the surrounding marine communities, the volume of discharge water, and the rate of dilution and dispersal of nutrients in the larger volume of ocean water. How ocean microbes, and in turn other higher trophic levels, would respond to an influx of nutrients is an area of active research (<http://cmore.soest.hawaii.edu/microbes.htm>; C-MORE 2014).

As discussed in [Section 4.2.3.1.1](#), the quality of the discharge water, both temperature and chemistry, would be subject to regulatory standards and permitting. The discharge of seawater could also disturb benthic communities through the physical force of the water in the immediate vicinity of the outflow pipe. This impact would be localized and could be mitigated by directing the outflow upward into the water column away from the ocean floor.

The intake pipe would be screened to prevent entrainment of biological organisms in the pipes. Although larger organisms should be effectively excluded, some entrainment of smaller organisms could occur. The actual mesh size for the intake screen is unknown but would likely exclude all but the smallest (e.g., less than an inch) marine organisms.

Sea water air conditioning systems require access to relatively cold waters that usually occur at depths of at least 1,500 feet; therefore, such project should not impact the Hawaiian Islands Humpback Whale National Marine Sanctuary, which is in relatively shallow waters (about 600 feet deep). However, temporary disturbance to benthic communities and marine mammals could occur if the intake pipe were laid through sanctuary waters to access deep water.

4.2.4.2 Best Management Practices and Mitigation Measures

The following best management practice could prevent or reduce the above-discussed impacts:

- The discharge piping should be designed to direct the outflow upward into the water column, away from the ocean floor.
- Establish a zone of mixing (per [HAR 11-54-9](#)) in accordance with permit requirements for the system's water discharge or if infeasible, treat water (for example, nutrient removal or temperature adjustment) before discharge.
- During installation of intake and outflow pipes, avoid sensitive marine habitats such as the Humpback Whale National Marine Sanctuary, coral reefs, and essential fish habitat. However, if an acceptable, alternative seafloor route was not feasible, use of HDD could reduce potential impacts. Select an HDD location onshore that would not impact anchialine pools that have an underground ocean connection and may contain threatened and endangered species.
- Install the outflow pipe at a depth where the expected temperature and nutrient level of the discharged water would most closely match that of the ambient ocean water.

4.2.5 LAND AND SUBMERGED LAND USE

4.2.5.1 Potential Impacts

The cooling stations could result in some minor changes in land use in the form of converting unused land for the use of the cooling stations, the demolition of existing structures to construct the cooling stations, and/or to repurpose existing structures or parking lots. During project construction, there would be temporary land disturbance at the location of the new cooling stations and along the route of the distribution lines to the end users. Once the system is operational, there would be no operational impacts to land use except as related to potential expansions/maintenance of the cooling stations and/or distribution network.

The potential environmental impact to submerged land uses begins with the nexus between the land and the sea. There would be temporary land and sea disturbances during the installation of the deep water intake and the shallower warm water effluent discharge. Maintenance of the pipe and screen would be performed regularly to prevent excessive biofouling and clogging. Automated systems are available for the pipe itself.

4.2.5.2 Best Management Practices and Mitigation Measures

The following best management practice could prevent or reduce the above-discussed impacts:

- The project may be required to obtain the necessary right-of-ways/easements and approvals for construction near and around existing subsurface utilities. The project may also require a lease for submerged lands from the Hawai'i Department of Natural Resources.
- When siting the cooling station and support structures, consider the existing State land use designations and any overlying county zoning districts, including county planning restrictions or guidelines to scenic resources and Coastal Zone Management Area guidelines.

- Given the possible pipeline lengths to meet the cold water temperature requirements, consideration of sensitive locations could include designated aquaculture and fishing areas, coral reefs, dump sites for munitions, undersea cables, and protected natural areas.
- The general designation of Hawai‘i’s commercial marine fisheries is based on geographic areas described in Section 3.5.3.2. Most of the known munitions dump sites are around the island of O‘ahu (see Section 3.5.3.4). Avoidance of such sites would reduce related impacts.
- Avoid or take necessary precautions when siting a project in the vicinity of a submarine telecommunication cable landing. Section 3.5.3.6 and Figure 3-66 provide general locations of these cables and where they make landfall.
- Avoid or take necessary precautions when siting a project in the vicinity of a protected natural area (see Section 3.5.3.7 and Figure 3-67).
- Use bathymetric analyses to help determine the shortest distance to the desired depth, as well as how to avoid interfering with sensitive habitats, including coral reefs, and assist in avoiding or minimizing impacts to fishing and recreational areas and recognizing the locations of undersea cables and munitions dumps.

4.2.6 CULTURAL AND HISTORIC RESOURCES

4.2.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operation of the representative project. In many locations, it is reasonable to expect that onshore surface and offshore archaeological and historic features are present. Sea water air conditioning projects could impact cultural and historic resources in the same manner as general construction and operational activities, which are addressed in Section 3.6.6.

4.2.6.2 Best Management Practices and Mitigation Measures

BMPs for cultural and historic resources are the same as those common across construction and operational projects (see Section 3.6.7).

4.2.7 COASTAL ZONE MANAGEMENT

4.2.7.1 Potential Impacts

A sea water air conditioning system would be of special concern under the Coastal Zone Management Program because it transects across both near onshore and offshore areas, potentially affecting the coastal zone. Assuming the representative project involves Federal agency activities, Federal license or permit activities, and Federal financial assistance activities, the representative project would require a Federal consistency review to ensure that it is consistent with the policies and regulations governing the management and development of the coastal zone. Because the representative seawater air conditioning project would be constructed in the vicinity of relatively large population centers to be economically feasible, the project would likely be consistent with existing uses. Depending on the location of the project, water pipeline installation across the coastline could disturb special management areas that were established to protect specific coastline resources and limit shorefront access.

4.2.7.2 Best Management Practices and Mitigation Measures

The following best management practice could prevent or reduce the above-discussed impacts:

- During site selection, avoid the beach and near offshore areas to minimize impacts to the shoreline.
- Use HDD to avoid the beach and near offshore areas and minimize impacts to the shoreline.

4.2.8 SCENIC AND VISUAL RESOURCES

4.2.8.1 Potential Impacts

Potential impacts to scenic and visual resources from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.8.3. The project may require construction of distribution lines, which would be installed beneath city streets and, therefore, cause short-term impacts to visual resources during construction of the lines.

Long-term visual impacts would be associated with operation of the new cooling station. The representative project would be constructed in an area already near facilities that could make use of the air conditioning. Potential sites for cooling stations include parking lots and unused buildings. For efficiency, the cooling station would be built close to the shoreline to ensure minimal change in the intake seawater temperature. Security lighting would be present but would need to be designed to be compatible with the existing setting.

4.2.8.2 Best Management Practices and Mitigation Measures

The following best management practice could prevent or reduce the above-discussed impacts:

- During site selection, consider sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the four designated scenic byways (three on Hawai‘i and one on Kaua‘i); State, National, and National Historical Parks; and reserves protected by the Natural Area Reserves System.
- Refer to the various land use plans and associated implementation tools, such as zoning ordinances and development standards, for each island for information regarding protecting and maintaining open space and scenic resources.

4.2.9 RECREATION RESOURCES

4.2.9.1 Potential Impacts

Potential impacts to recreation resources from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.9.3. In addition, depending on its location, some short-term impacts to offshore recreation could occur during installation of the subsurface piping. The short-term impacts could include: (1) restricted access to recreation areas near the area of installation of the underwater piping and on-shore facility and (2) possible visual impairment from areas near the construction of the facilities that could have a negative effect on the ongoing recreational activities.

Long-term impacts to recreation associated with the new cooling station or seawater intake are not anticipated.

4.2.9.2 Best Management Practices and Mitigation Measures

During site selection, consider locations of land-based and water-based recreation activities (Tables 3-47 and 3-48, respectively). The *State Comprehensive Outdoor Recreation Plan* (SCORP) provides detailed matrixes of all recreation areas on each island and the recreational activities that take place at each area ([DLNR 2009](#)).

4.2.10 LAND AND MARINE TRANSPORTATION

4.2.10.1 Potential Impacts

Potential impacts to land and marine transportation from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.10.3.

Any impacts to land transportation systems would be localized around the specific construction site and could involve temporary disruption of traffic if road crossings were needed. Depending on the specific project location, there could be temporary impacts on harbor operation, local marine transportation, and military marine operations during installation of the deep seawater intake pipe and the shallower outflow pipe.

Because the intake and outflow pipes would be near or on the ocean floor, no impacts to surface marine transportation would occur during operation of the seawater air conditioning system. However, the pipes would be taking in and releasing relatively large volumes of water and could potentially impact U.S. military submarine operations; any such impact would need to be coordinated with DoD dependent on the specific siting of the facility and associated piping.

4.2.10.2 Best Management Practices and Mitigation Measures

Coordinate with the U.S. Department of Defense to avoid or minimize potential impacts to military submarine operations.

4.2.11 AIRSPACE MANAGEMENT

As identified in [Table 4-2](#), there would be no potential impacts to airspace management from the representative sea water air conditioning project.

4.2.12 NOISE AND VIBRATION

4.2.12.1 Potential Impacts

Short-term noise and vibration impacts could result from the construction of a sea water air conditioning cooling station and associated underwater intake and outflow pipes. Local noise ordinances described in Section 3.12 could be temporarily exceeded during construction, which would require a permit variance, and construction noise outside of permitted hours could occur ([DBEDT 2009](#)). Offshore construction noise from equipment and vessels used to place pipes, and vibration caused by pile-driving, could exceed regulatory levels. Such noise could indirectly impact scenic and visual resources, recreation resources, cultural resources, worker health and safety, and possibly public health. Further, according to the Incidental Harassment Authorization ([77 FR 43259; July 24, 2012](#)) exposure to elevated sound levels

from vibratory and impact pile driving may result in temporary impacts to marine mammal hearing and behavior. However, in its Biological Opinion for the Issuance of an Incidental Harassment Authorization to Honolulu Seawater Air Conditioning, LLC to Take Marine Mammals by Harassment Incidental to Pile Driving Offshore Honolulu, the NMFS stated that it does not expect any takes of marine mammals by injury, serious injury, or mortality. Marine mammal prey species, such as fish, may also be temporarily impacted ([NMFS 2012](#)).

No long-term ambient noise or vibration impacts are expected during operation of the representative seawater air conditioning system. A positive benefit could be the elimination of noise currently generated from cooling towers as buildings convert to seawater cooling systems ([DBEDT 2009](#)).

4.2.12.2 Best Management Practices and Mitigation Measures

The following recommended BMPs could reduce the potential disturbances from noise and vibration ([NMFS 2012](#)):

- Temporal restrictions (such as not conducting vibratory pile driving during peak humpback whale season in Hawai‘i);
- Establishment of an exclusion zone (a buffer to prevent harassment [injury] of any marine mammal species);
- Pile driving shutdown and delay procedures (if a marine mammal approaches or enters an exclusion zone);
- Soft-start procedures (a technique that allows marine mammals to leave the immediate area before sound sources reach maximum noise levels);
- In-situ underwater sound monitoring (sound monitoring during sheet pile and test pile driving); and
- Visual monitoring (an onsite, biologically trained individual approved in advance to monitor sound during pile driving).

Additional BMPs include the following:

- Avoid sensitive receptors for noise and vibration (identified in Section 3.12).
- Restrict loud activities to daytime hours and use mufflers on gas- or air-powered equipment to reduce impacts from noise exceedances.

4.2.13 UTILITIES AND INFRASTRUCTURE

4.2.13.1 Potential Impacts

Pumps and other equipment in the cooling station would require relatively small amounts of electricity. Localized electricity demands would increase and impacts would depend on the capacity available at proposed site locations. However, a typical sea water air conditioning project integrated into a district cooling system would reduce regional electricity demands for air conditioning by up to 75 percent (77.5 million kilowatts per year) (see Section 2.3.1.5.2). The overall impact from the representative sea

water air conditioning project would be a beneficial decrease in total electrical power consumption by the facilities that connected to the sea water air conditioning system.

4.2.13.2 Best Management Practices

None noted.

4.2.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

4.2.14.1 Potential Impacts

4.2.14.1.1 Hazardous Materials

Potential impacts from exposure to hazardous materials from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.14.4.

Impacts during operation of the representative sea water air conditioning facility are not anticipated to involve hazardous materials. As opposed to conventional cooling, which may employ refrigerants; sea water air conditioning systems require only sea and fresh water. As such, it is not anticipated that chemicals would be used during project operations.

4.2.14.1.2 Waste Management

Potential impacts to groundwater from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.3.5.

Impacts related to waste management would be from the construction and installation of the pipeline, distribution lines, and the cooling station. Such impacts are typical of pipeline construction projects and are discussed in Section 3.14.4.

4.2.14.1.3 Wastewater

Potential wastewater impacts would occur during the release of effluent during operation of the sea water air conditioning facility. As noted in Section 2.3.1.5, the representative project would be in a zone of mixing,¹ which would require diluting the return sea water to a specified water quality standard. All wastewater discharge would be required to comply with applicable, Federal, State, and County requirements including NPDES permit requirements.

A potential beneficial impact of the sea water air conditioning facility is the ability to reuse treated wastewater discharge in its closed-loop system (in place of fresh water); it could therefore reduce the volume of wastewater discharged from cooling towers that would otherwise require processing at a municipal treatment plant.

4.2.14.2 Best Management Practices and Mitigation Measures

The following best management practice could prevent or reduce the above-discussed impacts:

¹ The purpose of a “zone of mixing” is to allow a discharge that would not initially meet water quality standards to be diluted to comply with appropriate standards within a reasonable distance. Without a “zone of mixing” no wastewater outfalls or discharges of generating station cooling waters would be permitted.

- During the siting process, review public records and perform site inspections to identify possible hazardous materials that may be present. See Section 3.14.1.2 for a list of known contaminated sites.
- Remove suspended particulates from the effluent and meet all other permit requirements prior to discharge.
- Treat wastewater using settling ponds or tanks, filtration systems, or both and test the effluent to ensure that discharges meet general water quality and toxic contaminant parameter requirements. See [Section 4.2.3](#) above for the discussion on discharge requirements.
- Perform regular maintenance on pipes and screens to prevent excessive biofouling and clogging.

4.2.15 SOCIOECONOMICS

4.2.15.1 Potential Impacts

Socioeconomic impacts in Hawai'i arising from a sea water air conditioning system would be very small. The 63-inch pipe, the cooling station apparatus, and the cooling station pumps likely would be manufactured outside of the State. Installation of the pipelines and construction of the cooling stations would require about 20 temporary positions and operation of the facility would require about 5 full-time workers. These positions likely would be filled by individuals residing within the State of Hawai'i and not by in-migrating workers. There would be little to no impact on population employment variables, such as the size of the labor force, unemployment rates, and employment in the State and county government sector; housing and living conditions; and personal income.

Long-term impacts to the State's tourism industry from the presence of a cooling station near the beach of population-dense areas are unknown.

4.2.15.2 Best Management Practices

None noted.

4.2.16 ENVIRONMENTAL JUSTICE

4.2.16.1 Potential Impacts

Depending on siting, impacts to visual and scenic resources could have the potential to be disproportionately high and adverse with respect to environmental justice communities.

The likelihood of significant environmental impacts from this technology is small. The likelihood for environmental justice impacts would equally be small.

4.2.16.2 Best Management Practices and Mitigation Measures

During site selection, conduct a study to determine the specific location of low-income and minority populations, specifically Native Hawaiians, and determine whether there would be disproportionately high and adverse impacts to such populations.

4.2.17 HEALTH AND SAFETY

4.2.17.1 Potential Impacts

Common potential impacts from typical construction activities are identified in Section 3.17.3. There would be no unique hazards or accident scenarios for sea water air conditioning.

4.2.17.2 Best Management Practices and Mitigation Measures

Common BMPs for typical construction activities are identified in Section 3.17.5.

4.3 Solar Water Heating

The solar water heating representative project is the installation of a residential solar water heater system with a 40-square-foot collector. The water would circulate between the collector and a 120-gallon storage tank located in the home, in place of the conventional water tank. Since freezing is not a concern in Hawai‘i, the system would utilize direct circulation, where the water itself is heated, rather than indirect circulation, which uses a heat-transfer fluid and a heat exchanger. Because the system itself would require electricity to run its pumps and control system, the collector would use photovoltaic modules to power the pumps and controls. The components for the representative project would be on the roof and interior of the house. Pipes would run from the rooftop collector to the tank through existing crawlspaces or under the eaves of the roof, and the tank would connect to existing plumbing.

[Table 4-3](#) presents a summary of the potential environmental impacts for solar water heating, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of this technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 4-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Solar Water Heating

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to geology and soils.	N/A
Climate and Air Quality		
Air Quality	Beneficial – potential air emissions reductions.	None.
Climate Change	Beneficial – greenhouse gas emissions reduction.	None.
Water Resources		
	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to water resources.	N/A

Table 4-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Solar Water Heating (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Biological Resources		
	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to biological resources.	N/A
Land and Submerged Land Use		
	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to land use.	N/A
Cultural and Historic Resources		
	Potentially adverse visual or architectural context impact to historic properties.	<p>Prior to installation of a solar water heater, resources should be identified and evaluated for their eligibility to the HRHP and the NRHP.</p> <p>In accordance with State law, if a historic property or structure that is listed or eligible for listing on the HRHP and/or NRHP is proposed for energy retrofits, the project proponent must complete and submit a Historic Preservation Review Form in compliance with HRS Chapter 6E such that the modifications may be reviewed and approved prior to project implementation.</p> <p>Comply with <i>The Secretary of the Interior's Standards for the Treatment of Historic Properties with Guidelines for Preserving, Rehabilitating, Restoring and Reconstructing Historic Buildings</i> (DOI 2011).</p>
Coastal Zone Management		
	None; installation of solar water heating units would typically be done on rooftops and therefore would be required to comply with CZMA.	N/A
Scenic and Visual Resources		
	Potential visual impacts due to visibility including to historic resources (site-specific).	Solar modules should be located to limit visibility and reduce potential visual impacts.
Recreation Resources		
	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to recreation resources.	N/A

Table 4-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Solar Water Heating (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Land and Marine Transportation		
	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to land and marine transportation.	N/A
Airspace Management		
	None; installation of solar water heating units would typically be done on rooftops but not result in any tall structures that could impact airspace.	N/A
Noise and Vibration		
	Same as those common among construction and operation projects (see Section 3.12.5).	Same as those common across construction projects (see Section 3.12.5).
Utilities and Infrastructure		
	Decrease in energy consumption. No significant impacts to utilities or infrastructure.	None.
Hazardous Materials and Waste Management		
Hazardous Materials	Potential impacts from exposure to hazardous materials encountered during installation including: asbestos materials, lead-based paint, polychlorinated biphenyls, and/or arsenic.	Perform surveys prior to installation to identify any areas in homes containing asbestos materials, lead-based paint, polychlorinated biphenyls, and/or arsenic. Perform all installations by trained and certified professionals. If areas are found to be contaminated, trained and certified abatement personnel would follow proper abatement procedures and remediation activities to comply with State and Federal OSHA and county air quality district requirements.
Waste Management	Potential impacts to waste management services from hazardous demolition debris waste during installation. Potential landfill impacts.	Consideration should be given to development and implementation of a recycling plan. A recycling program would effectively recover building materials that could contain potentially hazardous materials and substances (e.g., liquid wastes, paints, oil, and solvents).
Wastewater	None.	N/A
Socioeconomics		
	Beneficial – few jobs created.	None.

Table 4-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Solar Water Heating (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Environmental Justice		
	None; negligible adverse impacts to environmental resources. Therefore, no disproportionately high and adverse impacts to minority or low-income population.	N/A
Health and Safety		
	Potential worker exposure to hazardous materials including: asbestos materials, lead-based paint, polychlorinated biphenyls, and/or arsenic.	Handle and dispose of materials appropriately to ensure minimal exposure to hazardous materials.

4.3.1 GEOLOGY AND SOILS

As identified in [Table 4-3](#), there would be no potential impacts to geology and soils from the representative solar water heating project.

4.3.2 CLIMATE AND AIR QUALITY

4.3.2.1 Potential Impacts

The representative solar water heating system could save up to 90 percent of the electricity used in a conventional electrical water heating system, translating to an annual energy savings of about 2,800 kilowatt-hours per house (90 percent of 3,120 kilowatt-hours per year). A reduction of 2.8 megawatt-hours of electricity per year would reduce oil consumption from electricity generation by about 190 gallons per residential unit. On O’ahu, this would correspond with an annual reduction in greenhouse gas emissions of about 2.0 metric tons carbon dioxide equivalent per house based on EPA eGrid2012 emission factors. On other islands, an annual reduction of 2,800 kilowatt-hours of electricity usage per house would correspond to an annual reduction in greenhouse gas emissions of about 1.7 metric tons carbon dioxide equivalent due to a cleaner mix of technologies used to produce electricity on the islands.

4.3.2.2 Best Management Practices and Mitigation Measures

None noted.

4.3.3 WATER RESOURCES

As identified in [Table 4-3](#), there would be no potential impacts to water resources from the representative solar water heating project.

4.3.4 BIOLOGICAL RESOURCES

As identified in [Table 4-3](#), there would be no potential impacts to biological resources from the representative solar water heating project.

4.3.5 LAND AND SUBMERGED LAND USE

As identified in [Table 4-3](#), there would be no potential impacts to land or submerged land use from the representative solar water heating project.

4.3.6 CULTURAL AND HISTORIC RESOURCES

4.3.6.1 Potential Impacts

The representative solar water heating project involves installation on existing residences, so no impacts to archaeological sites would be expected. There is the possibility that installing a solar water heater in buildings or residences that are listed or eligible for listing on the *Hawai'i Register of Historic Places* (HRHP) or the *National Register of Historic Places* (NRHP), and/or are located in a historic district, would change the characteristics of the property such that the historic nature of the property would be altered. The alterations may have an adverse visual or architectural context impact to the historic property. Solar water heater system installation could affect residences and other buildings that not only qualify as historic properties but also as cultural resources whose alterations may require coordination with the OHA's Native Hawaiian Historic Preservation Council in accordance with applicable regulatory consultation requirements.

4.3.6.2 Best Management Practices and Mitigation Measures

The following best management practice could prevent or reduce the above-discussed impacts:

- Prior to installation of a solar water heater, identify and evaluate resources for eligibility to the HRHP and the NRHP.
- In accordance with State law, if a historic property or structure that is listed or eligible for listing on the HRHP and/or NRHP is proposed for installation of a solar water heater, the project proponent must complete and submit a Historic Preservation Review Form in compliance with [HRS Chapter 6E](#) such that the modifications may be reviewed and approved prior to project implementation.
- Historic resources that are listed on the HRHP or NRHP, such as buildings, sites, and structures would be considered sensitive locations regarding possible modifications from energy efficiency retrofits and may require retrofit design approval in coordination with the SHPO.
- Comply with *The Secretary of the Interior's Standards for the Treatment of Historic Properties with Guidelines for Preserving, Rehabilitating, Restoring and Reconstructing Historic Buildings* ([DOI 2011](#)), which allow for changes such as energy retrofits and installation of water heaters and photovoltaic panels while ensuring retention of historic characteristics.

4.3.7 COASTAL ZONE MANAGEMENT

As identified in [Table 4-3](#), there would be no potential impacts to coastal zone management from the representative solar water heating project.

4.3.8 SCENIC AND VISUAL RESOURCES

4.3.8.1 Potential Impacts

A residential solar water heating system can typically be installed in one day without any disruptions to the property and limited onsite construction. Therefore, visual impacts during installation of a system would be minimal.

Long-term visual impacts from the installation could include the sight of solar modules on rooftops and required piping along external walls. However, because solar water heating systems are common in Hawai'i, visual sensitivity to these systems is likely lower than in areas where they are not common. Further, the State of Hawai'i has mandated that all newly constructed single-family homes include solar water heaters (Act 204). Therefore, installers are more accustomed to placing solar heaters and associated hardware inconspicuously; i.e., under eaves, in the attic crawl spaces, or elsewhere that would lessen the visibility of these project components to the public.

The site of solar water heaters on residences near National and State parks would be unlikely to adversely impact park visitors or administration because these parks use such water heaters.

4.3.8.2 Best Management Practices and Mitigation Measures

The following best management practice could prevent or reduce the above-discussed impacts:

- The solar modules should be placed to limit visibility and reduce potential visual impacts, while remaining optimally positioned to receive the maximum solar exposure.
- During placement, consider the proximity to listed or eligible historic sites and the potential for solar water heating systems to change the historic character of an area. [Section 4.3.6](#) provides impact information for cultural and historic resources. Solar water heaters are used in National Parks and State Parks in Hawai'i. Thus, the visual impact of residential solar equipment on parks is likely to be negligible as it would be similar to having it in the park itself, which is acceptable to the park administration.

4.3.9 RECREATION RESOURCES

As identified in [Table 4-3](#), there would be no potential impacts to recreation resources from the representative solar water heating project.

4.3.10 LAND AND MARINE TRANSPORTATION

As identified in [Table 4-3](#), there would be no potential impacts to land or marine transportation from the representative solar water heating project.

4.3.11 AIRSPACE MANAGEMENT

As identified in [Table 4-3](#), there would be no potential impacts to airspace management from the representative solar water heating project.

4.3.12 NOISE AND VIBRATION

4.3.12.1 Potential Impacts

The representative solar water heaters project would involve installation on a rooftop and could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

4.3.12.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across construction projects (see Section 3.12.6).

4.3.13 UTILITIES AND INFRASTRUCTURE

4.3.13.1 Potential Impacts

For all Hawaiian Islands, the impact of converting each home to solar water heating would be a savings of up to approximately 2.8 megawatt-hours per year (see Section 2.3.1.6) and corresponding drop in overall demand for the local utility. These changes would contribute to the downward trend in the total annual electricity consumption and, by themselves, would not result in a significant impact to the utilities and infrastructure. On all islands, such changes would contribute to the need to modify the overall utility structure to meet the requirements of Hawai‘i’s RPS (refer to [HECO 2013](#)).

4.3.13.2 Best Management Practices and Mitigation Measures

None noted.

4.3.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

4.3.14.1 Potential Impacts

4.3.14.1.1 Hazardous Materials

The representative project involves the installation of solar water heaters in existing homes; therefore, there would be no impacts from new construction.

There would be no exposure to hazardous materials associated with operation of a solar water heater system.

4.3.14.1.2 Waste Management

The representative project would involve new construction that could result in demolition debris. Potential impacts to waste management services could occur during project construction/retrofitting, as special handling and disposal of materials may be required.

There would be no waste generated during operation of a solar water heater system.

4.3.14.1.3 Wastewater

The representative project would not result in impacts from or to wastewater.

4.3.14.2 Best Management Practices and Mitigation Measures

The following best management practice could prevent or reduce the above-discussed impacts:

- Prior to installation of the solar water heaters, perform surveys to identify any areas in homes containing asbestos materials, lead-based paint, polychlorinated biphenyls, and/or arsenic.
- Have solar water heaters installed by trained and certified professionals. If areas are found to be contaminated, trained and certified abatement personnel would follow proper abatement procedures and remediation activities to comply with State and Federal OSHA and county air quality district requirements.
- Follow proper handling, abatement, and disposal procedures and activities to comply with State and Federal requirements.

4.3.15 SOCIOECONOMICS

4.3.15.1 Potential Impacts

Socioeconomic impacts in Hawai‘i arising from the expanded use of solar water heating systems would be very small. The collection apparatus, pumps and controls, water tanks, piping, and, if used, photovoltaic modules could be manufactured within the State and, if so, the economic benefits associated with manufacturing would be small and accrue locally. Although Hawai‘i has a very small manufacturing base, light industry production of related equipment is feasible. As the number of households utilizing solar water heating systems increases, the number of jobs associated with installation and maintenance of the systems would grow too, but net new jobs created would be small. Jobs directly associated the manufacture of system components, installation of the system, and maintenance of solar water heating systems likely would be filled by individuals residing within the State of Hawai‘i and not by in-migrating workers. There would be little to no impacts on population employment variables, such as the size of the labor force, unemployment rates, and employment in the State and county government sector; housing and living conditions; and personal income. There would be beneficial impacts to the homeowner since, over time, their initial cost investment for the solar water heating system would be recouped and they would then realize cost savings from reduced power usage.

4.3.15.2 Best Management Practices and Mitigation Measures

None noted.

4.3.16 ENVIRONMENTAL JUSTICE

As identified in [Table 4-3](#), there would be no environmental justice impacts from the representative solar water heating project.

4.3.17 HEALTH AND SAFETY

4.3.17.1 Potential Impacts

Installation would require minor construction on the roof and the interior of a house, during which workers may encounter asbestos, lead-based paint, polychlorinated biphenyls, and/or arsenic. Exposure to such hazardous material could result in harmful health effects including cancer. Common potential impacts from typical construction activities are identified in Section 3.17.3.

4.3.17.2 Best Management Practices and Mitigation Measures

Common potential BMPs for typical construction activities are identified in Section 3.17.3. Additionally, contractors involved in the installation should handle and dispose of materials appropriately to ensure minimal exposure to hazardous materials.

5 ENVIRONMENTAL IMPACTS FROM DISTRIBUTED RENEWABLES

This chapter presents the potential environmental impacts from the distributed renewable energy technologies presented in Chapter 2, Section 2.3.2. Distributed scale projects could range from single family residences to larger commercial uses. The representative projects described in Section 2.3.2 were used to estimate the potential environmental impacts for each technology. The description of each technology within Section 2.3.2 includes a discussion of the differences between nameplate capacity and actual capacity based on efficiency and the range of typical capacity factors for that technology. Chapter 5 discusses how the impacts would scale (for example, linearly, exponentially, or not at all) for the range of potential technology applications to aid the reader in understanding the effects of smaller or larger projects and how impacts could change based on the size of the technology implemented.

The potential impacts are presented for each environmental resource area. As was described in Chapter 3 of this PEIS, many of the activities and technologies could result in environmental impacts that would be common of typical construction projects and may not be unique to the specific activity or technology. In these cases, the presentation of potential impacts in this chapter refers the reader to the appropriate section in Chapter 3 that presents these common impacts for that resource area. Therefore, the details in this chapter deal primarily with those impacts that would be unique to the specific activity or technology being evaluated.

Each of the sections below includes a summary table of the potential environmental impacts and best management practices for that technology. Not all technologies have the potential to impact all environmental resource areas analyzed in this document. Therefore, the summary table for each technology also identifies and screens those resource areas that are not expected to be impacted by that technology. This approach is consistent with DOE's sliding scale approach to the preparation of NEPA analyses.

5.1 Biomass

The representative distributed biomass energy project would involve the direct combustion of biomass in a steam boiler to produce steam for electricity generation and industrial steam (see Section 2.3.2.1). Biomass projects typically would not be used for residential applications; therefore, the representative project would produce about 50 kilowatts (0.05 megawatt) of electricity for commercial/industrial use. Construction of a 50-kilowatt project plant would require clearing, grading, and leveling an area of about 2 to 4 acres for the boiler and turbine building, biomass handling and feed system, and construction space, with an additional 1 to 2 acres for the extension of water and sewer lines and possibly new access road.

The boiler unit(s) would use a fibrous residue biomass material from either an agricultural or forest source. Biomass feedstock would be supplied by nearby sources either produced specifically for the electricity end user or from local commercial biomass producers. In either case, this PEIS assumes that the biomass is a crop residue produced as part of an existing operation and does not consider potential impacts from the biomass production, nor impacts from agricultural conditions related to water, fertilizer runoff, pesticide and herbicide use, or air emissions. (These impacts are evaluated for a larger scale project in Section 6.1 for utility-scale biomass projects.) Transportation of the biomass feedstock from the supplier to the biomass plant would be local and for relatively short distances (up to 5 miles).

[Table 5-1](#) presents a summary of the potential environmental impacts for biomass energy projects, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and best management practices and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 5-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	<p>General impacts during construction (short-term) (see Section 3.1.3).</p> <p>No impacts during operation.</p>	<p>Same as those common across construction projects (see Section 3.1.4).</p>
Climate and Air Quality		
Air Quality	<p>Burning of biomass at a biomass energy project would emit criteria pollutants. Additionally, the transport of the biomass feedstock would result in emissions from trucks and harvesting equipment.</p>	<p>Project design should incorporate a high efficiency combustion and boiler system to operate at or near design capacity.</p>
Climate Change	<p>Potential greenhouse gas impacts pending EPA ruling and dependent on project size (project-specific).</p> <p>Potentially beneficial impacts as a result of replacing fossil fuels for the production of electricity; thereby reducing greenhouse gas emissions.</p>	<p>Application of control technology to the project to reduce emissions during project operations (example: dust collectors to reduce particulate matter emissions).</p>
Water Resources		
Surface Water	<p>General impacts during construction (short-term) (see Section 3.3.5).</p> <p>Potential surface water impacts during operations (increased stormwater runoff).</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p>
Groundwater	<p>General impacts during construction (short-term) (see Section 3.3.5).</p> <p>Potential water resource impacts depending on design and use of groundwater.</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p>
Floodplains and Wetlands	<p>Minimal to no potential for common construction impacts (see Section 3.3.5).</p>	<p>None.</p>
Biological Resources		
	<p>Impacts common to construction and operations activities are identified in Section 3.4.5.</p> <p>Potential impacts to terrestrial wildlife and protected plants and animals during construction of the boiler, turbine, and local infrastructure.</p> <p>Potential impacts to terrestrial plants and wildlife from biomass production.</p> <p>Potential lighting impacts on flights of marine birds, such as shearwaters and petrels (site-specific).</p>	<p>Best management practices common to construction and operations activities are identified in Section 3.4.6.</p> <p>Design lighting and routine operations to minimize lighting needs.</p>

Table 5-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Land and Submerged Land Use		
Land Use	Potential land use impacts (site-specific).	During site selection, evaluate the State land use designations and county overlay zones.
Submerged Land Use	None; this technology would be terrestrial based and would not involve submerged lands.	N/A
Cultural and Historic Resources		
	General impacts during construction and operation (see Section 3.6.6).	Same as those common across construction projects (see Section 3.6.7).
Coastal Zone Management		
	Potential coastal zone impacts to special management areas, shorefront access, or shoreline erosion (project/site-specific).	Specific project locations should be evaluated to determine if impacts to special management areas designated under the Coastal Zone Management Program, shorefront access, and shoreline erosion would occur.
Scenic and Visual Resources		
	General impacts during construction (short-term) (see Section 3.8.3). Potential long-term visual impacts from outdoor and security lighting and visual character of project location (site-specific).	Same as those common across construction projects (see Section 3.8.3).
Recreation Resources		
	None; the biomass facility would be located near the commercial/industrial electricity users and would be compatible with existing land uses, which would not include recreation.	N/A
Land and Marine Transportation		
Land Transportation	Potential localized roadway and traffic impacts from increased truck traffic associated with biomass feedstock.	To the extent feasible, private roads should be utilized to minimize traffic impacts. Cover trucks to contain dust and to keep biomass material from falling out.
Marine Transportation	None; a small distributed biomass energy power generation project would not be expected to require nor effect marine transportation. Biomass would be obtained locally.	N/A

Table 5-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Airspace Management		
	None; a small distributed biomass energy power generation facility would not have an emission stack tall enough or produce a thermal plume large enough to cause an aviation hazard.	N/A
Noise and Vibration		
	Industrial noise would be produced from operation of the biomass handling facilities and removal of ash waste. Noise from the steam boilers and turbines mostly would be contained within the buildings.	Best management practices would be the same as those commonly implemented for construction and operation (see Section 3.12.6).
Utilities and Infrastructure		
	Minor impacts to electricity generating capacities. General impacts during construction and operation (see Section 3.13.3).	Same as those common across construction projects (see Section 3.13.4).
Hazardous Materials and Waste Management		
Hazardous Materials	General exposure impacts during construction and operation (see Section 3.14.4).	Same as those common across construction projects (see Section 3.14.5).
Waste Management	Potential waste management impacts related to ash disposal.	Same as those common across construction projects (see Section 3.14.5).
Wastewater	Potential wastewater contamination from trace chemicals and elevated temperatures.	Use settling ponds or filtration systems to meet NPDES wastewater discharge permit requirements.
Socioeconomics		
	Few operation and construction jobs created and economic benefits.	None.
Environmental Justice		
	Dependent on potentially adverse impacts to other resources in adjacent and nearby areas (site-specific).	Conduct an evaluation of potential effects to low-income and minority populations.
Health and Safety		
	General impacts during construction and operation (see Section 3.17.3).	None.

5.1.1 GEOLOGY AND SOILS

5.1.1.1 Potential Impacts

Potential impacts on geology and soils from construction of the 50-kilowatt steam boiler and associated facilities for the representative distributed biomass energy project would be the same as those expected for common construction actions as described in Section 3.1.3. The project would involve disturbance of 3 to 6 acres of land, so the permitting requirements described in Section 3.1.3 would be fully applicable.

Operation of the biomass boiler and steam turbine would not involve activities that would have the potential to affect geology and soils of the area.

Potentially sensitive areas with regard to impacting geology and soils or for the project to be affected by geology-related hazards would be the same as those described in Section 3.1.3.

5.1.1.2 Best Management Practices and Mitigation Measures

Best management practices for geology and soils would be the same as those common across construction projects (see Section 3.1.4).

5.1.2 CLIMATE AND AIR QUALITY

5.1.2.1 Potential Impacts

Potential impacts to climate and air quality from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.2.4.

5.1.2.1.1 Air Quality

The burning of biomass at a biomass energy project would emit nitrogen dioxide, particulate matter, carbon monoxide, sulfur dioxide, and carbon dioxide. The total amount of emissions would vary depending on the amount of material burned and its heating value. According to the EPA's *Compilation of Air Pollutant Emission Factors* (AP-42) Section 1.6, "Wood Residue Combustion in Boilers," the emission factors for nitrogen oxide range from 0.22 to 0.49 pounds per million British thermal unit (MMbtu) of heat input (EPA 2014). The maximum emission factors for particulate matter, carbon monoxide, sulfur dioxide, and carbon dioxide are 0.56, 0.60, 0.025, and 195 pounds per MMBtu of heat input, respectively.

In many cases, the biomass would be prepared (e.g., ground, chipped, dried, and sorted) offsite as part of the biomass production process and delivered to the power plant as a finished product. Onsite handling of biomass would be limited to storage and furnace/boiler feeding systems. Consequently, the impacts related to particulate matter emissions would need to be considered at the specific offsite locations.

Transport of the biomass feedstock from its source to the boilers would produce criteria pollutants from trucks and harvesting equipment. The total amount of emissions from transport of feedstock would depend upon the number and types of trucks used and the miles traveled. Published data for heavy duty diesel trucks show emission factors of 0.028, 0.0013, 0.0093, 0.000041, and 4.2 pounds per mile traveled for nitrogen oxide, particulate matter, carbon monoxide, sulfur dioxide, and carbon dioxide, respectively (<http://www.aqmd.gov/ceqa/handbook/onroad/onroad.html>; AQMD 2008).

5.1.2.1.2 Climate Change

Operation of a biomass facility would generate carbon dioxide, a greenhouse gas. Historically, carbon dioxide emissions from biomass facilities have been considered to be carbon neutral, but the premise of carbon neutrality during the burning of biomass is an unsettled issue. The basis for the premise is that as long as biomass resources are managed sustainably (that is, the annual amount of the biomass resource grown is greater or equal to the annual amount burned), the combustion of harvested materials presents no net increase of carbon to the ongoing carbon cycle. Therefore, the burning of biomass would not be considered an increase in greenhouse gas emissions. By comparison, the combustion of fossil fuels such as oil emits carbon that has been out of the current carbon cycle for millennia and therefore would contribute to an increase in greenhouse gas emissions. In January 2011, the EPA announced its plans to defer for three years the greenhouse gas permitting requirements for carbon dioxide emissions from biomass-fired boilers in order to seek further independent scientific analysis of the complex issue. On July 12, 2013, the U.S. Court of Appeals, D.C. Circuit, Case No. 11-1101 (*Center for Biological Diversity vs EPA 2013*) vacated the deferral by ruling that it could not be justified under any of the administrative law doctrines relied on by EPA ([CADC 2013](#)). Consequently, EPA is developing final permitting rules for biogenic carbon dioxide emissions. With the continuing lack of permitting rules concerning burning biomass and the uncertainty of the carbon neutrality of biomass energy, this PEIS includes, as one part of the impact analysis, the assumption that all reductions in the amount of oil burned will be reflected in a reduction of carbon dioxide and greenhouse gas emissions.

Under the representative project, a replacement of 350 megawatt-hours of electricity per year (Chapter 2) from the baseline electrical grid would reduce oil consumption from electricity generation by about 23,000 gallons. On O‘ahu, the annual replacement of 350 megawatt-hours of electricity from the baseline grid and the corresponding reduction in the use of oil would correspond with an annual reduction in greenhouse gas emissions of about 250 metric tons carbon dioxide equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid>; [EPA 2012](#)). On other islands, similar annual replacement of electricity usage from the baseline grid would see an annual reduction in greenhouse gas emissions of about 220 metric tons carbon dioxide equivalent due to a different mix of technologies used to produce electricity on the other islands.

Note: The EPA eGrid2012 “Year 2009 GHG Annual Output Emission Rates” lists emission factors for estimating greenhouse gas emissions from electricity generation ([EPA 2012](#)). The site contains one set of emission factors for the island of O‘ahu and a different set of emission factors for the other islands due to their different mix of technologies used in electricity production.

5.1.2.2 Best Management Practices and Mitigation Measures

Best management practices that could minimize potential air impacts include using a boiler system that is designed to achieve high combustion and boiler efficiency and can operate close to its design capacity and applying control technology to reduce emissions during operation of the facility (such as dust collectors to reduce particulate matter emissions). Air quality permits would be required before construction and operation of a biomass steam boiler to insure compliance with all local and Federal air quality regulations.

The following mitigation measures should be taken to minimize the identified potential impacts:

- Project design should incorporate a high-efficiency combustion and boiler system to operate at or near design capacity.

- The project would apply control technology to reduce emissions during project operations (example: dust collectors to reduce particulate matter emissions).

5.1.3 WATER RESOURCES

This section addresses potential environmental impacts to water resources from the representative distributed biomass energy project. The impacts are presented in terms of surface water, groundwater, and floodplains and wetlands.

5.1.3.1 Proposed Impacts

5.1.3.1.1 Surface Water

Effects on surface water from construction of the 50-kilowatt steam boiler and associated facilities would be the same as those expected for common construction actions as described in Section 3.3.5. The project would involve disturbance of 3 to 6 acres of land, so the permitting requirements described in Section 3.3.5 would be fully applicable.

During operation there likely would be no activities that would have the potential to affect surface waters other than possibly increasing storm water runoff from the site. The effects of facility construction generally involve increases in the amount of impervious surfaces with associated increases in runoff. Management of this increased volume of runoff would depend on the nature of the specific site (for example, whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns. If operation of the boiler system involved discharges of industrial wastewater, such as blowdown from an open cooling water system, it likely would go to a sanitary sewer system with formal approval of the treatment plant operator, or it would go through a discharge point with appropriate permits (such as an NPDES permit or a permit from the local municipal storm water system operator) and applicable monitoring and water quality requirements.

5.1.3.1.2 Groundwater

Potential impacts to groundwater from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.3.5.

During long-term operations of the biomass boiler and turbine facility, impacts to groundwater would be limited primarily to the water needs to operate the facility. Consistent with best management practices for construction projects (see Section 3.3.6), water going through the boiler and then steam to the turbine would be expected to be on a loop, recycling as much of the water as reasonable. Depending on the type of cooling system involved, there would be continuous losses from evaporation and blowdown that would have to be replenished from the local water supply (likely from groundwater as noted previously). The amount of fresh water needed for the system would not be expected to result in water availability issues, but would have to be evaluated on a case-by-case basis. Water required by the facility operators or other activities, such as biomass handling, likely would be minor in comparison with the requirements of the steam boiler system.

The long-term presence and operation of the biomass facility would be associated with increased runoff (as described previously) and potentially an associated decrease in groundwater recharge. However, the area involved would be relatively small and, depending on where storm water runoff from the facility would go or how it would be managed, the action may simply represent a change in where water soaks into the ground and possibly provides recharge.

5.1.3.1.3 Floodplains and Wetlands

The proponent of a distributed biomass facility would be expected to avoid floodplain and wetland areas if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

5.1.3.2 Best Management Practices and Mitigation Measures

Because it is assumed the representative biomass boiler and turbine facility would have access to a sewer system (Chapter 2), there would be no sanitary or process wastewater issues associated with facility operation and there would be no basis for avoiding areas with sensitive receiving waters. With regard to water resources to support the facility's water needs, most of O'ahu and all of Molokai have been designated Groundwater Management Areas (see Sections 3.3.2.3 and 3.3.2.4 in Chapter 3) because of concerns over the long-term availability of groundwater. This designation authorizes the State to manage groundwater through a permitting process. This does not mean the project could not be implemented on either island due to lack of water, it does identify a heightened level of concern that would have to be evaluated for a proposed action that involved any water demand.

5.1.4 BIOLOGICAL RESOURCES

5.1.4.1 Potential Impacts

Common impacts to biological resources from typical construction and operation activities are identified in Section 3.4.5.

Impacts to biological resources from the representative distributed biomass energy project would potentially occur through the biomass production and harvesting process and construction of the biomass facility. Up to 6 acres of land could be cleared of vegetation during construction. Impacts to terrestrial wildlife and protected plants and animals from construction of the boiler, turbine, and local infrastructure (i.e., access roads, water lines, and electrical lines) are expected to be minimal because the project would be part of an existing facility. Potential facility lighting during operation could have impacts on flights of marine birds, such as shearwaters and petrels, depending on the specific project location.

5.1.4.2 Best Management Practices and Mitigation Measures

Common best management practices associated with typical construction and operation activities to protect biological resources are identified in Section 3.4.6.

These additional best management practices could also be taken to minimize the identified potential impacts:

- Use lighting designs and operation routines to minimize lighting needs to avoid or reduce potential impacts to birds in flight.
- Select an existing agricultural operation, such as sugarcane or similar energy crop, to produce and harvest the biomass feedstock to minimize potential impacts to terrestrial plants and wildlife. The reasoning is that production fields that have been previously disturbed contain little wildlife or wildlife habitat.

5.1.5 LAND AND SUBMERGED LAND USE

5.1.5.1 Proposed Impacts

5.1.5.1.1 Land Use

The representative biomass energy facility would be adjacent to the commercial or industrial facility where the electrical power would be used and would need to be compatible with existing land uses. The State land use designations and county overlay zones would need to be evaluated for each specific project. However, changes in land ownership patterns would not be expected.

Operational impacts would involve facility maintenance and repair.

5.1.5.1.2 Submerged Land Use

As identified in [Table 5-1](#), no impacts to submerged land use would be expected from a distributed biomass energy project.

5.1.5.2 Best Management Practices and Mitigation Measures

During site selection, evaluate the State land use designations and county overlay zones.

5.1.6 CULTURAL AND HISTORIC RESOURCES

5.1.6.1 Potential Impacts

Potential impacts on cultural and historic resources from the representative distributed biomass energy project would be the same as those expected for common construction actions as described in Section 3.6.6.

5.1.6.2 Best Management Practices and Mitigation Measures

Best management practices for cultural and historic resources would be the same as those common across construction and operational projects (see Section 3.6.7).

5.1.7 COASTAL ZONE MANAGEMENT

5.1.7.1 Potential Impacts

Impacts to the coastal zone from the representative distributed biomass energy project could involve impacts to special management areas and shorefront access, depending on the project location. Because the entire State of Hawai‘i is considered part of the coastal zone, a Federal consistency review may be required if the representative project involves Federal agency activities, Federal license or permit activities, and Federal financial assistance activities (see Section 3.7.4).

5.1.7.2 Best Management Practices and Mitigation Measures

Specific project locations would require evaluation to determine if impacts would occur to special management areas designated under the State Coastal Zone Management Program, shorefront access, and shoreline erosion.

5.1.8 SCENIC AND VISUAL RESOURCES

5.1.8.1 Potential Impacts

Potential impacts to scenic and visual resources from construction of the representative distributed biomass energy project would be the same as those expected for common construction actions as described in Section 3.8.3.

Potential visual impacts during operation of the biomass energy plant would be from outdoor safety and security lighting. The magnitude of visual impacts would be location-dependent; that is, if the biomass steam boiler generator were located in an existing commercial or industrial setting, without adjacent sensitive viewsheds, impacts would be minimal.

5.1.8.2 Best Management Practices and Mitigation Measures

Best management practices for scenic and visual resources would be the same as those common across construction projects (see Section 3.8.4).

The following mitigation measures would reduce the identified potential impacts:

- When possible, locate the facility in areas without adjacent sensitive viewsheds.
- Redirect lighting away from external views.

5.1.9 RECREATION RESOURCES

As identified in [Table 5-1](#), there would be no potential impacts to recreation resources from the representative distributed biomass energy project.

5.1.10 LAND AND MARINE TRANSPORTATION

5.1.10.1 Potential Impacts

5.1.10.1.1 Land Transportation

Impacts to land transportation considered potential effects on traffic, alterations to existing roads, requirement for additional roads (excluding temporary or project specific access roads), and infrastructure. Potential impacts would occur from increased truck traffic for hauling biomass from the production facility to the biomass power plant. Because the biomass production would be close (up to 5 miles) to the power plant, any impact would be localized. In a worst-case scenario, truck traffic would occur on existing public access roads and impact traffic conditions (e.g., reduced traffic flow, added wear and tear on the roads). Because the representative distributed biomass energy project would be produced as part of an existing agricultural or forestry operation, some of the truck traffic could occur on private roads, minimizing or avoiding any traffic impacts.

5.1.10.1.2 Marine Transportation

As identified in [Table 5-1](#), there would be no potential impacts to marine transportation from the representative distributed biomass energy project.

5.1.10.2 Best Management Practices and Mitigation Measures

The following mitigation measures should be taken to minimize the identified potential impacts:

- Cover trucks hauling biomass to contain dust and to keep biomass material from falling out.
- To the extent feasible, private roads should be utilized to minimize traffic impacts.

5.1.11 AIRSPACE MANAGEMENT

As identified in [Table 5-1](#), there would be no potential impacts to airspace management from the distributed biomass energy project.

5.1.12 NOISE AND VIBRATION

5.1.12.1 Potential Impacts

Construction of the representative biomass project over 9-months could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

During operation, noise from the steam boilers and turbines mostly would be contained within the buildings and the energy facility would be adjacent to an existing commercial or industrial facility where the electrical power would be used. Long-term operational noise would be produced from operation of the biomass handling facilities and removal of ash waste. The representative biomass would have negligible long-term impact to existing noise and vibration levels. Noise levels would increase during short term steam blow events.

5.1.12.2 Best Management Practices and Mitigation Measures

Best management practices for noise would be the same as those commonly implemented for construction and operations (see Section 3.12.6).

5.1.13 UTILITIES AND INFRASTRUCTURE

5.1.13.1 Potential Impacts

The potential impact of adding 50 kilowatts of power generation capacity to each island's electricity service would be minimal. For O'ahu, with the largest island net capacity of 1,756 megawatts, the addition would equate to about 0.003 percent of its total capacity. For Lāna'i and Molokai with the smallest net capacities of 10 and 12 megawatts, respectively, the addition would equate to about 0.5 and 0.4 percent of their respective capacities (see Section 3.13.1).

Potential impacts to utilities and infrastructure from construction and operation of the 50-kilowatt generating plant would be the same as those described in Section 3.13.3.1.

5.1.13.2 Best Management Practices and Mitigation Measures

Best management practices for utilities and infrastructure would be the same as those common across construction projects (see Section 3.13.4).

5.1.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

5.1.14.1 Potential Impacts

5.1.14.1.1 Hazardous Materials

Potential impacts associated with exposure to hazardous materials from the representative distributed biomass energy project would occur during construction, if at all. Such potential impacts would be the same as those described in Section 3.14.4. There would be no operations impacts associated with exposure to hazardous materials.

5.1.14.1.2 Waste Management

Potential impacts to waste management from construction of the representative distributed biomass energy would be the same as those discussed in Section 3.14.4.

During project operation, combustion of biomass would result in about 18 tons of ash waste as a byproduct (with 3 percent ash content). Therefore, the representative project would integrate ash-handling facilities into the biomass energy facility. Ash residue typically is considered a hazardous waste and regulated by EPA; however, the ash residue for the representative project would come from sugarcane bagasse, which is not considered hazardous. Therefore, the ash waste could be transported to nearby agricultural fields for use as fertilizer. Leftover ash waste not used as fertilizer would be disposed of in a landfill, used as landfill cover, added to concrete mixtures for roads, or other acceptable uses. As such, potential waste management impacts during project operation would be minimal.

5.1.14.1.3 Wastewater

Potential wastewater impacts likely would be minimal during construction of the project and would be limited to wastewater generated by construction workers onsite.

During project operation, wastewater could discharge from the steam cycle and cooling system blowdown, and likely contain trace amounts of chemicals. However, the wastewater likely would go to a sanitary sewer system or discharge point. [Section 5.1.3.1.1](#) discusses permit requirements for wastewater release.

5.1.14.2 Best Management Practices and Mitigation Measures

Potential wastewater impacts could be mitigated by the use of settling ponds or filtration systems in order to meet NPDES wastewater discharge permit requirements.

5.1.15 SOCIOECONOMICS

5.1.15.1 Potential Impacts

Socioeconomic impacts in Hawai'i arising from construction and operation of the representative distributed biomass energy project would be very small. The turbines and supporting apparatus and appliances likely would be manufactured outside the State, and the economic benefits associated with the manufacturing would accrue elsewhere. Construction would require approximately 30 workers for about 9 months. Operations would require 2 employees per shift. The biomass would be provided by an existing agricultural operation, so very few new jobs would be created for that purpose. A few jobs in the

transportation field would be created to transport the biomass from the supplier to the production facility, and to transport the ash from the biomass facility to the landfill, as necessary.

Jobs directly associated with the biomass facility likely would be filled by individuals residing within the region of influence (the State of Hawai‘i) and not by in-migrating workers. There would be little to no impact on population employment variables, such as the size of the labor force, unemployment rates, and employment in the State and local government sector; housing and living conditions; and personal income.

5.1.15.2 Best Management Practices and Mitigation Measures

None noted.

5.1.16 ENVIRONMENTAL JUSTICE

5.1.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the representative distributed biomass energy project are expected to be small. The potential for environmental justice impacts also would be small.

5.1.16.2 Best Management Practices and Mitigation Measures

During site selection, conduct a study to determine the specific location of low-income and minority populations, specifically Native Hawaiians, and determine whether there would be disproportionately high and adverse impacts to such populations.

5.1.17 HEALTH AND SAFETY

5.1.17.1 Potential Impacts

Potential impacts to health and safety from construction and operation of the representative project would be the same as those expected for common construction and operation actions.

5.1.17.2 Best Management Practices and Mitigation Measures

None noted.

5.2 Hydroelectric

The representative distributed hydroelectric power project is characterized by two delivery methods: diversion, or redirecting water flow, and conduit systems (see Section 2.3.2.2). The representative diversion project would be located at a site identified with sufficient head and flow characteristics to sustain regular power generation, ideally on a steep slope or very close to a waterfall. Typically, this would be a rural area, on a farm, park, or similarly developed site. The hydropower plant would be designed to generate up to 10 megawatts of electricity, utilizing either pelton or turgo wheel technology, and require a shorter penstock due to the relative slope of the ideal deployment location. System configuration sizes may vary, depending on the river resource as well. Depending on the location, these power plants may also require construction of transmission or distribution lines to ensure grid connectivity.

The representative conduit hydropower project would be composed of a kinetic turbine and generator system rated from small kilowatt sizes up to 6 megawatts; sized to meet the municipal water flow of the chosen site. This technology would be installed at a water distribution/pressure control facility. The representative project would be located on an existing site; therefore, no new transmission or distribution lines would be needed.

As identified in Section 2.3.3.2, the river resources in Hawai‘i are not suitable for large hydroelectric impoundments; therefore, the PEIS only considers distributed hydroelectric facilities and will not evaluate hydroelectric projects in Chapter 6, Utility-Scale Renewables. This section evaluates the two representative projects (diversion and conduit) for a generating range from 6 megawatts to 10 megawatts.

[Table 5-2](#) presents a summary of the potential environmental impacts for hydroelectric projects, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and best management practices and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 5-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Hydroelectric

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	<p>Diversion System General impacts during construction (see Section 3.1.3). No impacts during operation.</p> <p>Conduit System None; the conduit system would be installed at an existing facility and not disturb additional land.</p>	Special consideration should be given to locations or receptors with sensitive geology or soil conditions to minimize erosion.
Climate and Air Quality		
Air Quality	General impacts during construction (see Section 3.2.4).	None.
Climate Change	Beneficial; potential reductions in greenhouse gas emissions.	N/A
Water Resources		
Surface Water	<p>Diversion System Potentially adverse impacts to water quality (decreased dissolved oxygen content and increased temperature), water supply, and existing uses (e.g., irrigation fisheries, and recreation).</p> <p>Conduit System None; the conduit system would be installed at an existing facility and not incrementally impact surface water.</p>	To the extent feasible, divert a smaller portion of the stream or decrease the volume of water diverted (and the amount of electricity produced during periods of low river flow) to reduce impacts.

Table 5-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Hydroelectric (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Groundwater	<p>Diversion System General impacts during construction (see Section 3.3.5).</p> <p>No impacts during operation.</p> <p>Conduit System None; the conduit system would be installed at an existing facility and not incrementally impact groundwater.</p>	None.
Floodplains and Wetlands	<p>Diversion and Conduit Systems Potential impacts during construction (site-specific)</p> <p>No impacts during operation.</p>	None.
Biological Resources		
	<p>Diversion System General construction impacts (see Section 3.4.5.1).</p> <p>Potential impacts from access roads during construction.</p> <p>Potentially adverse impacts to freshwater aquatic species.</p> <p>Conduit System Impacts are unlikely due to the use of an existing conduit flow system.</p>	<p>Minimize stream flows to allow for movement of fish.</p> <p>Include screens on diversion channels to prevent entrainment of aquatic species.</p>
Land and Submerged Land Use		
Land Use	<p>Diversion System Potential land disturbance during construction.</p> <p>Potential land use compatibility impacts.</p> <p>Conduit System General construction impacts (see Section 3.5.4).</p>	Follow appropriate outreach and consultation practices for those areas designated as conservation areas or parks or that may have sacred meaning to Native Hawaiians (wahi pana or wahi kapu).
Submerged Land Use	None; the projects are for installations on the interior of the islands and make use of rivers and stream rather than the ocean.	N/A

Table 5-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Hydroelectric (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Cultural and Historic Resources		
	<p>Diversion and Conduit Systems General impacts during construction and operation (see Section 3.6.6).</p>	Same as those common across construction and operational projects (see Section 3.6.7).
Coastal Zone Management		
	None; the projects are for installations on the interior of the islands and would not affect the shoreline.	N/A
Scenic and Visual Resources		
	<p>Diversion System General impacts during construction (short-term) (see Section 3.8.3). Potential long-term visual impacts (site-specific).</p> <p>Conduit System None.</p>	Same as those common across construction projects (see Section 3.8.3).
Recreation Resources		
	<p>Diversion System General short-term construction impacts (see Section 3.9.4). Potential impacts to river-based recreation activities, such as fishing and kayaking.</p> <p>Conduit System None.</p>	Same as those common across construction projects (see Section 3.9.5).
Land and Marine Transportation		
	<p>Diversion and Conduit Systems None; construction and operation of hydroelectric facilities would be unlikely to have any impacts to land and marine transportation.</p>	N/A
Airspace Management		
	<p>Diversion and Conduit Systems None; construction and operation of hydroelectric facilities would not affect airspace.</p>	N/A

Socioeconomics		
	<p>Diversion and Conduit Systems A few operation and construction jobs created. No operational impacts.</p>	None.
Environmental Justice		
	<p>Diversion and Conduit Systems Dependent on potentially adverse impacts to other resources in adjacent and nearby areas (site-specific).</p>	Conduct an evaluation of potential effects to low-income and minority populations.
Health and Safety		
	<p>Diversion and Conduit Systems General impacts during construction and operation (see Section 3.14.3).</p>	None.

5.2.1 GEOLOGY AND SOILS

5.2.1.1 Potential Impacts

Construction of the representative diversion hydropower plant would disturb about 1 acre of land for installation of the upstream intake channel or pipe, a forebay structure or tank, a penstock, a powerhouse, and a tailrace or outlet. Construction of an access road might be needed to access the construction areas; although this access road would be temporary and reclaimed once construction was completed. Permitting requirements would be the same and potential impacts on geology and soils would be as described for common construction actions in Section 3.1.3. One of these common impacts that could be greater with diversion hydropower systems is the potential for erosion, which would increase as the slope of the specific project site increased.

Since the conduit hydroelectric power system would be installed at an existing water facility, there would be little if any construction or land disturbance required; therefore, no impacts to geology or soils would be expected.

Long-term operation of either hydroelectric power system is not expected to impact geology or soils.

5.2.1.2 Best Management Practices and Mitigation Measures

Potential impacts to geology and soils and their severity would be dependent on project location; therefore, consideration should be given to locations with sensitive geology or soil conditions, such as areas with highly erodible soils and high slopes. Since locations potentially suitable for diversion hydroelectric power systems would be expected to include elevation changes, erosion issues would likely be of particular concern and could require additional measures to minimize erosion.

5.2.2 CLIMATE AND AIR QUALITY

5.2.2.1 Potential Impacts

A representative 10-megawatt hydroelectric project could reduce electricity requirements from the baseline electrical grid by 88,000 megawatt-hours per year if the turbine were run at full capacity every day for an entire year. Although a 100-percent capacity factor would not be achievable due to maintenance of the facility and potential periods of low water volume, it provides a theoretical maximum amount of electricity that could be generated per year if sufficient water were available. A realistic capacity factor of 44 percent ([DBEDT 2013](#)), which assumes seasonal shortages of water, would replace electricity requirements from the baseline electrical grid by 39,000 megawatt-hours per year.

Potential impacts to climate and air quality from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.2.4.

A replacement of 39,000 megawatt-hours of electricity per year from the baseline electrical grid would reduce oil consumption from electricity generation by about 2.6 million gallons (assuming 66.7 gallons of fuel oil per megawatt-hour of electricity). On O'ahu, this annual replacement of electricity from the baseline grid and the corresponding reduction in the use of oil would correspond to an annual reduction in greenhouse gas emissions of about 28,000 metric tons carbon dioxide equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid>; [EPA 2012](#)). On other islands, this same theoretical annual replacement of electricity usage from the baseline grid would see an annual reduction in greenhouse gas emissions of

24,000 metric tons carbon dioxide equivalent due to a different mix of technologies used to produce electricity on the other islands.

5.2.2.2 Best Management Practices and Mitigation Measures

None noted.

5.2.3 WATER RESOURCES

This section addresses potential environmental impacts to water resources from the representative hydroelectric power project. The impacts are presented in terms of surface water, groundwater, and floodplains and wetlands. The diversion project may also require construction of a transmission line to reach the nearest grid connection, but potential impacts associated with such an action are addressed under the On-Island Electrical Transmission technology in Chapter 8 and are not discussed here.

5.2.3.1 Potential Impacts

5.2.3.1.1 Surface Water

As described in [Section 5.2.1.1](#), construction of a diversion hydropower system would disturb about 1 acre of land. As such, potential impacts on surface water and associated permitting requirements would be the same as described in Section 3.3.5.

During operation of the diversion system, a portion of the stream flow would be diverted through the power plant and then be returned to the stream at a lower, downstream location. This type of action would require a stream channel alteration pursuant to [HAR 13-169, "Protection of Instream Uses of Water,"](#) which requires that any stream channel alteration obtain a permit from DLNR's Commission on Water Resources Management. In its decision to grant or deny such a permit, the Commission considers the following (from [HAR 13-169-52](#)):

- Alterations that would adversely affect quantity and quality of the stream water or the stream ecology should be minimized or not allowed;
- If in-stream flow standards have been set for the applicable stream, no permit should be allowed that would diminish the quantity or quality of stream water below the minimum established standards; and
- A channel alteration should not interfere with existing in-stream or non-in-stream uses.

As identified in the above regulatory considerations, primary concerns for adverse impacts from a diversion system would be to water quality and quantity and to existing uses of the stream water. The severity of impacts in each of these areas would depend on the characteristics of the project location, particularly the size of the natural flow in the river and the amount of flow that would be diverted. Concerns with water quantity and existing uses likely would be greatest in the stretch of river that would have reduced flow due to the diversion, although water uses could also be affected further downstream. The decreased water flow in this portion of the river could adversely impact uses such as irrigation, fisheries, and recreation.

Water quality concerns likely would be greatest at the point the diverted water was put back into the stream. The primary concerns would be decreased dissolved oxygen content and increased temperature.

Since the representative conduit hydroelectric power system would be installed at an existing water facility, there would be little if any construction or land disturbance; any impacts to surface water would be avoided or mitigated (see Section 3.3.6). Likewise, operation of the conduit system would not be anticipated to impact surface water resources.

5.2.3.1.2 Groundwater

Potential impacts to groundwater from construction and operation of the representative diversion hydroelectric power system would be expected to be the same as described from common construction actions in Section 3.3.5.

Since the representative conduit hydroelectric power system would be installed at an existing water facility, there would be little if any construction or land disturbance; no impacts to groundwater would be expected. Likewise, operation of the conduit system would not be anticipated to impact groundwater.

5.2.3.1.3 Floodplains and Wetlands

The proponent of a diversion hydroelectric power system would be expected to avoid floodplain and wetland areas if only to reduce costs and minimize regulatory requirements. However, if such areas could not be avoided, construction considerations would be the same as those described for common construction actions in Section 3.3.5. Since the conduit system would involve installing equipment at an existing water facility, floodplains or wetlands would not be affected.

5.2.3.2 Best Management Practices and Mitigation Measures

As described in [Section 5.2.3.1.1](#), locations with low water flow or other water quantity issues would likely be the most susceptible to impacts. Since flow in most streams can vary significantly over the course of a year, concerns over water quantity in the diversion areas may be periodic in nature.

The smaller the portion of the stream is diverted, the lower the potential for serious water quality concerns. These considerations and the severity of impacts would be evaluated in the permitting process and it is reasonable to assume that a proposed diversion system would not be permitted unless the regulatory agency felt impacts were minor or at acceptable levels to warrant the benefit that would be gained.

In general, the smaller the portion of the stream is diverted, the lower the potential for serious adverse impacts. Decreasing the volume of water diverted (and the amount of electricity produced) during periods of low river flow would also be an important means of reducing the severity of impacts.

5.2.4 BIOLOGICAL RESOURCES

5.2.4.1 Potential Impacts

Construction of the representative diversion hydropower system would disturb about 1 acre of land in a rural area, farm setting, park, or similar site for installation of the upstream intake channel or pipe, a forebay structure or tank, a penstock, a powerhouse, and a tailrace or outlet. The primary impact to biological resources would be the construction of access roads to construct the power system.

Threatened and endangered plant and animal species and designated critical habitat and protected land areas occur in many areas where streams or waterfalls are conducive to distributed hydroelectric power

development. Common impacts from the development of renewable energy technologies such as land disturbances and associated impacts to such biological resources are discussed in Section 3.4.5.1.

The representative project would potentially impact freshwater fish species through a reduction in stream flow between the point of flow diversion to the downstream release point. Types of impacts could include life history of the species (e.g., feeding, suitable habitat, reproduction ability, and mortality from increased water temperatures). The extent of impacts would depend on the remaining stream flow after diversion and the length of stream in which the flow is reduced.

Potential impacts to biological resources from a conduit hydroelectric system are expected to be less than those for a diversion system. A conduit system would be installed in an existing flow of water such as an irrigation or municipal water delivery system. Installation of a conduit system would require very little modification of vegetation or wildlife habitat and would most likely be installed in a previously developed area.

5.2.4.2 Best Management Practices and Mitigation Measures

The following best management practices could prevent or reduce the identified potential impacts:

- Reclaim land disturbances not required for operation or maintenance with native vegetation to minimize impacts following construction.
- Prior to site selection, review specific project locations to ensure the project would not adversely impact sensitive biological resources ranging from avian and land species to aquatic anadromous-amphidromous species with diadromous life-cycle patterns (see Section 3.4.1.3.3).
- Establish minimum stream flows to allow movement of fresh water fish through the impacted stream segment.
- Install screens on diversion channels to help prevent entrainment of aquatic species through the forebay reservoir, penstock pipe, and power station.

5.2.5 LAND AND SUBMERGED LAND USE

This section discusses the potential environmental impacts to land use from two representative hydroelectric projects: diversion system and a conduit system.

5.2.5.1 Potential Impacts

5.2.5.1.1 Land Use

Land disturbance from the representative diversion hydroelectric project would occur during construction of the system. Depending on the locations and linear distances between the water source and the powerhouse and then to the transmission grid, there could be changes in land use and ownership. Potential impacts associated with any required transmission lines are addressed in Section 8.1.

The representative conduit hydropower system would be installed at an existing water distribution/pressure control facility and is not anticipated to result in a change to land use. Therefore, impacts to land use from construction and operation of the representative project would be the same as those expected for common construction actions as described in Section 3.4.5.

5.2.5.1.2 Submerged Land Use

As identified in [Table 5-2](#), there would be no potential impacts to submerged land use from the representative hydroelectric power project.

5.2.5.2 Best Management Practices and Mitigation Measures

During site selection, the project proponent should evaluate the State land use designations and county overlay zones.

Because hydroelectric systems are, by necessity, in areas that include sloping terrain with surface water features, the potential exists that areas identified for development could include conservation areas or parks; some may have sacred meaning to Native Hawaiians (e.g., wahi pana or wahi kapu). Project proponents should include public outreach and tribal consultations as part of their siting process. Many sections of this PEIS address traditional and Native Hawaiian practices and rights (e.g., Section 3.6 and throughout Chapters 4 through 8).

5.2.6 CULTURAL AND HISTORIC RESOURCES

5.2.6.1 Potential Impacts

Potential impacts to cultural and historic resources from construction and operation of the representative project would be the same as those expected for common construction and operations actions as described in Section 3.6.6.

5.2.6.2 Best Management Practices and Mitigation Measures

Best management practices for cultural and historic resources would be the same as those common across construction and operational projects. See Section 3.6.7.

5.2.7 COASTAL ZONE MANAGEMENT

As identified in [Table 5-2](#), there would be no potential impacts to coastal zone management from the representative hydroelectric power project.

5.2.8 SCENIC AND VISUAL RESOURCES

5.2.8.1 Potential Impacts

Potential impacts to scenic and visual resources from construction and operation of the representative project would be the same as those expected for common construction actions as described in Section 3.8.3.

Operational impacts would be location-dependent but most certainly would introduce a new facility and would impact visual and scenic resources. The visibility of the new plant would depend on the terrain. The components of most diversion systems include an upstream intake, a forebay tank, a penstock for transporting the water to the powerhouse, the powerhouse itself (which includes all the necessary power generation and conversion equipment), and an outlet (or tailrace), where the water returns to the river (Figure 2-6 in Chapter 2). Some exterior lighting likely would be present for safety and security purposes.

The representative project would be designed to generate up to 10 megawatts of electricity. As a point of reference, a powerhouse for a 4-megawatt generator and associated equipment would be roughly the size of a 1-room cabin (16 × 28 feet). In addition to the plant footprint, the representative diversion hydroelectric power facility would require transmission or distribution lines to connect to the power grid. For remote locations, new access roads may be required to transport equipment and construction workers.

Because the conduit hydroelectric power project would be located within an existing water distribution system, impacts to visual and scenic resources would not be expected.

5.2.8.2 Best Management Practices and Mitigation Measures

Because hydroelectric power plants require a water source in a geographic area generally characterized by uneven terrain, such as hills or mountains, to have sufficient power-generation potential, protected lands and tourism considerations may block access to otherwise ideal water resource sites. Consideration should be taken to avoid siting a hydroelectric power plant in an area where lack of manmade features is an important contribution to the scenic value of the area.

Best management practices to minimize impacts to visual resources, including those from lighting, would be the same as those common across construction projects (see Section 3.8.4).

5.2.9 RECREATION RESOURCES

5.2.9.1 Potential Impacts

Potential impacts to recreation resources from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.9.4.

During project operation, there could be impacts to river-based recreation activities, such as fishing and kayaking.

A conduit hydroelectric power system would be located in an existing water distribution system and therefore have no incremental impacts to recreation resources.

5.2.9.2 Best Management Practices and Mitigation Measures

During project siting, consider avoiding areas where the lack of manmade features is an important contribution to the recreational value of the area or where the plant would impact river recreation. Tables 3-47 and 3-48 (in Chapter 3) list popular land-based and water-based recreation activities, respectively.

Project proponents should review the *State Comprehensive Outdoor Recreation Plan (SCORP)* for detailed matrixes of all recreation areas on each island and the recreational activities that take place at each area ([DLNR 2009](#)).

General best management practices to minimize impacts to recreation resources would be the same as those common across construction projects (see Section 3.9.5).

5.2.10 LAND AND MARINE TRANSPORTATION

As identified in [Table 5-2](#), there would be no potential impacts to land or marine transportation from the representative hydroelectric power project.

5.2.11 AIRSPACE MANAGEMENT

As identified in [Table 5-2](#), there would be no potential impacts to airspace management from the representative hydroelectric power project.

5.2.12 NOISE AND VIBRATION

5.2.12.1 Potential Impacts

The representative hydroelectric project could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

Long-term noise and vibration impacts would depend on the locations of new infrastructure and their compatibility with the existing noise levels and land uses. Depending on the location, noise and vibration impacts could result from operation of a diversion hydroelectric power system introduced in a relatively rural area, on a farm, or in a park. The representative conduit hydroelectric power system would be installed at an existing water distribution/pressure control facility and would have negligible long-term impact to existing noise and vibration levels.

5.2.12.2 Best Management Practices and Mitigation Measures

Best management practices for noise and vibration would be the same as those common across projects for construction and operations (see Section 3.12.6).

5.2.13 UTILITIES AND INFRASTRUCTURE

5.2.13.1 Potential Impacts

The potential impact on each island's electric utilities would be small to moderate from the addition of 6 to 10 megawatts of power generation to the power grid. For O'ahu, with the largest island net capacity of 1,756 megawatts, the addition would equate to about 0.6 percent of its total capacity. If feasible, the addition for Lāna'i, with the smallest net capacity of 10 megawatts, would equate to about 100 percent of its total capacity (see Section 3.13.1) and require major utility adjustments.

Potential impacts from connection to utilities for construction and operation of the representative project would be the same as those expected for common construction actions described in Section 3.13.3.1.

5.2.13.2 Best Management Practices and Mitigation Measures

General best management practices to minimize impacts to utilities, infrastructure, and public safety would be the same as those common across construction projects (see Section 3.13.4).

5.2.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

5.2.14.1 Potential Impacts

Potential impacts from exposure to hazardous materials and to waste management from construction and operation of the representative project would be the same as those expected for common construction actions as described in Section 3.14.3.

5.2.14.2 Best Management Practices and Mitigation Measures

General best management practices to minimize impacts to wastewater would be the same as those common across construction projects (see Section 3.14.5). In addition, the representative project would comply with NPDES wastewater discharge permit requirements.

5.2.15 SOCIOECONOMICS

5.2.15.1 Potential Impacts

Socioeconomic impacts in Hawai'i arising from construction and operation of the representative hydroelectric system would be very small. The generator and the supporting apparatus and appliances likely would be manufactured outside the State and any economic benefit associated with manufacturing would accrue elsewhere. The number of temporary jobs associated with the construction of the system and the number of jobs to operate and maintain it would be very small, perhaps 10 workers for a 6-month construction period and 1 permanent position for operations.

Jobs directly associated the hydroelectric station would be likely filled by individuals residing within the State of Hawai'i and not by in-migrating workers. There would be little to no impact on population employment variables, such as the size of the labor force, unemployment rates, and employment in the State and local government sector; housing and living conditions; and personal income.

5.2.15.2 Best Management Practices and Mitigation Measures

None noted.

5.2.16 ENVIRONMENTAL JUSTICE

5.2.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the representative hydroelectric power project are expected to be small. The potential for environmental justice impacts also would be small.

5.2.16.2 Best Management Practices and Mitigation Measures

During site selection, conduct a study to determine the specific location of low-income and minority populations, specifically Native Hawaiians, and determine whether there would be disproportionately high and adverse impacts to such populations.

5.2.17 HEALTH AND SAFETY

Potential impacts to health and safety from construction of the representative project would be the same as those expected for common construction actions.

5.3 Hydrogen Fuel Cells

This PEIS analyzes a representative hydrogen fuel cell project for both residential and commercial use (see Section 2.3.2.3). The representative residential project would be a 5-kilowatt fuel cell power system designed for use by a single-family residence. The power system would be housed in a container either inside or outside the residence and would use stacks of fuel cells in a modular system to produce the

power output specified. The hydrogen would be produced onsite as part of the modular system using water and electricity for the electrolysis process or be purchased from a centralized hydrogen production facility. Electricity could be supplied either via the existing electrical grid or via renewable resources at the site such as solar or wind.

This PEIS also analyzes a representative commercial hydrogen fuel cell project with a 50-kilowatt capacity. The operational parameters for fuel cell systems of increasing size tend to be linear with respect to size. For example, each individual 5-kilowatt fuel cell system would produce the same amount of electricity, consume the same amount of hydrogen, and have the same emissions, whether a single fuel cell system is used or 10 fuel cell systems are grouped for a 50-kilowatt system. Likewise, the space required for the fuel cell stacks of a 5-kilowatt system would increase linearly for larger systems (even though the required space may vary slightly due to specific system layouts). Therefore, the operational parameters for a 50-kilowatt fuel cell system would be about 10 times that of a 5-kilowatt system.

[Table 5-3](#) presents a summary of the potential environmental impacts for hydrogen fuel cell projects, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and best management practices and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 5-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Hydrogen Fuel Cells

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	General impacts during construction and operation (see Section 3.1.3).	Same as those common across construction projects (see Section 3.1.4).
Climate and Air Quality		
Air Quality	General impacts during construction. See Section 3.2.4.	None.
Climate Change	Minimal greenhouse gas emissions (unless supplied from a renewable energy source, in which case impacts would be lower).	None.
Water Resources		
	General impacts during construction and operation (see Section 3.3.5).	Same as those common across construction projects (see Section 3.3.6).
Biological Resources		
	None; since there would be no land disturbance associated with hydrogen fuel cells, there would be no impacts to biological resources.	N/A
Land and Submerged Land Use		
	None; since there would be no land disturbance associated with hydrogen fuel cells, there would be no impacts to land and submerged land use.	N/A

Table 5-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Hydrogen Fuel Cells (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Coastal Zone Management		
	None; since there would be no land disturbance associated with hydrogen fuel cells, there would be no impacts to coastal zone management.	N/A
Scenic and Visual Resources		
	None; since there would be no external facilities associated with hydrogen fuel cells, there would be no impacts to scenic and visual resources, the containers would be located either indoor or outdoor adjacent to existing facilities, negligible impacts to visual resources are expected.	N/A
Recreational Resources		
	None; since the containers would be located either indoor or outdoor adjacent to existing facilities, no impacts to recreation resources are expected. There would be no land disturbance or external facilities associated with hydrogen fuel cells. There would be no impacts to scenic and visual resources.	N/A
Land and Marine Transportation		
	None; Since there would be no land disturbance or external facilities associated with hydrogen fuel cells, there would be no impacts to land and marine transportation.	N/A
Airspace Management		
	None; since there would be no external facilities associated with hydrogen fuel cells, there would be no impacts to airspace management.	N/A
Noise and Vibration		
	None; since there would be no land disturbance or external facilities associated with hydrogen fuel cells and the fuel cells do not generate noise, there would be no impacts to noise and vibration.	N/A

Table 5-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Hydrogen Fuel Cells (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Utilities and Infrastructure		
	Negligible impacts to electricity generating capacities.	None.
Hazardous Materials and Waste Management		
Hazardous Materials	No exposure impacts during construction Minimal exposure impacts during operation.	Implement an emergency action plan to include training and proper procedures as well as the use of protective gear for workers in the event of an emergency.
Waste Management	None; no waste management impacts from construction or operation of hydrogen fuel cells.	N/A
Wastewater	None.	N/A
Socioeconomics		
	None; installation and use of hydrogen fuel cells would result in few jobs and would not impact socioeconomics.	N/A
Environmental Justice		
	None; since there would be no measurable impacts to the human environment, there would be no environmental justice impacts.	N/A
Health and Safety		
	Potential impacts related to hydrogen explosions are extremely unlikely.	Ensure proper handling, monitoring, and maintenance of the hydrogen system in accordance with operating system specifications.

5.3.1 GEOLOGY AND SOILS

5.3.1.1 Potential Impacts

The representative 5-kilowatt hydrogen fuel cell project would not require construction of a new facility, and there would be no land disturbance. If the project were increased to accommodate 50 kilowatts of power, potential impacts to geology and soils from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.1.3.

5.3.1.2 Best Management Practices and Mitigation Measures

If warranted by the project location, design the hydrogen fuel cell or its housing so that the probability of damage during an earthquake is low. Such measure could require a cost benefit analysis before finalizing site selection.

5.3.2 CLIMATE AND AIR QUALITY

5.3.2.1 Potential Impacts

Hydrogen fuel cells use the chemical energy of hydrogen combining electrochemically with oxygen to produce electricity and can be used for almost any application typically powered by batteries or internal combustion engines. Hydrogen fuel cells produce no criteria air pollutants or greenhouse gas emissions at the point of operation. A 5-kilowatt fuel cell would be a size appropriate for the average residential system.

5.3.2.1.1 Air Quality

Onsite air quality impacts associated with construction of a hydrogen fuel cell system would be short term, intermittent, and limited to the duration of the construction project. Criteria pollutant and greenhouse gas emissions would be minimal due to the small footprint of construction and the modular nature of fuel cell equipment. Most units of the system would be manufactured off-site and moved into position at the site.

An onsite hydrogen electrolyzer system that produces enough hydrogen for a 5-kilowatt fuel cell would require about 28 kilowatt-hours of electricity. Hydrogen produced using electricity from the existing electrical grid would not reduce overall air emissions because more electricity (with its resulting air emissions) would be required by the electrolyzer than would be produced by the fuel cell system. However, hydrogen produced using electricity from renewable resources such as wind power, solar, or geothermal would not use electricity from the grid. Such a 5-kilowatt fuel cell system would reduce electricity consumption from the baseline grid by 5 kilowatt-hours every hour during peak periods of the day.

5.3.2.1.2 Climate Change

A residential fuel cell system could replace the 600 kilowatt-hours of an average monthly residential electricity use. A replacement of 7.2 megawatt-hours of electricity per year from the baseline electrical grid would reduce oil consumption from electricity generation by about 480 gallons per residential unit. On O‘ahu, the annual replacement of 7.2 megawatt-hours of electricity per residential unit would correspond to an annual reduction in greenhouse gas emissions of about 5.2 metric tons carbon dioxide equivalent based on EPA eGrid2012 emission factors (<http://www.epa.gov/egrid>; EPA 2012). On other islands by comparison, an annual replacement of 7.2 megawatt-hours of electricity usage would correspond to an annual reduction in greenhouse gas emissions of about 4.4 metric tons carbon dioxide equivalent due to a different mix of technologies used to produce electricity.

A commercial fuel cell system would produce linearly scaled impacts to air quality. For example, the 50-kilowatt fuel cell suitable for commercial buildings could reduce electricity use from the grid by ten times that of a 5-kilowatt fuel cell. The corresponding reduction in greenhouse gas emissions would be 10 times that of a 5-kilowatt fuel cell.

5.3.2.2 Best Management Practices and Mitigation Measures

None note.

5.3.3 WATER RESOURCES

5.3.3.1 Potential Impacts

The representative 5-kilowatt hydrogen fuel cell would not be expected to impact water resources during construction. However, potential impacts could occur from a 50-kilowatt project if land disturbance was necessary, in which case potential impacts to water resources would be the same as those for common construction actions described in Section 3.3.5.

It is estimated the 5-kilowatt hydrogen fuel cell would require 1 gallon of water per hour for its operation. This would represent a very minor increase in water demand for an average household (for the representative project). Even scaling the project up by an order of magnitude or more would involve relatively minor water demands and have negligible effects on water resources.

5.3.3.2 Best Management Practices and Mitigation Measures

General best management practices to minimize impacts to water resources would be the same as those common across construction projects (see Section 3.3.6).

5.3.4 BIOLOGICAL RESOURCES

As identified in [Table 5-3](#), there would be no potential impacts to biological resources from the representative hydrogen fuel cells project.

5.3.5 LAND AND SUBMERGED LAND USE

As indicated in [Table 5-3](#), there would be no potential impacts to land use from the representative hydrogen fuel cells project.

5.3.6 CULTURAL AND HISTORIC RESOURCES

As indicated in [Table 5-3](#), there would be no potential impacts to cultural and historic resources from the representative hydrogen fuel cells project.

5.3.7 COASTAL ZONE MANAGEMENT

As identified in [Table 5-3](#), there would be no potential impacts to coastal zone management from the representative hydrogen fuel cells project.

5.3.8 SCENIC AND VISUAL RESOURCES

As indicated in [Table 5-3](#), there would be no potential impacts to scenic or visual resources from the representative hydrogen fuel cells project.

5.3.9 RECREATION RESOURCES

As indicated in [Table 5-3](#), there would be no potential impacts to recreation resources from the representative hydrogen fuel cells project.

5.3.10 LAND AND MARINE TRANSPORTATION

As identified in [Table 5-3](#), there would be no potential impacts to land or marine transportation resources from the representative hydrogen fuel cells project.

5.3.11 AIRSPACE MANAGEMENT

As identified in [Table 5-3](#), there would be no potential impacts to airspace management resources from the representative hydrogen fuel cells project.

5.3.12 NOISE AND VIBRATIONS

As indicated in [Table 5-3](#), there would be no potential impacts to noise and vibration from the representative hydrogen fuel cells project.

5.3.13 UTILITIES AND INFRASTRUCTURE

5.3.13.1 Potential Impacts

The potential impact on each island's electric utilities would be small from the addition of 5 kilowatts of hydrogen fuel cell generation to an individual household. The potential impacts for adding 50 kilowatts of hydrogen fuel cell generation to an existing industrial facility would be even lower, as the facility would remain connected to the grid to use utility power to run the facility when the renewable source was not sufficient.

As identified in Section 2.3.2.3, no large-scale use of stationary hydrogen fuel cells exists within the State of Hawai'i. This is due, in part, to the high cost of producing hydrogen as a fuel source. Although natural gas is used as a primary fuel for fuel cells in the continental United States and other countries, natural gas is not readily available in Hawai'i. As a result, the likely approach for hydrogen development in Hawai'i is electrolysis using renewable energy. As can see by the description in Section 2.3.2.3, it requires more electricity to generate the hydrogen through electrolysis than is generated from the fuel cells themselves. Therefore, until the production and distribution of hydrogen is better developed (perhaps using geothermal or wind power), the use of hydrogen fuel cells would not be an efficient renewable energy technology for use in Hawai'i.

5.3.13.2 Best Management Practices and Mitigation Measures

None noted.

5.3.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

5.3.14.1 Potential Impacts

5.3.14.1.1 Hazardous Materials

Potential impacts associated with exposure to hazardous materials from construction of the representative hydrogen fuel cell project would be the same as those expected for common construction actions as described in Section 3.14.4.

During project operations, hydrogen would be produced onsite as part of the modular system using water and electricity for the electrolysis process and could potentially leak. In addition, some fuel cells contain

flammable liquids, including methanol, formic acid, certain borohydride materials, and butane. Businesses that are classified as Small or Large Quantity Generators of hazardous material (pursuant to the *Resource Conservation and Recovery Act*; RCRA) must comply with Federal waste disposal regulations, as specified in the following section.

5.3.14.1.2 Waste Management

As identified in [Table 5-3](#), there would be no waste management impacts from the representative hydrogen fuel cells project.

Secondary impacts may result from byproducts during the manufacturing and decommissioning of fuel cells. However, it is not anticipated that the fuel cells would be manufactured in Hawai'i. Proper decommissioning of fuel cells would occur at the end-of-life, including reuse of useful materials (e.g., platinum, ruthenium or palladium) for manufacturing new fuel cells and the proper handling and treatment of hazardous waste in accordance with Federal State, and county laws and regulations. Nonhazardous components would be disposed of appropriately at the local landfill.

Hazardous waste generated by homeowners and contractors is not regulated by Federal hazardous waste regulations, such as RCRA. Thus, homeowners and contractors may dispose of discarded fuel cells as general refuse in a properly permitted municipal landfill. Retailers, commercial, and governmental entities, however, are subject to full RCRA regulation depending on the generator status of their business. Under RCRA, fuel cells discarded by businesses that are Conditionally Exempt Small Quantity Generators of hazardous waste may dispose of such waste in a properly permitted municipal landfill unless a State or local regulation prohibits or restricts such disposal. To qualify as a Conditionally Exempt Small Quantity Generator, a business must not generate more than 220 pounds of hazardous waste in any one month and must not accumulate more than 2,200 pounds of hazardous waste onsite at any one time. Those businesses that generate between 220 pounds and 2,200 pounds (about 100 to 1,000 kilograms) of hazardous waste in any one month are considered Small Quantity Generators. Those that generate more than 2,200 pounds of hazardous waste in any one month are considered Large Quantity Generators. Small and Large Quantity Generators of hazardous waste must dispose of discarded fuel cells at a properly permitted hazardous waste treatment, storage, or disposal facility.

5.3.14.1.3 Wastewater

As identified in [Table 5-3](#), there would be no wastewater impacts from the representative hydrogen fuel cells project. However, beneficial impacts could be realized if wastewater was used to produce hydrogen; i.e., use of wastewater for the production of hydrogen would decrease the load on existing wastewater treatment facilities.

5.3.14.2 Best Management Practices and Mitigation Measures

In the event of a hydrogen leak, all workers would be required to respond according to an emergency action plan, including wearing protective gear to protect workers from invisible flames and potential explosion hazards. Additional State and possibly Federal regulations would apply.

5.3.15 SOCIOECONOMICS

As identified in [Table 5-3](#), there would be no potential impacts to socioeconomics from the representative hydrogen fuel cells project.

5.3.16 ENVIRONMENTAL JUSTICE

As identified in [Table 5-3](#), there would be no potential environmental justice impacts from the representative hydrogen fuel cells project.

5.3.17 HEALTH AND SAFETY

5.3.17.1 Potential Impacts

Like many fuels, hydrogen is a flammable gas and can form explosive mixtures with air. Hydrogen is non-toxic and non-poisonous, is lighter than air and diffuses rapidly. An explosion cannot occur in a tank that contains only hydrogen. An oxidizer, such as oxygen (air) must also be present.

5.3.17.2 Best Management Practices and Mitigation Measures

Ensure proper handling, monitoring, and maintenance of the hydrogen system in accordance with the manufacturer’s recommendations.

5.4 Photovoltaics

The representative distributed photovoltaic (PV) project is characterized by two applications: installation of a rooftop 5-kilowatt PV system in a residence and installation of a rooftop 50-kilowatt PV system at a business (see Section 2.3.2.4). A typical home installation would cover about 350 square feet, and a typical business installation would cover about 3,500 square feet. The required number of solar modules for the system and the associated electrical equipment and wiring would depend on the power of the system (i.e., the 5-kilowatt system would have fewer modules and associated wiring than the 50-kilowatt system). Depending on the capacity of PV system there may also be batteries for storage or the system may be tied into the local utility distribution grid.

[Table 5-4](#) presents a summary of the potential environmental impacts for PV projects, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and best management practices and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 5-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Photovoltaics

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	None; installation and use of rooftop solar modules would not involve land disturbance and therefore would not impact geology and soils.	N/A
Climate and Air Quality		
Air Quality	General impacts during construction (see Section 3.2.4).	Same as those common across construction projects (see Section 3.2.5).
Climate Change	Beneficial; reduced oil consumption by use of renewable energy.	None.

Table 5-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Photovoltaics (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Water Resources		
	None; installation and use of rooftop solar modules would not involve land disturbance, would involve only minor water demand, and therefore would not impact water resources.	N/A
Biological Resources		
	None; installation and use of rooftop solar modules would not involve land disturbance or sensitive habitat and therefore would not impact biological resources.	N/A
Land and Submerged Land Use		
	None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact land and submerged land use.	N/A
Cultural and Historic Resources		
	Potential adverse visual or architectural context impact to an historic property/resource.	In accordance with State law, submit an Historic Preservation Review Form in compliance with HRS 6E .
Coastal Zone Management		
	None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact coastal zone management.	N/A
Scenic and Visual Resources		
	<p>Short-term visual resource impacts during installation.</p> <p>Potential long-term visual impacts (site-specific).</p> <p>Potential impacts to natural scenic and visual resources, or historic character of an area.</p>	<p>As feasible, solar modules should be installed to limit visibility and reduce impacts.</p> <p>Approval from the FAA and HDOT Airports Division may be required to ensure module glare would not interfere with nearby aircraft.</p> <p>Consider placement of PV system away from public or street views to minimize changes in viewsheds.</p>

Table 5-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Photovoltaics (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Recreation Resources		
	None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact recreation resources.	N/A
Land and Marine Transportation		
	None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact land and marine transportation.	N/A
Airspace Management		
	None; although installation of rooftop solar modules could cause some glare and reflection, which could be seen by pilots, installations at a distributed scale would typically not require consultations on airspace management.	N/A
Noise and Vibration		
	None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact noise and vibration.	N/A
Utilities and Infrastructure		
	<p>Minor impacts to electricity generating capacities.</p> <p>General impacts during construction and operation (see Section 3.13.3).</p>	Same as those common across construction projects (see Section 3.13.4).
Hazardous Materials and Waste Management		
Hazardous Materials	<p>General exposure construction impacts (see Section 3.14.4).</p> <p>Potential exposure impacts from end-of-life of the photovoltaic system and the battery energy storage.</p>	<p>Same as those common across construction projects (see Section 3.14.5).</p> <p>Ensure proper disposal of hazardous materials at end-of-life.</p>
Waste Management	<p>General construction impacts (see Section 3.14.4).</p> <p>Potential exposure to hazardous waste (i.e., potential for cadmium).</p> <p>Potential landfill impacts.</p>	Same as those common across construction projects (see Section 3.14.5).

Table 5-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Photovoltaics (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Wastewater	Potential impacts from the disposal of PV modules (i.e., potential for cadmium-contaminated wastewater).	Employ proper handling and transport of discarded PV systems at the appropriate hazardous waste facility to ensure that contaminated wastewater is disposed of appropriately.
Socioeconomics		
	None; installation and use of PV modules would result in few jobs and would not impact socioeconomics.	N/A
Environmental Justice		
	None; since there would be no measurable impacts to the human environment, there would be no environmental justice impacts.	N/A
Health and Safety		
	General impacts during construction and operation.	None.

5.4.1 GEOLOGY AND SOILS

As identified in [Table 5-4](#), there would be no potential impacts to geology and soils from the representative distributed PV project.

5.4.2 CLIMATE AND AIR QUALITY

Photovoltaic technology converts solar energy into electricity. The representative distributed 5-kilowatt PV project would be installed at a residence. Assuming a 20-percent capacity factor ([DBEDT 2013](#)), the project would provide base load electricity of about 8.8 megawatt-hours per year and could replace electricity requirements from the existing baseline electrical grid by that same amount. For comparison purposes, the average residential electricity use on O‘ahu in 2011 was 7.3 megawatt-hours ([DBEDT 2013](#)).

5.4.2.1 Potential Impacts

5.4.2.1.1 Air Quality

Air quality impacts from the representative project would be minimal, short-term, and limited to the duration of the construction project. Because the PV system would be installed on a rooftop, construction-related impacts to air quality would not be extensive. Fugitive dust should not be generated during construction. Large construction equipment, such as earth-moving equipment, cranes, and trucks, would not be required.

5.4.2.1.2 Climate Change

A residential PV system could replace 8.8 megawatt-hours of annual residential electricity usage. A replacement of 8.8 megawatt-hours of electricity per year from the baseline electrical grid would reduce

oil consumption from electricity generation by about 580 gallons per residential unit. On O‘ahu, the annual replacement of 8.8 megawatt-hours of electricity per residential unit would correspond with an annual reduction in greenhouse gas emissions of about 6.4 metric tons carbon dioxide equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid>; EPA 2012). On other islands, for comparison, an annual replacement of 8.8 megawatt-hours of electricity usage would achieve an annual reduction in greenhouse gas emissions of about 5.4 metric tons carbon dioxide equivalent due to a different mix of technologies used to produce electricity on the other islands.

A commercial PV system would produce linearly scaled impacts to air quality. For example, the 50-kilowatt commercial PV system could reduce electricity use from the grid by ten times that of a 5-kilowatt system. The corresponding reduction in greenhouse gas emissions would be 10 times that of a 5-kilowatt system.

5.4.2.2 Best Management Practices and Mitigation Measures

None noted.

5.4.3 WATER RESOURCES

As indicated in [Table 5-4](#), there would be no potential impacts to water resources, including surface water, groundwater, floodplains, and wetlands, from the representative distributed PV project.

5.4.4 BIOLOGICAL RESOURCES

As identified in [Table 5-4](#), there would be no potential impacts to biological resources from the representative distributed PV project.

5.4.5 LAND AND SUBMERGED LAND USE

As identified in [Table 5-4](#), there would be no potential impacts to land use from the representative distributed PV project.

5.4.6 CULTURAL AND HISTORIC RESOURCES

5.4.6.1 Potential Impacts

The representative 5-kilowatt PV system installed on a building or residence listed or eligible for listing on the HRHP or the NRHP, and/or is located in an historic district, could change the characteristics of the property such that the historic nature of the property would be altered. The alterations may have an adverse visual or architectural context impact to the historic property. When modifying historic buildings to retrofit for energy sustainability, the Department of the Interior provides standards and guidelines to help guide project proponents ([DOI 2011](#)). Additionally, PV system installation could affect residences and other buildings that not only qualify as historic properties, but also as cultural resources whose alterations may require coordination with the OHA’s Native Hawaiian Historic Preservation Council in accordance with applicable regulatory consultation requirements.

5.4.6.2 Best Management Practices and Mitigation Measures

Historic resources that are listed on the HRHP or NRHP, or are potentially eligible for inclusion in the NRHP, such as buildings, sites, and structures would be considered sensitive locations regarding possible

modifications from PV installations and may require retrofit design approval in coordination with the Hawai'i State Historic Preservation Department.

If a historic property or structure that is listed or eligible for listing on the HRHP and/or NRHP is proposed for a PV installation, in accordance with State law, the project proponent must complete and submit a Historic Preservation Review Form in compliance with [Hawai'i Revised Statutes \(HRS\) Chapter 6E](#) so the modifications can be reviewed and approved prior to project implementation.

5.4.7 COASTAL ZONE MANAGEMENT

As identified in [Table 5-4](#), there would be no potential impacts to coastal zone management resources from the representative distributed PV project.

5.4.8 SCENIC AND VISUAL RESOURCES

5.4.8.1 Potential Impacts

5.4.8.1.1 Scenic Resources

The representative distributed PV project, regardless of its capacity (i.e., 5 or 50 kilowatts), could impact scenic resources if the installation was in proximity to sites listed or eligible for listing in the HRHP or NRHP.

5.4.8.1.2 Visual Resources

Visual resources impacts during construction of the representative project would be from the installation of the PV modules on the rooftop of a residence or commercial unit. Such impacts would be short-term and intermittent.

Rooftop PV systems would result in long-term visual impacts from the PV modules and required infrastructure. The magnitude of potential visual impact of the PV systems would depend upon their visibility and the particular locations from where they are visible. However, because rooftop PV systems are common in Hawai'i, visual sensitivity to these systems is likely lower than in areas where they are not common. Some individuals consider PV modules as modernistic and a sign of progress toward renewable energy goals, while others feel they are an unnatural intrusion to the natural scenery and viewshed.

Visual impacts of a distributed PV system for a commercial facility could cause glaring that might be detected from a distance.

5.4.8.2 Best Management Practices and Mitigation Measures

The following best management practices should be used to reduce the identified potential impacts:

- Before installation, consider whether placement of PV system would change the historic character of an area.
- Carefully consider where the PV module would be placed on the residence. Use shrubbery to screen visual impacts from neighbors, while ensuring enough sunlight to enable the module to produce electricity.

- Coordinate with the FAA and HDOT, as appropriate, to address potential impacts to aircraft from PV module glare.
- Consider placement of PV system away from public or street views to minimize changes in viewsheds.

5.4.9 RECREATION RESOURCES

As indicated in [Table 5-4](#), there would be no potential impacts to recreation resources from the representative distributed PV project.

5.4.10 LAND AND MARINE TRANSPORTATION

As indicated in [Table 5-4](#), there would be no potential impacts to land or marine transportation from the representative distributed PV project.

5.4.11 AIRSPACE MANAGEMENT

As indicated in [Table 5-4](#), there would be no potential impacts to airspace management from the representative distributed PV project.

5.4.12 NOISE AND VIBRATION

As indicated in [Table 5-4](#), there would be no potential impacts to noise and vibration from the representative distributed PV project.

5.4.13 UTILITIES AND INFRASTRUCTURE

5.4.13.1 Potential Impacts

The potential impact on each island's electric utilities would be small from the addition of 5 kilowatts of PV cell generation to an individual household. The potential impacts for adding 50 kilowatts of PV cell generation to a single, existing industrial facility would also be small, as the facility would remain connected to the grid to use utility power to run the facility when the renewable source was not sufficient. Also, any excess power generated by the renewable source could be sold to the utility to balance the grid demand.

For O'ahu, with the largest island net capacity of 1,756 megawatts, the 5-kilowatt addition would equate to about 0.0003 percent of its total capacity. For Lāna'i and Molokai, with the smallest net capacity of 10 and 12 megawatts, respectively, the addition would equate to about 0.05 and 0.04 percent of their respective total capacities (see Section 3.13.1). Increased capacity (i.e., the 50-kilowatt commercial application) would be a linear increase of renewable power generated and similar decrease in the electricity needed from the local utility.

Potential impacts from connection to utilities for construction and operation of the representative project would be the same as those expected for common construction actions described in Section 3.13.3.1.

While an individual residential or commercial PV system would not have significant impacts to the utilities and existing infrastructure, there are potential impacts to utilities and infrastructure from large-scale use of residential or commercial PV systems. According to HECO, "the unprecedented rapid growth in rooftop solar in Hawai'i has resulted in some neighborhood circuits reaching extremely high levels of

photovoltaic systems. An increasing number of distribution level circuits have rooftop PV capacity exceeding 100 percent of the daytime minimum load, the trigger for interconnection studies and possible implementation of safety measures or upgrades before new PV systems on that circuit can be interconnected to the grid. This condition slowed the pace of rooftop solar growth in the last quarter of [2013]” (HECO 2014). As noted in Section 3.13.1, interconnection policies are rapidly evolving and are subject to change as more variable renewable energy comes online. For example, in February 2014, HECO announced updates to the 100 percent of the daytime minimum load threshold policy to allow more PV projects to proceed without an interconnection requirements study.

As a result, while an individual, residential, or commercial PV system would not have significant impacts to the utilities and existing infrastructure, there are potential cumulative impacts to utilities and infrastructure from a much larger use of this technology. The utility companies are aware of the challenges that are associated with a higher percentage of variable power sources.

5.4.13.2 Best Management Practices and Mitigation Measures

General best management practices to minimize impacts to utilities, infrastructure, and public safety would be the same as those described in Section 3.13.3

5.4.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

5.4.14.1 Potential Impacts

5.4.14.1.1 Hazardous Materials

Potential impacts from exposure to hazardous material from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.14.4. No construction would be required for storage of energy in batteries.

The use of PV systems or battery storage systems would not require the use of hazardous materials and would not result in hazardous material releases or spills. As such, no impacts would occur during project operations.

Hazardous material exposure impacts may result at the end-of-life of the PV system and the battery energy storage system. Associated impacts are discussed below.

5.4.14.1.2 Waste Management

Potential impacts related to waste management from construction of the representative project would be the same as those expected for common construction actions as described in Section 3.14.4.

To the extent feasible, it is anticipated that most components of PV modules, such as glass, aluminum, and semiconductor materials, would be successfully recovered and reused either for new PV modules or other products. However, some PV systems may need to be managed and disposed of as hazardous waste. In particular, the manufacturing, decommissioning, and disposal of some PV modules (some thin film PV products) may involve cadmium. Cadmium is a heavy metal that is considered a probable carcinogen in humans and animals and can accumulate in plant and animal tissues. While cadmium does not pose health risks when a PV module is in operation, the production of some PV modules can result in waste sludge and cadmium contaminated wastewater which would need to be properly disposed of at the appropriate hazardous waste facility (see below).

5.4.14.1.3 Wastewater

As identified in [Table 5-4](#), no impacts to wastewater services are expected from the installation and operation of PV systems.

Secondary impacts may result as the production of some PV modules can result in cadmium contaminated wastewater which would need to be properly disposed of at the appropriate hazardous waste facility. Although PV modules are not anticipated to be manufactured in the State, proper disposal of those PV modules at the appropriate hazardous waste facility would be required at its end-life, to ensure no leaching or contamination from cadmium occurs. As such, PV modules would require proper handling and transport of these materials for disposal at the appropriate hazardous material facility to ensure that hazardous substances do not leach or contaminate wastewater.

5.4.14.2 Best Management Practices and Mitigation Measures

As feasible, develop and implement a recycling plan including effectively recovering building materials that could contain potentially hazardous substances (e.g., liquid wastes, paints, oil, or solvents). This includes proper handling and transport for disposal at the appropriate hazardous material facility to ensure that no hazardous materials are disposed of at landfills and that no hazardous materials enter the waste stream.

Although PV modules are not anticipated to be manufactured in the State, proper disposal of some PV modules at the appropriate hazardous waste facility would be required at its end-life to ensure no leaching or contamination from cadmium. As such, PV modules would require proper handling and transport of these materials for disposal at the appropriate hazardous material facility to ensure no hazardous materials were disposed of at landfills and that hazardous materials did not enter the waste stream.

5.4.15 SOCIOECONOMICS

As indicated in [Table 5-4](#), there would be no potential impacts to socioeconomics from the representative distributed PV project.

5.4.16 ENVIRONMENTAL JUSTICE

As identified in [Table 5-4](#), there would be no environmental justice impacts from the representative distributed PV project.

5.4.17 HEALTH AND SAFETY

Potential impacts to health and safety from construction and operation of the representative distributed PV project would be the same as those expected for common construction actions.

5.5 Wind

The representative distributed wind project involves the construction and operation of a single 100-kilowatt wind turbine. It is further assumed that the turbine is a horizontal-axis unit, with a 60-foot rotor diameter (that is, it has blade lengths of about 30 feet), and is mounted on a 120-foot monopole. Details about these wind turbines can be found in Section 2.3.2.5.

[Table 5-5](#) presents a summary of the potential environmental impacts for distributed wind projects, whether such impacts are resource-specific, regardless of the technology employed, or occur solely

because of the technology and best management practices and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 5-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	General impacts during construction (see Section 3.1.3).	Same as those common across construction projects (see Section 3.1.4). Minimize the potential for loose soil or contaminants to leave the site by wind or stormwater runoff.
Climate and Air Quality		
Air Quality	General impacts during construction (see Section 3.2.4).	Same as those common across construction projects (see Section 3.2.5).
Climate Change	Beneficial; reduced oil consumption by use of renewable energy.	None.
Water Resources		
	General impacts during construction (see Section 3.1.3).	Same as those common across construction projects (see Section 3.1.4).
Biological Resources		
	General impacts during construction (see Section 3.4.5). Potential adverse impacts to the Hawaiian Hoary bat and a variety of bird species	During project siting, consideration should be given to the location of the wind turbine in relation to suitable bat roosting habitat and foraging areas (i.e., identify factors such as roost trees and foraging areas, proximity of bird habitats, and flight pathways for water birds, sea birds, and migratory species). Any lighting required on the wind turbine should be minimized to avoid attracting seabirds. During project design, early coordination with State and Federal wildlife agencies. To the extent feasible, the project should consider designing the wind turbine with rotor cutoff at low speeds.
Land and Submerged Land Use		
Land Use	Potential change in land use.	Consider State land use designations and county overlay zones.
Submerged Land Use	None; the wind turbine would be installed on land and would not impact the marine environment.	N/A

Table 5-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Cultural and Historic Resources		
	<p>General impacts during construction and operation (see Section 3.6.6).</p> <p>The visual impact of wind turbines may be unacceptable near cultural and historic areas where the historic integrity (setting, feeling, association, viewsheds) plays an important role in the value of the resource.</p>	<p>Same as those common across construction and operational projects (see Section 3.6.7).</p>
Coastal Zone Management		
	<p>Potential impacts to special management areas designated as a Coastal Zone Management Program, shorefront access, and shoreline erosion.</p>	<p>Specific project locations should be evaluated to determine if impacts to special management areas designated under the Coastal Zone Management Program, shorefront access, and shoreline erosion would occur.</p>
Scenic and Visual Resources		
	<p>Short-term visual resource impacts during installation.</p> <p>Potential long-term visual impacts (site-specific).</p> <p>Potential impacts to natural scenic and visual resources, or historic character of an area.</p> <p>Potential lighting and shadow flicker impacts (site-specific).</p>	<p>During project design, consider the use of setbacks or vegetative buffers.</p> <p>Conduct computer modeling to determine if specific buildings near turbines would experience shadow flicker.</p> <p>Chose color of the wind turbine to best blend into the background and the sky (white is often more intrusive than a muted gray).</p> <p>Prohibit the use of commercial markings, messages, or banners on the turbine or tower.</p> <p>Work with park units within the viewshed of the turbine.</p> <p>Consider potential impacts on visual resources in the project planning and siting phase, for example, when siting structures, consider landscape characteristics, lighting and glare from facility components, minimizing structure profiles, views from key observation points and nearby recreation lands, and integration of project components with natural land contours and colors.</p> <p>Consider potential visual impacts on the nature and character of nearby culturally sensitive and historic structures.</p>

Table 5-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
		<p>Consider visual effects of project location and components on nearby units of the National Park System and other areas under NPS management, including effects of light pollution.</p> <p>Consider visual effects of project components on local infrastructure facilities such as schools, hospitals, and housing developments in urban and rural communities.</p> <p>Consider the importance of dark night skies in the short term during construction and in the long term. Use low lumen lighting, on demand lighting, and well-directed lighting. Use the minimum amount of light necessary; select lamps using long-wavelength light [greater than 560 nm (in vacuum)].</p> <p>Limit the hours of construction at night, limit total lumen output of artificial lighting, and direct lighting downward and shield fixtures to reduce impacts from construction lighting.</p> <p>Provide accurate day and night visual simulations of the proposed project to local community and regulatory stakeholders (e.g., neighborhood boards) to adequately inform the community of what can be expected.</p>
Recreation Resources		
	Potential visual impacts to recreation resources (e.g., scenic lookouts and views).	See BMPs for Scenic and Visual Resources.
Land and Marine Transportation		
	None; construction and operation of a small wind turbine would not impact land and marine transportation.	N/A
Airspace Management		
	Potential impacts on airspace including military training airspace (site-specific).	Prior to site selection, consultation with the FAA and DoD to identify special use airspace.

Table 5-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Noise and Vibration		
	Minimal noise and vibration impacts during construction. Potential long-term noise and vibration impacts (site-specific)	A noise study should be conducted prior to turbine installation to develop expectations regarding operational noise levels. A separation distance of a minimum of 1,000 feet is recommended. Use turbines designed with soundproofing techniques.
Utilities and Infrastructure		
	Minor impacts to electricity generating capacities. General impacts during construction and operation (see Section 3.13.3).	Same as those common across construction projects (see Section 3.13.4).
Hazardous Materials and Waste Management		
Hazardous Materials	General construction exposure impacts (see Section 3.14.4). Potential for hazardous material exposure resulting from handling and disposal of batteries (project-specific).	Ensure proper handling and disposal of battery systems.
Waste Management	General construction impacts (see Section 3.14.4). Potential waste management impacts from toxic and hazardous waste contamination during disposal of batteries at their end-life (project specific)	Same as those common across construction projects (see Section 3.14.5). Ensure proper disposal of hazardous materials at end-of-life.
Wastewater	General construction and operation impacts (see Section 3.14.4).	None.
Socioeconomics		
	None; construction and operation of a small wind turbine would result in few jobs and would not impact socioeconomics.	N/A
Environmental Justice		
	None; since there would be no measurable impacts to the human environment, there would be no environmental justice impacts.	N/A
Health and Safety		
	General impacts during construction and operation.	None.

5.5.1 GEOLOGY AND SOILS

5.5.1.1 Potential Impacts

Potential impacts on geology and soils from construction and operation of the representative 100-kilowatt wind turbine would be the same as those expected for common construction actions as described in Section 3.1.3.

Although the foundation for a 100-kilowatt wind turbine is still a substantial structure, it is reasonable to assume it would require less than 1 acre of land disturbance. The wind turbine foundation would be expected to have a footprint size similar to, or smaller than, a single car garage and whether the foundation involved excavation/boring or pile driving, disturbances would not require an acre, particularly since the representative project does not assume an access road would be needed. Similarly, land disturbance for installation of two or three poles for 300 feet of power lines would be minor.

Further, because land disturbance would be expected to be less than an acre, construction of the turbine would not require a stormwater discharge permit (construction actions that will disturb one acre or more are required to obtain such a permit as described in Section 3.1.3). Without the discharge permit requirement, there may be fewer precautions taken during construction to ensure loosened soil was not carried off by wind or stormwater run-off. There may also be fewer assurances that the construction crew would pay particular attention to drips or leaks from their equipment or have materials and procedures in place for dealing with drips, leaks, or spills, should they occur. However, the relatively small amount of land disturbance and project scale would tend to minimize the potential for serious adverse impacts. Furthermore, the scope of the foundation work would require skilled workers, most likely working under procedures to minimize the potential for any loose soil or contaminants to leave the site by wind or stormwater runoff.

5.5.1.2 Best Management Practices and Mitigation Measures

The following mitigation measures should be followed to reduce the identified potential impacts:

- Work should be performed to mitigate drips or leaks from equipment and procedures followed for dealing with drips, leaks, and spills.
- Due diligence should be taken to ensure loosened soil was not carried off by wind or stormwater run-off.

5.5.2 CLIMATE AND AIR QUALITY

5.5.2.1 Potential Impacts

Wind turbines convert the kinetic energy of the wind to mechanical power. A representative 100-kilowatt wind turbine could have a capacity factor between 45 and 65 percent depending on site-specific conditions ([DBEDT 2013](#)). The representative wind turbine could replace electricity requirements from the baseline electrical grid by between 390 and 570 megawatt-hours per year when using those capacity factors as minimum and maximum values.

5.5.2.1.1 Air Quality

Potential impacts on air quality from construction and operation of the representative 100-kilowatt wind turbine would be the same as those expected for common construction actions as described in Section 3.2.4.

5.5.2.1.2 Climate Change

A replacement of between 390 and 570 megawatt-hours of electricity per year from the baseline electrical grid would reduce oil consumption from electricity generation by between 26,000 and 38,000 gallons (assuming 66.7 gallons of fuel oil per megawatt-hour of electricity). On O‘ahu, this annual replacement of electricity from the baseline grid would correspond to an annual reduction in greenhouse gas emissions of between 290 and 410 metric tons carbon dioxide equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid>; EPA 2012). On other islands, by comparison, this same annual replacement of electricity usage would see an annual reduction in greenhouse gas emissions of between 240 and 350 metric tons carbon dioxide equivalent due to a different mix of technologies used to produce electricity.

5.5.2.2 Best Management Practices and Mitigation Measures

None noted.

5.5.3 WATER RESOURCES

As identified in [Table 5-5](#), there would be no potential impacts to water resources, including surface water, groundwater, floodplains, and wetlands, from the representative distributed wind project.

5.5.4 BIOLOGICAL RESOURCES

5.5.4.1 Potential Impacts

The representative distributed wind project would require approximately 1 acre of land, most of which could be revegetated with low stature plants following construction. In addition to the common construction-related impacts discussed in Section 3.4.5.1, the wind turbine impacts would include potential mortality of the Federally-listed Hawaiian hoary bat and a variety of bird species from collisions with the turbine blades. Depending on the specific project locations, these could include Federally or State-listed species. Specific islands also may have higher potential for impacts (e.g., Kaua‘i and Hawai‘i) because of larger populations of bats. Similar mortality impacts could occur to bird species depending on the location of the wind turbine and surrounding habitats. Locations near wetlands or the coast could impact greater numbers of water birds, shorebirds, and migratory birds. Marine birds are far ranging and fly between terrestrial nesting sites and offshore foraging areas and may be vulnerable depending on the project location. Even though a single distributed wind turbine has a smaller rotor swept area than larger utility-scale wind turbines, a key factor in the probability of mortality is location and position of the wind turbine within the landscape and the surrounding habitat. The number and types of potentially affected species will be heavily dependent on the specific project siting.

5.5.4.2 Best Management Practices and Mitigation Measures

The following mitigation measures should be taken to reduce the identified potential impacts:

- Consider the location of the wind turbine in relation to suitable bat roosting habitat and foraging areas.
- Minimize any lighting required on the wind turbine to avoid attracting seabirds.
- During site selection, identify factors such as proximity of bat roost trees and foraging areas, proximity of bird habitats (e.g., forests, wetlands, nesting colonies), and flight pathways for water birds, sea birds, and migratory species when evaluating potential impacts. Coordinate with State and Federal wildlife agencies early in the project design process to assist in identifying these factors at the landscape level.
- Design the wind turbine with rotor cutoff at low speeds to help mitigate potential mortality impacts.

5.5.5 LAND AND SUBMERGED LAND USE

5.5.5.1 Potential Impacts

Siting of distributed wind turbines requires sufficient average wind speed and frequency to allow the turbine to operate efficiently. There should be no land obstacles with 300 feet of the tower. There would be temporary land disturbance due to site preparation and turbine installation. Depending upon the site, land could be converted from an undeveloped State or other land uses to energy uses.

5.5.5.2 Best Management Practices and Mitigation Measures

During site selection, evaluate the State land use designations and county overlay zones.

5.5.6 CULTURAL AND HISTORIC RESOURCES

5.5.6.1 Potential Impacts

Potential impacts on cultural and historic resources from construction and operation of the representative 100-kilowatt wind turbine would be the same as those expected for common construction actions as described in Section 3.6.6. Of particular importance in Hawai'i is the potential visual impact of wind turbines that might be unacceptable near cultural and historic areas where the historic integrity (setting, feeling, association, viewsheds) plays an important role in the value of the resource.

5.5.6.2 Best Management Practices and Mitigation Measures

General best management practices to minimize impacts to cultural and historic resources would be the same as those common across construction projects. See Section 3.6.7.

5.5.7 COASTAL ZONE MANAGEMENT

5.5.7.1 Potential Impacts

Impacts to the coastal zone from the representative distributed wind project could involve impacts to special management areas and shorefront access. Because the entire State of Hawai'i is considered part of the coastal zone, a Federal consistency review may be required (see Section 3.7.4).

5.5.7.2 Best Management Practices and Mitigation Measures

Specific project locations would require evaluation to determine if impacts to special management areas designated under the State Coastal Zone Management Program, shorefront access, and shoreline erosion would occur.

5.5.8 SCENIC AND VISUAL RESOURCES

5.5.8.1 Potential Impacts

Potential impacts on scenic and visual resources from construction of the representative 100-kilowatt wind turbine would be the same as those expected for common construction actions as described in Section 3.8.3.

Operation of the wind turbine would introduce a 150-foot-tall structure into the viewshed of the area. Small turbines are designed to blend in with their surroundings as much as possible. Studies show that turbines best blend into the sky when painted the factory-default color ([AWEA 2008](#)). Wind turbines vary in color, depending on the manufacturer, and can include white, gray, blue, and yellow. Turbines that begin a bright silver color soon weather to a muted gray, which helps the turbine blend in with the background or against the sky.

The visual impact of a wind turbine depends, to some extent, on the sensitivity of the viewer. Some individuals consider the aerodynamic design of the turbines graceful and modernistic, while others feel they are an unnatural intrusion to the natural scenery and viewshed. Utility poles, cellular phone towers, and satellite dishes might be considered comparable features of the existing landscape. Shadow flicker occurs when the blades of a turbine pass in front of the sun to create a recurring shadow on an object. Computer models in wind development software can determine the days and times during the year that buildings near turbines may experience shadow flicker ([AWEA 2010](#)).

Because of the strobe-like effect of shadow flicker, there have been investigations into whether it might have the potential to produce epileptic seizures in individuals with photosensitivity. It has been determined that modern utility-scale wind turbines do not have the potential to cause these types of problems because of their relatively slow blade rotation. One study ([Harding et al. 2008](#)) reported that flickers with a frequency greater than 3 hertz could pose a potential for inducing photosensitive seizures (that is, a light flashing at a rate of more than 3 times per second). The Epilepsy Foundation of America reports that lights flashing in the range of 5 to 30 hertz are most likely to trigger seizures and recommends that flash rates of visual alarms be kept under 2 hertz ([Epilepsy Foundation of America 2013](#)). A wind turbine with three blades would have to make a full revolution every second (or 60 revolutions per minute) to reach a frequency of 3 hertz. Any specific wind turbine would be evaluated for flicker frequencies depending on its configuration, rotational speed, and orientation relative to the sun.

Some data suggest that shadow flicker has the potential to cause a disorienting effect on a small segment of the population. The data also suggest that rotor rotation below 2.5 hertz can avoid such effects ([BLM 2005](#)).

5.5.8.2 Best Management Practices and Mitigation Measures

The visual impact of wind turbines may be unacceptable in areas with historic significance where aesthetics play an important role in an area's long-established character. Shadow flicker also can be more than just an irritant to some sensitive segments of the population. Areas of shadow flicker should be minimized or avoided for sensitive locations such as residences, schools, and hospitals.

The following mitigation measures may reduce the identified impacts:

- Consider setbacks or vegetative buffers to avoid shadow flicker. A setback is a distance from a property line within which a turbine cannot be located. Computer modeling can determine if specific buildings near turbines would experience shadow flicker and this information can assist in determining appropriate mitigation measures ([AWEA 2010](#)).
- Use a color for the turbine that blends into the background and the sky. White is often more intrusive than a muted gray.
- Prohibit the use of commercial markings, messages, or banners on the turbine or tower.
- Consult any park units within the viewshed of a wind turbine early in the planning process.
- Consider potential impacts on visual resources in the project planning and siting phase, for example, when siting structures, consider landscape characteristics, lighting and glare from facility components, minimizing structure profiles, views from key observation points and nearby recreation lands, and integration of project components with natural land contours and colors.
- Consider potential visual impacts on the nature and character of nearby culturally sensitive and historic structures.
- Consider visual effects of project location and components on nearby units of the National Park System and other areas under NPS management, including effects of light pollution.
- Consider visual effects of project components on local infrastructure facilities such as schools, hospitals, and housing developments in urban and rural communities.
- Consider the importance of dark night skies in the short term during construction and in the long term. Use low lumen lighting, on demand lighting, and well-directed lighting. Use the minimum amount of light necessary; select lamps using long-wavelength light [greater than 560 nm (in vacuum)].
- Limit the hours of construction at night, limit total lumen output of artificial lighting, direct lighting downward, and shield fixtures to reduce impacts from construction lighting.
- Provide accurate day and night visual simulations of the proposed project to local community and regulatory stakeholders (e.g., neighborhood boards) to adequately inform the community of what can be expected.

5.5.9 RECREATION RESOURCES

5.5.9.1 Potential Impacts

The representative distributed wind project could cause an adverse impact to recreation resources if incompatible with the recreational activity, for example, visiting a scenic lookout, hang-gliding, off-road racing, and bird-watching. Some individuals may feel the wind turbine is an unnatural intrusion to the natural scenery, which could adversely affect their recreational experience. Others may find the wind turbine an interesting landmark and a destination for recreation activities, such as picnicking and hiking.

5.5.9.2 Best Management Practices and Mitigation Measures

The visual impact of wind turbines may be unacceptable near recreation areas where aesthetics play an important role in the value of the recreation resource. Consider the *State Comprehensive Outdoor Recreation Plan* ([DLNR 2009](#)) before siting the turbine to mitigate potential impacts.

5.5.10 LAND AND MARINE TRANSPORTATION

As identified in [Table 5-5](#), there would be no potential impacts to land or marine transportation from the representative distributed wind project.

5.5.11 AIRSPACE MANAGEMENT

5.5.11.1 Potential Impacts

The representative distributed wind project could impact airspace depending on the specific location of the project. Although the height of the turbine (approximately 150 feet) is not considered an FAA obstruction and subject to navigation review, the project may require a Notice of Proposed Construction or Alteration of Airspace depending on the location in relation to airports and defined airspace. Structures that penetrate imaginary surfaces extending outward from runways as defined in FAA regulations require review and evaluation for impacts to airspace. In addition, various special use airspaces for military training could potentially be impacted depending project location.

5.5.11.2 Best Management Practices

Prior to site selection, consult with the FAA and DoD to identify various special use airspace.

5.5.12 NOISE AND VIBRATION

5.5.12.1 Potential Impacts

Potential noise and vibration impacts from construction of the representative 100-kilowatt wind turbine would be the same as those expected for common construction actions as described in Section 3.12.5.

Wind turbines operate when wind conditions are favorable, day or night. Wind turbines generate both aerodynamic sounds (generated by the blades passing through the air) and mechanical noise (generated from the turbine's internal gears). The mechanical noise generated from small wind turbines, such as the representative project, is minimal. Depending on the wind turbine design and wind speed, the aerodynamic noise produces a repetitive sound that may seem like a buzzing, whooshing, or pulsing. Wind turbine noise is present at all frequencies, which includes infrasound (low frequency sound inaudible to the human ear), frequencies in the audible range for humans, and high frequencies. Infrasound is inaudible to the human ear, but this unheard sound can cause human annoyance, sensitivity, disturbance, and disorientation, and the effects on birds, bats, and other wildlife may be more profound ([USFWS 2011](#)). Frequency varies with wind speed, blade pitch, and blade speed, and wind turbines can have different acoustics on different days even at the same wind speed ([NREL 2012](#)). Additionally, the noise the human ear can detect from a wind turbine is dependent on background noise levels. Noise would be more audible at lower levels in rural areas compared to urban areas.

Operational noise levels produced by a representative distributed wind turbine project would be 55 dBA at a distance of 130 feet. Continuous and long-term noise levels in excess of 65 dBA are normally unacceptable for noise-sensitive land uses such as residences, schools, churches, and hospitals (see

Section 3.12). Long-term noise and vibration impacts could be potentially significant and would depend on the location of the wind turbine and compatibility with the existing land uses.

5.5.12.2 Best Management Practices and Mitigation Measures

Noise and vibration impacts should be considered when siting a distributed wind turbine. Noise and vibration best management practices and mitigation measures are a much bigger consideration for a proposed distributed wind turbine in a residential setting compared to one in a commercial setting. Developers must comply with Federal, State, and local noise regulations and ordinances. Because small wind turbines would be located close to people, homeowners and local authorities could use available noise data or perform a noise study to develop expectations regarding operational noise levels before a wind turbine is installed. Although there are no county or State requirements, an appropriate separation distance is recommended (such as at least three times the height of the turbine). Manufacturers may also mitigate noise levels through the use of noise reduction materials and soundproofing techniques when designing wind turbines.

5.5.13 UTILITIES AND INFRASTRUCTURE

5.5.13.1 Potential Impacts

The potential impact on each island's electric utilities would be small to moderate from the addition of 100 kilowatts of wind project on any island. The existing household or industrial facility would remain connected to the grid to use utility power to run the facility when the renewable source was not sufficient. Also, any excess power generated by the renewable source could be sold to the utility.

For O'ahu, with largest island net capacity of 1,756 megawatts, the 100-kilowatt addition would equate to about 0.006 percent of its total capacity. For Lāna'i and Molokai, with the smallest net capacity of 10 and 12 megawatts, respectively, the addition would equate to about 1.0 to 0.8 percent of their respective total capacities (see Section 3.13.1).

Potential impacts from connection to utilities for construction and operation of this representative project would be the same as expected for common construction actions described in Section 3.13.3.1.

5.5.13.2 Best Management Practices and Mitigation Measures

General best management practices to minimize impacts to utilities, infrastructure, and public safety would be the same as those common across construction projects (see Section 3.13.4).

5.5.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

5.5.14.1 Potential Impacts

5.5.14.1.1 Hazardous Materials

The representative distributed wind project could produce hazardous waste that could result in hazardous material exposure impacts in the event a battery was used for energy storage. Battery impacts would be similar to those discussed in Section 8.5.14. Please refer to Section 8.5.14 for additional discussion.

5.5.14.1.2 Waste Management

Potential impacts could occur from toxic and hazardous waste contamination during disposal of batteries at their end-life.

5.5.14.1.3 Wastewater

Potential wastewater impacts from construction and operation of the representative 100-kilowatt wind turbine would be the same as those expected for common construction actions as described in Section 3.14.3.

5.5.14.2 Best Management Practices and Mitigation Measures

General best management practices to minimize impacts associated with hazardous materials and waste management would be the same as those common across construction projects (see Section 3.14.4).

The following mitigation measures should be taken to prevent battery fires:

- Use insulation boards between blocks in battery module to prevent leaking molten materials from causing a short circuit,
- Use anti-fire boards between battery modules to prevent fires from spreading,
- Implement a monitoring system, the installation of fire prevention equipment and a fire-fighting structure for fire preparedness and safety, as well as a fire evacuation and guidance plan.

5.5.15 SOCIOECONOMICS

As identified in [Table 5-5](#), there would be no potential impacts to socioeconomics from the representative distributed wind project.

5.5.16 ENVIRONMENTAL JUSTICE

As identified in [Table 5-5](#), there would be no environmental justice impacts from the representative distributed wind project.

5.5.17 PUBLIC HEALTH AND SAFETY

Potential impacts to health and safety from construction and operation of the representative distributed wind project would be the same as those expected for common construction actions.

CHAPTER 6

Environmental Impacts from Utility-Scale Renewables

CONTENTS

6 ENVIRONMENTAL IMPACTS FROM UTILITY-SCALE RENEWABLES 6-1

- 6.1 Biomass 6-1
 - 6.1.1 Geology and Soils 6-13
 - 6.1.1.1 Potential Impacts 6-13
 - 6.1.1.2 Best Management Practices and Mitigation Measures 6-14
 - 6.1.2 Climate and Air Quality 6-14
 - 6.1.2.1 Potential Impacts 6-14
 - 6.1.2.1.1 Air Quality 6-14
 - 6.1.2.1.2 Climate Change 6-15
 - 6.1.2.2 Best Management Practices and Mitigation Measures 6-16
 - 6.1.3 Water Resources 6-16
 - 6.1.3.1 Potential Impacts 6-16
 - 6.1.3.1.1 Surface Water 6-17
 - 6.1.3.1.2 Groundwater 6-18
 - 6.1.3.1.3 Floodplains and Wetlands 6-18
 - 6.1.3.2 Best Management Practices and Mitigation Measures 6-19
 - 6.1.4 Biological Resources 6-19
 - 6.1.4.1 Potential Impacts 6-19
 - 6.1.4.1.1 Direct Combustion Biomass Project 6-19
 - 6.1.4.1.2 Biodiesel Fueled Biomass Project 6-20
 - 6.1.4.2 Best Management Practices and Mitigation Measures 6-20
 - 6.1.5 Land and Submerged Land Use 6-21
 - 6.1.5.1 Potential Impacts 6-21
 - 6.1.5.1.1 Land Use 6-21
 - 6.1.5.1.2 Submerged Land Use 6-21
 - 6.1.5.2 Best Management Practices and Mitigation Measures 6-21
 - 6.1.6 Cultural and Historic Resources 6-21
 - 6.1.6.1 Potential Impacts 6-21
 - 6.1.6.2 Best Management Practices and Mitigation Measures 6-22
 - 6.1.7 Coastal Zone Management 6-22
 - 6.1.7.1 Potential Impacts 6-22
 - 6.1.7.2 Best Management Practices and Mitigation Measures 6-22
 - 6.1.8 Scenic and Visual Resources 6-22
 - 6.1.8.1 Potential Impacts 6-22
 - 6.1.8.1.1 Direct Combustion Biomass Fueled Steam Turbine Generator 6-22
 - 6.1.8.1.2 Biodiesel Plant and Electric Power Plant 6-23
 - 6.1.8.2 Best Management Practice and Mitigation Measures 6-23
 - 6.1.9 Recreation Resources 6-24
 - 6.1.9.1 Potential Impacts 6-24
 - 6.1.9.1.1 Direct Combustion Biomass-Fueled Steam Turbine Generator 6-24
 - 6.1.9.1.2 Biodiesel Plant and Electric Power Plant 6-24
 - 6.1.9.2 Best Management Practices and Mitigation Measures 6-24
 - 6.1.10 Land and Marine Transportation 6-24
 - 6.1.10.1 Potential Impacts 6-25
 - 6.1.10.1.1 Land Transportation 6-25
 - 6.1.10.1.2 Marine Transportation 6-25
 - 6.1.10.2 Best Management Practices and Mitigation Measures 6-25
 - 6.1.11 Airspace Management 6-25
 - 6.1.11.1 Potential Impacts 6-25

6.1.11.2	Best Management Practices and Mitigation Measures	6-25
6.1.12	Noise and Vibration.....	6-26
6.1.12.1	Potential Impacts	6-26
6.1.12.2	Best Management Practices and Mitigation Measures	6-26
6.1.13	Utilities and Infrastructure.....	6-26
6.1.13.1	Potential Impacts	6-26
6.1.13.2	Best Management Practices and Mitigation Measures.....	6-27
6.1.14	Hazardous Materials and Waste Management	6-27
6.1.14.1	Potential Impacts	6-27
6.1.14.1.1	Hazardous Materials.....	6-27
6.1.14.1.2	Waste Management.....	6-28
6.1.14.1.3	Wastewater.....	6-28
6.1.14.2	Best Management Practices and Mitigation Measures.....	6-28
6.1.15	Socioeconomics.....	6-28
6.1.15.1	Potential Impacts	6-28
6.1.15.2	Best Management Practices and Mitigation Measures.....	6-29
6.1.16	Environmental Justice	6-29
6.1.16.1	Potential Impacts	6-29
6.1.16.2	Best Management Practices and Mitigation Measures.....	6-29
6.1.17	Health and Safety	6-29
6.1.17.1	Potential Impacts	6-29
6.1.17.2	Best Management Practices and Mitigation Measures.....	6-29
6.2	Geothermal.....	6-29
6.2.1	Geology and Soils	6-38
6.2.1.1	Potential Impacts	6-38
6.2.1.2	Best Management Practices and Mitigation Measures.....	6-39
6.2.2	Climate and Air Quality	6-39
6.2.2.1	Potential Impacts	6-39
6.2.2.1.1	Air Quality	6-39
6.2.2.1.2	Climate Change.....	6-40
6.2.2.2	Best Management Practices and Mitigation Measures.....	6-40
6.2.3	Water Resources.....	6-41
6.2.3.1	Potential Impacts	6-41
6.2.3.1.1	Surface Water.....	6-41
6.2.3.1.2	Groundwater.....	6-42
6.2.3.1.3	Floodplains and Wetlands	6-44
6.2.3.2	Best Management Practices and Mitigation Measures.....	6-44
6.2.4	Biological Resources.....	6-44
6.2.4.1	Potential Impacts	6-44
6.2.4.2	Best Management Practices and Mitigation Measures.....	6-45
6.2.5	Land and Submerged Land Use	6-45
6.2.5.1	Potential Impacts	6-45
6.2.5.1.1	Land Use	6-45
6.2.5.1.2	Submerged Land Use.....	6-45
6.2.5.2	Best Management Practices and Mitigation Measures.....	6-45
6.2.6	Cultural and Historic Resources.....	6-46
6.2.6.1	Potential Impacts	6-46
6.2.6.2	Best Management Practices and Mitigation Measures.....	6-46
6.2.7	Coastal Zone Management.....	6-46
6.2.7.1	Potential Impacts	6-46
6.2.7.2	Best Management Practices and Mitigation Measures.....	6-47

6.2.8	Scenic and Visual Resources.....	6-47
6.2.8.1	Potential Impacts	6-47
6.2.8.2	Best Management Practices and Mitigation Measures.....	6-47
6.2.9	Recreation Resources	6-47
6.2.9.1	Potential Impacts	6-47
6.2.9.2	Best Management Practices and Mitigation Measures.....	6-48
6.2.10	Land and Marine Transportation.....	6-48
6.2.10.1	Potential Impacts	6-48
6.2.10.1.1	Land Transportation.....	6-48
6.2.10.1.2	Marine Transportation.....	6-48
6.2.11	Airspace Management.....	6-48
6.2.12	Noise and Vibration.....	6-48
6.2.12.1	Potential Impacts	6-48
6.2.12.2	Best Management Practices and Mitigation Measures.....	6-49
6.2.13	Utilities and Infrastructure.....	6-50
6.2.13.1	Potential Impacts	6-50
6.2.13.2	Best Management Practices and Mitigation Measures.....	6-50
6.2.14	Hazardous Materials and Waste Management	6-50
6.2.14.1	Potential Impacts	6-50
6.2.14.1.1	Hazardous Materials.....	6-50
6.2.14.1.2	Waste Management.....	6-51
6.2.14.1.3	Wastewater.....	6-52
6.2.14.2	Best Management Practices and Mitigation Measures.....	6-52
6.2.15	Socioeconomics.....	6-52
6.2.15.1	Potential Impacts	6-52
6.2.15.2	Best Management Practices and Mitigation Measures.....	6-52
6.2.16	Environmental Justice	6-52
6.2.16.1	Potential Impacts	6-52
6.2.16.2	Best Management Practices and Mitigation Measures.....	6-53
6.2.17	Health and Safety	6-53
6.2.17.1	Potential Impacts	6-53
6.2.17.2	Best Management Practices and Mitigation Measures.....	6-54
6.3	Municipal Solid Waste (MSW).....	6-54
6.3.1	Geology and Soils	6-61
6.3.1.1	Potential Impacts	6-61
6.3.1.2	Best Management Practices and Mitigation Measures.....	6-61
6.3.2	Climate and Air Quality	6-61
6.3.2.1	Potential Impacts	6-61
6.3.2.1.1	Air Quality	6-61
6.3.2.1.2	Climate Change.....	6-62
6.3.2.2	Best Management Practice and Mitigation Measures	6-62
6.3.3	Water Resources.....	6-63
6.3.3.1	Potential Impacts	6-63
6.3.3.1.1	Surface Water.....	6-63
6.3.3.1.2	Groundwater.....	6-64
6.3.3.1.3	Floodplains and Wetlands	6-65
6.3.3.2	Best Management Practices and Mitigation Measures.....	6-65
6.3.4	Biological Resources.....	6-65
6.3.4.1	Potential Impacts	6-65
6.3.4.2	Best Management Practices and Mitigation Measures.....	6-65
6.3.5	Land and Submerged Land Use	6-65

6.3.5.1	Potential Impacts	6-65
6.3.5.1.1	Land Use	6-65
6.3.5.1.2	Submerged Land Use	6-66
6.3.5.2	Best Management Practices and Mitigation Measures	6-66
6.3.6	Cultural and Historic Resources	6-66
6.3.6.1	Potential Impacts	6-66
6.3.6.2	Best Management Practices and Mitigation Measures	6-67
6.3.7	Coastal Zone Management	6-67
6.3.7.1	Potential Impacts	6-67
6.3.7.2	Best Management Practices and Mitigation Measures	6-67
6.3.8	Scenic and Visual Resources	6-67
6.3.8.1	Potential Impacts	6-67
6.3.8.2	Best Management Practices and Mitigation Measures	6-67
6.3.9	Recreation Resources	6-68
6.3.9.1	Potential Impacts	6-68
6.3.9.2	Best Management Practices and Mitigation Measures	6-68
6.3.10	Land and Marine Transportation	6-68
6.3.10.1	Potential Impacts	6-69
6.3.10.1.1	Land Transportation	6-69
6.3.10.1.2	Marine Transportation	6-69
6.3.10.2	Best Management Practices and Mitigation Measures	6-69
6.3.11	Airspace Management	6-69
6.3.11.1	Potential Impacts	6-69
6.3.11.2	Best Management Practices and Mitigation Measures	6-69
6.3.12	Noise and Vibrations	6-69
6.3.12.1	Potential Impacts	6-69
6.3.12.2	Best Management Practices and Mitigation Measures	6-70
6.3.13	Utilities and Infrastructure	6-70
6.3.13.1	Potential Impacts	6-70
6.3.13.2	Best Management Practices and Mitigation Measures	6-70
6.3.14	Hazardous Materials and Waste Management	6-70
6.3.14.1	Potential Impacts	6-70
6.3.14.1.1	Hazardous Materials	6-70
6.3.14.1.2	Waste Management	6-71
6.3.14.1.3	Wastewater	6-72
6.3.14.2	Best Management Practices and Mitigation Measures	6-72
6.3.15	Socioeconomics	6-72
6.3.15.1	Potential Impacts	6-72
6.3.15.2	Best Management Practices and Mitigation Measures	6-72
6.3.16	Environmental Justice	6-72
6.3.16.1	Potential Impacts	6-72
6.3.16.2	Best Management Practices and Mitigation Measures	6-73
6.3.17	Health and Safety	6-73
6.3.17.1	Potential Impacts	6-73
6.3.17.2	Best Management Practices and Mitigation Measures	6-73
6.4	Marine Hydrokinetic Energy (MHK)	6-73
6.4.1	Geology and Soils	6-80
6.4.1.1	Potential Impacts	6-80
6.4.1.2	Best Management Practices and Mitigation Measures	6-80
6.4.2	Climate and Air Quality	6-81
6.4.2.1	Potential Impacts	6-81

6.4.2.1.1	Air Quality	6-81
6.4.2.1.2	Climate Change.....	6-81
6.4.2.2	Best Management Practices and Mitigation Measures	6-81
6.4.3	Water Resources.....	6-81
6.4.3.1	Potential Impacts	6-81
6.4.3.1.1	Surface Water.....	6-82
6.4.3.1.2	Groundwater.....	6-83
6.4.3.1.3	Floodplains and Wetlands	6-83
6.4.3.2	Best Management Practices and Mitigation Measures	6-84
6.4.4	Biological Resources	6-84
6.4.4.1	Potential Impacts	6-84
6.4.4.2	Best Management Practices and Mitigation Measures	6-85
6.4.5	Land and Submerged Land Use	6-85
6.4.5.1	Potential Impacts	6-85
6.4.5.1.1	Land Use	6-85
6.4.5.1.2	Submerged Land Use	6-85
6.4.5.2	Best Management Practices and Mitigation Measures	6-86
6.4.6	Cultural and Historic Resources.....	6-86
6.4.6.1	Potential Impacts	6-86
6.4.6.2	Best Management Practices and Mitigation Measures	6-86
6.4.7	Coastal Zone Management	6-86
6.4.7.1	Potential Impacts	6-86
6.4.7.2	Best Management Practices and Mitigation Measures	6-87
6.4.8	Scenic and Visual Resources.....	6-87
6.4.8.1	Potential Impacts	6-87
6.4.8.2	Best Management Practices and Mitigation Measures	6-88
6.4.9	Recreation Resources	6-88
6.4.9.1	Potential Impacts	6-88
6.4.9.2	Best Management Practices and Mitigation Measures	6-88
6.4.10	Land and Marine Transportation	6-89
6.4.10.1	Potential Impacts from the Representative Project.....	6-89
6.4.10.1.1	Land Transportation	6-89
6.4.10.1.2	Marine Transportation.....	6-89
6.4.10.2	Best Management Practices and Mitigation Measures	6-89
6.4.11	Airspace Management.....	6-89
6.4.12	Noise and vibration	6-89
6.4.12.1	Potential Impacts	6-89
6.4.12.2	Best Management Practices and Mitigation Measures	6-90
6.4.13	Utilities and Infrastructure.....	6-91
6.4.13.1	Potential Impacts	6-91
6.4.13.2	Best Management Practices and Mitigation Measures	6-91
6.4.14	Hazardous Materials and Waste Management	6-91
6.4.14.1	Potential Impacts	6-91
6.4.14.1.1	Hazardous Materials.....	6-92
6.4.14.1.2	Waste Management.....	6-92
6.4.14.1.3	Wastewater.....	6-92
6.4.14.2	Best Management Practices and Mitigation Measures	6-92
6.4.15	Socioeconomics.....	6-92
6.4.16	Environmental Justice	6-92
6.4.17	Health and Safety	6-92
6.4.17.1	Potential Impacts	6-92

6.4.17.2 Best Management Practices and Mitigation Measures	6-93
6.5 Ocean Thermal Energy Conversion (OTEC)	6-93
6.5.1 Geology and Soils	6-99
6.5.2 Climate and Air Quality	6-99
6.5.2.1 Potential Impacts	6-99
6.5.2.1.1 Air Quality	6-99
6.5.2.1.2 Climate Change	6-100
6.5.2.2 Best Management Practices and Mitigation Measures	6-100
6.5.3 Water Resources	6-100
6.5.3.1 Potential Impacts	6-100
6.5.3.1.1 Surface Water (Marine Water)	6-101
6.5.3.1.2 Groundwater	6-102
6.5.3.1.3 Floodplains and Wetlands	6-103
6.5.3.2 Best Management Practices and Mitigation Measures	6-103
6.5.4 Biological Resources	6-103
6.5.4.1 Potential Impacts	6-103
6.5.4.2 Best Management Practices and Mitigation Measures	6-104
6.5.5 Land and Submerged Land Use	6-105
6.5.5.1 Potential Impacts	6-105
6.5.5.1.1 Land Use	6-105
6.5.5.1.2 Submerged Land Use	6-105
6.5.5.2 Best Management Practices and Mitigation Measures	6-105
6.5.6 Cultural and Historic Resources	6-105
6.5.6.1 Potential Impacts	6-105
6.5.6.2 Best Management Practices and Mitigation Measures	6-105
6.5.7 Coastal Zone Management	6-106
6.5.7.1 Potential Impacts	6-106
6.5.7.2 Best Management Practices and Mitigation Measures	6-106
6.5.8 Scenic and Visual Resources	6-106
6.5.8.1 Potential Impacts	6-106
6.5.8.2 Best Management Practices and Mitigation Measures	6-106
6.5.9 Recreation Resources	6-107
6.5.9.1 Potential Impacts	6-107
6.5.9.2 Best Management Practices and Mitigation Measures	6-107
6.5.10 Land and Marine Transportation	6-107
6.5.10.1 Potential Impacts	6-107
6.5.10.1.1 Land Transportation	6-107
6.5.10.1.2 Marine Transportation	6-107
6.5.10.2 Best Management Practices and Mitigation Measures	6-108
6.5.11 Airspace Management	6-108
6.5.11.1 Potential Impacts	6-108
6.5.11.2 Best Management Practices and Mitigation Measures	6-108
6.5.12 Noise and vibration	6-108
6.5.12.1 Potential Impacts	6-108
6.5.12.2 Best Management Practices and Mitigation Measures	6-109
6.5.13 Utilities and Infrastructure	6-109
6.5.13.1 Potential Impacts	6-109
6.5.13.2 Best Management Practices and Mitigation Measures	6-110
6.5.14 Hazardous Materials and Waste Management	6-110
6.5.14.1 Potential Impacts	6-110
6.5.14.1.1 Hazardous Materials	6-110

6.5.14.1.2	Waste Management	6-111
6.5.14.1.3	Wastewater	6-111
6.5.14.2	Best Management Practices and Mitigation Measures	6-111
6.5.15	Socioeconomics	6-111
6.5.15.1	Potential Impacts	6-111
6.5.15.2	Best Management Practices and Mitigation Measures	6-111
6.5.16	Environmental Justice	6-112
6.5.16.1	Potential Impacts	6-112
6.5.16.2	Best Management Practices and Mitigation Measures	6-112
6.5.17	Health and Safety	6-112
6.5.17.1	Potential Impacts	6-112
6.5.17.2	Best Management Practices and Mitigation Measures	6-112
6.6	Photovoltaic (PV) Systems	6-112
6.6.1	Geology and Soils	6-117
6.6.1.1	Potential Impacts	6-117
6.6.1.2	Best Management Practices and Mitigation Measures	6-117
6.6.2	Climate and Air Quality	6-118
6.6.2.1	Potential Impacts	6-118
6.6.2.1.1	Air Quality	6-118
6.6.2.1.2	Climate Change	6-118
6.6.2.2	Best Management Practices and Mitigation Measures	6-118
6.6.3	Water Resources	6-118
6.6.3.1	Potential Impacts	6-118
6.6.3.1.1	Surface Water	6-118
6.6.3.1.2	Groundwater	6-119
6.6.3.1.3	Floodplains and Wetlands	6-119
6.6.3.2	Best Management Practices and Mitigation Measures	6-119
6.6.4	Biological Resources	6-119
6.6.4.1	Potential Impacts	6-119
6.6.4.2	Best Management Practices and Mitigation Measures	6-120
6.6.5	Land and Submerged Land Use	6-120
6.6.5.1	Potential Impacts	6-120
6.6.5.1.1	Land Use	6-120
6.6.5.1.2	Submerged Land Use	6-120
6.6.5.2	Best Management Practices and Mitigation Measures	6-120
6.6.6	Cultural and Historic Resources	6-120
6.6.6.1	Potential Impacts	6-120
6.6.6.2	Best Management Practices and Mitigation Measures	6-121
6.6.7	Coastal Zone Management	6-121
6.6.7.1	Potential Impacts	6-121
6.6.7.2	Best Management Practices and Mitigation Measures	6-121
6.6.8	Scenic and Visual Resources	6-121
6.6.8.1	Potential Impacts	6-121
6.6.8.2	Best Management Practices and Mitigation Measures	6-122
6.6.9	Recreation Resources	6-123
6.6.9.1	Potential Impacts	6-123
6.6.9.2	Best Management Practices and Mitigation Measures	6-123
6.6.10	Land and Marine Transportation	6-123
6.6.11	Airspace Management	6-123
6.6.11.1	Potential Impacts	6-123
6.6.11.2	Best Management Practices and Mitigation Measures	6-123

6.6.12	Noise and Vibration.....	6-123
6.6.12.1	Potential Impacts	6-123
6.6.12.2	Best Management Practices and Mitigation Measures	6-124
6.6.13	Utilities and Infrastructure.....	6-124
6.6.13.1	Potential Impacts	6-124
6.6.13.2	Best Management Practices and Mitigation Measures	6-124
6.6.14	Hazardous Materials and Waste Management	6-124
6.6.14.1	Potential Impacts	6-124
6.6.14.1.1	Hazardous Materials.....	6-124
6.6.14.1.2	Waste Management	6-124
6.6.14.1.3	Wastewater	6-125
6.6.14.2	Best Management Practices and Mitigation Measures	6-125
6.6.15	Socioeconomics.....	6-126
6.6.15.1	Potential Impacts	6-126
6.6.15.2	Best Management Practices and Mitigation Measures	6-126
6.6.16	Environmental Justice	6-126
6.6.16.1	Potential Impacts	6-126
6.6.16.2	Best Management Practices and Mitigation Measures	6-126
6.6.17	Health and Safety	6-126
6.6.17.1	Potential Impacts	6-126

6 ENVIRONMENTAL IMPACTS FROM UTILITY-SCALE RENEWABLES

This chapter presents the potential environmental impacts that could be expected for activities that are associated with utility-scale renewable energy technologies. These activities and technologies were presented in Chapter 2, Section 2.3.3. For each technology evaluated in this chapter, there is a representative project that aids the PEIS in presenting and characterizing the potential environmental impacts. These representative projects are described in detail in Section 2.3.3 and are summarized again here for each technology.

The representative projects were developed to assess the potential impacts (benefit and detriment) of utility-scale renewable energy technology options. In general, for each of the technologies in this section, a standard-sized representative project was identified as one that would generate 5 megawatt of electricity, unless there was a valid reason (feasibility) for a particular technology be a different size. This would allow for comparison of the relative level of environmental impacts across the utility-scale technologies. The description of each technology within Section 2.3.3 includes a discussion of the differences between nameplate capacity and actual capacity based on efficiency and the range of typical capacity factors for that technology. The potential impacts are presented for each environmental resource area. As was described in Chapter 3, many of the activities and technologies could result in environmental impacts that would be common of typical construction projects and may not be unique to the specific activity or technology. In these cases, the presentation of potential impacts in this chapter refers the reader to the appropriate section in Chapter 3 that presents these common impacts for that resource area. Therefore, the details in this chapter deal primarily with those impacts that would be unique to the specific activity or technology being evaluated. Chapter 6 discusses how the impacts would scale (for example, linearly, exponentially, or not at all) for the range of potential technology applications to aid the reader in understanding the effects of smaller or larger projects and how impacts could change based on the size of the technology implemented.

Each of the sections below includes a summary table of the potential environmental impacts and best management practices (BMPs) for that technology. Not all technologies have the potential to impact all environmental resource areas analyzed in this document. Therefore, the summary table for each technology also identifies and screens those resource areas that are not expected to be impacted by that technology. This approach is consistent with DOE's sliding scale approach to the preparation of NEPA analyses.

6.1 Biomass

The biomass technology is a diverse technology with a wide range of applications; therefore this PEIS identifies two representative projects to provide a better perspective of potential impacts. They include the construction and operation of a 10-megawatt-capacity direct combustion power plant and a 10-megawatt-capacity electrical power plant fueled with biodiesel (see Section 2.3.3.1.4). The direct combustion biomass steam generating station (power plant) would use a fibrous biomass source such as sugar cane, banagrass, or wood from dedicated crops or forests to fire steam boilers. Local sources (i.e., typically less than 10 miles from the generating site) would be assumed to supply the biomass feedstock to minimize transportation costs. The biodiesel-fueled power plant would use biodiesel produced from biomass oil crops to fire steam boilers to generate electricity. The PEIS assumed that the biomass used in utility-scale energy applications would be produced by dedicated energy crops. Therefore, the impacts of the biomass production are considered part of the energy technology. Depending on specific, future projects, it would be possible that utility-scale biomass energy development could include interisland transport of feedstock; however, this PEIS does not evaluate that scenario.

[Table 6-1](#) and [Table 6-2](#) present a summary of the potential environmental impacts for biomass energy projects for a direct combustion power plant and a biodiesel power plant, respectively, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 6-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass (Direct Combustion Biomass-Fueled Steam Turbine Generating Project)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	<p>General construction impacts (see Section 3.1.3).</p> <p>Potential soil erosion and degradation from agricultural activities.</p>	<p>Same as those common across construction projects (see Section 3.1.4).</p> <p>In accordance with applicable building codes, the facility design and construction should incorporate seismic provisions appropriate for the project location.</p>
Climate and Air Quality		
Air Quality	<p>General construction impacts (see Section 3.2.4).</p> <p>Potential increase in criteria pollutant emissions (including nitrogen dioxide, particulate matter, carbon monoxides, and sulfur dioxide, as well as carbon dioxide) during combustion.</p> <p>Potential increase in criteria pollutant emissions (including carbon dioxide) from biomass production (equipment, fertilizer/pesticide application, harvest, and transport).</p>	<p>Same as those common across construction projects (see Section 3.2.5).</p> <p>Projects should use a boiler system designed to achieve high combustion and boiler efficiency and that can operate close to design capacity.</p> <p>Apply control technologies to reduce emissions during project operations (i.e., dust collectors to reduce particulate matter emissions).</p>
Climate Change	<p>Potential impacts from increased biogenic carbon dioxide emissions and increased greenhouse gas.</p> <p>Decreased greenhouse gas emissions from electricity production.</p>	<p>Apply control technologies to reduce emissions during project operations.</p>

Table 6-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass (Direct Combustion Biomass-Fueled Steam Turbine Generating Project) (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Water Resources		
Surface Water	<p>General construction impacts (see Section 3.3.5).</p> <p>Potential for increased stormwater runoff.</p> <p>Increased water demand for crop irrigation (example: sugar cane crop – more water/acre).</p> <p>Potential adverse impacts from runoff contamination associated with fertilizer/pesticide applications.</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p> <p>Fertilizer/pesticide applications should be used appropriately, be approved or licensed for the intended use, and must be handled, stored, and applied in accordance with the manufacturer guidelines and the chemical-specific material safety data sheets.</p>
Groundwater	<p>General construction impacts (see Section 3.3.5).</p> <p>Potential for long-term increased runoff.</p> <p>Potential decrease in groundwater recharge.</p> <p>Potential for groundwater contamination from fertilizer/pesticide applications via runoff or local recharge.</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p> <p>Fertilizer/pesticide applications should be used appropriately, be approved or licensed for the intended use, and must be handled, stored, and applied in accordance with the manufacturer guidelines and the chemical-specific material safety data sheets.</p>
Floodplains and Wetlands	<p>Potential for general construction impacts (see Section 3.3.5).</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p>
Biological Resources		
	<p>Potential for general construction impacts (see Section 3.4.5).</p> <p>Potential impacts to vegetation or wildlife (including to the wide-ranging Hawaiian hawk and the Hawaiian hoary bat) species (site-specific).</p> <p>Potential beneficial impacts – may create a market for selective harvesting of invasive woody species, such as albizia trees.</p> <p>Potential impacts from the introduction of new, invasive plant species.</p> <p>Potential impacts associated with use of genetically modified plants.</p> <p>Potential secondary impacts to marine resources from possible runoff and sedimentation from cultivated fields.</p>	<p>Same as those common across construction projects (see Section 3.4.6).</p> <p>Biomass production sites in proximity to areas with critical habitat and other high value habitats such as wetlands, areas of native vegetation, and protected land areas would need evaluation to ensure that potential impacts to wildlife or protected plant species are minimized or avoided.</p> <p>Screening new plant species for invasive characteristics, conducting field trials prior to commercial production, developing monitoring programs, and designing controls measures, if needed, would be ways to avoid the potential impacts of introduced species.</p>

Table 6-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass (Direct Combustion Biomass-Fueled Steam Turbine Generating Project) (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Land and Submerged Land Use		
Land Use	<p>Potential change in landownership patterns if the site is acquired by purchase or land use easement.</p> <p>Potential conversion of undeveloped land or land under current land uses.</p>	Consider State designated land uses and county overlay zones.
Submerged Land Use	None.	N/A
Cultural and Historic Resources		
	<p>Common construction and operation impacts to cultural resources (see Section 3.6.6).</p> <p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities,</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	Common construction and operation BMPs for cultural resources (see Section 3.6.7).
Coastal Zone Management		
	Potential impacts to special management areas (CZMPs), shorefront access, and shoreline erosion (site-specific) through water runoff and sedimentation.	Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.
Scenic and Visual Resources		
	<p>Short-term visual impacts during construction (see Section 3.8.3).</p> <p>Long-term visual impacts from introduction of a new facility.</p> <p>Potential impacts from harvest of biomass.</p> <p>Potential visual impacts from truck traffic during delivery.</p>	<p>Same as those common across construction projects (see Section 3.8.4).</p> <p>Sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the four designated scenic byways (three on Hawai‘i and one on Kaua‘i); State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System should be</p>

Table 6-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass (Direct Combustion Biomass-Fueled Steam Turbine Generating Project) (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
		<p>considered and avoided when locating a power generating plant.</p> <p>Consideration should be given to general land use plans and associated implementation tools such as zoning ordinances and development standards to protect and maintain open space and scenic resources, consistent with the State’s land use designations.</p>
Recreation Resources		
	<p>General short-term construction impacts (see Section 3.9.4).</p> <p>Potential long-term recreation resource impacts from visual and noise effects.</p> <p>Potential recreational resource impacts from truck traffic.</p>	<p>Same as those common across construction projects (see Section 3.9.5).</p> <p>During site selection, consideration should be given to sensitive locations such as the recreation areas listed in Appendix A of the <i>State Comprehensive Outdoor Recreation Plan (DLNR 2009)</i>.</p> <p>During site selection, additional consideration should also be given to each island’s general land use plans and associated implementation tools such as zoning ordinances and development standards.</p>
Land and Marine Transportation		
Land Transportation	<p>Potential increase in truck traffic for biomass delivery.</p> <p>Potential increased wear on paved roads and road maintenance</p>	<p>Deliveries could be scheduled to avoid peak traffic hours to minimize potential impacts.</p> <p>Using covered trucks would prevent potential hazards of dust and feedstock from falling or blowing onto roadways during transport.</p>
Marine Transportation	None; it is unlikely that bulk biomass would be shipped between islands.	N/A
Airspace Management		
	Potential hazards to aircrafts from emission stacks for those project locations nearby airports.	Project locations near airports would require evaluation to ensure emissions stacks less than 200 feet do not interfere with regulated airspace or create thermal plume turbulence that would be a hazard to aircraft.

Table 6-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass (Direct Combustion Biomass-Fueled Steam Turbine Generating Project) (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Noise and Vibration		
	<p>Short-term noise and vibration construction impacts.</p> <p>Potential long-term impacts to existing noise and vibration levels, depending on the location of facilities and compatibility with existing noise levels and land uses</p> <p>Noise impacts from truck traffic delivery (site-specific).</p>	<p>Same as those common across construction projects (see Section 3.12.6).</p>
Utilities and Infrastructure		
Utilities	<p>Varying impacts to utilities (site/island-specific i.e., small effects to O‘ahu, larger effects to Lāna‘i), requiring potential adjustment/management of power grids and overall power production.</p>	<p>Same as those common across construction projects (see Section 3.13.4).</p>
Hazardous Materials and Waste Management		
Hazardous Materials	<p>Potential hazardous materials exposure impacts from contaminated sites during construction.</p> <p>Potential exposure to high quantities of fertilizers (primarily nitrogen), herbicides, and pesticides.</p>	<p>Same as those common across construction projects (see Section 3.14.5).</p> <p>Fertilizers, herbicides, and pesticides must be handled, stored, and disposed of in accordance with Federal, State, and county laws and regulations to ensure that hazardous materials are not released into the environment.</p> <p>In the event a spill or release occurs, appropriate safety precautionary measures should be taken including following procedures outlined in safety response plans, EPA materials data and safety sheets, OSHA requirements, and notifying the appropriate authorities including the State DOH and first responders (as necessary).</p>
Waste Management	<p>General construction impacts (see Section 3.14.4).</p>	<p>Same as those common across construction projects (see Section 3.14.5).</p>
Wastewater	<p>General construction impacts (see Section 3.14.4).</p> <p>Potential impacts to wastewater services from trace amounts of chemicals and elevated temperatures during blowdown from the steam cycle and cooling system.</p>	<p>Same as those common across construction projects (see Section 3.14.5).</p> <p>As necessary, treatment using settling ponds or filtration systems could be required in order to meet NPDES wastewater discharge permit requirements.</p>

Table 6-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass (Direct Combustion Biomass-Fueled Steam Turbine Generating Project) (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Socioeconomics		
	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	None.
Environmental Justice		
	Small potential impacts to the general population. Site-specific evaluation of impacted populations required.	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.
Health and Safety		
	General construction and operation impacts (see Section 3.17.3). Construction and operation of a utility-scale biomass facility would not introduce any unique public health hazards and therefore would not result in any environmental impacts to public health and safety. General construction and operation impacts to public safety services (see Section 3.13.3.1). Construction and operation of a utility-scale biomass facility would not introduce any unique accident scenarios and therefore would not result in any environmental impacts from accidents or intentional destructive acts.	Same as those common across construction projects (see Section 3.17.5).

Table 6-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass (Biodiesel Plant and Electric Power Plant Project)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	Noise impacts from truck traffic delivery (site-specific).	
Utilities and Infrastructure		
	<p>General construction and operational impacts (see Section 3.13.3.1).</p> <p>Varying impacts to utilities (site/island-specific i.e., small effects to O‘ahu, large effects to Lāna‘i), requiring potential adjustment/management of power grids and overall power production.</p>	Same as those common across construction projects (see Section 3.13.4).
Hazardous Materials and Waste Management		
Hazardous Materials	<p>Potential hazardous materials exposure impacts from contaminated sites during construction.</p> <p>Potential exposure to high quantities of fertilizers, herbicides, and pesticides.</p> <p>Potential hazardous materials exposure impacts from biodiesel leaks or accidents.</p>	Prior to construction, the proposed project location would be investigated via the review of public records and the performance of site inspections to identify possible hazardous materials that may be present at the project site. In the event that the project location is sited at one of these sites, site remediation would be recommended prior to project development.
		<p>Fertilizers, herbicides, and pesticides must be handled, stored, and disposed of in accordance with Federal, State, and county laws and regulations to ensure that hazardous materials are not released into the environment.</p> <p>In the event a spill or release occurs, appropriate safety precautionary measures should be taken including following procedures outlined in safety response plans, EPA materials data and safety sheets, OSHA requirements, and notifying the appropriate authorities including the State DOH and first responders (as necessary).</p> <p>Prior to project approval, ensure all project operations are compliant with regulatory requirements related to standards of performance for equipment leaks.</p>

Table 6-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Biomass (Biodiesel Plant and Electric Power Plant Project) (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Waste Management	None.	N/A
Wastewater	Potential impacts to wastewater services from trace amounts of chemicals and elevated temperatures during the blowdown from the steam cycle and cooling system.	As necessary, treatment using settling ponds or filtration systems could be required in order to meet NPDES wastewater discharge permit requirements.
Socioeconomics		
	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	None.
Environmental Justice		
	Small potential impacts to the general population. Site-specific evaluation of impacted populations required.	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically, Native Hawaiians.
Health and Safety		
	General construction and operation impacts (see Section 3.17.3). Health risks from the use of pesticides, herbicides, and fertilizers. Additional risks of traffic accidents associated with the transport of biomass materials.	Same as those common across construction projects (see Section 3.17.5). See related sections on transportation and hazardous materials.

6.1.1 GEOLOGY AND SOILS

6.1.1.1 Potential Impacts

Potential impacts on geology and soils from construction of a 10-megawatt biomass plant, of either type (direct combustion or biodiesel), would be the same as those expected for common construction actions as described in Section 3.1.3. Construction of either project would involve disturbance of 6 to 8 acres of land, so the permitting requirements described in Section 3.1.3 would be fully applicable.

Operation of either power plant facility (i.e., a direct combustion biomass fueled steam turbine generator project or a biodiesel plant and electric power project) would not involve activities that would have the potential to affect geology and soils of the area. In accordance with applicable building codes, the facility’s design and construction would have required incorporation of seismic provisions appropriate for the project location. As a result, the potential risk of the facility being adversely impacted by the site’s geology, from earthquakes, would be at an acceptably low level.

Other operations associated with this technology that could impact geology and soils are the agricultural activities that would be needed to support the biomass power plants. The amount of land needed to support a 10-megawatt direct combustion power plant is estimated at 3,340 acres if all the biomass came

from dedicated sugar cane to 5,100 acres if it came from dedicated forest growth. Oil crop acreage required to support a 10-megawatt biodiesel power plant is estimated at 14,000 to 27,000 acres depending on whether precipitation or irrigation allowed two crops per year. Agricultural activities, whether on land already being used for that purpose or on land transitioned from some other use, are associated with soil erosion and degradation impacts. The natural process of erosion by moving water or wind is increased by plowing and the associated periods of no or minimal vegetation covering the ground. Continued agricultural action on the same site also results in soil breakdown and loss of nutrients. Fertilizers and, in some cases, conditioners are added to the soil to help lessen these effects, and pesticides are added to control unwanted vegetation or insects. These soil additives represent potential soil contaminants if they are carried with eroded soils to other locations, particularly to surface waters ([Section 6.1.3](#)). Agricultural practices have evolved over time to minimize adverse impacts associated with soil erosion and degradation, but the impacts have not been eliminated.

Construction of a power plant facility larger than the representative 10 MW, of either type, would involve the same types of potential soil erosion concerns as the representative project, but because more land would be disturbed, the amount of erosion that could occur would likely be proportionately greater. Similarly, a larger construction project would involve the same type of potential soil contaminants, but because of more construction equipment and a longer construction period, the probability of a leak or release of fuel or lubricants occurring might also be proportionately greater. The normal precautions and controls implemented during construction (Sections 3.1.3 and 3.1.4) would still appropriately reduce potential for soil erosion or contamination.

Operation of a larger biomass-based power plant would not involve activities that would have the potential to affect geology and soils of the area. However, the larger facility would require a proportionately larger agricultural operation to produce the larger amount of biomass for fuel or biodiesel production. The larger agricultural operation would involve a similar potential for soil, with or without contamination (with fertilizer and pesticides), to erode and leave the site, but with the larger operation it can be assumed that the amount of soil without vegetation cover and more susceptible to erosion would be greater at any given time.

6.1.1.2 Best Management Practices and Mitigation Measures

As discussed above, normal precautionary and control measures should be implemented during construction (Sections 3.1.3 and 3.1.4).

6.1.2 CLIMATE AND AIR QUALITY

6.1.2.1 Potential Impacts

6.1.2.1.1 Air Quality

Direct Combustion Biomass-Fueled Steam Turbine Generator

This technology could result in impacts commonly associated with general construction activities, which are addressed in Section 3.2.4.

The burning of biomass at a biomass energy project would emit the criteria pollutants of nitrogen dioxide, particulate matter, carbon monoxide, and sulfur dioxide as well as carbon dioxide. The total amount of emissions would vary depending on the amount of material burned and its heating value. According to the EPA's *Compilation of Air Pollutant Emission Factors* (AP-42) Section 1.6, "Wood Residue Combustion in Boilers," the emission factors for nitrogen oxide range from 0.22 to 0.49 pound per million British thermal units of heat input ([EPA 2014](#)). The maximum emission factors for particulate matter, carbon

monoxide, and sulfur dioxide are 0.56, 0.60, and 0.025 pound per million British thermal units of heat input, respectively. The emission factor for carbon dioxide is 195 pounds per million British thermal units.

Production of the biomass would create criteria pollutant and carbon dioxide emissions. Equipment required for planting, applying fertilizers and pesticides, and harvesting the biomass would typically burn fossil fuels. In addition, transport of the biomass feedstock from its source (within ten miles of the boilers) to the boilers would produce criteria pollutants from truck emissions. The total amount of emissions from transport of feedstock would depend upon the number and types of trucks used and the miles traveled. Published emission factors for heavy duty diesel trucks show emission factors of 0.028 pound per mile traveled for nitrogen oxide. Emission factors for particulate matter, carbon monoxide, sulfur dioxide, and carbon dioxide are 0.0013, 0.0093, 0.000041, and 4.2 pounds per mile traveled, respectively (<http://www.aqmd.gov/ceqa/handbook/onroad/onroad.html>) (AQMD 2008).

Scaled versions of a direct combustion biomass energy project would produce linearly scaled impacts to air quality. For instance, a 20-megawatt biomass project could replace electricity use from the baseline grid by two times that of a 10-megawatt biomass project. The corresponding reduction in greenhouse gases would be 2 times that of a 10-megawatt biomass project and the increase in criteria pollutants would be about 2 times greater. The biomass feedstock would increase linearly and be acquired from a larger area, so criteria pollutant emissions from growing and transporting the feedstock would also increase.

Biodiesel Plant and Electric Power Plant

Air quality impacts associated with construction of the power plant would be similar to those for the direct combustion plant. Both projects would disturb the same amount of land (fugitive dust) and would require the same amount of construction time. However, this representative project would also require construction of a biodiesel production facility on 6 to 8 acres of land and a construction period of 12 to 18 months. This would result in additional criteria pollutant and carbon dioxide emissions.

Production of the biomass would create criteria pollutant and carbon dioxide emissions. Equipment required for planting, applying fertilizers and pesticides, and harvesting the biomass would typically burn fossil fuels. In addition, transport of biomass feedstock from its source (within ten miles of the project) to the facility would produce criteria pollutants from truck emissions. These emissions would be similar to those for the direct combustion plant. The conversion of biomass to biodiesel would emit the criteria pollutants of nitrogen dioxide, particulate matter, carbon monoxide, and sulfur dioxide.

6.1.2.1.2 Climate Change

Direct Combustion Biomass-Fueled Steam Turbine Generator

Operation of a biomass facility would generate carbon dioxide, a greenhouse gas. Historically, carbon dioxide emissions from biomass facilities have been considered to be carbon neutral, but the premise of carbon neutrality during the burning of biomass is still an unsettled issue. The basis for the premise is that as long as biomass resources are managed sustainably (that is, the resource's rate of carbon absorption is maintained or increased), the combustion of harvested materials presents no net increase of carbon to the on-going carbon cycle. Therefore, the burning of biomass should not be considered an increase in greenhouse gases. By comparison, the combustion of fossil fuels such as oil emits carbon that has been out of the current carbon cycle for millennia and therefore does contribute to an increase in greenhouse gases. In January 2011, the EPA announced its plans to defer, for three years, the greenhouse gas permitting requirements for carbon dioxide emissions from biomass-fired boilers in order to seek further independent scientific analysis of the complex issue. On July 12, 2013, the U.S. Court of Appeals, D.C. Circuit, Case No. 11-1101, vacated the deferral rule. EPA is developing final permitting rules for biogenic

carbon dioxide emissions. With the continuing lack of permitting rules concerning the carbon neutrality of biomass energy, this PEIS assumes that, for the purposes of comparing greenhouse gas emissions (under certain provisions of the Clean Air Act) to the baseline of burning oil for electricity, that burning biomass is carbon neutral and that all reductions in the amount of oil burned will be reflected in a reduction of carbon dioxide and greenhouse gases.

A replacement of about 70,000 megawatt-hours of electricity per year from the baseline electrical grid would reduce oil consumption from electricity generation by about 4.7 million gallons. On O‘ahu, the annual replacement of 70,000 megawatt-hours of electricity from the baseline grid and the corresponding reduction in the use of oil would correspond with an annual reduction in greenhouse gas emissions of about 51,000 metric tons CO₂ equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid>; EPA 2012a). On other islands by comparison, an annual replacement of 70,000 megawatt-hours of electricity usage would correspond to an annual reduction in greenhouse gas emissions of about 43,000 metric tons CO₂ equivalent due to a different mix of technologies used to produce electricity.

Biodiesel Plant and Electric Power Plant

The power plant would produce about 10 megawatt of electricity. Assuming an 80 percent capacity factor, the project would provide base load electricity of about 70,000 megawatt-hours per year. These are the same assumptions used for the direct combustion biomass-fueled turbine generator. Because the same replacement of electricity production from the baseline grid would occur for the biodiesel electric power plant and for the direct combustion plant, the reduction in oil consumption and the corresponding reduction in greenhouse gases would be the same from producing electricity in both representative projects.

6.1.2.2 Best Management Practices and Mitigation Measures

BMPs that could minimize air impacts from a direct combustion biomass-fueled steam turbine generator include using a boiler system that is designed to achieve high combustion and boiler efficiency and can operate close to its design capacity and applying control technology to reduce emissions during operation of the facility (such as dust collectors to reduce particulate matter emissions). Air quality permits would be required before construction and operation of a biomass steam boiler to ensure compliance with all county and Federal air quality regulations.

BMPs that could minimize potential air impacts from a biodiesel gasification plant and electric power plant include designing equipment with low emissions and applying control technology to further reduce emissions during operation of the facilities (such as dust collectors to reduce particulate matter emissions). Similarly, air quality permits would be required before construction and operation of a biodiesel plant and electric power plant to ensure compliance with all county and Federal air quality regulations. These regulations include New Source Performance Standards, National Ambient Air Quality Standards, and Prevention of Significant Air Quality Deterioration.

6.1.3 WATER RESOURCES

6.1.3.1 Potential Impacts

Potential impacts to water resources are similar from both representative projects (i.e., direct combustion biomass fueled steam turbine generator and a biodiesel gasification plant and electric power plant). As such, they are discussed together herein and one or the other is singled out when potential effects would be different.

6.1.3.1.1 Surface Water

Potential impacts on surface water from construction of either type of biomass power plant would be the same as those expected for common construction actions as described in Section 3.3.5. The power plant facilities are both estimated to require 6 to 8 acres of land disturbance, so the permitting requirements described in Section 3.3.5 would be fully applicable.

During operation of the power plant facility, there would be no activities that would have the potential to affect surface waters other than possibly increasing storm water runoff from the site and the possible need for irrigation water to support a dedicated biomass crop. With regard to runoff, if the pre-construction project site was agricultural land or land with natural vegetation, the completed project site would have a significantly higher percentage of impermeable surfaces and accordingly would generate more storm water runoff. Management of this increased volume of runoff would depend on the nature of the specific site (i.e., whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns.

A primary difference between the direct combustion and biodiesel plants is the amount of water that would be required by the biomass crops and which is part of the environmental impacts evaluation. As presented in the technology description in Chapter 2, sugar cane, an example biomass crop that could be used for direct combustion, requires 180,000 to 250,000 cubic feet of water per acre per year, and 3,340 acres of the crop would be needed to supply the necessary biomass for a 10 megawatt plant. This acreage and water requirement equates to an average water demand of about 12 to 17 million gallons per day. Depending on the location of the crop, a good portion of the water needs could be supplied by precipitation. The example oil crop, the *Jatropha* tree, described for the biodiesel representative project requires less water per acre, but a larger total acreage to support a 10 megawatt plant. As described in the Chapter 2 technology description, it is assumed 14,000 to 27,000 acres would be needed for *Jatropha* tree crops and that supplemental irrigation amounting to 20 inches per year would be required with the remaining water needs being provided by precipitation. This acreage and water requirement equates to an average water demand of about 21 to 40 million gallons per day.

It is assumed that whatever supplemental irrigation water was needed for either biomass power plant project would be provided by surface water resources. This was the primary source of irrigation water during the peak of Hawai'i's sugar industry and, also as described in Section 3.3.1.1.2, there are still numerous working stream diversions on many of the islands that were constructed for irrigation. Although 800 million gallons of surface water was used each day by the sugar industry in 1920, the amount of surface water used in irrigation over the entire State was down to about 74 million gallons per day in 2005 (see Section 3.3.1.1.4). Accordingly, the 21 to 40 million gallons per day potentially needed to support the representative project would be a large increase in demand for irrigation water, particularly since it would be in localized area. The water need is small in comparison to the average amount of runoff from rain created from the islands each day, which is estimated at 10 to 40 percent of 21 billion gallons per day (see Section 3.3.2.1.2), but there would be existing competing water uses on every island, even if it were only to maintain stream habitat. On a Statewide basis, the water need may appear to be well within the carrying capacity of the resource, but water needs for a dedicated biomass crop would have to be evaluated further on a site-specific basis.

Operation of the dedicated biomass crop would also result in potential for runoff contamination from the fields as a result of fertilizer or pesticide applications. This runoff could then reach surface water resources. Depending on their characteristics and concentrations, fertilizer and pesticide chemicals can produce adverse environmental impacts if they reach surface waters. The potential for such impacts is minimized if the materials used are appropriately approved or licensed for the intended use and they are

handled, stored, and applied in accordance with the manufacturer guidelines and the chemical-specific material safety data sheets.

Water needs for a dedicated biomass crop would have to be evaluated further on a site-specific basis. The substantial amount of water needed for some biomass feedstocks may dictate siting locations because certain sites may not have sufficient water resources.

6.1.3.1.2 Groundwater

Potential impacts on groundwater from construction of either type of biomass power plant would be the same as those expected for common construction actions as described in Section 3.3.5.

During long-term operations of the power plant, impacts to groundwater would be limited primarily to the water needs to operate the facility. A boiler producing steam which then goes to a power generating turbine is the power plant configuration described for the direct combustion representative project and is an optional configuration for the biodiesel project. In such a configuration, water going through the boiler and then steam to the turbine would be expected to be on a loop, recycling as much of the water as reasonable. But depending on the type of cooling system involved, there would be continuous losses from evaporation and blowdown that would have to be replenished from the local water supply (likely involving primarily groundwater). It is assumed that a steam turbine in either representative project would require a steam flow of about 300,000 pounds per hour to produce 10 megawatts of electricity ([EEA-ICFI 2008](#)). This steam flow equates to a water flow of 36,000 gallons per hour or 0.86 million gallons per day. If it is further assumed that the water-steam system must be constantly replenished at a rate of about 10 percent of this flow, then the power production element of the project requires fresh water at a rate of about 90,000 gallons per day. This would include other minor water needs from the plant, including the personal needs of the 25 employees and any biomass handling needs. This amount of additional groundwater demand is minor in comparison to the State's total groundwater sustainable yield, which is estimated at about 3.6 billion gallons per day. Accordingly, the water needed for the long-term operation of the system would not be expected to result in water availability issues, but would have to be evaluated on a site-specific basis taking into consideration the groundwater sustainable yield for the applicable Aquifer System Area on the affected island and the existing groundwater demand from that area.

The long-term presence and operation of the biomass facility would be associated with increased runoff (as described previously) and potentially an associated decrease in groundwater recharge. However, the area involved is relatively small and, depending on where storm water runoff from the facility goes or how it is managed, the action may simply represent a change in where water soaks into the ground and possibly provides recharge.

Operation of the dedicated biomass crop would also represent potential for contamination from fertilizer or pesticide applications to reach groundwater either via runoff or local recharge. Fertilizer and pesticide chemicals potentially can be carried down by infiltrating water and result in groundwater areas where drinking water standards are threatened or even exceeded. The potential for such impacts is minimized if the materials used are appropriately approved or licensed for the intended use and they are handled, stored, and applied in accordance with the manufacturer guidelines and the chemical-specific material safety data sheets.

6.1.3.1.3 Floodplains and Wetlands

The proponent of a utility-scale biomass energy project (of either type) would be expected to avoid floodplains and wetland areas if only to reduce costs and minimize regulatory requirements. However, if

unavoidable, construction considerations would be the same as described for common construction actions in Section 3.3.5.

6.1.3.2 Best Management Practices and Mitigation Measures

Because it is assumed that either type biomass-based power plant would have access to a sewer system, there would be no sanitary or process wastewater issues associated with facility's operation and there would be no basis for avoiding areas with sensitive receiving waters.

With regard to water resources to support the facility's water needs, most of O'ahu and all of Molokai have been designated Groundwater Management Areas (refer to Sections 3.3.2.3 and 3.3.2.4) because of concerns over the long term availability of groundwater. This designation authorizes the State to manage groundwater through a permitting process. This does not mean the project could not be implemented on either island due to lack of water, but it does identify a heightened level of concern that would have to be evaluated for a proposed action that involved any water demand. Also, Lāna'i has no surface water resources that could be used to support irrigation of a dedicated biomass crop and groundwater resources are very limited.

Potential BMPs for water resources (surface waters, groundwater, and floodplains and wetlands) from construction or operations of either type of biomass power plant would be the same as those described in Section 3.3.6.

6.1.4 BIOLOGICAL RESOURCES

Potential impacts to biological resources may occur from land clearing and disturbance to construct the power plant, installation of facility lighting, human disturbance during construction, and potential spread of invasive species by creating disturbed areas. Construction of the power plants would be expected to disturb approximately 6 to 8 acres of land. These are impacts that also occur with other renewable energy technologies and are discussed in Section 3.4.5.1. Impacts to biological resources specific to the development utility-scale biomass energy projects based on the representative projects are discussed in the following sections.

6.1.4.1 Potential Impacts

6.1.4.1.1 Direct Combustion Biomass Project

Approximately 3,300 and 5,100 acres would be needed to produce sugar cane (or comparable agricultural crop) and woodchip biomass, respectively, to fuel the steam boilers for a 10-megawatt direct combustion power plant. Growing dedicated biomass feedstock would put existing fallow agricultural cropland into dedicated energy crop production. Alternatively, if woody biomass was selected as a biomass feedstock forest plantations planted with non-native species such as eucalyptus trees would be used to produce the wood biomass. Agriculture energy crops would be harvested annually or biannually. Forest crops would be harvested at longer rotation periods of approximately 6 years. Approximately 850 acres of forest would be harvested annually. Potential impacts to either vegetation or wildlife species would depend on existing vegetation and wildlife habitat on the fallow cropland or in the forest plantation. With the decline of the sugar and pineapple industries, large areas of former cropland are now fallow and some have developed vegetation that could provide habitat to wildlife. Similarly, many forest plantations contain largely introduced species, but still provide habitat to some species of wildlife. Placing either former croplands or forest plantations into energy crop production could directly impact some species of wildlife that occupy those lands and indirectly impact marine environments through sediment or chemical runoff. Potential species that could be impacted include the wide-ranging Hawaiian hawk and the Hawaiian hoary bat.

Because energy crops produced on agricultural lands would be harvested either annually or biannually, any existing wildlife value on those lands would be lost. Forest plantations would be harvested less frequently and therefore would retain trees in different age classes and retain some value as wildlife habitat. Newly cultivated biomass crops also have the potential to attract protected species seeking habitat, which could significantly impact the ability to harvest those crops. Biomass production sites in proximity to areas with critical habitat and other high value habitats such as wetlands, areas of native vegetation, and protected land areas would need evaluation to ensure that potential impacts to wildlife or protected plant species are minimized or avoided. Use of forest biomass for energy production would open a potential market for selective harvesting of invasive woody species, such as albizia trees, from surrounding lands and provide a cost effective means for managing and reducing this and other invasive species.

Developing markets for dedicated energy crops to support electrical power production opens the possibility of establishing new energy crops. One potential impact is the introduction of new plant species that may become invasive. Screening new plant species for invasive characteristics, conducting field trials prior to commercial production, developing monitoring programs, and designing controls measures, if needed, would be ways to avoid the potential impacts of introduced species. The other potential impact from a commercial market for energy crops would be the use of genetically modified plants (GMOs) in developing plants with superior characteristics (e.g., increased growth rate, plant size, and oil content) that improve their value as energy crops. However, the impacts of GMOs are not fully understood even though they are widely used in the United States and exist in the Hawaiian Islands. Some counties in Hawai'i have or are considering actions to limit the production of genetically modified crops.

6.1.4.1.2 Biodiesel Fueled Biomass Project

The production of biodiesel from oil crops such as the seeds of the *Jatropha* tree could have many of the same potential impacts as the production of biomass fiber for direct combustion. An estimated 14,000 to 27,000 acres of *Jatropha* trees would be needed to produce enough biodiesel to fuel a 10 megawatt steam boiler electrical power plant per year. The range of acreage needed depends on the growing conditions and number of seed crops that can be harvested per year. Because *Jatropha* and many other potential oil crops would be grown in monocultures (cultivation of a single crop in a given area), any wildlife habitat value that existed on those lands dedicated to seed production would be lost. Using land that has lower wildlife value (e.g., former abandoned agricultural land) would minimize potential impacts. Also locating production sites farther from high value native vegetation communities would reduce but not eliminate the potential for invasive plant species. Secondary impacts could occur to marine environments if sediment and chemical runoff occurred from biomass production, although BMPs designed to control and minimize soil erosion would minimize such potential impacts.

The same concerns regarding invasive species and potential use of GMOs apply to plant species that could be used as oil crops. The same screening and preventive measures for invasive species used for biomass fiber crops could be used for oil crops.

6.1.4.2 Best Management Practices and Mitigation Measures

In addition to the common BMPs that were identified in Section 3.4.6, the use of dedicated biomass crops could also implement the following measure:

- Screening new plant species for invasive characteristics, conducting field trials prior to commercial production, developing monitoring programs, and designing controls measures, if needed, would be ways to avoid the potential impacts of introduced species.

6.1.5 LAND AND SUBMERGED LAND USE

This section discusses the potential environmental consequences to land use from a utility-scale biomass facility.

6.1.5.1 Potential Impacts

Construction of either representative 10-megawatt project (i.e., direct combustion biomass fueled steam turbine generator or a biodiesel plant and electric power plant) would require clearing, grading, and leveling of an area of 6 to 8 acres. The site would have a boiler and turbine building, biomass handling and feed systems, possibly a transformer station, and construction laydown yards. The site would also include parking areas and access roads. Utilities required would include water and sewer, electrical service, communications, and above ground electrical distribution lines, with connections to the existing electrical grid. Operations would include maintenance and repair activities.

6.1.5.1.1 Land Use

For the direct combustion facility, either sugar cane or wood chips would be used as the feedstock. Land requirements for the production of sugar cane would be approximately 3,340 acres; the land requirements for the production of wood feedstock would be about 5,100 acres. A biodiesel plant is assumed to use the *Jatropha* tree as the feedstock. The land required to produce *Jatropha* trees on a sustained basis is estimated at 14,000 to 27,000 acres.

State designated land uses and county overlay zones would need to be considered. There could be a change in landownership patterns if the site is acquired by purchase or land use easement. Undeveloped land or land under current land uses could be converted to energy uses.

6.1.5.1.2 Submerged Land Use

As identified in [Table 6-1](#) and [Table 6-2](#), there would be no potential impacts to submerged land use from either representative utility-scale biomass project.

6.1.5.2 Best Management Practices and Mitigation Measures

None noted.

6.1.6 CULTURAL AND HISTORIC RESOURCES

6.1.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operational phases of a utility-scale biomass renewable energy project if effective conservation and BMPs are not implemented. During construction, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an

adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6.

Any biomass-fueled energy facility site selection process would include a detailed environmental impact study, which would include a more detailed evaluation of potential impacts to cultural and historic resources.

6.1.6.2 Best Management Practices and Mitigation Measures

Associated BMPs to reduce potential impacts to cultural, historic, and related natural resources during construction and operation are discussed in Section 3.6.7.

6.1.7 COASTAL ZONE MANAGEMENT

Impacts to coastal zones were evaluated based on the extent to which a project would conflict with the policies of the Hawai'i Coastal Zone Management Program and potentially affect special management areas, shorefront access, and shoreline erosion.

6.1.7.1 Potential Impacts

Because the entire State of Hawai'i is considered as part of the coastal zone, a Federal consistency review could be required. Potential impacts to special management areas designated under the Coastal Zone Management Program, shorefront access, and shoreline erosion would depend on specific locations proposed for either the power plant and the area used for the production of the biomass considering both direct and indirect effects. Large-scale development of energy biomass production could potentially impact soil erosion and impact coastal waters through water runoff and sedimentation.

6.1.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

6.1.8 SCENIC AND VISUAL RESOURCES

6.1.8.1 Potential Impacts

6.1.8.1.1 Direct Combustion Biomass Fueled Steam Turbine Generator

Construction would require clearing, grading and leveling an area of about 6 to 8 acres for the boiler and turbine building, biomass handling and feed system, possibly an electrical transformer station, and construction space. On final grading, approximately 2 to 3 acres may be landscaped or used for worker parking lots. Construction would last about 18 months. Potential short-term impacts to visual resources from construction activities are described in Section 3.8.3.

Operations of the generating plant would cause long-term visual impacts from introduction of a new facility. The buildings would be approximately 30 feet tall with an emission stack height of approximately 80 feet. The energy facility would be near existing biomass sources (0-10 miles) such as agricultural

fields or forests. Road access and utility services such as water and sewer would require extension into the power plant and require disturbance of approximately 2 to 5 acres of land. Approximately 1 mile of aboveground electrical distribution lines would connect the power plant to the local electrical grid. Exterior lighting for safety and security purposes would be installed on the generating plant facilities. Visual impacts would also occur from harvesting the biomass; however, these activities should be compatible with existing or historic uses of the site for the biomass source. In addition, visual impacts would be caused by truck traffic delivering biomass to the plant.

6.1.8.1.2 Biodiesel Plant and Electric Power Plant

A biodiesel production facility would also require about 6 to 8 acres. The facility would require road access, electrical, sewer, water, and communication utilities. Construction activity would consist of site clearing, grading, excavation for foundations, and trenching and would require approximately 18 months. Construction of a 10 megawatt generating plant would require clearing, grading and leveling an area of about 6 to 8 acres. On final grading, approximately 2 to 3 acres may be landscaped or used for worker parking lots. Road access and utility services such as water and sewer would require extension into the power plant and require disturbance of approximately 2 to 5 acres of land. Construction would require approximately 18 months. Potential short-term impacts to visual resources from construction activities are described in Section 3.8.3.

Long-term visual impacts would occur from the new facilities. The project would include storage tanks and bulk liquid handling facilities. Exterior lighting for safety and security purposes would be installed on the facilities. Approximately 1 mile of high voltage electrical line would be constructed to connect the power plant to the local utility grid. Visual impacts would also occur from harvesting the oil crop; however, these activities should be compatible with existing or historic uses of the site. Visual impacts would also be caused by truck traffic delivering crops to the plant. In addition, if the biodiesel production facility and the power plant are not co-located, tanker truck transportation would be required to transport the biodiesel from the production facility to the power plant. Assuming the use of 7,500 gallon tanker trucks, approximately 1,066 deliveries would be required annually to transfer the biodiesel from production plant to power plant.

6.1.8.2 Best Management Practice and Mitigation Measures

Sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the four designated scenic byways (three on Hawai'i and one on Kaua'i); State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System should be considered and avoided when locating a power generating plant.

In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards. Some of the counties' plans include more detail than others, but all include objectives related to protecting and maintaining open space and scenic resources consistent with the State's land use designations.

Best management impacts to minimize impacts to visual resources, including those from lighting, are provided in Section 3.8.4.

6.1.9 RECREATION RESOURCES

6.1.9.1 Potential Impacts

6.1.9.1.1 Direct Combustion Biomass-Fueled Steam Turbine Generator

Construction would require clearing, grading and leveling an area of about 6 to 8 acres for the boiler and turbine building, biomass handling and feed system, possibly an electrical transformer station, and construction space. On final grading, approximately 2 to 3 acres may be landscaped or used for worker parking lots. Construction would last about 18 months. Potential short-term impacts on recreation resources from construction activities are described in Section 3.9.4.

If the existing land use of a proposed site is recreation, the recreational value of the site would be permanently lost or altered by the new power plant. Operations of the generating plant would cause long-term visual and noise impacts that could affect recreation resources. Potential visual impacts are discussed in Section 6.1.8 and potential noise impacts are discussed in [Section 6.1.12](#). The energy facility would be near existing biomass sources (0-10 miles) such as agricultural fields or forests. Road access and utility services such as water and sewer would require extension into the power plant and require disturbance of approximately 2 to 5 acres of land. Approximately 1 mile of aboveground electrical distribution lines would connect the power plant to the local electrical grid. In addition, impacts to recreation resources, such as bicycling, could be caused by truck traffic delivering biomass to the plant.

6.1.9.1.2 Biodiesel Plant and Electric Power Plant

Construction of a 10 megawatt generating plant would require clearing, grading, and leveling an area of about 6 to 8 acres. On final grading, approximately 2 to 3 acres maybe landscaped or used for worker parking lots. Road access and utility services such as water and sewer would require extension into the power plant and require disturbance of approximately 2 to 5 acres of land. Construction would require approximately 18 months. Potential short-term impacts to recreation resources from construction activities are described in Section 3.9.4.

Long-term impacts to recreation resources would occur from the new facilities as described above for direct combustion. Approximately 1 mile of high voltage electrical line would be constructed to connect the power plant to the local utility grid. In addition, impacts to recreation resources such as bicycling could be caused by truck traffic delivering oil crops to the biodiesel facility and biodiesel to the power plant.

6.1.9.2 Best Management Practices and Mitigation Measures

Sensitive locations such as the recreation areas listed in Appendix A of the *State Comprehensive Outdoor Recreation Plan (DLNR 2009)* should be considered when locating a power generating plant. In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards. BMPs to minimize impacts to recreation resources are described in Section 3.9.5.

6.1.10 LAND AND MARINE TRANSPORTATION

Impacts to land transportation considered potential effects on traffic, alterations to existing roads, and requirement for additional road (excluding temporary or project specific access roads) infrastructure. Impacts to marine transportation considered potential effects on operation of the harbor systems, primary

shipping routes between islands, general marine transportation around the islands (tourism, fishing), and military marine surface and subsurface operations.

6.1.10.1 Potential Impacts

6.1.10.1.1 Land Transportation

Local impacts could occur from increased truck traffic for hauling biomass from the point of production to the power plant. Because the biomass production would occur in close proximity (up to 10 miles) to the power plant, this impact would be localized. In a worst case scenario, this truck traffic would occur on existing public access roads and require 4 to 5 truck deliveries per day, depending on the size of the power plant. Daily truck traffic could also increase wear on paved roads and increase the need for more frequent road maintenance.

There are also potential impacts to health and safety in the form of increased truck traffic, increased risk of debris on roadway, and dust from the trucks.

6.1.10.1.2 Marine Transportation

As identified in [Table 6-1](#) and [Table 6-2](#), there would be no potential impacts to marine transportation from either representative utility-scale biomass project.

6.1.10.2 Best Management Practices and Mitigation Measures

- Deliveries of biomass feedstock could be scheduled to avoid peak traffic hours to minimize potential impacts to traffic on local roadways.
- Using covered trucks would prevent potential hazards of dust and feedstock from falling or blowing onto roadways during transport.

6.1.11 AIRSPACE MANAGEMENT

6.1.11.1 Potential Impacts

Construction and operation of a utility-scale biomass power plant is not likely to require an FAA obstruction to navigation evaluation because the height of the emission stack would likely be less than 200 feet. However, project locations near airports would require evaluation to ensure emissions stacks less than 200 feet do not interfere with regulated airspace or create thermal plume turbulence that would be a hazard to aircraft.

6.1.11.2 Best Management Practices and Mitigation Measures

As discussed above, it is recommended that during project siting, evaluation be conducted to ensure emissions stacks less than 200 feet do not interfere with regulated airspace or create thermal plume turbulence that would be a hazard to aircraft.

6.1.12 NOISE AND VIBRATION

6.1.12.1 Potential Impacts

Construction of the representative biomass projects over 18 months could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

The representative biomass projects could potentially result in long-term impacts to existing noise and vibration levels. Noise from the steam boilers and turbines would be mostly contained within the building, although noise levels would increase during short term steam blow events. Industrial noise would be produced from operation of the biomass handling facilities, truck deliveries, and removal of ash waste. The representative biomass-fueled steam turbine generating plant would be located near existing biomass sources (0-10 miles) such as agricultural fields or forests, and noise would be generated by truck traffic delivering biomass to the plant. If the representative biodiesel production facility and the power plant are not co-located, tanker truck transportation (approximately 1,066 deliveries annually using 7,500 gallon tanker trucks) would be required to transport the biodiesel from the production facility to the power plant. Such noise could indirectly impact scenic and visual resources, recreation resources, cultural resources, worker health and safety, and possibly public health. Impacts would depend on the location of facilities and compatibility with existing noise levels and land uses.

6.1.12.2 Best Management Practices and Mitigation Measures

BMPs for noise and vibration would be the same as those common across projects for construction and operation. See Section 3.12.6.

6.1.13 UTILITIES AND INFRASTRUCTURE

For utilities and infrastructure, the biomass representative projects would have very similar consequences, therefore they are discussed together and one or the other is singled out when potential effects would be different.

6.1.13.1 Potential Impacts

Effects on each island's electric utilities would range from small to large from the addition of 10 megawatts of power generation to any island's overall power grid. For O'ahu, with the largest island net capacity of 1,756 megawatts, the change would be about 6 percent and for Lāna'i with the smallest net capacity of 10 megawatts the change would be about 100 percent (see Section 3.13.1). Higher percentage change increases the likelihood that the affected island utility would need to adjust management of power on the grid and overall power production. On all islands, 1 mile of transmission lines was assumed to be installed to connect either biomass facility to the power grid (see Section 8.1 for impacts related to new transmission lines). The distance of the transmission lines would vary for specific situations.

The electricity generated from a biomass facility would be considered "baseload" power because it would be fairly reliable and would not vary as a function of its renewable source (as compared to wind or solar). This attribute provides a benefit to the utilities since it increases their ability to plan on the availability of this generation source. Impacts from connection to utilities for construction and operation of these representative projects would be the same as those described in Section 3.13.3.1, as applicable.

6.1.13.2 Best Management Practices and Mitigation Measures

BMPs for construction would be expected to be implemented to avoid conflicts with existing utilities (see Section 3.13.4).

6.1.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

6.1.14.1 Potential Impacts

6.1.14.1.1 Hazardous Materials

Direct Combustion Biomass-Fueled Steam Turbine Generating Plant

Construction of the utility-scale biomass-fueled steam turbine generating plant would likely require clearing, grading and leveling for the boiler and turbine building, biomass handling and feed system, a possible electrical transformer station, and construction space. Road access and utility services such as water and sewer extension lines would likely also be required resulting in land disturbance. Aboveground electrical distribution lines would be constructed to connect the power plant to the local grid. The energy facility would be located near existing biomass sources such as agricultural fields or forests. As such, the proposed project locations would be investigated via the review of public records and the performance of site inspections to identify possible hazardous materials that may be present prior to development at the proposed project locations.

Biomass production for the feedstock may require the use of fertilizers, herbicides, and pesticides. Weeds are controlled through applications of pre-emergent herbicides and inter-row herbicides prior to canopy closure. In addition, sugar cane, in particular would require relatively high fertilizer use of nitrogen, potassium, and phosphorus. The forest feedstock (including the eucalyptus forest for the wood chip feedstock) would require fertilizer, primarily nitrogen. In addition, small quantities of hazardous materials would likely be used for cleaning and maintenance of agricultural and logging equipment. These would be handled, stored, and disposed of in accordance with Federal, State, and county laws and regulations to ensure that hazardous materials are not released into the environment. In the event a spill or release occurs, appropriate safety precautionary measures should be taken including following procedures outlined in safety response plans, EPA materials data and safety sheets, OSHA requirements, and notifying the appropriate authorities including the State DOH and first responders (as necessary).

The project would produce ash waste byproducts. As such, ash handling facilities would be integrated into the generating station. The ash waste would be used on nearby agricultural fields or forest plantations as fertilizer with small quantities disposed of in the appropriate landfill. Discussion regarding the disposal of the ash waste in landfills is provided in [Section 6.1.14.1.2](#).

Biodiesel and Electric Power Plants

The representative biodiesel energy system could be comprised of an oil crop production system, a facility to extract and process the plant oils into biodiesel, and an electrical power plant. The power plant would be a 10 megawatt capacity facility that could use either diesel combustion engines or biodiesel – fired steam boilers to generate electricity. Similar construction activities would be required for the biodiesel plant and electric power plant.

Similar handling, storage and disposal requirements would be required for the fertilizer used for the oil crops feedstock as for the biodiesel-fueled plant and electric power plant.

During project operations, the potential for hazards exists if a biodiesel leak or accident were to occur. However, prior to approval of the power plant, testing, including inspections and subsequent monitoring,

and reporting would be required to ensure that all project operations are compliant with regulatory requirements related to standards of performance for equipment leaks.

Byproducts of a gasification process include char and other solid carbonaceous material that would be disposed of in a landfill if alternative uses of the waste cannot be found. The byproducts from the gasification of the wood chips would not be considered hazardous waste. Discussion regarding the disposal of these byproducts in landfills is provided in [Section 6.1.14.1.2](#).

6.1.14.1.2 Waste Management

Potential impacts from either the biomass fueled steam turbine generating plant or the biodiesel plant or electric power plant would likely occur during the construction phase. A discussion of general construction impacts is provided in Section 3.14.4.

Both types of biomass plants would also produce ash waste and or char/carbonaceous material. Ash residue is considered a hazardous material, depending on the makeup of what is being combusted. As the project would use feedstock from agricultural and forestry operations it is anticipated that the byproducts from the biomass plants would not be considered hazardous wastes. Therefore, it is anticipated that the use of these byproducts for other applications such as fertilizer, landfill cover, and construction uses would not result in waste management impacts. Only leftover byproducts (that is not used for alternative purposes) would be disposed of at the appropriate landfill.

6.1.14.1.3 Wastewater

Wastewater impacts may occur during the operation of the biomass power plant during blowdown from the steam cycle and cooling system, as water discharge would likely contain trace amounts of chemicals and elevated temperatures. However, the project would likely be required to incorporate BMPs to deal with the wastewater, which may include but is not limited to treatment using settling ponds or filtration systems in order to meet NPDES wastewater discharge permit requirements.

6.1.14.2 Best Management Practices and Mitigation Measures

Prior to construction, the proposed project location would be investigated via the review of public records and the performance of site inspections to identify possible hazardous materials that may be present at the project site. In the event that the project location is sited at one of these sites, site remediation would be recommended prior to project development.

6.1.15 SOCIOECONOMICS

6.1.15.1 Potential Impacts

Socioeconomic impacts in Hawai‘i arising from construction and operations of either type biomass energy facility would be very small. The major equipment would likely be manufactured outside the State and, if so, economic benefits associated with the manufacturing would accrue elsewhere. The number of temporary jobs associated with the construction of the plant and the number of jobs to operate and maintain the plant would be very small, perhaps 40 workers for a 9- to 18-month construction period and 3 to 6 positions for operations. The plant would use agricultural and forest residues from existing, nearby agricultural operations so few new agricultural or transportation jobs would be created.

Jobs directly associated either type biomass energy facility would be likely filled by individuals residing within the area of influence (the State of Hawai‘i) and not by workers migrating to the State to fill those

positions. The representative project would not create many new net jobs. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and county government sector; to rental housing; and to personal income would be very small.

6.1.15.2 Best Management Practices and Mitigation Measures

None identified.

6.1.16 ENVIRONMENTAL JUSTICE

6.1.16.1 Potential Impacts

The potential environmental impacts to the general population associated with representative biomass projects, are expected to be small. The potential for environmental justice impacts also would be small.

6.1.16.2 Best Management Practices and Mitigation Measures

Any biomass-fueled energy facility site selection process would include a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

6.1.17 HEALTH AND SAFETY

6.1.17.1 Potential Impacts

Common health and safety impacts for typical construction and operations activities are identified in Section 3.17.3. Regulations and controls necessary to prevent potential health risks associated with insecticides, pesticides, and herbicides related to production of biomass materials are addressed in [Section 6.1.14.1.1](#). There would be a slight increase in the potential for traffic accidents; additional traffic associated with the transport of biomass materials is addressed in [Section 6.1.10.1.1](#). There are no additional potential health and safety risks that would be unique to biomass energy projects.

6.1.17.2 Best Management Practices and Mitigation Measures

Common health and safety BMPs for typical construction and operations activities are identified in Section 3.17.5.

6.2 Geothermal

The representative project for geothermal is the exploration, development, and operation of a 25-megawatt power plant (see Section 2.3.3.2.4). Similar to the existing Puna Geothermal Venture Power Plant on Hawai'i Island, the representative power plant would consist of a combined flash and binary system with all geothermal liquids and condensable gases re-injected into the subsurface reservoir.

The amount of land required for such a project would include:

- 5 acres for exploration including access road work and slim holes or coring wells;
- 53 acres for drilling operations and utilization including 15 acres for drilling and well-field development; 8.2 acres of road improvement/construction; 15.5 acres for power plant construction; 4.5 acres for well field equipment and pipelines; and 10 acres for transmission lines.

Table 6-3 present a summary of the potential environmental impacts for the representative geothermal energy project, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 6-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Geothermal

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils

Submerged Land Use	None.	N/A
Cultural and Historic Resources		
	<p>Common construction and operation impacts to cultural resources (see Section 3.6.6).</p> <p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p> <p>Potential adverse impacts to ethnographic resources as active volcanoes and rift zones are considered sacred by Native Hawaiians.</p> <p>Potential for adverse viewshed impacts from facility development, transmission lines, and other ancillary facilities; particularly to geothermal resources located within and adjacent to the Hawai‘i Volcanoes National Park.</p>	<p>Common construction and operation BMPs for cultural resources (see Section 3.6.7).</p>
Coastal Zone Management		
	<p>Potential impacts to designated special management areas, shorefront access, and shoreline erosion (site-specific).</p>	<p>Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.</p>

Table 6-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Geothermal (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Scenic and Visual Resources		
	<p>Potential short-term construction impacts (see Section 3.8.4).</p> <p>Potential long-term visual impacts from the power plant, night lighting, visibility of the transmission line, and the presence of steam plumes at facilities using water-cooled systems.</p>	<p>Same as those common across construction projects (see Section 3.8.5).</p> <p>Avoid sensitive locations, such as coastal scenic resources from public viewing points and coastal highways; the four designated scenic byways (three on Hawai‘i and one on Kaua‘i); State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System when locating a power plant.</p> <p>Consider Hawai‘i and Maui’s general land use plans and associated implementation tools such as zoning ordinance and development standards.</p> <p>During project design, consider painting the power facility forest green to blend in with the surrounding landscape.</p> <p>Use non-specular conductors to reduce reflection and glare on transmission lines.</p> <p>Use dry-cooling technology to avoid visual impacts from water vapor plumes.</p> <p>Screen pipelines with topography or vegetation to reduce visual impacts.</p>
Recreation Resources		
	<p>General recreation resource impacts during construction (see Section 3.9.4).</p> <p>Potential long-term recreational resource impacts including access restrictions, noise, and visual impacts from the new facilities.</p> <p>Potential permanent loss of recreational values (site-specific).</p> <p>Potential lighting impacts to nearby recreation resources such as campgrounds where dark night sky is valued.</p>	<p>Same as those common across construction projects (see Section 3.9.5).</p> <p>Sensitive locations such as recreation areas in Appendix A of the <i>State Comprehensive Outdoor Recreation Plan (DLNR 2009)</i> should be considered when locating a geothermal project. Recreation areas that value a dark night sky should also be considered.</p> <p>See Section 6.2.8 and Section 6.2.12 for BMPs related to scenic/visual resources and noise resources.</p>
Land and Marine Transportation		
Land Transportation	Potential short-term impacts on roadway traffic during project construction.	None.

Table 6-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Geothermal (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Marine Transportation	None.	N/A
Airspace Management		
	None; the development and operation of a geothermal facility would not result in any tall structures or steam exhausts that would require further consultation on airspace management impacts.	N/A
Noise and Vibration		
	Short-term and long-term noise and vibration impacts would result from exploration, construction, and operation. Potential impacts from noise and vibration would be wholly dependent on sound levels and the proximity of sensitive receptors to the source.	<p>Avoid sensitive receptors for noise and vibration (identified in Section 3.12).</p> <p>Take measurements to assess the existing background noise levels at a given site and compare them with the anticipated noise levels associated with the proposed project. Develop site-specific noise contours that include day and night noise and vibration levels, peak levels, and energy-averaged levels.</p> <p>Proposed drilling near residences and sensitive noise receptors may require mitigation measures to ensure compliance with all State and County laws, rules and ordinances regarding noise (County of Hawai'i 2014).</p> <p>If blasting or other noisy activities are required during the construction period, notify nearby residents in advance.</p> <p>Only use explosives within specified times and at specified distances from sensitive wildlife or streams and lakes, as established by the Federal and State agencies (BLM 2008).</p> <p>Use equipment with sound-control devices, including use of noise-mitigating drilling technology. Equipment should be adequately muffled and maintained.</p>

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Socioeconomics		
	Very small socioeconomic impacts; minimal job and population effects.	None.
Environmental Justice		
	Small environmental justice impacts. Site-specific evaluation of impacted populations required.	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.
Health and Safety		
	<p>Common health and safety impacts for typical construction and operations activities are identified in Section 3.17.3.</p> <p>Potential health and safety effects from drilling including hydrogen sulfide worker exposure, etc.</p> <p>Potential health and safety impacts from physical, thermal, and chemical hazards such as hydrogen sulfide exposure.</p> <p>Potential well blowouts and/or lava intrusion during drilling.</p>	<p>Common health and safety BMPs for typical construction and operations activities are identified in Section 3.17.5</p> <p>Develop a health and safety program to protect both workers and the general public during exploration, construction, and operation of geothermal projects. The program should include health and safety training procedures, and emergency protocols.</p> <p>Prior to any geothermal resource development, prepare a health and safety plan that addresses worker and site safety, emergency response protocols, and procedures for managing hazardous and toxic substances. The plan would identify requirements for notices to State and county emergency response authorities, include emergency response plans and procedures, and define health and safety performance standards.</p> <p>Air monitoring for the presence and concentration of hydrogen sulfide by a qualified person using air monitoring equipment (such as hydrogen sulfide detector tubes or a multi-gas meter that detects the gas).</p> <p>Personnel working in areas containing hydrogen sulfide would be required to wear appropriate respiratory protection and any other necessary personal protective equipment, rescue, and communication equipment, and be monitored for signs of overexposure.</p>

6.2.1 GEOLOGY AND SOILS

6.2.1.1 Potential Impacts

Undertaking drilling or ground-based geophysical surveys in areas of geothermal activity would unlikely have effects on the area's geology. However, drilling into geothermal resources is accompanied by the potential for well blowouts (the uncontrolled flowing of geothermal fluids and gases out of the well) and in areas of active volcanoes, such as Maui and Hawai'i, there is always the potential that drilling could reach lava or provide a route for lava intrusion. The standard drilling methods of sealing the upper portions of the boreholes and using blow-out prevention devices would reduce the potential for such events to cause damage or injury at the surface. Although today's sophisticated and fast-acting blowout preventers have practically eliminated their occurrence ([MIT 2006](#)), well blowouts can present an immediate risk to personnel and equipment at the rig from hot fluids and steam, and geothermal gases such as hydrogen sulfide, if present, could present toxicity concerns to a broader area around the rig. The few worldwide instances where lava has been encountered in, or entered drill holes, including the 2005 event when magma was encountered in a deep borehole on Hawai'i and a similar occurrence in 2009 in Iceland, have not resulted in problems at or near the surface ([Nature News 2008](#) and [UC Davis 2009](#)). There was no indication that the drill hole might provide a route for the magma to reach the surface. Exploratory boreholes not developed into geothermal systems would be sealed in accordance with well establish methods and would not be expected to present any geologic concerns or weak spots.

Potential impacts on geology and soils from surface construction activities associated with a 25-megawatt geothermal power plant would be the same as those expected for common construction actions as described in Section 3.1.3. Construction would involve disturbance of well over one acre of land, so the permitting requirements described in Section 3.1.3 would be fully applicable.

The representative project includes construction of 10 miles of transmission lines to connect the power plant with the nearest electrical grid. Potential impacts associated with those activities are similar to and are addressed in the On Island Electrical Transmission technology in Chapter 8.

Geothermal projects involving injection of water under high pressures or cold or cool water into a geothermal reservoir can result in induced seismicity. The seismicity typically induced in these types of actions is of relatively low magnitudes, with most events not being felt by people ([NRC 2012](#)) and not resulting in damage to facilities or infrastructure. In the case of the representative project, however, geothermal fluids would be injected back to the reservoir under relatively low pressures and while still in a warm or hot condition, so induced seismicity would not be an expected issue. In some geologic settings, removal of large quantities of groundwater can cause the formation to consolidate or settle and result in areas of surface subsidence. Again, with the representative project injecting geothermal fluids back into the reservoir, subsidence would not be an expected concern.

Operation of a geothermal power plant as described for the representative project would not be expected to affect geology and soils of the area; that is, other than the inherent mining of heat energy from the area's geologic formation. A primary objective for geothermal projects is to design and operate systems in a manner that makes them as sustainable as possible, so that the power plant can be operated successfully over its designed life. Given this logical intent to minimize the subsurface effects of heat removal (through steady, sustainable heat recovery) and the active, volcanic nature of the energy source, it is reasonable to assume that overall effects on existing subsurface thermal gradients would be relatively minor and localized.

The areas on Maui and Hawai'i that are identified as having potential geothermal resources are volcanic rift areas on active volcanoes. By their nature, these are also areas associated with lava flow hazards.

Therefore, the long-term operation of a geothermal power plant in any of these areas puts it at some risk from the natural geology of the site. It is assumed that with the volcanic monitoring and the nature of activity associated with these volcanoes that this risk is primarily to facilities and that people would be able to be evacuated if a hazard were to arise, but a risk is still present. This would include the potential release of any hazardous materials that might be stored in facilities in the path of lava flows and which could not be safely relocated.

The construction of a geothermal power plant substantially larger than the representative project would involve disturbance of a greater area of land, but as described for a common construction project, the project would be required to obtain a storm water discharge permit, and to plan and implement measures to minimize erosion and discharge of pollutants. It is expected that the same type of BMPs would be implemented independent of the size of the disturbed area and that the measures would be equally protective. Because the primary concern with regard to pollutants would be spills or leaks of fuel and lubricants from the equipment, the longer construction period and the increased amount of construction equipment may be associated with a higher probability for such an incident to occur. But the types of precautions normally implemented (for example, response plans, cleanup equipment, secondary containment, etc.) would keep potential for on- or offsite soil contamination at a minimum.

The risk of lava flows in areas where geothermal energy is most likely to be available, would not increase with a larger power plant, but the facilities at risk would represent a greater monetary loss if an eruption were to occur.

6.2.1.2 Best Management Practices and Mitigation Measures

The common construction BMPs identified in Section 3.1.3 would apply to general surface construction activities. Additionally, as identified above, the following BMPs would apply to the construction and operation of a geothermal energy facility for the prevention, minimization, or mitigation of impacts to geology and soils:

- Standard drilling techniques involving sealing of the upper borehole and use of blowout prevention equipment.
- Develop response plans, cleanup equipment, and secondary containment to keep on- and off-site contamination to a minimum.

6.2.2 CLIMATE AND AIR QUALITY

6.2.2.1 Potential Impacts

Geothermal energy recovery systems use heat from the Earth to generate electricity. A representative utility-scale geothermal project would consist of the exploration, development, and operation of a 25-megawatt power plant. A representative 25-megawatt geothermal project could theoretically replace electricity requirements from the baseline electrical grid by 188,000 megawatt-hours per year if the representative project has the same 86 percent capacity factor as the existing Puna Geothermal Venture Power Plant on Hawai'i Island.

6.2.2.1.1 Air Quality

This technology could result in impacts commonly associated with general construction activities, which are addressed in Section 3.2.4.

During operations of the representative geothermal project, the non-condensable gases in the geothermal fluid going to the flash systems would be lost or need to be controlled. This could be done by injecting the non-condensable gases into the subsurface with the used geothermal fluids or having off-gas treatment systems as scavenger or re-generable catalyst systems. These systems involve passing the off-gas through beds of materials designed to react with and remove the gas of concern. Emissions of the non-condensable gases could be possible during these processes.

Geothermal power plants release very few air emissions because they do not burn fossil fuels. Geothermal plants emit only trace amounts of nitrogen oxides, almost no sulfur dioxide or particulate matter, and small amounts of carbon dioxide. The primary pollutant at some geothermal plants is hydrogen sulfide, which is naturally present ([GEA 2007](#)). Health impacts from high concentrations of hydrogen sulfide include nausea, headache, and eye irritation, while extremely high levels can result in death. As a result of standard abatement measures, geothermal plants typically produce only minimal hydrogen sulfide emissions ([GEA 2007](#)). The amount of carbon dioxide released at a geothermal plant varies depending on the amount of carbon dioxide in the geothermal fluid and the plant design.

The air emissions for a combined flash and binary system are 0 pounds per megawatt hour for nitrogen oxide, sulfur dioxide, and carbon dioxide. The air emissions for particulate matter are negligible ([GEA 2007](#)). Therefore, the air emissions for the representative project would be zero or negligible for these pollutants.

6.2.2.1.2 Climate Change

A replacement of about 188,000 megawatt-hours of electricity per year from the baseline electrical grid would reduce oil consumption from electricity generation by about 12.6 million gallons. On O‘ahu, the annual replacement of 188,000 megawatt-hours of electricity would correspond to an annual reduction in greenhouse gas emissions of about 140,000 metric tons CO₂ equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid>; [EPA 2012a](#)). On other islands by comparison, the same annual replacement of electricity usage would see an annual reduction in greenhouse gas emissions of about 120,000 metric tons CO₂ equivalent due to a different mix of technologies used to produce electricity.

Scaled versions of a utility-scale geothermal project would produce linearly scaled impacts to air quality. For instance, a 50-megawatt project would replace electricity usage from the baseline grid by two times that of a 25-megawatt project. The corresponding reduction in greenhouse gases also would be two times that of a 25-megawatt project. Air emissions during construction and operations would also be proportional.

6.2.2.2 Best Management Practices and Mitigation Measures

BMPs that could minimize air impacts include maintaining equipment during exploration and drilling to reduce air emissions, designing equipment and procedures to minimize hydrogen sulfide emissions (including emergency response procedures) during operation, and installing control technology to reduce air emissions (such as injecting non-condensable gases into the subsurface or sending the gases to treatment systems). Air quality permits would be required before construction and operation of a geothermal facility to ensure compliance with all county and Federal air quality regulations. During operation, air quality monitoring would be required to determine the quantity of hydrogen sulfide that might be released.

6.2.3 WATER RESOURCES

6.2.3.1 Potential Impacts

This section addresses potential environmental consequences to water resources from development, construction, and operation of a geothermal power plant. Potential impacts are addressed in terms of surface water, groundwater, and floodplains and wetlands.

Construction and drilling may present different types of potential impacts to water resources. Therefore, it is addressed separately as two activities taking place prior to plant operations.

The representative project is also described as including construction of 10 miles of transmission lines to connect the power plant with the nearest electrical grid. Potential impacts associated with those activities are addressed in the “On Island Electrical Transmission” technology in Section 8.1.

6.2.3.1.1 Surface Water

Construction and Drilling

Effects on surface water from surface construction activities associated with a 25-megawatt geothermal power plant would be the same as those expected for common construction actions as described in Section 3.3.5.

As described for common construction actions (Section 3.3.5), the water discharge permit for construction actions includes a requirement to describe the measures that would be taken to minimize the discharge of pollutants to the storm water after construction is complete. So it is reasonable to assume there would be protective measures in place during drilling activities that would be similar to, or the same as, those implemented during construction. However, drilling activities are addressed separately because they would involve process fluids that would be managed separately from runoff from the site. Drilling fluids or muds are used in most geothermal drilling actions. Drilling mud, consisting primarily of water and bentonite clay, is sent down the borehole to cool and lubricate the drill bit, help keep the borehole open, and to carry cuttings back up to the surface. At the surface, the drilling mud is generally screened to remove cuttings, reconditioned as needed, and recycled down the borehole. The drilling muds can also contain small amounts of other chemicals and constituents that are adjusted to control density and viscosity as needed depending on down-hole conditions.

During drilling of exploratory wells, drilling muds are generally managed in mobile tanks brought into the site and which are then hauled away when the drilling is complete. In the drilling of large production wells, larger working capacity is required and the well pads are generally constructed with lined ponds that can be used for drilling muds. Also with regard to production wells, flow testing of the wells is generally performed to characterize the geothermal reservoir and can involve large quantities of the geothermal fluids (groundwater). Drilling muds can ultimately be removed from the site for disposition at a permitted disposal facility or possibly disposed onsite with appropriate approval. Flow test water is often reinjected back into the subsurface. In either case, however, any action to discharge either fluid to the surface would require a separate discharge permit to ensure any receiving waters were not adversely affected.

Operations

During operation of a geothermal power plant, potential impacts to surface water would be expected to be minor. There would be no routine production or discharge of process waters; geothermal fluids brought up from the subsurface would be reinjected. Depending on the nature of the cooling system used in the plant, however, geothermal fluids could possibly be run through cooling tower-type equipment. Small

amounts of the fluid, referred to as drift, could be carried out of the equipment as mist and small droplets that can then settle onto nearby ground. Geothermal fluids can often be relatively high in minerals or gases that can then find their way to runoff from areas around the cooling tower equipment. Any contaminants in the runoff from this source would be expected to be very small and would be naturally occurring materials. If there were any geothermal springs in the area, it is very likely they would have higher concentrations of the same constituents than runoff from the plant area. Also with regard to runoff, if the pre-construction project site was land with natural vegetation, the completed project site would likely have a higher percentage of impermeable surfaces and accordingly would generate more storm water runoff. Management of this increased volume of runoff would depend on the nature of the specific site (for example, whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns.

The binary cycle portion of the power plant would have a low-boiling point organic working fluid such as isobutene or isopentane. This working fluid is intended to be within a closed system, but if there were leaks or releases during operations, this fluid could represent a contaminant were it to reach runoff or receiving waters.

If a project larger than the representative project were considered, the potential impacts to surface waters during construction and drilling would be as described for the representative project. The amount of land disturbed would increase, but the same requirements would be applicable and the same types of BMPs to control storm water discharge would be equally effective. The longer construction period and the increased number of construction equipment may be associated with a higher probability for spills or leaks of fuel and lubricants from equipment. But the types of precautions normally implemented (for example, response plans, cleanup equipment, secondary containment, etc.) would minimize the potential for contaminants to reach surface water. Drilling mud and other fluids associated with drilling operations such as flow test water, would be greater in volume, but would be associated with a corresponding increase in tanks and ponds to support their proper management. Again, an action to discharge these fluids to surface areas that could affect surface water, would require a separate discharge permit. During operations the larger facilities would tend to generate more runoff, but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns.

6.2.3.1.2 Groundwater

Construction and Drilling

Potential impacts on groundwater from surface construction activities associated with a 25-megawatt geothermal power plant would include those expected for common construction actions as described in Section 3.3.5.

As described above, drilling performed in geothermal projects typically involves the use of drilling muds. Although geothermal fluids are generally not considered drinking water sources, there could be overlying aquifers that are. It might be noted, however, that the aquifer on the southeastern side of the Kilauea East Rift Zone on Hawai'i Island (Figure 2-20) is naturally warm and salty, and not considered potable. In any case, drilling muds represent materials intentionally put down wells and which could come into contact with groundwater used as a drinking water source. One of the functions of drilling mud is to seal the walls of the borehole, keeping formation water out of the borehole and drilling fluids out of the formation. This is consistent with the physical characteristics of the bentonite clay used in drilling muds. The clay solids coat against the walls of the borehole forming a layer with very low permeability, so the drilling mud should not travel far from the borehole. There are, of course, always exceptions to this, for example if large pockets or fissures are encountered, plus groundwater can always come into contact with the outside

wall of a clay barrier. As a result, it is important to know the additives using in drilling mud and to evaluate their toxicity in case they were to reach groundwater and ultimately a drinking water source. Non-toxic formulations also make ultimate disposal of the mud easier and likely less expensive.

Formulation of the drilling fluids or mud also involves a demand for water, which is assumed to come from a local groundwater source. The representative project is described as requiring 7 million gallons of water for all of the construction activities, of which drilling represents the largest water demand. Seven (7) million gallons over several months represents only a minor demand. The two islands identified with geothermal resources, Maui and Hawai'i (see Section 2.3.3.2), have estimated groundwater sustainable yields of 427 and 2,410 million gallons per day, respectively (see Sections 3.3.2.6 and 3.3.2.7, respectively). However, water use records for the Central aquifer sector on Maui indicate current water demand exceeds the sector's sustainable yield, and one of Maui's geothermal resource areas extends into the Central aquifer sector. Accordingly, although water demand for the representative project's construction is minor, water could be an issue if it were to come from Maui's Central aquifer sector. Water use in all other aquifer sectors in Maui and Hawai'i are well below their sustainable yield values.

Operations

During operation of the geothermal power plant, impacts to groundwater primarily would be limited to the geothermal fluid removed from the subsurface. Based on several binary geothermal plants in California, it is estimated that the 25-megawatt facility would produce about 9 million gallons of water per day to put through the power plant ([Clark et al. 2011](#)). Essentially all of this water would then be injected back into the geothermal reservoir. Geothermal well completion requirements specify that any overlying aquifers of fresh water be sealed off in the well, so either production or injection of the geothermal fluid would not impact groundwater that could be a source of drinking water. Depending on the specific design of the geothermal plant, a small portion of the produced water could be lost to evaporation during cooling processes and could require some make up water to be added to that injected. Again, based on the same binary geothermal plants considered previously, it is estimated that up to about 5 percent of the produced water could be lost in the process. So up to about 450,000 gallons of water per day could be required to support the power plant. As described above, this water demand is minor in comparison to the sustainable yield of both Maui and Hawai'i. However, if this amount of water needed to come from groundwater resources within the Central aquifer sector on Maui, there could be issues because that aquifer sector is already over exploited.

The long-term presence and operation of the geothermal power plant likely would be associated with an increased amount of impermeable surfaces as compared to natural conditions and, as a result, could cause an increase in the amount of runoff from the site. Correspondingly, there potentially could be an associated decrease in groundwater recharge. However, the area involved is relatively small and, depending on where runoff from the facility goes or how it is managed, the action may simply represent a change in where water soaks into the ground and possibly provides recharge. As noted above, the working fluid in the binary cycle portion of the power plant would likely be an organic fluid. The normal plant design would have a heat exchanger for transferring heat from the geothermal fluid to the working fluid without having the fluids coming into contact with each other. However, were leaks to occur in the heat exchanger, the organic fluid could find its way into the geothermal fluid that was then injected back into the ground. Operational monitoring of the working fluid and the injected geothermal fluid could be used to determine if leaks were occurring.

For a project larger than the representative project, potential impacts to groundwater during construction and drilling basically would be as described for the smaller project. Water demand for construction and drilling activities would increase proportionally to the size of the power plant, but since the demand would be over several months, it would be expected to be a relatively small amount compared to Maui's and Hawai'i's sustainable yields. However, that demand would have to be evaluated on a site-specific

basis because one of the Maui's aquifer sectors is already experiencing groundwater demand that is higher than the sector's sustainable yield. Operation of the larger facility would be expected to require a proportional increase in the amount of geothermal water produced. Again, essentially all of this water would be injected back into the geothermal reservoir. If there were losses because of the type of cooling system included in the plant design, makeup water would be required. On a Maui or Hawai'i island-wide basis, this level of water demand would still appear to be within the sustainable yields of the groundwater resources, but the greater the quantity required, the greater the need for a site-specific evaluation. Groundwater availability can change significantly by location.

6.2.3.1.3 Floodplains and Wetlands

The proponent of a utility-scale, geothermal energy project would be expected to avoid floodplain and wetland areas if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

The floodplain and wetlands discussion for common construction impacts (Section 3.3.5) would be independent of project size and applies equally to a potentially larger project.

6.2.3.2 Best Management Practices and Mitigation Measures

Considering the limited areas where geothermal resources are likely to be found and the minimal potential for impacts to water resources from a geothermal project, with a few exceptions there would be no sensitive water resource locations or receptors that should be given special consideration. Floodplains and wetlands are possible exceptions to this, but were addressed above. Areas with limited availability of groundwater resources could be another exception. The Central aquifer sector on Maui is the only identified area fitting this description, but it coincides with an identified geothermal resource area. This does not mean the project could not be implemented due to lack of water, but it does identify a heightened level of concern that would have to be evaluated for a proposed action that involved any water demand from the Central aquifer sector.

A geothermal project should consider the common BMPs identified in Section 3.3.6 to prevent or minimize potential impacts to water resources.

6.2.4 BIOLOGICAL RESOURCES

6.2.4.1 Potential Impacts

Potential impacts to biological resources would be limited to specific areas on Maui and Hawai'i where suitable geothermal resources are available. Potential impacts to biological resources include common construction and operational impacts that with most renewable energy technologies such as land disturbances, potential increase in establishment of invasive species, and facility lighting. These common impacts are discussed in Section 3.4.5.1 and are discussed only briefly here. Construction of a 25-megawatt geothermal plant would disturb approximately 58 acres, including exploration. The location of a geothermal power plant would be largely constrained by the location of the available geothermal resource. Potential impacts to biological resources would be a function of the resources at the location and in the surrounding environment. Threatened and endangered species, critical habitat, and protected land areas occur throughout the islands of Maui and Hawai'i. Native vegetation occurs at upper elevations on both islands. The extent to which the project location overlaps or occurs in close proximity to these resources would determine potential impacts. Impacts would occur primarily from loss of habitat, disturbance by human activity, and possible establishment of invasive species in disturbed sites. Facility

lighting during operation could have potential impacts on flights of marine birds such as shearwaters and petrels, depending on the project location. Lighting designs and operation routines to minimize lighting needs could be used to avoid or reduce this potential impact. Ongoing noise associated with construction and operations would have a disturbing impact to species in the immediate vicinity of the project, however, these wildlife would likely relocate to areas away from the source of the noise.

6.2.4.2 Best Management Practices and Mitigation Measures

Many of the disturbed areas created by initial exploration and construction can be restored with native vegetation following completion of construction to minimize the operational footprint of the project. Lighting designs and operation routines to minimize lighting needs could be used to avoid or reduce potential impacts to birds. Additional BMPs are discussed in Section 3.4.6.

6.2.5 LAND AND SUBMERGED LAND USE

This section addresses the potential environmental impacts on land use from a 25-megawatt geothermal facility.

6.2.5.1 Potential Impacts

6.2.5.1.1 Land Use

A 25-megawatt facility would require a total land area of about 58 acres (approximately 5 acres for exploration and 53 acres for drilling operations and utilization, based on estimates provided in Table 2-14 in Chapter 2). Within this area there would be land disturbances related to exploration, access road construction, core drilling and well field development, pipelines, and tie-ins to the existing transmission grid.

Land use impacts could include the change of land use or ownership by purchase or through leases. Undeveloped land or land with current uses could be converted to an energy facility. For the linear aspects of the project (such as the transmission line), land use easements could be required. Operations would include maintaining the production wells, other facilities/structures, and managing waste products.

If the scope of the representative project were increased (by a factor of two for example), it is reasonable to assume the associated impact elements (that is, amount of land disturbance) would increase by a similar factor.

The State's land use designations would be considered along with the respective county's overlay zoning.

6.2.5.1.2 Submerged Land Use

As identified in [Table 6-3](#), there would be no potential impacts to submerged land use from the representative geothermal project.

6.2.5.2 Best Management Practices and Mitigation Measures

Maui and Hawai'i are the only islands with the necessary high temperature resources to support electricity production from geothermal energy. Both islands have existing land uses related to parks, known scenic areas, and Native Hawaiian sacred sites. The State land use designations and the county's overlay zones should be considered in the siting of any geothermal facility.

6.2.6 CULTURAL AND HISTORIC RESOURCES

6.2.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operational phases of a utility scale, geothermal power project if effective conservation and BMPs are not implemented. During construction, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Active volcanoes and their associated rift zones are considered sacred by Native Hawaiians and geothermal development may negatively affect cultural traditions and practices. For example, a significant Native Hawaiian deity is the volcano goddess, Pele. Her home is in and around the active volcano, Kīlauea in Hawai‘i Volcanoes National Park on the Big Island. Pele is often referred to with reverence and should be part of cultural evaluations when considering geothermal development. A large portion of geothermal resources available on Hawai‘i Island are within or adjacent to the Hawai‘i Volcanoes National Park, which could result in significant viewshed impacts from facility development, transmission lines, and other ancillary facilities.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6.

Any geothermal facility site selection process would include a detailed environmental impact study, which would include a more detailed evaluation of potential impacts to cultural and historic resources.

6.2.6.2 Best Management Practices and Mitigation Measures

Associated BMPs to reduce potential impacts to cultural, historic, and related natural resources during construction and operation are discussed in Section 3.6.7.

6.2.7 COASTAL ZONE MANAGEMENT

Impacts to coastal zones were evaluated based on the extent to which a project would conflict with the policies of the Hawai‘i Coastal Zone Management Program and potentially affect special management areas, shorefront access, and shoreline erosion.

6.2.7.1 Potential Impacts

Because the entire State of Hawai‘i is considered as part of the coastal zone, a Federal consistency review could be required. Potential impacts to special management areas designated under the Coastal Zone Management Program, shorefront access, and shoreline erosion would depend on specific locations selected for a geothermal power plant. Because geothermal development is restricted to the location of

geothermal resources, potential impacts to the coastal zone would depend on the proximity of geothermal and coastal resources.

6.2.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

6.2.8 SCENIC AND VISUAL RESOURCES

6.2.8.1 Potential Impacts

Potential impacts to visual resources from common construction activities are discussed in Section 3.8.4.

Long-term visual impacts related to geothermal development include the power plant, night lighting on the power plant, visibility of the transmission line, and the presence of steam plumes at facilities using water-cooled systems. Geothermal power plants do not require significant storage, transportation, or combustion of fuels that cause visual impacts similar to other types of power plants. These qualities reduce the overall visual impact of geothermal power plants in scenic regions.

6.2.8.2 Best Management Practices and Mitigation Measures

Sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the three designated scenic byways on Hawai‘i; State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System should be considered and avoided when locating a geothermal power plant.

In addition, the islands of Hawai‘i and Maui have general land use plans and associated implementation tools such as zoning ordinances and development standards. Some of the counties’ plans include more detail than others, but all include objectives related to protecting and maintaining open space and scenic resources consistent with the State’s land use designations.

Detailed site planning, facility design, materials selection, landscaping programs, and adjustment to transmission line routing are key aspects of geothermal operations that can reduce impacts. Developers may paint their power facility forest green to blend in with the surrounding landscape. Additionally, some companies use non-specular conductors, which reduce reflection and glare on transmission lines. Dry-cooling technology could be used to avoid visual impacts from water vapor plumes. Visual impacts of pipelines can often be reduced by screening with topography or vegetation. Additional BMPs to minimize impacts to visual resources, including those from lighting, are discussed in Section 3.8.4.

6.2.9 RECREATION RESOURCES

6.2.9.1 Potential Impacts

A total of approximately 58 acres of land disturbance would occur for the representative project. Potential short-term impacts to recreation from construction activities are provided in Section 3.9.4.

Potential long-term impacts to recreation resources related to geothermal development include access restrictions, noise, and visual impacts of the new facilities. Potential visual and noise impacts of a geothermal facility are discussed in [Sections 6.2.8](#) and [6.2.12](#). If the existing land use of the proposed site is recreation, the recreational value of the site would be permanently lost or altered by the new power

plant. Potential visual and noise impacts from the power plant would affect nearby recreation areas. Lighting on the plant could affect nearby recreation resources, such as campgrounds, where a dark night sky is valued.

6.2.9.2 Best Management Practices and Mitigation Measures

Sensitive locations such as recreation resources listed in Appendix A of the *State Comprehensive Outdoor Recreation Plan* (DLNR 2009) should be considered when locating a power plant. In addition, the Counties of Hawai'i and Maui have general land use plans and associated implementation tools such as zoning ordinances and development standards. Possible permits that may be required for construction of a geothermal power plant are listed in Section 2.3.3.2.3.

Detailed site planning, facility design, materials selection, landscaping programs, and adjustment to transmission line routing are key aspects of geothermal operations that can reduce impacts. Potential BMPs to reduce scenic and visual impacts and noise and vibration are discussed in [Section 6.2.8](#) and [Section 6.2.12](#). Additional BMPs to reduce impacts to recreation resources are provided in Section 3.9.5.

6.2.10 LAND AND MARINE TRANSPORTATION

6.2.10.1 Potential Impacts

6.2.10.1.1 Land Transportation

As identified in [Table 6-3](#), other than temporary, localized traffic impacts due to construction, there would be no potential impacts to land transportation from the representative geothermal project.

6.2.10.1.2 Marine Transportation

As identified in [Table 6-3](#), there would be no potential impacts to marine transportation from the representative geothermal project.

6.2.11 AIRSPACE MANAGEMENT

As identified in [Table 6-3](#), there would be no potential impacts to airspace management from the representative geothermal project.

6.2.12 NOISE AND VIBRATION

6.2.12.1 Potential Impacts

Short-term noise and vibration impacts would result from exploration and construction of a representative utility-scale geothermal project. Potential impacts from noise and vibration would be wholly dependent on sound levels and the proximity of sensitive receptors to the source. Construction activities prior to drilling are estimated to generate noise levels that can reach approximately 89 dBA at a distance of 50 feet (DOE 2013). The well drilling, stimulation, and testing phases of exploration can last from one to five years. Drilling activities for the injection wells could generate 98 dBA at a distance of 50 feet based on typical noise levels for rock drilling (DOE 2013). Sound measurements of diesel-powered generators have shown that an individual generator produced sound levels at about 102 dBA at a distance of 10 feet and combined with drilling, at 200 feet from the rig, the average drilling sounds ranged from 71 to 79 dBA (Behrens and Associates 2006). Such noise could indirectly impact scenic and visual resources, recreation resources, cultural resources, worker health and safety, and possibly public health. To evaluate

the potential for impacts to sensitive receptors when selecting site locations, anticipated noise levels from the drilling activities with and without noise mitigation berms should be estimated. An evaluation of potential noise and vibration impacts would not only have to identify sound levels that would be produced by the specific project equipment, but it would also have to identify and characterize nearby receptors including sensitive receptors. Noise study data (measurements) from the drilling of a stratigraphic well indicates that at approximately 1,570 feet from the well, with the noise berms in place, the sound level during drilling activities would be reduced to approximately 36 dBA ([DOE 2013](#)). Local noise ordinances described in Section 3.12 would be temporarily exceeded during exploration and construction, which would require a permit variance, and short-term noise outside of permitted hours could occur.

Long-term noise and vibration impacts would result from operation of the representative geothermal project. Potential impacts from noise and vibration would be wholly dependent on sound levels and the proximity of sensitive receptors to the source. Noise and vibration generated by drilling operations would be similar to those produced during exploration, but over a longer duration. Normal operations of a geothermal power plant typically generate noise levels in the 71 to 83 decibel range at a distance of one-half mile ([BLM 2008](#)). Potential impacts to sensitive noise and vibration receptors (identified in Section 3.12) would be limited to specific areas on Maui and Hawai'i where suitable geothermal resources are available. Long-term noise and vibration impacts would depend on the locations of the utility-scale geothermal plant and compatibility with the existing land uses.

Noise levels decrease, or attenuate, with distance from the source of noise (see Section 3.12.1). Noise levels from point sources typically attenuate at a rate of 6 to 7.5 dBA each time the distance from the noise source is doubled, and noise levels from line sources attenuate at a rate of 3 to 4.5 dBA each time the distance from the source is doubled (see Section 3.12.1).

6.2.12.2 Best Management Practices and Mitigation Measures

Noise permits would be required if noise levels exceed regulatory limits. A noise permit variance would be necessary when permitted noise limits would be exceeded. Noise avoidance and mitigation measures may be imposed directly as conditions of permit issuance.

The following recommended BMPs could further reduce noise levels:

- Avoid sensitive receptors for noise and vibration (identified in Section 3.12).
- Take measurements to assess the existing background noise levels at a given site and compare them with the anticipated noise levels associated with the proposed project. Develop site-specific noise contours that include day and night noise and vibration levels, peak levels, and energy-averaged levels.
- Proposed drilling near residences and sensitive noise receptors may require mitigation measures to ensure compliance with all State and County laws, rules and ordinances regarding noise ([County of Hawai'i 2014](#)). Locate stationary construction equipment such as compressors and generators as far as practicable from nearby residences.
- If blasting or other noisy activities are required during the construction period, notify nearby residents in advance.
- Only use explosives within specified times and at specified distances from sensitive wildlife or streams and lakes, as established by the Federal and State agencies ([BLM 2008](#)).

- Use equipment with sound-control devices, including use of noise-mitigating drilling technology. Equipment should be adequately muffled and maintained.
- Install physical barriers such as walls, earth berms, or vegetation and screening mechanisms between sources of noise and vibration, such as well drilling, and the offsite receptors.

6.2.13 UTILITIES AND INFRASTRUCTURE

6.2.13.1 Potential Impacts

Potential impacts on Maui or Hawai‘i’s electric utilities would range from small to moderate from the addition of 25-megawatt of power generation to either island’s overall power grid. For Maui and Hawai‘i, with island net capacity of 262 megawatt and 292 megawatt respectively, the change would be about 9.5 percent and 8.6 percent, respectively (see Section 3.13.1). The likelihood that the affected island utility would need to make a large adjustment to power management on the grid and overall power production for this change is moderate. Ten (10) miles of transmission lines would be installed to connect the geothermal facility to the power grid (see Section 8.1 for impacts related to new transmission lines). Impacts from connection to utilities for construction and operation of this representative project would be the same as those described in Section 3.13.3.1, as applicable.

6.2.13.2 Best Management Practices and Mitigation Measures

BMPs for construction would be expected to be implemented to avoid conflicts with existing utilities (see Section 3.13.4).

6.2.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

6.2.14.1 Potential Impacts

6.2.14.1.1 Hazardous Materials

During the resource exploration and drilling phase, hazardous materials associated with the development (improvement or construction) of access roads and exploratory and flow testing wells may be utilized. These include hydraulic fluids, pipe dope, used oils and oil filters, rigwash, spilled fuel, drill cuttings, drums and containers, spent and unused solvents, paint and paint washes, sandblast media, and scrap metal associated with drilling that would produce hazardous waste. The wastes associated with drilling fluids include oil derivatives (e.g., such as polycyclic aromatic hydrocarbons [PAHs], spilled chemicals, suspended and dissolved solids, phenols, cadmium, chromium, copper, lead, mercury, nickel, and drilling mud additives, including potentially harmful contaminants such as chromate and barite). Adverse impacts could result if the hazardous materials were not properly handled or were released to the environment. However, standard industry practices would be implemented and disturbed areas would be restored with natural vegetation once drilling activities are completed. Produced geothermal fluids would be re-injected back into the geothermal reservoir. Therefore, no sludge would likely be generated. If any sludge were generated, it is anticipated that remaining sludge would be removed and transported to licensed offsite locations for disposal.

During construction of the geothermal facility, similar impacts as those addressed for the exploration and drilling phase may occur. Additional discussion regarding construction impacts can be found in Section 3.14.4.

Typical activities during the operations phase include operation and maintenance of production and injection wells and pipeline systems, operation and maintenance of the power plant, waste management, and maintenance and replacement of facility components. Project operations and maintenance may result in some amounts of hazardous materials (e.g., lubricating oils, hydraulic fluids, coolants, solvents, and cleaning agents). Impacts could result if these materials were not properly handled and were released to the environment. Environmental contamination could occur from accidental spills of herbicides or, more significantly, oil. As such, hazardous materials would be handled, stored, and transported properly by a licensed hauler to the appropriate permitted offsite disposal facility as a standard practice. See Section 3.14.4 for additional discussion.

During operations, hydrogen sulfide, which is naturally present ([GEA 2007](#)), may be released from geothermal fluids exposing workers and the offsite public to hazards. [Section 6.2.2.1.1](#) addresses these air quality releases. In addition, it is anticipated that air monitoring for the presence and concentration of hydrogen sulfide by a qualified person using air monitoring equipment (such as hydrogen sulfide detector tubes or a multi-gas meter that detects the gas) shall occur. Those personnel working in areas containing hydrogen sulfide would also be required to wear appropriate respiratory protection and any other necessary personal protective equipment, rescue, and communication equipment, and be monitored for signs of overexposure.

6.2.14.1.2 Waste Management

Project construction of a 25-megawatt geothermal project may require land clearing, excavation, drilling, and other related construction activities. These activities would generate general construction waste and potential impacts to landfills accepting these wastes can be minimized through recycling efforts and resultant diversion of generated wastes. A general discussion of potential waste management impacts is provided in Section 3.14.4.

As discussed in Section 3.14, it is noted that some landfills in Hawai‘i are currently at capacity. As such, depending on the proposed project location (either on the island of Maui or Hawai‘i), the disposal of non-recyclable materials may add to existing landfill capacity constraints. The resolution of landfill siting and expansion in Hawai‘i is pending or in process. Therefore, additional waste produced on Hawai‘i may result in potential impacts, pending the resolution of existing landfill capacity constraints.

During the resource exploration and drilling phase, seismic and exploratory well crews may generate waste (plastic, paper, containers, fuel leaks/spills, food, and human waste). Wastes produced by drilling would include drilling fluid and muds, potential geothermal fluids/sludge, used oil and filters, spilled fuel, drill cuttings, spent and unused solvents, scrap metal, solid waste, and garbage.

During construction, impacts would be similar to but more extensive than those addressed for the exploration and drilling phase. Solid waste generated would mostly be nonhazardous, consisting of containers and packaging materials, miscellaneous wastes from equipment assembly and presence of construction crews (food wrappers and scraps), and woody vegetation. However some hazardous waste would be generated including minor amounts of paints, coatings, and spent solvents. Most of these materials would likely be transported offsite for disposal. In forested areas, commercial-grade timber could be sold, while slash may be spread or burned near the well site.

During project operations and maintenance, hazardous waste may be generated including lubricating oils, hydraulic fluids, coolants, solvents, and cleaning agents. However, these wastes would be handled, stored, and transported by a licensed hauler to the appropriate permitted offsite disposal facility as a standard practice. This would ensure that no environmental contamination could occur from accidental spills of herbicides or, more significantly, oil.

6.2.14.1.3 Wastewater

Wastewater impacts could result from geothermal waste fluid containing elevated levels of arsenic, mercury, lithium, and boron if released during exploration and drilling activities. These pollutants can damage aquatic life or drinking water supplies and water for irrigation. However, all geothermal liquids and condensable gases are expected to be closed loops (although minor leakage could occur). This means that the working fluid stays in the powerhouse and the geothermal fluids would be injected back into the subsurface reservoir. Since the working fluid is a pure material, the condenser's cooling system fluid, which can be either air or water, would not come into contact with the working fluid. In the event of leakage, produced geothermal fluids would be routed to sumps or pits and left to evaporate. The remaining sludge would then be removed, transported, and disposed of at the appropriate disposal facility.

6.2.14.2 Best Management Practices and Mitigation Measures

Prior to construction, the proposed project location would be investigated via the review of public records and the performance of site inspections to identify possible hazardous materials that may be present at the project site. In the event that the project location is sited at one of these sites, site remediation would be recommended prior to project development. Additional BMPs related to hazardous materials, waste management, and wastewater are discussed in Section 3.14.5.

6.2.15 SOCIOECONOMICS

6.2.15.1 Potential Impacts

Socioeconomic impacts in Hawai'i arising from the exploration, development, and operation of a 25-megawatt geothermal power plant would be small. The plant apparatus and appliances and the drilling equipment would likely be manufactured outside the State and, if so, economic benefits associated with the manufacturing would accrue elsewhere. The number of temporary jobs associated with the drilling operation, about 20 positions, and the numbers of jobs to monitor, operate, and maintain the plant, perhaps two dozen positions, would be small. Jobs directly associated the plant during both construction and operations would be likely filled by individuals residing within the area of influence (the State of Hawai'i) and not by workers migrating to the State to fill those positions. The geothermal power plant representative project would not create a large number of new net jobs. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and county government sector; to rental housing; and to personal income would be very small.

6.2.15.2 Best Management Practices and Mitigation Measures

None noted.

6.2.16 ENVIRONMENTAL JUSTICE

6.2.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the representative geothermal project are expected to be small. Populations of special focus in an environmental justice analysis, i.e., racial and ethnical minorities and low-income residents, as well the general population, could benefit from job creation associated with the representative project.

6.2.16.2 Best Management Practices and Mitigation Measures

Any geothermal energy plant project site selection process would include a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

6.2.17 HEALTH AND SAFETY

6.2.17.1 Potential Impacts

Common potential health and safety impacts from typical construction and operations activities are identified in Section 3.17.3.

The development of geothermal resources has the same potential for health and safety impacts associated with oil and gas production and other technologies that involve drilling. The substantial experience gained over more than 100 years of drilling activities has resulted in techniques and the associated processes and procedures to monitor and mitigate the potential for health and safety impacts.

Physical hazards from geothermal project construction and operation would usually be associated with construction, exploration, drilling, flow testing, well venting, and power plant operation. Thermal hazards would be associated with heated fluids, and workers could be potentially burned by geothermal fluids. Chemical hazards would be associated with naturally occurring contaminants in the geothermal fluid. Health effects from chemical exposure may be acute or chronic, and exposure may be via inhalation of geothermal steam or ingestion of geothermal fluids (such as drinking contaminated water). Non-condensable gases form when geothermal fluids turn to steam, and the primary gas of concern is hydrogen sulfide (mercury, radon, and benzene may also be present, but are typically not at levels considered hazardous to human health) ([BLM 2008](#)). Steam would be produced during drilling, flow testing, well venting, and cooling of geothermal fluids during power plant operation. Binary geothermal power plants re-inject geothermal fluids, which reduces emissions; however, emissions do still occur during flow testing and well venting. Health impacts from high concentrations of hydrogen sulfide include nausea, headache, and eye irritation, while extremely high levels can result in death. However, as a result of standard abatement measures, geothermal plants typically produce only minimal hydrogen sulfide emissions ([GEA 2007](#)). While abatement systems may reduce levels of hydrogen sulfide, some abatement systems have their own suite of chemicals and wastes, exposure to which can also result in occupational illness ([BLM 2008](#)).

As noted above in [Section 6.2.1](#), although today's sophisticated and fast-acting blowout preventers have practically eliminated their occurrence ([MIT 2006](#)), well blowouts can present an immediate risk to personnel and equipment at the rig from hot fluids and steam, and geothermal gases such as hydrogen sulfide, if present, could present toxicity concerns to a broader area around the rig.

During project development, the potential exists for the project to encounter lava. The few worldwide instances where lava has been encountered in, or entered drill holes, including the 2005 event when magma was encountered in a deep borehole on Hawai'i and a similar occurrence in 2009 in Iceland, have not resulted in significant problems at or near the surface ([Nature News 2008](#); [UC Davis 2009](#)). There was no indication that the drill hole might provide a route for the magma to reach the surface. Exploratory boreholes not developed into geothermal systems would be sealed in accordance with well establish methods and would not be expected to present any geologic concerns or weak spots.

Potential impacts on public safety services from construction and operation of this representative project would be the same as those as described in Section 3.13.3.2.

6.2.17.2 Best Management Practices and Mitigation Measures

Common BMPs for construction are identified in Section 3.17.4. Additionally, the following bullets identify BMPs that are specific to geothermal technologies ([BLM 2008](#)):

- Develop a health and safety program to protect both workers and the general public during exploration, construction, and operation of geothermal projects. The program should include health and safety training procedures.
- Prior to any geothermal resource development, prepare a health and safety plan that addresses worker and site safety, emergency response protocols, and procedures for managing hazardous and toxic substances. The plan would identify requirements for notices to State and county emergency response authorities, include emergency response plans and procedures, and define health and safety performance standards.
- Air monitoring for the presence and concentration of hydrogen sulfide by a qualified person using air monitoring equipment (such as hydrogen sulfide detector tubes or a multi-gas meter that detects the gas).
- Personnel working in areas containing hydrogen sulfide would be required to wear appropriate respiratory protection and any other necessary personal protective equipment, rescue, and communication equipment, and be monitored for signs of overexposure.

6.3 Municipal Solid Waste (MSW)

The representative MSW-to-energy project would be a direct combustion facility designed to produce 5 megawatts of energy on 10 acres of land. It would require 165 tons of solid waste per day (see Section 2.3.3.4). Although the representative project assumes that the MSW facility would be co-located with the waste feedstock source, in some cases, the source of the municipal waste (which could be a dump or transfer station) could be miles away from the MSW facility. The feedstock source and the transportation of the waste would both have potential for additional environmental impacts.

If the scope of the representative project were increased by an order of magnitude (that is, increased from 5 megawatts to 50 megawatts), the land required and the daily feedstock requirements would increase linearly, by a factor of 10.

[Table 6-4](#) presents a summary of the potential environmental impacts for the representative MSW-to-energy project, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 6-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – MSW-to-Energy Facility

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	<p>General construction impacts (see Section 3.1.3).</p> <p>No operational impacts.</p>	<p>Same as those common across construction projects (see Section 3.1.4).</p>
Climate and Air Quality		
Air Quality	<p>General construction impacts (see Section 3.2.4).</p> <p>Increased criteria pollutant emissions (nitrogen dioxide, particulate matter, carbon monoxide, and sulfur dioxide, as well as carbon dioxide) from combustion.</p>	<p>Same as those common across construction projects (see Section 3.2.5).</p> <p>Design a boiler system to achieve high combustion and boiler efficiency.</p> <p>Apply maximum achievable control technologies to reduce emissions during project operations (i.e., dust collectors to reduce particulate matter emissions).</p>
	<p>Potential increase in pollutant emissions (including cadmium, carbon monoxide, dioxins/furans, hydrogen chloride, lead, mercury, nitrogen oxides, particulate matter, and sulfur dioxide) emissions during project operations</p>	
Climate Change	<p>Decreased greenhouse gas from electricity production.</p>	<p>Apply control technologies to reduce emissions during project operations.</p>
Water Resources		
Surface Waters	<p>General construction impacts (see Section 3.3.5).</p> <p>Potential water resource discharge impacts from blowdown chemicals.</p> <p>Potential stormwater contamination from solid waste activities, such as stockpiling, dumping, and moving.</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p> <p>Implement precautionary measures during construction, such as response plans, cleanup equipment, and secondary containment.</p> <p>Incorporate water treatment measures to meet discharge permit limit requirements, as necessary.</p> <p>The project should be designed to eliminate the potential for precipitation or stormwater runoff to come into contact with waste materials (i.e., keep all waste storage areas covered and inside the facility).</p>

		<p>scenic resources, consistent with the State’s land use designations.</p> <p>Detailed site planning, facility design, materials selection, landscaping programs, and adjustments to transmission line routing can reduce visual impacts caused by MSW combustion facilities.</p>
Recreation Resources		
	<p>General short-term construction impacts (see Section 3.9.4).</p> <p>Potential long-term recreation resource impacts including from visual and noise impacts (site-specific).</p> <p>Potential recreational resource impacts from truck traffic.</p> <p>Potential impacts to recreation resources (i.e., nearby campgrounds or areas where a dark night sky is valued) from facility lighting.</p>	<p>Same as those common across construction projects (see Section 3.9.5).</p> <p>During site selection, consideration should be given to sensitive locations such as the recreation areas listed in Appendix A of the <i>State Comprehensive Outdoor Recreation Plan (DLNR 2009)</i>.</p> <p>During site selection, additional consideration should also be given to each island’s general land use plans and associated implementation tools such as zoning ordinances and development standards.</p>
Land and Marine Transportation		
Land Transportation	Potential for localized transportation impacts from hauling or transporting MSW.	<p>Deliveries could be scheduled to avoid peak traffic hours to minimize potential impacts.</p> <p>Using covered trucks would prevent potential hazards of dust and feedstock from falling or blowing onto roadways during transport.</p>
Marine Transportation	None; the MSW-to-energy facility would be entirely land-based, Transfer of MSW between islands is not anticipated.	N/A
Airspace Management		
	Potential impacts if emission stacks are less than 200 feet.	Project locations near airports would require evaluation to ensure emissions stacks less than 200 feet would not interfere with regulated airspace or create thermal plume turbulence that would be a hazard to aircraft.

Table 6-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – MSW-to-Energy Facility (continued)Error! Bookmark not defined.

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Noise and Vibration		
	General impacts during construction and operation (see Section 3.12.5).	Same as those common across construction projects (see Section 3.12.6). If sited near the MSW landfill, the potential noise impacts would likely be more suitable for the surrounding environment.
Utilities and Infrastructure		
Utilities	General construction and operational impacts (see Section 3.13.3.1). Varying impacts to utilities (site/island-specific i.e., small effects to O‘ahu, larger effects to Lāna‘i), requiring potential adjustment/management of power grids and overall power production.	Same as those common across construction projects (see Section 3.13.4).
Hazardous Materials and Waste Management		
Hazardous Materials	Potential hazardous material exposure impacts during project operations and maintenance. Potential exposure to hazardous materials from MSW delivered to the site. Potential impact from exposure to hazardous materials associated with the flammability of syngas production.	Same as those common across construction projects (see Section 3.14.5). Handled, store, and dispose of hazardous materials to the appropriate permitted facility. Manage the materials in accordance with standard industrial practices and in accordance with specific manufacturer’s recommendations and applicable regulatory requirements.
Waste Management	Potential exposure to hazardous waste (i.e., infectious waste, electronics, lead acid batteries, firearms, propane tanks, sludge, agricultural wastes, soil, and some noncombustible inorganic materials (such as concrete, stone).	Identified, separate, and dispose of hazardous waste received onsite at the appropriate permitted landfill. Ensure hazardous waste is picked up by a licensed contractor and disposed of appropriately.

Table 6-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – MSW-to-Energy Facility (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	<p>Potential waste management impacts from ash waste byproducts.</p> <p>Potentially beneficial impacts resulting from decreased MSW in landfills.</p>	<p>Upon completion of toxicity testing and deemed nonhazardous, use ash waste (to the extent feasible) for daily cover at lined landfills, roadbed construction, or concrete applications.</p> <p>If the ash waste could not be reused and is not deemed hazardous, dispose of the byproduct as an industrial waste at the appropriate landfill facility.</p> <p>If the ash way was determined to be hazardous, store and/or dispose of the byproducts at the appropriate hazardous waste facility.</p>
Wastewater	Potential impacts to wastewater services from blowdown.	As necessary, incorporate water treatment measures to meet wastewater discharge permit requirements (including point source NPDES permit requirements) prior to wastewater discharge to any surface water or the municipal sewer network.
Socioeconomics		
	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	None.
Environmental Justice		
	<p>Small potential impacts to the general population.</p> <p>Site-specific evaluation of impacted populations required.</p>	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.
Health and Safety		
	<p>General construction and operation impacts (see Section 3.17.3).</p> <p>No potential for accidents and intentional destructive acts effects. Construction and operation of an MSW-to-energy facility would not introduce any unique accident scenarios and therefore would not result in impacts from accidents and intentional destructive acts.</p>	Same as those common across construction projects (see Section 3.17.5).

6.3.1 GEOLOGY AND SOILS

6.3.1.1 Potential Impacts

Potential impacts on geology and soils from construction of a 5-megawatt MSW-to-energy facility would be the same as those expected for common construction actions as described in Section 3.1.3.

Construction would involve disturbance of 10 acres of land, so the permitting requirements described in Section 3.1.3 would be fully applicable.

Construction of a MSW-to-energy facility larger than the representative project would involve disturbance of a greater area of land, but as described for a common construction project, the project would be required to obtain a storm water discharge permit, and to plan and implement measures to minimize erosion and discharge of pollutants. It is expected that the same type of BMPs would be implemented independent of the size of the disturbed area and that the measures would be equally protective. Because the primary concern with regard to pollutants would be spills or leaks of fuel and lubricants from the equipment, the longer construction period and the increased number of construction equipment may be associated with a higher probability for such an incident to occur. But the types of precautions normally implemented (i.e., response plans, cleanup equipment, secondary containment, etc.) would keep potential for on- or offsite soil contamination at a minimum.

Operation of the MSW-to-energy facility would not involve activities that would have the potential to affect geology and soils of the area.

6.3.1.2 Best Management Practices and Mitigation Measures

The BMPs for constructing and operating a MSW-to-energy facility would be the same as described for common construction projects in Section 3.1.3.

6.3.2 CLIMATE AND AIR QUALITY

6.3.2.1 Potential Impacts

Municipal solid waste systems convert municipal solid waste and other forms of waste into energy. A representative municipal solid waste project would include a 5-megawatt facility located near a municipal solid waste landfill that would burn about 165 tons of waste per day. The representative 5-megawatt project would have an assumed capacity factor of 75 percent and could theoretically replace electricity requirements from the existing baseline electrical grid by about 33,000 megawatt-hours per year. This could reduce oil consumption from electricity generation by about 2.2 million gallons per year.

6.3.2.1.1 Air Quality

The burning of municipal solid waste would emit carbon dioxide and the criteria pollutants of nitrogen dioxide, particulate matter, carbon monoxide, and sulfur dioxide. The total amount of emissions would vary depending on the amount of material burned and its heating value. Using emission factors defined in the EPA's *Compilation of Air Pollutant Emission Factors* (AP-42) Section 2.1, "Refuse Combustion", the estimated annual emissions from a solid waste project that burns about 165 tons of waste per day (60,000 tons per year) would be about 54,000 metric tons of carbon dioxide, 110 tons of nitrogen oxide, 6.3 tons of particulate matter, 14 tons of carbon monoxide, and 100 tons of sulfur dioxide ([EPA 2014](#)). The burning of municipal solid waste could thus produce more carbon dioxide than is reduced by not burning oil in the baseline electrical grid.

This technology could result in impacts commonly associated with general construction activities, which are addressed in Section 3.2.4. Municipal solid waste systems are subject to a number of air emissions regulations. A newly built small system is subject to [40 CFR Part 60 Subpart AAAA](#), “Standards of Performance for Small Municipal Waste Combustion Units for which Construction is Commenced after August 30, 1999, or for which Modification or Reconstruction is Commenced after June 6, 2001.” In addition, Section 129 of the *Clean Air Act* requires EPA to set numerical emissions limitations on nine pollutants for both small and large municipal waste combustion units. The nine pollutants are cadmium, carbon monoxide, total mass basis dioxins/furans and toxic equivalency basis dioxins/furans, hydrogen chloride, lead, mercury, nitrogen oxides, particulate matter, and sulfur dioxide (<http://www.combustionportal.org/mswi.html>; [Combustion Portal 2014](#)). All standards established due to Section 129 must reflect maximum achievable control technology.

New Source Performance Standards are Federal standards adopted by the EPA to regulate air emissions by many types of industrial facilities. The standards are intended to promote use of the best air pollution control technologies. New Source Performance Standards exist for both small and large municipal waste combustors. The standards require the operator of the municipal waste combustor to meet certain general requirements, such as monitoring and recordkeeping. The complete New Source Performance Standards for a small waste combustor are located in [40 CFR Part 60 Subpart AAAA](#).

Title V of the Clean Air Act establishes a sulfur dioxide/nitrous oxide emissions program designed to reduce the formation of acid rain. County governments that operate municipal waste combustors may be subject to these requirements (<http://www.combustionportal.org/mswi.html>; [Combustion Portal 2014](#)).

Scaled versions of a MSW-to-energy facility would produce linearly scaled impacts to air quality. For instance, a 50-megawatt project would increase air emissions by ten times that of a 5-megawatt project. A 50-Megawatt facility would burn about 1,650 tons of waste per day and would thus be classified as a large combustor.

6.3.2.1.2 Climate Change

On O‘ahu, the annual replacement of 33,000 megawatt-hours of electricity from the baseline electrical grid and the resulting reduction of 2.2 million gallons of fuel oil required to generate electricity would correspond to an annual reduction in greenhouse gas emissions of about 24,000 metric tons CO₂ equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid>; [EPA 2012a](#)). On other islands by comparison, the same annual replacement of 33,000 megawatt-hours of electricity usage would see an annual reduction in greenhouse gas emissions of about 20,000 metric tons CO₂ equivalent due to a different mix of technologies used to produce electricity.

6.3.2.2 Best Management Practice and Mitigation Measures

BMPs that could minimize air impacts include designing a boiler system to achieve high combustion and boiler efficiency and applying control technology to reduce emissions during operation of the facility (such as dust collectors to reduce particulate matter emissions). Air quality permits would be required before construction and operation of a municipal solid waste facility to insure compliance with all county and Federal air quality regulations.

6.3.3 WATER RESOURCES

This section addresses potential environmental consequences to water resources from construction and operation of a MSW-to-energy direct combustion facility. Potential impacts are addressed in terms of surface water, groundwater, and floodplains and wetlands. Potential impacts associated with the construction and operation of an onshore transmission line, as associated with the representative project, would be the same as addressed under the “On Island Electrical Transmission” technology in Section 8.1 and are not repeated here.

6.3.3.1 Potential Impacts

6.3.3.1.1 Surface Water

Effects on surface water from construction of a 5-megawatt MSW-to-energy facility would be the same as those expected for common construction actions as described in Section 3.3.5.

During operations there would be process wastewater discharged from the facility and, depending on the design of the facility, stormwater runoff could continue to be a concern. At a minimum, process wastewater would consist of blowdown from the power plant’s cooling system. Water in cooling systems typically consists of good quality water to which small concentrations of treatment chemicals are added to prohibit or reduce system corrosion and build-up of algae. Water in the system is cycled in the loop of the cooling system, but as water is lost to evaporation in the cooling tower, natural salt and mineral concentrations increase in what remains. The blowdown is water drained from the cooling system and replaced with fresh water, along with that added to replace evaporated water, in order to keep salts and minerals at acceptable levels. The blowdown may be relatively non-toxic (and depending on the treatment chemicals used in its formulation and the characteristics of the receiving water, would likely have no serious impacts), but could not be discharged to any surface water without a point source NPDES permit to ensure the water quality of the applicable receiving water was not degraded. As necessary, the MSW facility would have to incorporate water treatment measures to meet the discharge permit limits. If the MSW facility were connected to a municipal sewage treatment plant, another possibility for the disposition of the blowdown would be discharge to the sewage system. In this case, the discharge would still require a permit, but it would be one issued by the treatment plant. The offsite treatment plant would levy whatever discharge limits were needed to ensure that it could still meet its own discharge permit. Again, the MSW facility would have to incorporate water treatment measures if needed to meet the municipal sewage treatment plant’s requirements. In either case, the applicable discharge requirements would ensure that the process wastewater from the MSW facility did not adversely impact surface waters.

The MSW energy recovery facility would not be one of the industrial activities identified in [40 CFR 122.26\(b\)\(14\)\(i\)-\(xi\)](#) that automatically requires its stormwater discharge to be covered under a NPDES permit. However, there would be large amounts of solid waste dumped, moved, and stockpiled at the facility and, depending on the facility’s design, it is easy to imagine that runoff from any areas where solid waste is managed could present stormwater contamination issues. It is assumed that the representative project would be designed to eliminate the potential for precipitation or stormwater runoff to come into contact with waste materials. This would require all waste handling and storage areas to be inside the facility, or at least under a cover. If this were not the case, it is reasonable to assume that the State would require a permit for the discharge of stormwater from the facility and the facility would be required to incorporate any treatment measures needed to meet the limits imposed by the permit. Again, with these requirements in place, it can be assumed that stormwater from the facility during its operation would not adversely impact surface waters of the area.

Outside of the concerns discussed above, it is likely that the operating MSW facility site would have a higher percentage of impermeable surfaces than the pre-construction site and, accordingly, would generate more storm water runoff. Management of this increased volume of runoff would depend on the nature of the specific site (for example, whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns.

During construction of a larger scale MSW-to-energy project, potential impacts to surface waters would be similar to the representative project. The amount of land disturbed would increase, but the same requirements would be applicable and the same types of BMPs to control storm water discharge would be equally effective. The longer construction period and the increased number of construction equipment may be associated with a higher probability for spills or leaks of fuel and lubricants from equipment, but the types of precautions normally implemented (for example, response plans, cleanup equipment, and secondary containment) would minimize the potential for contaminants to reach surface water. During operations, the blowdown wastewater produced from a larger scaled facility would be proportionately larger, but the same requirements described for the smaller facility would still apply. Similarly, the potential for stormwater runoff from the facility to be contaminated would be the same as described previously, as would be the requirements, but because of an increased amount of impervious surfaces, the volume of runoff would be greater. If necessary, and because of the larger surface area, the facility could include onsite measures such as a stormwater detention pond to control the rate at which stormwater left the site.

6.3.3.1.2 Groundwater

Effects on groundwater from construction of a 5-megawatt MSW-to-energy facility would be the same as those expected for common construction actions as described in Section 3.3.5.

During long-term operations of the MSW-to-energy facility, impacts to groundwater would be limited primarily to the water needs to operate the facility. As described above, water going through the boiler and then steam to the turbine would be expected to be on a loop, but there would be continuous losses from evaporation and blowdown that would have to be replenished from the local water supply, which would likely involve groundwater. The representative project is described as requiring 4 million gallons of make-up water per month for this system. That equates to about 0.13 million gallons per day. Other water demands from the facility, including needs for the 14-person operations staff, facility cleanups, etc., would be minor in comparison, but it is assumed the facility's entire water demand would be about 0.14 million gallons per day. This amount of additional groundwater demand is very minor in comparison to the State's total groundwater sustainable yield, which is estimated at about 3.6 billion gallons per day. Accordingly, the water needed for the long-term operation of the system would not be expected to result in water availability issues, but would have to be evaluated on a site-specific basis taking into consideration the groundwater sustainable yield for the applicable Aquifer System Area and the existing groundwater demand from that area.

The long-term presence and operation of the MSW-to-energy facility would be associated with increased runoff and potentially an associated decrease in groundwater recharge. However, the area involved is relatively small and, depending on where runoff from the facility would go or how it was managed, the action may simply represent a change in where water would soak into the ground and possibly provide recharge.

Potential impacts to groundwater during construction of a larger scale MSW-to-energy project would be as described above for the representative project. The larger facility would be expected to require a proportional increase in the amount of water needed to support construction and operation. It is expected

the higher groundwater demand would still be minor in comparison to the State's total groundwater sustainable yield, but again would have to be evaluated on a site-specific basis taking into consideration the groundwater sustainable yield for the applicable Aquifer System Area and the existing groundwater demand from that area.

6.3.3.1.3 Floodplains and Wetlands

The proponent of a utility-scale, MSW-to-energy project would be expected to avoid floodplain and wetland areas if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

6.3.3.2 Best Management Practices and Mitigation Measures

BMPs associated with water resources for typical construction projects are presented in Section 3.3.6. In addition to these BMPs, the following BMPs would also be applicable to the representative MSW project:

- Whether discharged to surface waters or a municipal sewer system, applicable discharge requirements would be needed to ensure that the process wastewater from the MSW facility would not adversely impact surface waters.
- Waste handling and storage areas should be inside the facility, or at least under a cover.

6.3.4 BIOLOGICAL RESOURCES

6.3.4.1 Potential Impacts

MSW power plants, such as a waste-to-energy direct combustion facility, are often co-located in the vicinity of the municipal waste which is used as fuel. Therefore, a MSW power plant would most likely be located in a previously disturbed or heavily developed area in or near a municipal landfill. Potential impacts to biological resources are expected to be minimal because of the existing disturbance and lack of habitat at the site of development. However, project siting is an important consideration and if located either on the edge of an industrial area or in a rural agricultural processing area, potential impacts to wildlife from land disturbance during construction (see Section 3.4.5.1) and disturbance to wildlife in adjacent habitats could occur, particularly if the site is near important nesting and feeding areas, wetlands, or roost sites.

6.3.4.2 Best Management Practices and Mitigation Measures

As noted above, project siting is an important consideration during siting of a MSW power plant to ensure that potential impacts to wildlife do not occur. As such, it is anticipated that a MSW power plant would be located in a previously disturbed or heavily developed area in or near a municipal landfill.

6.3.5 LAND AND SUBMERGED LAND USE

6.3.5.1 Potential Impacts

6.3.5.1.1 Land Use

The representative project is a 5-megawatt MSW-to-energy project. The site would require about 10 acres and would include refuse receiving, handling and storage facilities; a combustion and steam generation

facility (boiler); flue gas cleaning system; power generation equipment (steam turbine and generator); condenser cooling water system; and residue hauling and storage system (fly and bottom ash). There would be site preparation and land disturbances during the construction phases of the project. The project assumes a 1-mile corridor for tie-in with the existing electrical grid. Operational activities would include maintenance and repair work.

Although there could be changes in land ownership patterns, those changes would not themselves have an impact on the environment. The potential environmental impacts would come from the conversion of land from one use to another, such as the creation of transmission corridors. The facility would most likely locate in or near a municipal landfill or industrial site. Therefore, the MSW facility would be compatible with existing uses. State land use designations and county overlay zones would still be considered.

6.3.5.1.2 Submerged Land Use

As identified in [Table 6-4](#), there would be no potential impacts to submerged land use from the representative MSW-to-energy project.

6.3.5.2 Best Management Practices and Mitigation Measures

None noted.

6.3.6 CULTURAL AND HISTORIC RESOURCES

6.3.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operational phases of a utility scale, MSW power project if effective conservation and BMPs are not implemented. During construction, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6.

Any MSW-to-energy facility site selection process would include a detailed environmental impact study, which would include a more detailed evaluation of potential impacts to cultural and historic resources.

6.3.6.2 Best Management Practices and Mitigation Measures

Associated BMPs to reduce potential impacts to cultural, historic, and related natural resources during construction and operation are discussed in Section 3.6.7.

6.3.7 COASTAL ZONE MANAGEMENT

Impacts to coastal zones were evaluated based on the extent to which a project would conflict with the policies of the Hawai'i Coastal Zone Management Program and potentially affect special management areas, shorefront access, and shoreline erosion.

6.3.7.1 Potential Impacts

Because the whole State of Hawai'i is considered as part of the coastal zone, a Federal consistency review could be required. MSW power plants are typically constructed in close vicinity to solid waste resources such as landfills or urban collection centers. A MSW power plant would likely be consistent with existing surrounding land uses. However, urban and industrial areas in Hawai'i that generate MSW typically occur along coastal regions and each project location would require evaluation for potential impacts to special management areas designated under the Coastal Zone Management Program, shorefront access, and shoreline erosion.

6.3.7.2 Best Management Practices and Mitigation Measures

As noted above, a Federal consistency review could be required for the project. In addition, each project location would be evaluated for potential impacts to special management areas designated under the Coastal Zone Management Program, shorefront access, and shoreline erosion.

6.3.8 SCENIC AND VISUAL RESOURCES

6.3.8.1 Potential Impacts

Land use requirements for a 5-megawatt facility are expected to be approximately 10 acres. Construction would last 18 months to two years. Potential impacts to visual resources from construction activities are discussed in Section 3.8.3.

Long-term visual impacts include the MSW combustion facilities and truck traffic to deliver the MSW. MSW combustion facilities would ideally co-locate with or be near a MSW landfill that would supply the facility with feedstock to minimize transportation distances of the waste to the fuel receiving area. Facilities would include various structures, such as refuse receiving, handling, and storage facilities; combustion and steam generation system (a boiler); flue gas cleaning system; power generation equipment (steam turbine and generator); condenser cooling water system; and residue hauling and storage system (fly and bottom ash). Exterior lighting would be installed on the facilities for safety and security purposes. It is assumed that 1 mile of transmission line would be needed to connect the plant to the power grid.

6.3.8.2 Best Management Practices and Mitigation Measures

Viewpoints from where the facilities would be seen should be taken into consideration when siting a MSW-to-energy facility to avoid visual impacts to scenic resources. Sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the three designated scenic byways on Hawai'i; State, National, and National Historical Parks; National Historic Trails and Landmarks; National

Natural Landmarks; and reserves protected by the Natural Area Reserves System should be considered and avoided when locating a MSW-to-energy facility. Each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards. Some of the counties' plans include more detail than others, but all include objectives related to protecting and maintaining open space and scenic resources consistent with the State's land use designations.

Detailed site planning, facility design, materials selection, landscaping programs, and adjustments to transmission line routing can reduce visual impacts caused by MSW combustion facilities. Additional BMPs to minimize impacts to visual resources, including those from lighting, are provided in Section 3.8.4.

6.3.9 RECREATION RESOURCES

6.3.9.1 Potential Impacts

Land use requirements are expected to be approximately 10 acres. Construction would last 18 months to two years. Potential impacts to recreation resources from construction activities are provided in Section 3.9.4.

Long-term impacts to recreation resources would include the loss of recreational value if the existing land use of the proposed site is recreation. However, MSW combustion facilities would ideally co-locate with or be near a MSW landfill that would supply the facility with feedstock to minimize transportation distances of the waste to the fuel receiving area. In addition, potential visual and noise impacts from the new facility could affect nearby recreation areas. Truck traffic to deliver the MSW has the potential to impact some recreational activities, for example, bicycling. Lighting on the facility could affect resources, such as nearby campgrounds, that where a dark night sky is valued.

6.3.9.2 Best Management Practices and Mitigation Measures

Sensitive locations such as the recreation areas listed in Appendix A of the *State Comprehensive Outdoor Recreation Plan* ([DLNR 2009](#)) should be considered when siting a MSW-to-energy facility. Viewpoints from where the facilities would be seen should be considered to avoid visual impacts that could affect recreation areas. Each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards.

BMPs to minimize impacts to recreation resources, including those from lighting, are provided in Section 3.9.5.

6.3.10 LAND AND MARINE TRANSPORTATION

Impacts to land transportation considered potential effects on traffic, alterations to existing roads, requirement for additional roads (excluding temporary or project specific access roads) infrastructure. Impacts to marine transportation considered potential effects on operation of the harbor systems, primary shipping routes between islands, general marine transportation around the islands (tourism, fishing), and military marine surface and subsurface operations.

6.3.10.1 Potential Impacts

6.3.10.1.1 Land Transportation

Because MSW power plants are likely to be constructed in relatively close proximity to the MSW source, potential impacts to land transportation systems from hauling or transporting MSW are expected to be localized and minor. Local impacts could occur from increased truck traffic for hauling MSW from the point of production to the power plant. Because the MSW production would occur close (i.e., up to 10 miles) to the power plant, this impact would be localized. In a worst-case scenario, this truck traffic would occur on existing public access roads and require 4 to 5 truck deliveries per day, depending on the size of the power plant. Daily truck traffic could also increase wear on paved roads and increase the need for more frequent road maintenance.

There are also potential impacts to health and safety in the form of increased truck traffic, increased risk of debris on roadway, and dust from the trucks.

6.3.10.1.2 Marine Transportation

As identified in [Table 6-4](#), there would be no potential impacts to marine transportation systems from the representative MSW-to-energy project.

6.3.10.2 Best Management Practices and Mitigation Measures

None noted.

6.3.11 AIRSPACE MANAGEMENT

6.3.11.1 Potential Impacts

Construction and operation of a utility-scale MSW power plant is not likely to require an FAA obstruction to navigation evaluation because the height of the emission stack would likely be less than 200 feet. However, project locations near airports would require evaluation to ensure emissions stacks less than 200 feet do not interfere with regulated airspace or create thermal plume turbulence that would be a hazard to aircraft.

6.3.11.2 Best Management Practices and Mitigation Measures

As noted above, project locations near airports would require evaluation to ensure emissions stacks less than 200 feet do not interfere with regulated airspace or create thermal plume turbulence that would be a hazard to aircraft.

6.3.12 NOISE AND VIBRATIONS

6.3.12.1 Potential Impacts

Construction of the representative MSW project over 18-months to 2-years could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

The representative MSW project could potentially result in long-term impacts to existing noise and vibration levels. Impacts are expected to be minimal because MSW combustion facilities would ideally co-locate with or be near a MSW landfill that would supply the facility with feedstock and thus would be

in a compatible setting. In addition, noise would be generated by truck traffic delivering feedstock to the plant. Impacts would depend on the location of facilities and compatibility with existing noise levels and land uses.

6.3.12.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation. See Section 3.12.6.

6.3.13 UTILITIES AND INFRASTRUCTURE

6.3.13.1 Potential Impacts

Effects on each island's electric utilities would range from small to large from the addition of 5 megawatts of power generation to any island's overall power grid. For O'ahu, with the largest island net capacity of 1,756 megawatts, the change would be about 0.3 percent and for Lāna'i with the smallest net capacity of 10-megawatt the change would be about 50 percent (see Section 3.13.1). With the higher percentage increase, Lāna'i would need to adjust management of power on the grid and overall power production. On all islands, 1 mile of transmission lines would be installed to connect either biomass facility to the power grid (see Section 8.1 for impacts related to new transmission lines). Impacts from connection to utilities for construction and operation of this representative project would be the same as those described in Section 3.13.3.1, as applicable.

6.3.13.2 Best Management Practices and Mitigation Measures

BMPs to avoid conflicts with existing utilities would be the same as those common across projects for construction and operation. See Section 3.13.4.

6.3.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

6.3.14.1 Potential Impacts

6.3.14.1.1 Hazardous Materials

Hazardous materials may be used during project operations and maintenance that if released or spilled could result in environmental contamination or pollution. These could include the use of oils, greases or lubricants, or chemicals such as ethylene glycol, various metals and glass oxides, hydraulic fluids of various quantities as part of the generator and cooling systems and facility equipment. In addition to hazardous materials used onsite as part of project operations, hazardous materials from the MSW may be brought into the facility which would need to be separated and removed prior to processing. Such materials would be handled, stored, and disposed of to the appropriate permitted facility. However, these hazardous materials received would be expected to be relatively minor in quantity and hazard. Management of these materials would occur in accordance with standard industrial practices and in accordance with specific manufacturer's recommendations and applicable regulatory requirements.

Project operations would also result in a flammable syngas that would be generated, stored, and combusted which would require proper handling, storage, and use.

In addition, combustion of municipal solid waste could contain hazardous constituents (which would need to be handled as a hazardous waste) if the municipal waste stream included minor amounts of hazardous

materials or hazardous waste. Proper handling, transport, and disposal of hazardous materials or substances would be required to comply with State and Federal OSHA, and county requirements. Additional discussion is provided in Section 3.14.4.

6.3.14.1.2 Waste Management

During construction, the proposed project would use common construction materials that may include concrete, concrete block, asphalt, metals, gypsum board, glass and ceramic items, and similar materials. Waste generated during facility construction would be stored properly onsite, and would likely be combusted during project operations. Those materials that can be recycled, such as construction demolition and debris would likely be transported offsite to the appropriate recycling facility. Similarly, hazardous waste would be separated and transported offsite by a licensed hauler to the appropriate permitted facility.

During project operations, personnel and activities supporting operation of the facility would produce small quantities of typical office waste which would be processed by the combustor onsite. Waste that the facility cannot process (such as hazardous materials used in operations) would be diverted to an appropriate storage facility or landfill through a contracted vendor.

Waste received onsite would likely vary and can include everyday items commonly used and thrown away, such as packaging, grass clippings, furniture, clothing, bottles, food scraps, newspapers, appliances, paint, and batteries and come from homes, schools, hospitals, and businesses. As feasible, those waste that can be recycled (primarily polyethylene terephthalate (#1 plastic) and high-density polyethylene (#2 plastic) plastic containers, and aluminum cans and other scrap metals, clean cardboard and paper, steel) would be separated out for transport to the appropriate recycling facility. Unacceptable waste such as hazardous waste, infectious waste, electronics, lead acid batteries, firearms, propane tanks, sludge, agricultural wastes, soil, and some noncombustible inorganic materials (such as concrete, stone) would be separated out and disposed of at the appropriate permitted landfill. Hazardous materials would be picked up by a contractor and disposed of appropriately.

Combustion of the waste would result in a solid waste byproduct or residue, which would likely be ash waste. To the extent feasible, this byproduct would be reused pending characterization of the byproducts and testing to ensure that no hazardous waste is present in the ash. The ash could be used for daily cover at lined landfills, roadbed construction, or concrete applications. However, changes to equipment operations and feedstock could alter composition and the reuse potential of the solid byproducts. As such, analytical testing would be required to determine reuse feasibility and to ensure that the byproducts (if to be reused) would not exceed thresholds of pollutants. Beneficial reuse would be subject to annual toxicity testing and certification/sampling pursuant to EPA SW-846, Sampling Methods, and other State laws and regulations. If the ash waste cannot be reused and is not deemed hazardous, the byproduct would be disposed of as an industrial waste at the appropriate landfill facility. If determined to be hazardous, the byproducts would be stored and disposed of at the appropriate hazardous waste facility in compliance with EPA pursuant to [40 CFR 261](#).

Potential impacts to landfills may occur as a result of the operation of a MSW combustion facility, as the amount of waste that would be processed by a MSW facility would reduce the amount of waste diverted to landfills (i.e., 165 tons per day for the representative project). This effect may be considered beneficial in those areas where landfill space is currently limited (i.e., O'ahu, Hawai'i, Kaua'i); but may not be considered beneficial in those areas where the amount of MSW generated is not currently considered sufficient to supply a MSW facility with adequate MSW feedstock to keep the facility in operation.

6.3.14.1.3 Wastewater

As discussed in [Section 6.3.3](#), during operations there would be process wastewater discharged from the facility, consisting of (at minimum) wastewater blowdown from the power plant's cooling system. The blowdown is water drained from the cooling system and replaced with fresh water, along with that added to replace evaporated water, in order to keep salts and minerals at acceptable levels. The blowdown may be relatively non-toxic, but could not be discharged to any surface water without a point source NPDES permit to ensure the water quality of the applicable receiving water is not degraded. As necessary, the MSW facility would likely incorporate water treatment measures to meet wastewater discharge permit limits.

If the project were connected to a municipal sewage treatment plant, the blowdown would be discharged to the sewage system in compliance with wastewater discharge permit requirements by the wastewater treatment plant. Again, the project would likely be required to incorporate wastewater treatment measures to meet the municipal sewage treatment plant's requirements.

6.3.14.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation (see Section 3.14.5).

6.3.15 SOCIOECONOMICS

6.3.15.1 Potential Impacts

Socioeconomic impacts in Hawai'i arising from the development and operation of a 5-megawatt MSW-to-energy direct combustion power plant would be very small. The plant apparatus and appliances including pollution control devices would likely be manufactured outside the State and, if so, economic benefit associated with that production accruing elsewhere. The number of temporary jobs associated with the construction would be approximately 25 for a period of about 18-24 months. The number of jobs to monitor, operate, and maintain the plant would be very small, perhaps 14 positions. Jobs directly associated the plant during both construction and operations would be likely filled by individuals residing within the area of influence (the State of Hawai'i) and not by workers migrating to the State to fill those positions. The MSW-to-energy direct combustion power plant representative project would create only a few new net jobs. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and county government sector; to rental housing; and to personal income would be very small.

6.3.15.2 Best Management Practices and Mitigation Measures

None noted.

6.3.16 ENVIRONMENTAL JUSTICE

6.3.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the representative MSW-to-energy direct combustion power plant are expected to be small. The potential for environmental justice impacts also would be small.

6.3.16.2 Best Management Practices and Mitigation Measures

Any MSW plant project site selection process would include a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

6.3.17 HEALTH AND SAFETY

6.3.17.1 Potential Impacts

Common health and safety impacts for typical construction and operations activities are identified in Section 3.17.3. There are no additional potential health and safety risks that would be unique to MSW-to-energy projects.

6.3.17.2 Best Management Practices and Mitigation Measures

Common health and safety BMPs for typical construction and operations activities are identified in Section 3.17.5.

6.4 Marine Hydrokinetic Energy (MHK)

Due to the uncertainty of MHK technology readiness, it is difficult to describe with any accuracy what a representative project might look like and would ultimately depend on the type of wave or tidal technology selected. For the purposes of this PEIS, the potential environmental impacts of MHK technologies presented in this chapter consider the range of potential applications identified in Section 2.3.3.5.2 that address potential impacts to the shoreline, near-shore, and offshore environments. All three scenarios would involve electrical transmission lines from the onshore facility to the nearest grid connection; potential impacts associated with such an action are addressed under the “On-Island Electrical Transmission” technology in Section 8.1 and are not repeated here. The near-shore and offshore scenarios would include an undersea cable and associated land/sea transition site. The impacts of the cable and transition site are addressed in Section 8.2. Aspects of the representative project are discussed in more detail in the following sections.

[Table 6-5](#) present a summary of the potential environmental impacts for a utility-scale MHK project, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 6-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Marine Hydrokinetic Energy

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	<p>General construction impacts including soil disturbance (see Section 3.1.3).</p> <p>Potential impacts associated with on-island electrical transmission lines are discussed in Section 8.1.1.</p> <p>Potential impacts to marine sediments and marine communities are discussed in Section 8.2.1 and Section 6.4.4, respectively.</p> <p>No operational impacts.</p>	<p>Same as those common across construction projects (see Section 3.1.3).</p> <p>During project siting, identify an area of good stability for installation of cables and pipes in the land-sea transition zones.</p>
Climate and Air Quality		
Air Quality	<p>General construction impacts (see Section 3.2.4).</p> <p>Potential land disturbance and associated fugitive dust at nearby onshore construction related areas.</p> <p>Potential short-term, minor increase in criteria pollutant emissions from construction equipment and marine vessels.</p> <p>Typically, no air quality impacts during operations</p>	Same as those common across construction projects (see Section 3.2.5).
Climate Change	<p>Potential increase in greenhouse gas emissions from construction equipment and marine vessels.</p> <p>Potentially beneficial impacts from greenhouse gas reduction associated with less electricity production.</p>	None.

Table 6-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Marine Hydrokinetic Energy (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Water Resources		
Surface Waters	<p>Onshore General construction impacts (see Section 3.3.5). Potential for increased stormwater runoff from new building sites (site-specific).</p> <p>Offshore Potential ocean sediment disturbance. Potential increased turbidity to communities of concern (site-specific) in marine waters. See Section 8.2.3.</p>	<p>Onshore Same as those common across construction projects (see Section 3.3.6).</p> <p>Offshore Devices such as silt curtains should be deployed in locations (such as the breakout point) to reduce impacts to communities of concern. Schedule project activities during seasonal periods when wave, current, and wind will be expected to be at lows.</p>
Groundwater	<p>Onshore General construction impacts (see Section 3.3.5). Limited water supply impacts for facility operations.</p> <p>Offshore No groundwater impacts.</p>	Same as those common across construction projects (see Section 3.3.6).
Floodplains and Wetlands	<p>Onshore Potential for general construction impacts (on-site) (see Section 3.3.5).</p> <p>Offshore Potential impacts offshore during placement of the MHK device, cables, or pipes.</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p> <p>Activities involving discharges of dredged or fill materials into the waters of the U.S. (in this case territorial seas) require a Section 404 permit.</p>
Biological Resources		
	<p>Potential construction impacts include displacement of marine mammals, reptiles, and fish both from physical activity and noise transmission through ocean waters.</p> <p>Potential marine habitat impacts including to marine pools, beaches (both rocky and sand), coral reefs, and essential fish habitat.</p> <p>Potential loss of beach nesting habitat for sea turtles and marine birds; and resting sites for the Hawaiian monk seal.</p>	Many of the marine-based BMPs to prevent or minimize potential impacts to biological resources are identified in Section 3.4.6.2. Additional technology-specific BMPs would be dependent on the MHK system selected for implementation.

Table 6-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Marine Hydrokinetic Energy (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	<p>Potential collision hazards to marine mammals and reptiles during anchor cabling.</p> <p>Potential localized noise (sound waves) impacts (potential auditory injury), avoidance, physical injury to marine mammals, fish, or other species, and alteration of water dynamics from submerged oscillating or rotating components.</p> <p>Potential electromagnetic field impacts from the undersea power cable.</p>	
Land and Submerged Land Use		
Land Use	Potential land disturbance impacts during construction.	None.
Submerged Land Use	Potential localized impacts to the ocean floor from tethering and power cable installation, including obstruction of local marine habitats.	None.
Cultural and Historic Resources		
	<p>Common construction and operation impacts to cultural resources (see Section 3.6.6).</p> <p>Potential direct impacts from onshore and offshore construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	Common construction and operation BMPs for cultural resources (see Section 3.6.7).

Table 6-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Marine Hydrokinetic Energy (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Coastal Zone Management		
	<p>Potential impacts including land disturbances, structural developments, lighting, and other impacts to special management areas (CZMPs), shorefront access.</p> <p>Potential alteration of shorefront access (site-specific) and alteration of ocean currents.</p>	<p>Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.</p>
Scenic and Visual Resources		
	<p>General visual impacts during construction (see Section 3.8.3).</p> <p>Long-term visual impacts (i.e., onshore/offshore—MHK technology and location specific).</p> <p>Long-term visual impacts from navigation lighting for devices.</p>	<p>Same as those common across construction projects (see Section 3.8.4).</p> <p>Sensitive locations such as coastal scenic resources from public viewing points, marine recreational areas; State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System should be considered and avoided when locating devices in the shoreline, near-shore, and offshore environments.</p> <p>Consult with each island’s general land use plans and associated implementation tools such as zoning ordinances and development standards.</p> <p>Identify and consult key stakeholders early in the planning stage i.e., during project siting.</p>
Recreation Resources		
	<p>General short-term construction impacts (see Section 3.9.4).</p> <p>Potential long-term recreation resource impacts from visual impacts (MHK technology and site specific).</p> <p>Potential effects to water-based recreation activities (i.e., swimming, surfing, boating, and fishing) resulting from access restrictions or use alterations to promote recreation user safety and prevent collisions or malfunctions to offshore technologies.</p>	<p>Same as those common across construction projects (see Section 3.9.5).</p> <p>During site selection, consideration should be given to sensitive locations such as the recreation areas listed in Appendix A of the <i>State Comprehensive Outdoor Recreation Plan (DLNR 2009)</i>.</p> <p>During site selection, areas where devices would attenuate waves at popular surfing beaches should be avoided.</p>

Table 6-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Marine Hydrokinetic Energy (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	Potential wave attenuation impacts at the shore (technology and site-specific; i.e., dependent on the array of devices and location)	During site selection, consideration should be given to each island’s general land use plans and associated implementation tools such as zoning ordinances and development standards. Identify and consult key stakeholders early in the planning stage i.e., during project siting.
Land and Marine Transportation		
Land Transportation	None.	N/A
Marine Transportation	Potential obstruction impacts to marine navigation including to tourist cruises, passenger ferries, fishing vessels (recreational and commercial), and large commercial cargo ships. Potential impacts to military marine operations, surface and subsurface navigation from both floating and submerged structures.	Review and possible marking may be required under the U.S. Coast Guard’s U.S. Aids to Navigation System.
Airspace Management		
	None; MHK would not include any tall structures and therefore would not impact airspace management.	N/A
Noise and Vibration		
	Short-term noise and vibration impacts to sensitive noise receptors, including potential impacts to marine mammals and sea turtles.	Avoid sensitive receptors for noise and vibration (identified in Section 3.12). Temporal restrictions. Establishment of an exclusion zone and shutdown, soft-start, and delay procedures (if a marine mammal or sea turtle approaches or enters an exclusion zone). Visual monitoring. Use maintained equipment with sound-control devices. Place hydrodynamic foils on the upper half of the mooring line. Use video equipment and sonar imaging equipment to screen for species interactions and to monitor turbines during operation.

Table 6-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Marine Hydrokinetic Energy (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
		Requests for Incidental Harassment Authorization must include monitoring and reporting plans.
Utilities and Infrastructure		
Utilities	General short-term construction impacts (see Section 3.13.3.1).	Refer to Section 3.13.4.
Hazardous Materials and Waste Management		
Hazardous Materials	Common short-term construction impacts (see Section 3.14.4). Potential exposure to hazardous materials including fuels from boats, marine vessels, barges, lubricants and hydraulic fluids contained in the wave or tidal energy devices during operations and maintenance.	Same as those common across construction projects (see Section 3.14.5).
Waste Management	Common short-term construction impacts (see Section 3.14.4). Potential landfill impacts to O‘ahu and Hawai‘i (pending the resolution of existing landfill capacity constraints) if non-recyclable materials add to existing landfill capacity constraints.	Same as those common across construction projects (see Section 3.14.5).
Wastewater	Potential impacts to wastewater services from vessel effluent during construction. No operational impacts.	Vessels are subject to the EPA NPDES requirements, including EPA’s Vessel General Permit requirements (for vessels greater than 79 feet).
Socioeconomics		
	None; MHK would result in few jobs and would not impact socioeconomics.	N/A
Environmental Justice		
	None; there would be no measurable impacts to the human environment, and there would be no environmental justice impacts.	N/A
Health and Safety		
	General construction and operation impacts (see Section 3.17.3). Potential for public health and safety effects including to boats, both civilian and military marine vessels, and to the public onshore in the event the device were destroyed, damaged or if the loss of mooring/spatial stabilization were to occur.	Same as those common across construction projects (see Section 3.17.5).

6.4.1 GEOLOGY AND SOILS

6.4.1.1 Potential Impacts

The representative project to be evaluated for the MHK energy technology is a range of technologies consisting of those that would be deployed in the shoreline, near-shore, and offshore environments. For the purposes of evaluating potential impacts to geology and soils, the different deployment scenarios would have basically the same concerns. None of the scenarios would be expected to impact geology and the primary means by which soils could be affected would be through soil disturbing actions, such as during construction, which would occur under each of the scenarios. Under the shoreline scenario, the MHK device and power conversion equipment would likely all be included in a single facility, or joined facilities, at the shoreline. In the other two scenarios, the MHK device would be deployed offshore, but an associated electrical substation and possibly power conversion facility would have to be constructed onshore. The onshore facility would include power conversion equipment, for example, if the MHK device involved pumping water to the shore. It is also assumed that both of the offshore scenarios would involve horizontal directional drilling during construction to install connecting power cables (and possibly water lines) through the sea-to-land transition zone.

All three scenarios would involve electrical transmission lines from the onshore facility to the nearest grid connection, but potential impacts associated with such an action are addressed under the “On Island Electrical Transmission” technology in Section 8.1.1 and are not repeated here. The two offshore scenarios would also involve some means to anchor or moor the MHK devices to the ocean floor. Similarly, the deployment of an offshore MHK device would be expected to include some means of burying cables (and possibly water lines) in the ocean floor between the device location and the sea-to-land transition zone. These offshore elements of MHK projects would not involve potential soil-related impacts because of their marine location, but there would be corresponding effects on the marine sediments. For example, anchor devices would be expected to have impacts on the natural migration of sand. Potential impacts to marine sediments from offshore elements of MHK actions would basically be the same as described in Section 8.2.1 for placement of undersea cables and the associated land-sea transition zones for those cables. As a result, those potential impacts are also not repeated here. Potential impacts to marine communities associated with the affected ocean sediments are discussed in [Section 6.4.4](#).

Potential impacts on geology and soils from onshore construction associated with MHK projects would be the same as those expected for common construction actions as described in Section 3.1.3. Based on the size of the shoreline facilities described in section 2.3.3.5 and the assumption that the near-shore and offshore scenarios would involve horizontal directional drilling, it is reasonable to assume that each MHK scenario would involve the disturbance of more than one acre, so the permitting requirements described in Section 3.1.3 would be fully applicable.

Operation of a MHK device would not involve activities that would have the potential to affect geology and soils of the area.

6.4.1.2 Best Management Practices and Mitigation Measures

BMPs include the consideration of sensitive locations or receptors with regard to onshore construction and operations of MHK facilities, which would be the same as described for common construction projects in Section 3.1.3. The horizontal directional drilling (HDD) operations that would likely be involved in installing cables or pipes in the land-sea transition zones require an area of good stability. However, a basic premise of the HDD technology (that is, tunneling under areas where surface actions are

to be avoided) provides a mechanism to avoid areas that would present difficulties for drilling and subsequent construction.

6.4.2 CLIMATE AND AIR QUALITY

6.4.2.1 Potential Impacts

MHK technologies are devices that use the kinetic energy from moving water (e.g., waves, tides, and ocean currents) to generate electricity. Due to the uncertainty around MHK technology, a representative project could be either shore-based or offshore.

6.4.2.1.1 Air Quality

For shore-based installations, this technology could result in impacts commonly associated with general construction activities, which are addressed in Section 3.2.4.

Off-shore construction of MHK devices would not generate fugitive dust at the site of installation, but the construction project could result in land disturbances and associated fugitive dust at nearby onshore construction-related areas. Construction equipment, including marine vessels, which are powered by fossil fuels such as diesel or gasoline would emit criteria pollutants, small amounts of hazardous air pollutants, and greenhouse gases during the duration of the construction project.

Operation of shore-based and off-shore MHK devices would not directly impact air quality.

The MHK devices should not produce emissions of criteria pollutants. Marine vessels servicing off-shore MHK devices would be powered by fossil fuel engines that would emit criteria pollutants during their time of operation. The frequency of trips by marine vessels should be low.

6.4.2.1.2 Climate Change

The MHK devices should not produce greenhouse gases. Marine vessels servicing off-shore MHK devices would be powered by fossil fuel engines that would emit air pollutants during their time of operation. The frequency of trips by marine vessels should be low. As an indirect impact, any reduction of electricity use from the baseline electrical grid would reduce oil consumption from electricity generation and thus reduce greenhouse gas emissions.

6.4.2.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation (see Section 3.2.5).

6.4.3 WATER RESOURCES

6.4.3.1 Potential Impacts

The representative project to be evaluated for the MHK energy technology is actually a range of technologies consisting of those that would be deployed in the shoreline, near-shore, and offshore environments. For the purposes of evaluating potential impacts to water resources, each of these deployment scenarios is assumed to consist of a group of activities, and in many cases an action under one scenario is the same or very similar to that in another. [Table 6-6](#) shows the different activities to be considered in the water resources evaluation and the MHK deployment scenario under which they are

assumed to occur. As shown in the table, it is being assumed that horizontal directional drilling from a point set back from the shore would be used to install cables or other lines through the sea-to-land transition zone, and that beyond the drilling exit point, the cables would be buried into the ocean floor. The near shore deployment scenario does not show cable burial as an activity because it is being assumed in this case that “near shore” is define by the practical limit of horizontal directional drilling.

Table 6-6. Activities Considered in the Water Resources Evaluation and the Applicable MHK Deployment Scenario

Activity Description	Range of MHK Deployment Scenarios		
	Shoreline	Near Shore	Offshore
At- or onshore construction and other land disturbing activities			
MHK device housing, power conversion facility, and electrical substation	✓		
Electrical substation and power conversion facility (would incorporate turbine if MHK device pumps water to shore)		✓	✓
Horizontal directional drilling for placing cable through sea-to-shore transition zone		✓	✓
Transmission line to grid	✓	✓	✓
Ocean floor disturbing activities			
MHK device anchoring		✓	✓
Bury cable on sea floor, from MHK device to sea-shore transition zone			✓
Break-out location of horizontal directional drilling for placing cable through sea-to-shore transition zone		✓	✓

In general, potential impacts to water resources would be very similar for each of the construction or soil disturbing activities that would occur onshore. Potential impacts from any of the ocean floor disturbing activities would also be similar to one another. Accordingly, potential impacts to water resources are addressed in terms of onshore and offshore activities and can be used as a guideline for which MHK deployment scenario is applicable. All three scenarios would involve electrical transmission lines from the onshore facility to the nearest grid connection, but potential impacts associated with such an action are addressed under the On Island Electrical Transmission technology in Section 8.1.3 and are not repeated here.

This section addresses potential environmental consequences to water resources from installation and operation of a MHK device. Potential impacts are addressed in terms of surface water, groundwater, and floodplains and wetlands.

6.4.3.1.1 Surface Water

Onshore Activities

Effects on surface water from the onshore construction elements of a MHK project would be the same as those expected for common construction actions as described in Section 3.3.5.

During operations there would be no activities that would have the potential to affect surface waters other than possibly increasing storm water runoff from the sites of new buildings. If the pre-construction project site was land with natural vegetation, the completed project site would have a higher percentage of impermeable surfaces and accordingly would generate more storm water runoff. Management of this increased volume of runoff would depend on the nature of the specific site (for example, whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns.

Offshore Activities

At the locations where the HDD would breakout on the ocean floor, the MHK device would be anchored to the ocean floor, and electrical cables or other conduits were buried, ocean sediments would be disturbed and dispersed to some degree. Some of the drilling mud or slurries used in the HDD likely would be released at the breakout point. These dispersed sediments increase turbidity for at least some period of time and would settle out in different locations, possibly in areas of coral or other bottom communities of concern. Potential impacts to such communities would not only depend on whether they are present near MHK device deploy site and the cable installation path, but also whether they are periodically subjected to naturally occurring high turbidity. Devices such as silt curtains could be deployed in specific locations such as the breakout point to help reduce potential impacts. However, devices such as silt curtains often have limited effects, particularly if wave or current action is high at the site. Correspondingly, another mitigation measure normally considered would be to schedule such project activities during seasonal periods when wave, current, and wind would be expected to be at lows. These potential impacts to marine waters actions are very similar to those described in Section 8.2.3 for placement of undersea cables and the associated land-sea transition zones for those cables.

There would be no expected impacts to marine water quality during operation of the MHK device.

6.4.3.1.2 Groundwater

Onshore Activities

Effects on groundwater from the onshore construction elements of a MHK project would be the same as those expected for common construction actions as described in Section 3.3.5.

During long-term operations of the MHK system, impacts to groundwater would be limited to the water needs to operate the surface facilities, which would be very minor since there would be no constant demand for process water.

Offshore Activities

No groundwater impacts would be expected from the offshore activities associated with deployment or operation of a MHK system.

6.4.3.1.3 Floodplains and Wetlands

Onshore Activities

It is reasonable to assume that the proponent of a MHK project would avoid construction in a floodplain or wetland if at all possible, if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

Offshore Activities

A Section 404 permit from the Corps of Engineers would likely also be required for the placement of the MHK device and cables on the ocean side of the system. Activities involving discharges of dredged or fill materials into the waters of the U.S. (in this case, territorial seas) require a Section 404 permit. Although placement of pipes may not be a traditional dredge or fill action, the breakout point for the lines (from the HDD) could require placement of fill material to stabilize the location and areas along the ocean floor could require similar actions to ensure the MHK device was supported and stable. If there was any

question about the applicability of a Section 404 permit, discussion with the Corps of Engineers would be the appropriate course of action.

6.4.3.2 Best Management Practices and Mitigation Measures

As discussed above, to avoid impacts to floodplains and wetlands, it is recommended that floodplains and wetlands be avoided during project siting. Devices such as silt curtains could be deployed in specific locations such as the breakout point to help reduce potential impacts due to sediment dispersal.

6.4.4 BIOLOGICAL RESOURCES

This section addresses environmental consequences to biological resources from the development of MHK energy technologies. Potential impacts are addressed in terms of terrestrial coastal habitats, marine habitats, threatened and endangered species, and other protected marine species considering the type, intensity, duration, and physical extent of potential impacts.

6.4.4.1 Potential Impacts

MHK energy projects would be developed in near onshore and offshore marine environments and would have potential impacts on land and in the ocean depending on the type of technology deployed. All technologies would require power cables that would cross the shoreline to transmit power to land-based transmission lines. Several technologies, such as overtopping and oscillating water column devices would require semi-submerged structures built into the shoreline or in shallow water. Depending on the project location, potential marine habitats that could be affected include marine pools, beaches (both rocky and sand), and coral reefs. Native coastal vegetation has been largely eliminated due to human development but remnant areas still exist and could be impacted by land clearing. Other potential impacts would include loss of beach nesting habitat for sea turtles and marine birds and resting sites for the Hawaiian monk seal.

Other MHK energy technologies require the deployment of various devices offshore that are anchored to the ocean floor. The anchoring points or foundations for the various types of devices would cause physical disturbances of shallow benthic communities and coral reefs or through deposition of suspended sediments that would affect growth and metabolism. The growth rate of some types of deep water corals (i.e., black, red, and gold) is slow and recovery from impacts can take a long time. Placement of structures (i.e., power generation devices, cabling, and anchors) in the ocean would provide surfaces for establishment of marine organisms (i.e., biofouling). Depending on the location, essential fish habitat would be affected by placement of structures and alteration of the environment around the power generation devices. In some cases, the underwater structures could serve as fish aggregation devices that attract fish owing to the physical structure and habitat created by the biofouling organisms. Anchor cabling could be a potential collision hazard to marine mammals and reptiles although most species should be able to detect and avoid them.

Potential construction impacts include displacement of marine mammals, reptiles, and fish (i.e., avoidance of construction activity) both from physical activity and noise transmission through ocean waters. Several of the technologies involve placement of submerged oscillating (e.g., surge converters or hydrofoils) or rotating (turbines) components. These types of technologies have several types of potential operational impacts on marine environments including noise, avoidance, injury, and alteration of water dynamics. Rotating or oscillating devices would create sound waves that could cause marine mammals, reptiles, and fish to avoid an area surrounding the project. Sufficiently loud sounds can cause auditory injury but it is not known whether hydrokinetic energy devices produce sounds capable of causing auditory injury. Hydrokinetic energy devices with moving parts also could cause physical injury to

marine mammals and fish or cause species to avoid the area creating loss of habitat. Depending on location or position in relation to the shoreline, hydrokinetic energy devices could alter water dynamics in the area surrounding the project. The dynamics of water affects movement of ocean nutrients, phyto- and zooplankton, and sediments. Water flow in marine environments is affected by the shape and slope of the ocean floor, position relative to the shoreline, surface winds, tidal flows, and local heating of the surface layers. Unless deployed in large arrays of generators, most of these impacts would be relatively localized and minor.

Marine hydrokinetic energy devices represent a range of technologies that could vary in size and operating environment. Therefore, the potential impacts to marine mammals by displacement from direct disturbance during facility construction or operation (e.g., from sound emissions or water column disturbance) could vary depending specific technologies and locations. Detailed evaluation of the potential displacement impacts on marine mammals would be performed prior to implementation of specific technologies and projects.

An undersea power cable transmitting power to land would introduce an electromagnetic field (EMF) into the marine environment along the cable. This is a potential impact associated with all marine energy projects (see Section 3.4.5.2). However, the EMF is attenuated fairly quickly with distance from the cable (15 feet) and the potential impact is likely to be negligible ([Normandeau et al. 2011](#)).

6.4.4.2 Best Management Practices and Mitigation Measures

Many of the marine-based BMPs to prevent or minimize potential impacts to biological resources are identified in Section 3.4.6.2. Additional technology-specific BMPs would be dependent on the MHK system selected for implementation.

6.4.5 LAND AND SUBMERGED LAND USE

6.4.5.1 Potential Impacts

6.4.5.1.1 Land Use

MHK devices can be located on the shoreline or offshore, depending on the technology. Because MHK technologies are in the early stages of development, there are a number of designs that vary in their current feasibility.

Under the shoreline scenario, the MHK device and power conversion equipment would be in a single or joint warehouse type facility. In two other scenarios, the device would be deployed offshore. The associated electrical substation and power conversion facility would be constructed onshore.

With regard to potential surface land use impacts, there would be land disturbance during the construction phase, followed by maintenance and the potential replacement or expansion of equipment. With regard to submerged land use impacts, any offshore technology would require tethering to the ocean floor; power cables would also be installed leading from the devices to the shoreline facilities. Attenuator technology designs would resemble semi-submerged train cars, a 750-kW device could be about 400 feet in length, and 11 feet wide.

6.4.5.1.2 Submerged Land Use

Some of these technologies can be semi-submerged, with some of the structure protruding above the water surface by about 10 to 30 feet.

Submerged land use impacts would result in localized changes to the sea bottom in terms of introducing obstructions to local marine habitats.

6.4.5.2 Best Management Practices and Mitigation Measures

None noted.

6.4.6 CULTURAL AND HISTORIC RESOURCES

6.4.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operational phases of a utility scale, semi-submersible, offshore MHK power project and associated onshore ancillary facilities if effective conservation and BMPs are not implemented. During construction in onshore, nearshore, and offshore locations, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting and fishing locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6.

Any MHK project site selection process would include a detailed environmental impact study, which would include a more detailed evaluation of potential impacts to cultural and historic resources.

6.4.6.2 Best Management Practices and Mitigation Measures

Associated BMPs to reduce potential impacts to cultural, historic, and related natural resources during construction and operation are discussed in Section 3.6.7.

6.4.7 COASTAL ZONE MANAGEMENT

Impacts to coastal zones were evaluated based on the extent to which a project would conflict with the policies of the Hawai'i Coastal Zone Management Program and potentially affect special management areas, shorefront access, and shoreline erosion.

6.4.7.1 Potential Impacts

Development of MHK energy systems would include potential construction on the shoreline and in the near offshore depending on the type of technology deployed. All technologies would require installation of undersea power cables or a cable across the beach area to connect to onshore power grids. These types of developments would potentially create land disturbances, structural developments, lighting and other impacts which are inconsistent with the purpose for which the special management areas was designated

by the counties under the Coastal Zone Management Program. The projects would include development within shore setback areas and have the potential to impact shorefront access in areas of project development. Development on the shoreline or in the offshore area could alter natural ocean currents and affect shoreline erosion processes.

6.4.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

6.4.8 SCENIC AND VISUAL RESOURCES

6.4.8.1 Potential Impacts

Each MHK technology category utilizes distinct designs to capture energy based on the kinetic properties of the water. MHK devices can be situated on the shoreline or offshore, depending on the technology. Because MHK technologies are in early stages of development, there is a large number of designs in various stages of viability for commercial deployment or even product testing. Therefore, the representative project is a range of technologies consisting of those that would be deployed in the shoreline, near-shore, and offshore environments.

Potential impacts to visual resources from construction activities are discussed in Section 3.8.3. Under the shoreline scenario, the MHK device and power conversion equipment would likely all be included in a single facility, or joined facilities, at the shoreline. In the other two scenarios, the MHK device would be deployed offshore, but an associated electrical substation and possibly power conversion facility would have to be constructed onshore. It is also assumed that both of the offshore scenarios would involve horizontal directional drilling during construction to install connecting power cables (and possibly water lines) through the sea-to-land transition zone.

Long-term visual impacts would depend upon the MHK technology. Each technology would cause some visual impact onshore from the new facilities as described above. In addition, for some near-shore and offshore technologies, some elements of the technology would be above the water line. The devices would be fitted with marine navigation lighting to indicate the presence of the structures. Attenuator technology designs resemble semi-submerged train cars; a 750-kW device may be about 400 feet in length and 11 feet in width and are composed of multiple segments, depending on technology design ([NNMREC / OSU 2013](#)).

Overtopping devices can be semi-submerged in the water and moored to the ocean floor, or be shore-based to capture waves on the shoreline. Currently, deployed prototype devices range in size, but commercially viable units will likely be between 5 to 10 megawatt per unit, and would be about 1,000 feet long by 600 feet wide and would rise approximately 10 to 30 feet out of the water.

Oscillating water column designs are partially submerged structures. These devices are large structures built into the shoreline or moored at sea. A 500-kilowatt shore-based facility can be roughly the size of a two-story house made of concrete, built half on the shore, half in the water. At-sea designs are still in the development phase; however, current designs range from 0.5 to 3 megawatts and about 100 feet long by 30 feet wide, with the surface floating about 8 feet above water level. At-sea devices would increase in size, depending on capacity ([Oceanlinx 2013](#)).

Visibility of the near-shore and offshore devices from the shoreline would depend upon the technology and the location of the devices.

6.4.8.2 Best Management Practices and Mitigation Measures

Sensitive locations such as coastal scenic resources from public viewing points, marine recreational areas; State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System should be considered and avoided when locating devices in the shoreline, near-shore, and offshore environments.

In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards. Some of the counties' plans include more detail than others, but all include objectives related to protecting and maintaining open space and scenic resources consistent with the State's land use designations.

With the abundance of marine recreational and commercial activities in Hawai'i, project siting and stakeholder outreach are critical. Key stakeholders must be identified and consulted early in the planning stage. Additional BMPs to minimize impacts to visual resources are provided in Section 3.8.4.

6.4.9 RECREATION RESOURCES

6.4.9.1 Potential Impacts

Potential impacts to recreation resources from construction activities are discussed in Section 3.9.4. Under the shoreline scenario, the MHK device and power conversion equipment would likely all be included in a single facility, or joined facilities, at the shoreline. In the other two scenarios, the MHK device would be deployed offshore, but an associated electrical substation and possibly power conversion facility would have to be constructed onshore. It is also assumed that both of the offshore scenarios would involve horizontal directional drilling during construction to install connecting power cables (and possibly water lines) through the sea-to-land transition zone.

Long-term impacts to recreation resources would depend upon the MHK technology. Each technology would cause some visual impact onshore from the new facilities. In addition, for some near-shore and offshore technologies, some elements of the technology would be above the water line. The devices would be fitted with marine navigation lighting to indicate the presence of the structures. The devices range in size depending on the technology.

Offshore technologies would affect water-based recreation activities, such as swimming, surfing, boating, and fishing. Activities would be impacted by access restrictions or use alterations to prevent intentional or unintentional damage to the device and promote recreation user safety by preventing collisions or interactions with the device. Since MHK devices remove energy from waves, they have the potential to cause wave attenuation at the shore. Potential impacts to surfers would depend on the array of devices and their locations. One report modeled wave attenuation at the shore from a MHK device at 3 to 6 percent ([ASR 2007](#)). Visibility of the near-shore and offshore devices from the shoreline would depend upon the technology and the location of the devices.

6.4.9.2 Best Management Practices and Mitigation Measures

Sensitive locations such as the recreation areas listed in Appendix A of the *State Comprehensive Outdoor Recreation Plan* ([DLNR 2009](#)) should be considered when locating devices in the shoreline, near-shore, and offshore environments. Particularly, areas where devices would attenuate waves at popular surfing beaches should be avoided. In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards.

With the abundance of marine recreational activities in Hawai‘i, project siting and stakeholder outreach are critical. Key stakeholders must be identified and consulted early in the planning stage. Additional BMPs to minimize impacts to recreation resources are provided in Section 3.9.5.

6.4.10 LAND AND MARINE TRANSPORTATION

Impacts to land transportation considered potential effects on traffic, alterations to existing roads, requirement for additional roads (excluding temporary or project specific access roads) infrastructure. Impacts to marine transportation considered potential effects on operation of the harbor systems, primary shipping routes between islands, general marine transportation around the islands (tourism, fishing), and military marine surface and subsurface operations.

6.4.10.1 Potential Impacts from the Representative Project

6.4.10.1.1 Land Transportation

As identified in [Table 6-5](#), there would be no potential impacts to land transportation from a utility-scale MHK project.

6.4.10.1.2 Marine Transportation

Several MHK energy systems would require deployment offshore and would either be floating or submerged and tethered to the ocean floor with cables or fixed on a seafloor foundation. Several of the technologies involve deployment of relative large devices (several hundred feet). Regardless of specific location, these projects are potential obstructions to marine navigation and would require review and possible marking under the U.S. Coast Guard’s U.S. Aids to Navigation System. Depending on distance from shore, these projects could affect navigation by tourist cruises, passenger ferries, fishing vessels (recreational and commercial), and possibly large commercial cargo ships. Military marine operations, surface and submarine navigation, could potentially be affected by both floating and submerged structures.

6.4.10.2 Best Management Practices and Mitigation Measures

The typical BMPs for marine transportation are presented in Section 3.10.4. Technology-specific BMPs for MHK projects would depend entirely on the type of project implemented. The selected practices would also depend on whether the project affected the near shore or offshore environments.

6.4.11 AIRSPACE MANAGEMENT

As identified in [Table 6-5](#), there would be no potential impacts to airspace management resources from a utility-scale MHK project.

6.4.12 NOISE AND VIBRATION

6.4.12.1 Potential Impacts

Short-term noise and vibration impacts would result from the construction of MHK facilities. Local noise ordinances described in Section 3.12 could be temporarily exceeded during construction, which would require a permit variance, and construction noise outside of permitted hours could occur. Offshore construction noise from equipment and vessels, and vibration caused by potential pile-driving, could exceed regulatory levels. Potential acoustic sources from survey activity may include single beam

echosounders, multi-beam echosounders, side-scan sonars, and shallow-penetration sub-bottom profilers. All MHK technologies would require installation of undersea power cables that would cross the shoreline using HDD drilling in order to transmit power to land-based transmission lines. Several technologies, such as overtopping and oscillating water column devices would require semi-submerged structures built into the shoreline or in shallow water. Other MHK technologies require the deployment of various devices offshore that are anchored to the ocean floor. Construction noise could indirectly impact scenic and visual resources, recreation resources, cultural resources, worker health and safety, and possibly public health. Further, according to the Incidental Harassment Authorization ([77 FR 43259, July 24, 2012](#)) exposure to elevated sound levels from vibratory and impact pile driving may result in temporary impacts to marine mammal hearing and behavior. However, in its Biological Opinion, the NMFS stated that it does not expect any takes of marine mammals by injury, serious injury, or mortality ([NMFS 2012](#)). Marine mammal prey species, such as fish, and sea turtles may also be temporarily impacted.

MHK could potentially result in long-term noise and vibration impacts. Several of the technologies operate using submerged oscillating (e.g., surge converters or hydrofoils) or rotating (turbines) components. Rotating or oscillating devices would create sound waves that could cause marine mammals, reptiles, and fish to avoid an area surrounding the project. Operational sound pressure levels and frequencies from turbines would be project-specific. Use of mooring lines creates what is called a “strum effect” from the current rushing past the mooring line and causing it to vibrate and hum ([BOEM 2012](#)). Sufficiently loud sounds can cause auditory injuries to marine mammals and sea turtles, but it is not known whether hydrokinetic energy devices produce sounds capable of causing auditory injury.

6.4.12.2 Best Management Practices and Mitigation Measures

The following recommended BMPs could reduce the potential disturbances from noise and vibration ([NMFS 2012](#)):

- Temporal restrictions (such as not conducting vibratory pile driving during peak humpback whale season in Hawai‘i);
- Establishment of an exclusion zone (a buffer to prevent harassment [injury] of any marine mammal species or sea turtles);
- Shutdown and delay procedures (if a marine mammal or sea turtle approaches or enters an exclusion zone);
- Soft-start procedures (a technique that allows marine mammals or sea turtles to leave the immediate area before sound sources reach maximum noise levels);
- In-situ underwater sound monitoring (sound monitoring during sheet pile and test pile driving); and
- Visual monitoring (an onsite, biologically trained individual approved in advance to monitor sound during pile driving); and
- Per *Marine Mammal Protection Act* implementing regulations at [50 CFR 216.104 \(a\)\(13\)](#), requests for Incidental Harassment Authorization must include monitoring and reporting plans.

Additional BMPs include the following:

- Avoid sensitive receptors for noise and vibration (identified in Section 3.12).

- Use equipment with sound-control devices. Equipment should be adequately muffled and maintained. In order to decrease the strum effect, place hydrodynamic foils on the upper half of the mooring line ([BOEM 2012](#)).
- Use video equipment and sonar imaging equipment to screen for species interactions and to monitor turbines during operation ([BOEM 2012](#)).

6.4.13 UTILITIES AND INFRASTRUCTURE

This section addresses potential environmental consequences to utilities and infrastructure from construction and operation of MKH energy projects. The MKH energy projects are actually a range of technologies consisting of those that could be deployed in the shoreline, near-shore, and offshore environments. For the purposes of evaluating potential impacts to utilities and infrastructure, the different deployment scenarios would have basically the same concerns. Under the shoreline scenario, the MKH device and power conversion equipment would likely all be included in a single facility, or joined facilities, at the shoreline. In the other two scenarios, the MKH device would be deployed offshore, but an associated electrical substation and possibly power conversion facility would have to be constructed onshore. The onshore facility would include power conversion equipment, for example, if the MKH device involved pumping water to the shore. It is also assumed that both of the offshore scenarios would involve horizontal directional drilling during construction to install connecting power cables (and possibly water lines) through the sea-to-land transition zone.

All three scenarios would involve electrical transmission lines from the onshore facility to the nearest grid connection, but potential impacts associated with such an action are addressed under the “On Island Electrical Transmission” technology in Section 8.1 and are not repeated here.

6.4.13.1 Potential Impacts

Effects on each island’s electric utilities would be small. The amount of potential electricity that could be generated from an MKH technology ranges widely from kilowatts to megawatts since several of these devices could be installed in arrays. The technology is still developing and is not yet ready for mature applications. The interface with utilities will depend somewhat on the type of MKH project selected and the projected capacity factor of that particular project. As the capacity factor increases, the power source becomes more reliable; which means that the project could replace other fossil-fueled base-load power sources. Common impacts from connection to utilities for construction and operation of these types of projects are described in Section 3.13.3.1.

6.4.13.2 Best Management Practices and Mitigation Measures

BMPs to avoid conflicts with existing utilities would be the same as those common across projects for construction and operation (see Section 3.13.4).

6.4.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

6.4.14.1 Potential Impacts

The representative project is the range of MKH technologies consisting of those that would be deployed in the shoreline, near-shore, and offshore environments. Potential hazardous material and waste management impacts on land and in the ocean depend on the type of technology deployed.

6.4.14.1.1 Hazardous Materials

Short-term hazardous material exposure impacts could result from the construction of MHK facilities. These are identified in Section 3.14.4.

Hazardous materials associated with the operation and maintenance of a utility scale MHK facility include the fuel for boats, vessels, and barges, and lubricants and hydraulic fluids contained in the wave or tidal energy devices. Adverse impacts could result if hazardous wastes are not properly handled and were released to the environment.

6.4.14.1.2 Waste Management

Short-term waste management impacts could result from the construction of MHK facilities. These are identified in Section 3.14.

Operation of an MHK facility is not anticipated to generate waste levels that would constrain existing landfill operations. Long-term waste impacts would not occur from the operation of an MHK facility.

6.4.14.1.3 Wastewater

Wastewater impacts would be minimal and may occur largely from vessel effluent during the construction of the proposed project. However, such vessels would be subject to the EPA NPDES requirements, including EPA's Vessel General Permit requirements (for vessels greater than 79 feet).

No adverse impacts to wastewater services are anticipated from the operation of the MHK facilities.

6.4.14.2 Best Management Practices and Mitigation Measures

BMPs for hazardous materials, waste management, and wastewater are discussed in Section 3.14.5.

6.4.15 SOCIOECONOMICS

As identified in [Table 6-5](#), there would be no potential impacts to socioeconomics from the representative utility-scale MHK project.

6.4.16 ENVIRONMENTAL JUSTICE

As identified in [Table 6-5](#), there would be no potential impacts to environmental justice from the representative utility-scale MHK project.

6.4.17 HEALTH AND SAFETY

6.4.17.1 Potential Impacts

The representative project may present public health and safety concerns to boats, both civilian and military marine vessels, and to the public onshore in the event the device were destroyed, damaged or if the loss of mooring/spatial stabilization were to occur. Such events are more likely occur as a result of rough seas and breaking waves associated with 50 and 100-year storms (particularly in shallow water) or in the event of natural disasters including a tsunami. While the possibility of such events is small, it may occur within the life expectancy of a future project. Therefore potential hazards and safety risks may occur as a result of accidents.

Effects on public safety services from construction and operation of this representative project would be the same as those as described in Section 3.13.3.2.

6.4.17.2 Best Management Practices and Mitigation Measures

None identified.

6.5 Ocean Thermal Energy Conversion (OTEC)

The representative OTEC project would consist of a 50-megawatt, closed-cycle system located in deep water 3.5 miles offshore from a land-sea cable transition site (see Section 2.3.3.6.4). A deep-water pipe 30 feet in diameter and 3,280 feet deep would draw deep cold seawater. Deep water would be retrieved at a temperature of 39° to 41°F and surface water would be 75° to 82°F. Warm sea water would be drawn through two 33-foot diameter pipes. Seawater flow rates would be 70,000 gallons per second of warm water and 36,300 gallons per second of cold water. The effluent sea water (both warm and cool waters combined) would be returned via two 40-foot-diameter pipes at a depth of 200 feet, in accordance with environmental standards and Zone of Mixing regulations to prevent alteration of natural ocean temperature profiles or disruption of thermohaline cycling.

The floating platform would be 650 feet long with a 128-foot beam, an operating draft of 53 feet, and be anchored to the ocean floor via mooring lines. The closed-cycle system would use pressurized anhydrous ammonia as the working fluid, which would pass through evaporating and condensing plate-fin heat exchangers. The facility would use the anhydrous ammonia at a rate of 6,063 pounds per second. The project would use chlorine to protect the heat exchangers from biofouling. It has been determined that there would be negligible bio-fouling from cold sea water and that evaporator fouling can be controlled effectively by intermittent chlorination (50 to 100 parts per billion of chlorine for 1 hour per day) ([Vega 2003](#)).

An undersea power cable no more than 5 inches in outside diameter would run approximately 6 miles to an onshore land-sea cable transition site, which would connect to the power grid to power the pumps and to deliver electricity to the entire facility. The floating platform would keep auxiliary diesel-powered generators to provide backup power to maintain operation of the OTEC system.

If this ocean thermal energy conversion facility was scaled down to produce 5 megawatts of energy the diameter of the pipes and seawater flow rates would decrease, but depths would remain the same. The size of the floating platform would decrease, as would the power transmission requirements and diameter of the undersea cable. The scaled project would use less ammonia and chlorine and at a lower rate.

[Table 6-7](#) present a summary of the potential environmental impacts for the representative OTEC project, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 6-7. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Ocean Thermal Energy Conversion

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	None; the only potential impacts to geology and soils would be the interface of the undersea cable to connect the OTEC facilities with the grid. These impacts are addressed in Section 8.1.	N/A
Climate and Air Quality		
Air Quality	<p>General construction impacts (see Section 3.2.4).</p> <p>Limited, intermittent, and short-term air quality impacts during construction.</p> <p>Potential land disturbance and related fugitive dust at nearby onshore construction related areas, including areas where offshore electrical lines connect with the onshore regional electric grid.</p> <p>Potential increase in criteria pollutant emissions during construction from equipment or marine vessels powered by fossil fuels.</p> <p>Potential operational emissions from auxiliary diesel generators on the platform.</p>	Same as those common across construction projects (see Section 3.2.5).
Climate Change	<p>Potential increase in greenhouse gas emissions from construction equipment and operation of diesel generators on the platform.</p> <p>Potential greenhouse gas emissions reduction from a mix of technologies used to produce electricity.</p>	None.

Table 6-7. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Ocean Thermal Energy Conversion (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Water Resources		
Surface Waters (Marine Water)	<p>Potential ocean sediment disturbance resulting in increased turbidity and impacts to coral or other bottom communities of concern.</p> <p>Potential water quality impacts from discharge not meeting water quality criteria for marine waters (i.e., nutrient levels such as nitrite plus nitrate, phosphate, phosphorous, etc.).</p> <p>Potential increased algal bloom impacts from increased nutrient levels.</p> <p>Potential impacts from temperature variation and elevated chlorine levels of discharge. See Section 6.5.4 for impacts to biological resources.</p>	<p>To the extent feasible, deploy devices such as silt curtains in locations to reduce impacts to communities of concern.</p> <p>Schedule project activities during seasonal periods when wave, current, and wind is expected to be at lows.</p> <p>A Section 404 permit from the Army Corps of Engineers as well as a certification from the State is required pursuant to Section 401 and Section 404 of the <i>Clean Water Act</i> for seafloor disturbing activities.</p> <p>Establish a zone of mixing (per HAR 11-54-9) and obtain approval under the permitting process for the system’s water discharge in order for the discharge to meet the State’s water quality regulations (not applicable in designated class AA waters).</p> <p>Ensure the project design includes a diffuser system for the discharge outfall in order to minimize the size of the zone of mixing and perform modeling to demonstrate compliance is achievable (with the specific diffuser design and proposed zone of mixing) under all reasonable conditions.</p>
Groundwater	Minimal groundwater impacts during construction and operations.	The facility could include in its design, water treatment (desalination) capabilities.
Floodplains and Wetlands	None.	N/A
Biological Resources		
	<p>Potential for short-term and small disturbances during placement of the cabling lines, moors, and anchors.</p> <p>Potential disturbance to deep and shallow marine habitats and shorelines (including marine pools, sandy and rocky beaches, seagrass habitat, shallow benthic communities, and coral reefs at multiple depths) during construction (site-specific).</p>	<p>Deepwater corals should be avoided to minimize impacts as these corals have slow growth rates and would take a long time to recover from either physical disturbance or impacts from sediment deposition caused by seafloor disturbances.</p> <p>Screening could be considered in the large intake pipes during project design to reduce the potential hazard to all but the smallest of organisms.</p>

Table 6-7. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Ocean Thermal Energy Conversion (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	<p>Potential impacts to the marine environment from introduction of an electromagnetic field along the undersea cable.</p> <p>Potential attraction of marine fish, mammals, and seabirds to structures and for biofouling organisms.</p> <p>Potential impacts to marine communities from nutrient rich discharge waters.</p> <p>Potential impacts to marine organisms due to intake pipes.</p> <p>Potential collision hazards to marine mammals from mooring lines.</p>	<p>Any night safety lighting should be minimized and designed to not attract seabirds to minimize potential collisions with the above water structure.</p>
Land and Submerged Land Use		
Land Use	See Section 8.2.5 for typical land use impacts associated with the interface of an undersea cable and the electrical grid.	None.
Submerged Land Use	Potential for large obstructions in the ocean floor from structures.	Refer to Section 8.2.5.2
Cultural and Historic Resources		
	<p>Common construction and operation impacts to cultural resources (see Section 3.6.6).</p> <p>Potential direct impacts from onshore and offshore construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	<p>Common construction and operation BMPs for cultural resources (see Section 3.6.7).</p>

Table 6-7. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Ocean Thermal Energy Conversion (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Coastal Zone Management		
	<p>Potential impacts to designated special management areas from the cable crossing the shoreline (site-specific).</p> <p>Potential shorefront access impacts from the cable crossing the shoreline (site-specific).</p> <p>Potential shoreline erosion impacts from the cable crossing the shoreline (site-specific).</p>	<p>Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.</p>
Scenic and Visual Resources		
	<p>General visual impacts during construction (see Section 3.8.3).</p> <p>See Section 8.2.8 for potential visual impacts from land/sea cable transition sites.</p> <p>Potential long-term visual impacts onshore from the introduction of a transition site.</p>	<p>Same as those common across construction projects (see Section 3.8.4).</p> <p>During project siting for the onshore transition site, consider sensitive locations identified in Section 3.8.</p>
Recreation Resources		
	<p>General short-term construction impacts (see Section 3.9.4).</p> <p>Potential long-term recreation resource impacts in the vicinity of onshore and offshore facilities from access restrictions and potential visual impacts from the facilities.</p>	<p>Same as those common across construction projects (see Section 3.9.5).</p>
Land and Marine Transportation		
Land Transportation	None.	N/A
Marine Transportation	<p>Potential obstruction impacts to marine navigation including to tourist cruises, passenger ferries, fishing vessels (recreational and commercial), and large commercial cargo ships.</p> <p>Potential impacts to military marine operations, surface and subsurface navigation from both floating and submerged structures.</p>	<p>Review and possible marking may be required under the U.S. Coast Guard's U.S. Aids to Navigation System.</p>

Table 6-7. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Ocean Thermal Energy Conversion (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Airspace Management		
	<p>Potential impacts to military transportation operations (marine surface and aviation operations).</p> <p>Potential impacts on approach paths to airports.</p>	<p>Consider military airspace transportation operations.</p> <p>Project siting should include coordination with FAA and military organizations and avoidance of airport flight paths, if possible.</p>
Noise and Vibration		
	<p>Short-term noise and vibration impacts to sensitive noise receptors, including potential impacts to marine mammals and sea turtles.</p>	<p>Avoid sensitive receptors for noise and vibration (identified in Section 3.12).</p> <p>Adhere to temporal restrictions.</p> <p>Establish an exclusion zone and shutdown, soft-start, and delay procedures (if a marine mammal or sea turtle approaches or enters an exclusion zone).</p> <p>Conduct visual monitoring.</p> <p>Use maintained equipment with sound-control devices.</p> <p>Place hydrodynamic foils on the upper half of the mooring line.</p> <p>Requests for Incidental Harassment Authorization must include monitoring and reporting plans.</p>
Utilities and Infrastructure		
Utilities	<p>General construction impacts (see Section 3.13.3.1).</p> <p>Potentially moderate effects to electric utilities (site-specific).</p>	<p>Same as those common across construction projects (see Section 3.13.4).</p> <p>If feasible, an alternative smaller project should be considered for those smaller grids on Lānaʻi or Molokai.</p>
Hazardous Materials and Waste Management		
Hazardous Materials	<p>General construction impacts (see Section 3.14.4).</p> <p>Potential exposure to hazardous materials during operations from large quantities of ammonia and/or chlorine gas/liquid, including through accidental releases or leaks.</p> <p>Potential for fires or explosions from chlorine and gaseous ammonia combinations.</p>	<p>Same as those common across construction projects (see Section 3.14.5).</p> <p>Monitor the OTEC facility for leaks during operation and maintenance.</p> <p>Develop, approve, and implement a risk management program and emergency management plan prior to delivery of ammonia.</p>

Table 6-7. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Ocean Thermal Energy Conversion (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Waste Management	General construction impacts (see Section 3.14.4).	Same as those common across construction projects (see Section 3.14.5).
Wastewater	Potential impacts to wastewater effluent from added chlorine. See Section 6.5.3 for additional discussion on impacts to water resources.	None.
Socioeconomics		
	Very small socioeconomic impacts; minimal job and population effects.	None.
Environmental Justice		
	Small potential impacts to the general population. Site-specific evaluation of impacted populations required.	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.
Health and Safety		
	General construction and operation impacts (see Section 3.17.3). Potential worker exposure to chlorine and ammonia gases.	Same as those common across construction projects (see Section 3.17.5). Safe handling, use, and storage of hazardous materials.

6.5.1 GEOLOGY AND SOILS

As identified in [Table 6-7](#), there would be no potential impacts to geology and soils from the representative OTEC project.

6.5.2 CLIMATE AND AIR QUALITY

6.5.2.1 Potential Impacts

OTEC systems rely on temperature gradients in the oceans to generate electricity. A representative utility-scale project would consist of the construction and operation of a 50-megawatt offshore system. A representative 50-megawatt project could theoretically replace electricity requirements from the existing baseline electrical grid by 440,000 megawatt-hours per year if electricity was produced at full capacity every day for an entire year. Although a 100 percent capacity factor would not be achievable, it provides a theoretical maximum number that can be used for air quality impact analysis and comparison.

6.5.2.1.1 Air Quality

Air quality impacts associated with construction of a utility-scale offshore project would be short term, intermittent, and limited to the duration of the construction project. Off-shore installation of a floating platform would not generate fugitive dust at the site of installation, but the construction project could

result in land disturbances and related fugitive dust at nearby onshore construction-related areas, including locations where the offshore electrical lines connect with the onshore regional electric grid. Construction equipment, including marine vessels, which are powered by fossil fuels such as diesel or gasoline, would emit criteria pollutants, small amounts of hazardous air pollutants, and greenhouse gases during the duration of the construction project. Refer to Section 3.2.4 for common construction-related impacts to air quality from onshore construction.

Operation of an OTEC project would not be a large source of criteria pollutant emissions, although auxiliary diesel generators on the platform would be a source of emissions.

6.5.2.1.2 Climate Change

Operation of an OTEC project would not be a large source of greenhouse gas emissions, although auxiliary diesel generators on the platform would be a source of emissions. A replacement of about 440,000 megawatt-hours of electricity per year from the existing baseline electrical grid would reduce oil consumption from electricity generation by about 29 million gallons. On O‘ahu, the annual replacement of 440,000 megawatt-hours of electricity would correspond to an annual reduction in greenhouse gas emissions of about 320,000 metric tons CO₂ equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid>; EPA 2012a). On other islands by comparison, the same annual replacement of 440,000 megawatt-hours of electricity usage would correspond to an annual reduction in greenhouse gas emissions of about 270,000 metric tons CO₂ equivalent due to a different mix of technologies used to produce electricity.

Scaled versions of a utility-scale project would produce linearly scaled impacts to air quality. For instance, a 5-megawatt project would replace electricity usage from the existing baseline grid by 10 percent of that of a 50-megawatt project. The corresponding reduction in greenhouse gases also would be 10 percent that of a 50-megawatt project. Air emissions during construction would also be proportional due to the decreased size and power transmission requirements of the system.

6.5.2.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures for general air quality and climate change impacts are discussed in Section 3.2.5.

6.5.3 WATER RESOURCES

This section addresses potential environmental consequences to water resources from construction and operation of an OTEC facility. Potential impacts are addressed in terms of surface water, groundwater, and floodplains and wetlands.

6.5.3.1 Potential Impacts

The representative project is described as a 50-megawatt offshore OTEC facility and the project includes bringing the undersea power cable towards shore as far as the onshore land/sea cable transition site. Evaluations of potential impacts associated with an onshore land-sea cable transition project are addressed separately in Section 8.2.3. As a result of this project definition, there would be no onshore land actions or disturbances associated with the action and, accordingly, the discussion of impacts to surface water deals solely with marine waters.

6.5.3.1.1 Surface Water (Marine Water)

At the locations where the floating OTEC platforms would be anchored to the sea floor and along the route where the power cable would be buried, ocean sediments would be disturbed and dispersed to some degree. These dispersed sediments increase turbidity for at least some period of time and will settle out in different locations, possibly in areas of coral or other bottom communities of concern. Potential impacts to such communities would not only depend on whether they are present near the pipe installation path, but also whether they are periodically subjected to naturally occurring high turbidity. Devices such as silt curtains could be deployed in specific locations, but such devices often have limited effects, particularly if wave or current action is high at the site. Correspondingly, another mitigation measure normally considered would be to schedule such project activities during seasonal periods when wave, current, and wind would be expected to be low.

Activities in the navigable waters of the U.S. are regulated by the U.S. Army Corps of Engineers under Section 404 of the *Clean Water Act*. Accordingly, a Section 404 permit from the Corps of Engineers would likely be required for the seafloor disturbing activities. Any action that requires a Section 404 permit from the Corps of Engineers must also obtain certification from the State pursuant to Section 401 of the *Clean Water Act*. The certification dictates BMPs and monitoring and assessment plans to ensure project actions comply with State water quality standards. If there was any question about the applicability of a Section 404 permit, discussion with the Corps of Engineers would be the appropriate course of action.

During operation, the OTEC system would pull cold water from a depth of almost 3,300 feet below the surface, use it for cooling (via a heat exchanger), combine it with water taken from near the ocean surface, and return the combined water flow to a depth of about 200 feet below the surface. The combined flow back to the ocean is characterized as consisting of roughly 2 parts of near surface water to 1 part deep water. Although the process would return ocean water back to the ocean with no additives other than chlorine, there could still be issues with the discharge meeting water quality criteria for marine waters because the ocean water at 3,300 feet below the surface does not meet the criteria. A primary example would be nutrient levels as indicated by nitrite plus nitrate ($\text{NO}_2 + \text{NO}_3$) values. As shown in Figure 3-36, nitrite plus nitrate values at a depth of 3,300 feet would be about 40 micromoles per kilogram, which converts to about 560 micrograms per liter (as nitrogen). The water quality standard set by State regulation ([HAR 11-54](#)) for nitrite plus nitrate is 1.5 micrograms per liter (as nitrogen) in oceanic waters. (The standards also set higher concentrations not to be exceeded for specific percentages of the time.) The discharge from the OTEC system would be well over the standard even when combined with the near surface water, which has essentially none of the nutrients, and would be expected to be over the standard on a continuous basis. As indicted in Section 3.3.4.2, other parameters such as phosphate (PO_4) would be expected to have vertical distributions similar to that of nitrite plus nitrate nutrients; that is, there would be depleted or very low concentrations in the upper layers where photosynthesis takes place. The State water quality standards include criteria for total phosphorus (P), so it could also be an issue. Increased nutrient levels at depths where photosynthesis occurs could result in changes such as unusual algal blooms. Although algae is a normal component of marine life, increased density in an area has the potential to affect the existing balance of the area's ecosystem as well as recreational and other uses of the area. Changes in temperature and chlorine levels, as described below, could also affect existing conditions by other mechanisms (see [Section 6.5.4](#) for potential impacts to biological resources).

The representative project describes chlorine applications being required only one hour per day at concentrations of 50 to 100 micrograms per liter, and only for the warm surface water. The State's standard for chlorine in any saltwater is 13 micrograms per liter as a maximum, acute level at any time and 7.5 micrograms per liter as chronic, long-term level not to be exceeded as an average over any 24-hour period. During the hour in which chlorine was applied, the discharges would exceed the acute

standard even after being combined with the non-chlorinated deep water, but over a 24-hour period the average chronic level would be met. To ensure that chlorine was effectively diluted, chlorine concentrations would need to be modeled or otherwise estimated at various distances from the OTEC facility. Other parameters would have to be similarly evaluated.

Temperature would also be an expected problem for the discharge because the ocean's surface mixing layer can vary from less than 100 to nearly 400 feet in thickness depending on the season (see Section 3.3.4.2). The temperature of the mixing layer is in the mid to upper 70s °F, or higher, and as the thickness of that layer changes (by roughly 300 feet over the course of the year) the underlying thermocline position and gradient changes accordingly. The temperature of the water discharged from the OTEC facility would remain relatively constant, but at a depth of about 200 feet, it would be expected to be in and out of the mixing layer over the course of the year. As a result, it could not match the ocean temperature year-around. The State's water quality standard for oceanic waters is that temperature should not vary by more than one degree Celsius (or about two degrees Fahrenheit) from ambient conditions.

Were the OTEC discharge in State-regulated waters, a zone of mixing (per [HAR 11-54-9](#)) would have to be established and approved under the permitting process for the system's water discharge in order for the discharge to meet the State's water quality standards. The zone of mixing is a limited area around the discharge outfall where dilution would be allowed. The permit would then stipulate that applicable standards be met at the boundary of the zone of mixing. As part of the permitting process, the action proponent would likely have to design a diffuser system for the discharge outfall in order to minimize the size of the zone of mixing and perform modeling to demonstrate compliance could be achieved (with the specific diffuser design and proposed zone of mixing) under all reasonable conditions. At a distance of about 6 miles from shore, the primary permitting requirements for the OTEC facility would be a Federal responsibility. However, stipulations of the *Coastal Zone Management Act* and State certification requirements under Section 401 of the *Clean Water Act* would require that Federal permitting actions comply with State standards, including in this instance, State water quality standards. So it is reasonable to assume that the State's water quality limits and need for establishment of a zone of mixing would be part of the OTEC project requirements, whether as a direct State permit or as part of the Federal permit. If the OTEC discharge was in Federal waters, the Section 401 certification would not be required, so State water quality standards would not strictly apply, but EPA could consider using them in developing limits for its own permit. Practical means of meeting water quality standards would likely be limited to actions such as designing a diffuser system as part of establishing a zone of mixing. Alternatives such as treating the water (for example, nutrient removal or temperature adjustment) before discharge would normally be a consideration, but at the scale (about 106,000 gallons per second) and location of water discharge required for the representative project, any treatment other than mixing would likely be impractical.

6.5.3.1.2 Groundwater

Construction of the representative project would not impact groundwater. The defined project in this instance would include no onshore actions.

During long-term operations of the OTEC, potential impacts to groundwater would be limited to the water needs to operate the offshore facilities. Since the fresh water would have to be transported by boat to the facilities, it is reasonable to assume these demands would be minor. Alternatively, the facility could include its own treatment (desalination) capabilities. In either case, the project would not be expected to have adverse impacts on water availability.

6.5.3.1.3 Floodplains and Wetlands

Since there would be no land activities associated with the representative project, there would be no potential for impacts to floodplains or wetlands

6.5.3.2 Best Management Practices and Mitigation Measures

As described above, discharges back to the ocean from the OTEC project would be expected to require a discharge permit with a zone of mixing stipulation because the discharge would not meet all water quality standards set for coastal waters. According to State Water Quality Standards ([HAR 11-54](#)), marine waters designated as class AA waters are not permitted to have zones of mixing under certain conditions. However, these conditions do not extend beyond depths of 59 feet where there is a defined reef or beyond 1,000 feet offshore if there is no defined reef area. The ocean depth requirements associated with the representative project would not allow it to be sited in the restricted areas. Other than offshore areas not meeting the physical requirements for an OTEC, there would be no sensitive locations or receptors with respect to impacts to water resources.

6.5.4 BIOLOGICAL RESOURCES

6.5.4.1 Potential Impacts

The floating OTEC system would be tethered to the seafloor with cable mooring lines and anchors. The anchors would create small disturbances during placement but the impacts are expected to be small and short term. The power plant would be anchored 3.5 miles offshore in deep water (at or greater than 3,500 feet deep) and would avoid more productive shallow marine habitats near shore. However, deepwater corals should be avoided to minimize impacts as these corals have slow growth rates and would take a long time to recover from either physical disturbance or impacts from sediment deposition caused by seafloor disturbances. An approximately 5-inch undersea power cable would be installed from the platform to an onshore land/sea cable transition site to deliver power and obtain power for the water pumps. The cable would cross deep and shallow marine habitats and the shoreline and would cause disturbances during construction. The specific habitats that would be impacted would depend on the specific installation location but could include marine pools, sandy and rocky beaches, seagrass habitat, shallow benthic communities, and coral reefs at multiple depths.

An undersea power cable could introduce an electromagnetic field (EMF) into the marine environment along the cable. This is a potential impact associated with all marine energy projects as power cables are needed to transmit power to land (see Section 3.4.5.2). However, the EMF is attenuated fairly quickly with distance from the cable (15 feet) and the potential impact is likely to be negligible ([Normandeau et al. 2011](#)).

The floating platform is a large structure (650 feet long). The structure could serve as an attractant to fish and potentially a surface for biofouling organisms. Large volumes of cold deep water (from about 3,200 feet) would be extracted and returned at a depth of 200 feet with a comparable temperature of the surrounding water. Even though the nutrient rich (i.e., nitrogen and phosphorus) deepwater would be mixed with the nutrient-poor surface water at a ratio of 2 to 1, the discharge water at 200 feet would still be relatively nutrient rich compared to the surrounding water. The surface mixing zone for the ocean can vary from 100 to 400 feet and the water temperature at the discharge point would not match the surrounding water throughout year. An influx of nutrient rich discharge water could create an area of increased marine productivity. How large of an effect nutrient enrichment could have on the marine ecosystem would depend on the surrounding marine communities, the volume of discharge water, and the rate of dilution and dispersal of nutrients in the larger volume of ocean water. How ocean microbes, and

in turn other higher trophic levels, would respond to an influx of nutrients is an area of active research (<http://cmore.soest.hawaii.edu/microbes.htm>). With potential biofouling of the floating platform, influx of nutrient rich water, and possible attraction of marine fish and mammals to the in-ocean structures, a localized area of enhanced marine biological activity and productivity could develop. The increase in marine productivity would have a positive effect on the marine community. However, the attraction of marine organisms, including larger marine mammals, sea birds, and fish, to the area surrounding the floating platform and could expose them to hazards such as collisions with the mooring cables and above and below water platform structures or entrainment in the water intake pipes. The amount of chlorine used periodically to control biofouling on the heat exchangers would have negligible impact on water quality and would be effectively diluted.

The project would have large intake pipes (approximately 30-33 feet in diameter) for both cold deepwater and shallow warm water. These pipes could be an entrainment hazard for marine organisms depending on the volume and rate of water intake. Screening could be considered as a method to reduce the potential hazard to all but the smallest of organisms. The smaller life stages of various fish, invertebrates, and corals that float and disperse in ocean currents before settling on or in protective cover of sea floor substrates would be most susceptible to impact through entrainment in the intake flow. Although entrainment is a recognized potential hazard, more detailed analysis of the potential effects on populations of marine organisms cannot be meaningfully conducted until specific project locations are known.

The mooring lines represent a potential collision hazard to marine mammals. The probability that a whale or other marine mammal would strike a cable is very low. The cable mooring lines would remain taut and would not be an entanglement hazard to whales. No impacts would occur to the Hawaiian Islands Humpback Whale National Marine Sanctuary because the floating power system platform would be anchored in water depths much greater than those found in the sanctuary. Cable mooring lines could impact marine mammal migration corridors and habitats used for breeding, feeding, resting, and raising young. However, the potential impacts would depend on specific project locations in relation to migration corridors and habitats used for specific life history functions which should be considered during project site selection and evaluated in more detail during project development.

The above water structure of the floating platform could be an attractant to seabirds, particularly if there is an increase in marine fish and other marine life in the waters surrounding the platform. Any night safety lighting should be minimized and designed to not attract seabirds to minimize potential collisions with the above water structure.

6.5.4.2 Best Management Practices and Mitigation Measures

As noted above, deepwater corals should be avoided to minimize impacts to corals as corals have slow growth rates and a long recovery time.

In addition, night safety lighting should be minimized and designed to not attract seabirds and minimize potential collisions with the above water structure.

Other BMPs for marine ecosystems are identified in Section 3.4.6.2.

6.5.5 LAND AND SUBMERGED LAND USE

6.5.5.1 Potential Impacts

6.5.5.1.1 Land Use

The representative OTEC project would be a 50-megawatt, closed-cycle system located in deep water 3.5 miles offshore. A 650-foot-long floating platform with a 128-beam would be constructed. Onshore, a land/sea cable transition site would be required to connect to the electrical grid to power the pumps as well as to deliver the electricity produced.

6.5.5.1.2 Submerged Land Use

The installation of mooring lines and the electrical cable to the shoreline would have impacts to the sea floor and local marine habitat. A submerged lands lease would be required.

6.5.5.2 Best Management Practices and Mitigation Measures

Section 8.2.5 describes BMPs associated with the undersea power cable connecting the OTEC facility with the onshore power grid.

6.5.6 CULTURAL AND HISTORIC RESOURCES

6.5.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operational phases of a utility scale, floating, OTEC power project and associated onshore ancillary facilities if effective conservation and BMPs are not implemented. During construction in onshore, nearshore, and offshore locations, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting and fishing locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6. Any OTEC facility site selection process would include a detailed environmental impact study, which would include a more detailed evaluation of potential impacts to cultural and historic resources.

6.5.6.2 Best Management Practices and Mitigation Measures

Associated BMPs to reduce potential impacts to cultural, historic, and related natural resources during construction and operation are discussed in Section 3.6.7.

6.5.7 COASTAL ZONE MANAGEMENT

Impacts to coastal zones were evaluated based on the extent to which a project would conflict with the policies of the Hawai'i Coastal Zone Management Program and potentially affect special management areas, shorefront access, and shoreline erosion.

6.5.7.1 Potential Impacts

Development of the OTEC project could require a Federal consistency review to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program. The project would require a power cable from the floating platform to land. Depending on the location where the cable crosses the shoreline, the project could impact designated special management areas, restrict shorefront access, and affect shoreline erosion. However, these potential impacts would be evaluated and reviewed during the Federal consistency review.

6.5.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

6.5.8 SCENIC AND VISUAL RESOURCES

6.5.8.1 Potential Impacts

Significant visual impacts to viewers on the shoreline from the representative OTEC project are unlikely due to the distance from shore. A 1982 study found that if a platform was moored between 3 and 5 miles offshore and had a superstructure or components that extended 150 feet above the water, the facility would be visible from shore. However, the plant would appear much smaller than actual size and would probably be perceived as a ship coming over the horizon. The closer to shore the plant is moored, the more discernible the plant components would be and the plant would appear more visually intrusive ([Hawai'i 1982](#)). It is likely that any safety or navigation lighting on the platform could be seen from shore at night.

Onshore, a land/sea cable transition site would be required to connect to the grid to power the pumps as well as to deliver the electricity produced. Section 8.2 analyzes potential impacts from land/sea cable transition sites. Construction of the transition site would take 24 months. Potential impacts to visual resources from construction activities are described in Section 3.8.3.

Long-term visual impacts onshore from the transition site would occur in the vicinity of the site. The representative transition site project analyzed in Section 8.2 is a converter station that would have a footprint of 6 acres and would be located 0.5 mile from the beach. The tallest structure would extend up to 40 feet above ground level.

6.5.8.2 Best Management Practices and Mitigation Measures

Sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the four designated scenic byways (three on Hawai'i and one on Kaua'i); State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System should be considered and avoided when locating an onshore transition site.

In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards. Some of the counties' plans include more detail than others, but all include objectives related to protecting and maintaining open space and scenic resources consistent with the State's land use designations.

BMPs to minimize impacts to visual resources, including those from lighting, are provided in Section 3.8.4.

6.5.9 RECREATION RESOURCES

6.5.9.1 Potential Impacts

Construction of the transition site would take 24 months. Potential impacts to recreation resources from construction activities are described in Section 3.9.4.

Long-term impacts to recreation would occur in the vicinity of the onshore and offshore facilities from access restrictions and potential visual impacts of the facilities.

6.5.9.2 Best Management Practices and Mitigation Measures

Sensitive locations such as recreation areas listed in Appendix A of the *State Comprehensive Outdoor Recreation Plan (DLNR 2009)* should be considered when locating an OTEC project. In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards.

BMPs to minimize impacts to recreation resources, including those from lighting, are provided in Section 3.9.5.

6.5.10 LAND AND MARINE TRANSPORTATION

Impacts to land transportation considered potential effects on traffic, alterations to existing roads, requirement for additional roads (excluding temporary or project specific access roads) infrastructure. Impacts to marine transportation considered potential effects on operation of the harbor systems, primary shipping routes between islands, general marine transportation around the islands (tourism, fishing), and military marine surface and subsurface operations.

6.5.10.1 Potential Impacts

6.5.10.1.1 Land Transportation

As identified in [Table 6-7](#), there would be no potential impacts to land transportation from the representative OTEC project.

6.5.10.1.2 Marine Transportation

The representative OTEC project would require deployment of a large floating platform in deep water approximately 3.5 miles offshore that is tethered to the ocean floor with cables. Regardless of specific location, these projects are potential obstructions to marine navigation and would require review and possible marking under the U.S. Coast Guard's Aids to Navigation System. Depending on distance from shore, these projects could affect navigation by tourist cruises, passenger ferries, fishing vessels

(recreational and commercial), and large commercial cargo ships. Military marine operations, surface and submarine navigation, could potentially be affected by both floating and submerged structures.

6.5.10.2 Best Management Practices and Mitigation Measures

OTEC projects may require review and possible marking under the U.S. Coast Guard's Aids to Navigation System to minimize potential obstructions to marine navigation.

6.5.11 AIRSPACE MANAGEMENT

6.5.11.1 Potential Impacts

The above water structure of the OTEC project would extend about 150 feet above the ocean surface. Although this is below the 200 foot level for an aviation obstruction evaluation, the Departments of Defense and Homeland Security conduct many marine operations in the waters surrounding Hawai'i including low elevation operations with helicopters. Many military operations may have linked marine surface and aviation operations. Because the OTEC could have impacts on marine transportation, potential impacts to airspace should be considered. Depending on the location of the project off of the coast, it could have potential impact on approach paths to airports.

6.5.11.2 Best Management Practices and Mitigation Measures

Potential impacts to airspace should be considered to minimize potential impacts on marine transportation. Typical construction and operations-related BMPs for airspace management are identified in Section 3.11.4.

6.5.12 NOISE AND VIBRATION

6.5.12.1 Potential Impacts

Short-term noise and vibration impacts would result from the construction of OTEC facilities. Noise sources from construction would include installation of an undersea power cable that would cross the shoreline using HDD drilling, a floating platform tethered to the seafloor with cable mooring lines and anchors, and installation of intake and effluent pipes. Offshore construction noise from equipment and vessels, and vibration caused by pile-driving, could exceed regulatory levels. Construction noise could indirectly impact scenic and visual resources, recreation resources, cultural resources, worker health and safety, and possibly public health. Further, according to the Incidental Harassment Authorization ([77 FR 43259, July 24, 2012](#)) exposure to elevated sound levels from vibratory and impact pile driving may result in temporary impacts to marine mammal hearing and behavior. However, in its Biological Opinion, the NMFS stated that it does not expect any takes of marine mammals by injury, serious injury, or mortality ([NMFS 2012](#)). Marine mammal prey species, such as fish, and sea turtles may also be temporarily impacted.

OTEC could potentially result in long-term noise and vibration impacts. Noise and vibration would result from operation of the pumps, turbine, heat exchanger, piping, and undersea cables. Mooring lines create what is called a "strum effect" from the current rushing past the mooring line and causing it to vibrate and hum ([BOEM 2012](#)). Sufficiently loud sounds can cause auditory injuries to marine mammals and sea turtles, but it is not known whether hydrokinetic energy devices produce sounds capable of causing auditory injury.

6.5.12.2 Best Management Practices and Mitigation Measures

The following recommended BMPs could reduce the potential disturbances from noise and vibration ([NMFS 2012](#)):

- temporal restrictions (such as not conducting vibratory pile driving during peak humpback whale season in Hawai‘i);
- establishment of an exclusion zone (a buffer to prevent harassment [injury] of any marine mammal species or sea turtles);
- shutdown and delay procedures (if a marine mammal or sea turtle approaches or enters an exclusion zone);
- soft-start procedures (a technique that allows marine mammals or sea turtles to leave the immediate area before sound sources reach maximum noise levels);
- in-situ underwater sound monitoring (sound monitoring during sheet pile and test pile driving);
- visual monitoring (an onsite, biologically trained individual approved in advance to monitor sound during construction); and
- per Marine Mammal Protection Act implementing regulations at [50 CFR § 216.104 \(a\)\(13\)](#), requests for Incidental Harassment Authorization must include monitoring and reporting plans.

Additional BMPs include the following:

- Avoid sensitive receptors for noise and vibration (identified in Section 3.12).
- Use equipment with sound-control devices. Equipment should be adequately muffled and maintained.
- In order to decrease the strum effect, place hydrodynamic foils on the upper half of the mooring line.

6.5.13 UTILITIES AND INFRASTRUCTURE

6.5.13.1 Potential Impacts

Effects on each island’s electric utilities would range from medium to large from the addition of 50 megawatts of power generation to any island’s overall power grid. For O‘ahu, with largest island net capacity of 1,756 megawatts, the change would be about 3 percent and for Kaua‘i with capacity of 125-megawatt the change would be about 40 percent (see Section 3.13.1). A 50-megawatt facility for O‘ahu would be a small addition but may require some adjustment to the utility’s management of power on the grid and overall power production. The 40 percent increase for Kaua‘i would represent a large change, and it would require adjustment to grid power management and rescheduling of other current power generation capability on Kaua‘i. For the smaller grids, such as Lāna‘i or Molokai, a 50 megawatt project would be too large and, if feasible, an alternative smaller project would need to be considered. Impacts from connection to utilities for construction and operation of this representative project would be the same as those described in Section 3.13.3.1, as applicable.

6.5.13.2 Best Management Practices and Mitigation Measures

For the smaller grids, such as Lānaʻi or Molokai, a 50 megawatt project would be too large and, if feasible, an alternative smaller project would need to be considered. BMPs for construction would be expected to be implemented to avoid conflicts with existing utilities (see Section 3.13.4).

6.5.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

6.5.14.1 Potential Impacts

6.5.14.1.1 Hazardous Materials

The OTEC facility would use and store both ammonia, the working fluid for thermal energy conversion, and chlorine gas or liquid to prevent biofouling and maintain the efficiency of the heat exchangers in the OTEC. In addition, a large amount of polyester resin will be used during construction. All of these compounds are considered hazardous materials in industrial quantities ([NELHA 2012](#)).

Prior to construction, it is recommended that the proposed project locations be investigated to identify possible hazardous materials that may be present at the proposed development locations. In the event that the project location is sited in a contaminated site (including MEC sites), abatement and remediation activities would be required before construction can occur by trained and certified professionals or a new site location should be selected.

Short-term hazardous material exposure impacts could result from the construction of a 50-megawatt utility-scale closed-cycle offshore OTEC facility. Construction activities would involve the use of hazardous materials such as fuels, oils, solvents, and glues as well as polyester resins (similar to surfboard resin) for bonding. In addition, inadvertent spills could occur during onsite fueling of equipment or by accident (for example, a puncture of a fuel tank through operator error or slope instability). Therefore, the use of hazardous materials would be required to comply with developed site-specific BMPs related to fueling, use, and storage of chemicals to minimize any risk to workers or the public. Transport, use, and disposal of these materials are regulated along with maximum permissible exposure to workers. The concentrations of vapors are likely to be noticeable depending on wind speed and direction during the construction period. Additional discussion of general hazardous material exposure impacts during construction are discussed in Section 3.14.4.

Long-term hazardous material exposure impacts could occur from the operation of a 50-megawatt offshore OTEC facility. Ammonia would alternate between a liquid and gas state inside the power block of the facility and would be stored in a storage tank. No perceptible releases of ammonia to the water or atmosphere are expected under normal operating conditions. If a leak were to occur in the heat exchangers, the ammonia would dissolve in seawater but it is unlikely that significant concentrations of ammonia would be released into the atmosphere. An ammonia leak in other machinery outside of the heat exchangers is less likely because of design safety standards; however, pressurized ammonia leaking into air spaces would result in an airborne plume that may be hazardous ([NELHA 2012](#)). The OTEC facility would be monitored for ammonia leaks during operation. Toxic levels for ammonia exposure are 200 ppm according to the U.S. EPA. A Risk Management Program and Emergency Management Plan would be developed, approved and implemented prior to delivery of ammonia.

Because of the intermittence and reactivity of chlorine in seawater, residual chlorine is expected to be negligible at the time of discharge from the system and effluent seawater is not anticipated to result in adverse effects. Biofouling tests at NELHA demonstrated that microbial film production on heat exchanger surfaces is controlled by chlorination at levels roughly one order of magnitude lower than is

required in temperate waters and that free and combined chlorine-produced oxidants are significantly more persistent in subtropical than in temperate waters, thus requiring a lower dosage to achieve the desired effects ([NELHA 2012](#)). Chlorine would be stored in pressurized cylinders located in an enclosed facility away from workers. Spills or leaks of chlorine are most likely to occur during delivery or cylinder change. Unlike ammonia, chlorine gas is 2.5 times heavier than air and in a worst case scenario, chlorine gas is not likely to represent a hazard due to the limited quantities stored and characteristically slow dispersal. Although chlorine is not flammable, it can combine with other substances, particularly gaseous ammonia, to cause fires or explosions ([NELHA 2012](#)).

Operation of a utility-scale OTEC facility would involve the use of hazardous materials such as fuels, oils, solvents, and glues. In addition, inadvertent spills could occur during onsite fueling of equipment or by accident (for example, a puncture of a fuel tank through operator error or slope instability). Therefore, the use of hazardous materials onsite would be required to comply with developed site-specific BMPs related to fueling, vehicle washing and handling, use, and storage of chemicals to minimize any risk to workers or the public.

6.5.14.1.2 Waste Management

Common waste management impacts are identified Section 3.14. Long-term waste management impacts would not be expected from the operation of an OTEC facility.

6.5.14.1.3 Wastewater

Minimal to no wastewater impacts would likely result from construction personnel and during project operations. The project would require no additives other than minimal amounts of chlorine. However, there may still be issues meeting wastewater quality discharge requirements. As such, the project would likely incorporate BMPs to meet water quality standard limits and OTEC project requirements such as a zone of mixing, whether required by the State or as part of the Federal permit requirements. Additional discussion is provided in [Section 6.5.3](#).

6.5.14.2 Best Management Practices and Mitigation Measures

BMPs for hazardous materials, waste management, and wastewater are discussed in Section 3.14.5.

6.5.15 SOCIOECONOMICS

6.5.15.1 Potential Impacts

Socioeconomic impacts in Hawai'i arising from a 50-megawatt OTEC operation would be very small. The deep water pipe, heat exchangers, floating platform and the related apparatus would likely be manufactured outside the State and, if so, economic benefits associated with the manufacturing would accrue elsewhere. The number of temporary construction jobs would be relatively small. Jobs directly associated the project would be likely filled by individuals residing within the area of influence (the State of Hawai'i) and not by workers migrating to the State to fill those positions. The representative project would not create many new net jobs. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and county government sector; to rental housing; and to personal income would be very small.

6.5.15.2 Best Management Practices and Mitigation Measures

None noted.

6.5.16 ENVIRONMENTAL JUSTICE

6.5.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the representative OTEC project are expected to be small. The potential for environmental justice impacts also would be small.

6.5.16.2 Best Management Practices and Mitigation Measures

Any OTEC project site selection process would include a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

6.5.17 HEALTH AND SAFETY

6.5.17.1 Potential Impacts

There would be the potential for exposure to chlorine and ammonia gases on the operating platform of the OTEC facility. BMPs would be implemented to ensure the safe handling, use, and storage of these hazardous materials. Other standard industrial hazards are identified in Section 3.17.3

6.5.17.2 Best Management Practices and Mitigation Measures

BMPs would be implemented to ensure the safe handling, use, and storage of hazardous materials. Common BMPs for protection of workers and the public from standard industrial hazards are identified in Section 3.17.5.

6.6 Photovoltaic (PV) Systems

The representative utility-scale PV project involves a facility with 5 megawatts of generating capacity that ties directly into the electrical distribution grid and has a footprint of approximately 25 acres with about 20,000 solar modules (see Section 2.3.3.7.4).

[Table 6-8](#) present a summary of the potential environmental impacts for the representative utility-scale PV project, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 6-8. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – PV Systems

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	General construction impacts from land disturbance/soil erosion (see Section 3.1.3). No operational impacts.	Same as those common across construction projects (see Section 3.1.4).
Climate and Air Quality		
Air Quality	General construction impacts (see Section 3.2.4). No operational impacts.	Same as those common across construction projects (see Section 3.2.4).

Table 6-8. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – PV Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Climate Change	Potential greenhouse gas emissions reduction from a mix of cleaner technologies used to produce electricity.	None.
Water Resources		
Surface Waters	General construction impacts (see Section 3.3.5). Potential stormwater runoff from the site (dependent on the amount of impermeable surface/nature of the pre-construction site).	Same as those common across construction projects (see Section 3.3.6). Management of stormwater runoff may be included in project design as needed, including but not limited to collection ditches or stormwater detention ponds to control the rate of flows from the site.
Groundwater	General construction impacts (see Section 3.3.5). Potential changes in runoff to the site and potential associated change in groundwater recharge.	Same as those common across construction projects (see section 3.3.6).
Floodplains and Wetlands	Potential impacts during construction and operation (site-specific) (see Section 3.3.5).	Same as those common across construction projects (see Section 3.3.6). To the extent feasible, the project shall avoid floodplains and wetlands areas during project siting. Flood mitigation measures may be required (e.g., raising panels to a certain height).
Biological Resources		
	General construction impacts (see Section 3.4.5). Potential impacts to biological resources including migratory birds, threatened and endangered plants and animals, critical habitat, protected land areas, and wetlands from habitat loss during site development (site-specific). For locations near the ocean, potential impacts may occur to marine anchialine pools.	Same as those common across construction projects (see Section 3.4.6). Site selection that avoids known locations of sensitive biological resources or high value habitats should be considered to reduce potential impacts.
Land and Submerged Land Use		
Land Use	Potential land use impacts including land disturbance and possible conversion of undeveloped land and land in other current use to an energy generating facility.	Consider State land use designations and county overlay zones in locating the project site.

Table 6-8. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – PV Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	<p>Potential change in land ownership patterns and/or easements required for the project (i.e., project site, access roads, corridors to the nearest electrical grid).</p> <p>Potential impacts to adjacent land uses (roads, residential/commercial areas, historic sites, scenic locations, and airports) from the glint and glare of the solar panels.</p>	
Submerged Land Use	None; PV projects would be land-based and not impact submerged land uses.	N/A
Cultural and Historic Resources		
	<p>Common construction and operation impacts to cultural resources (see Section 3.6.6).</p> <p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	Common construction and operation BMPs for cultural resources (see Section 3.6.7).
Coastal Zone Management		
	Potential impacts to designated special management areas, shorefront access, and shoreline erosion (site-specific).	Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.
Scenic and Visual Resources		
	<p>General visual impacts during construction (see Section 3.8.3).</p> <p>Potential long-term visual impacts from solar panels, including in association with new facilities and associated buildings.</p>	<p>Same as those common across construction projects (see Section 3.8.4).</p> <p>Solar facilities should be sited and designed to ensure that glint and glare do not have significant effects on roadway users, nearby residences, commercial areas, or other</p>

Table 6-8. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – PV Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	<p>Potential glinting, glare, and visual effects depending on the panel orientation, sun angle, viewing angle, viewer distance, and other visibility factors; may also be dependent on individual viewer sensitivity.</p> <p>Potential long term visual effects from routine maintenance activities.</p>	<p>highly sensitive viewing locations. Sensitive viewing locations include areas with historic significance where aesthetics play an important role in an area’s long-established character and areas valued for their lack of man-made intrusions, such as National and State parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves.</p> <p>The Bureau of Land Management has outlined the following measures as BMPs to minimize the visual impacts from utility-scale PV systems (BLM 2013):</p> <ul style="list-style-type: none"> • Site and operate the modules to avoid offsite glare • Screen solar modules to avoid offsite glare with fencing, berms, or vegetation • Use and maintain non-reflective or color-treated backs and support structures to decrease visual contrast • Avoid complete removal of vegetation beneath the modules or consider re-vegetation consistent with facility operations and safety considerations • Prohibit commercial messages and symbols on the modules. • The Federal Aviation Administration and the Hawai‘i Department of Transportation, Airports Division requires review of all PV projects sited near active airports to ensure panel glare does not interfere with nearby aircraft.
Recreation Resources		
	<p>General construction impacts (see Section 3.9.4).</p> <p>Potential long-term recreation resource impacts such as land cover required for the arrays and associated facilities required for the project resulting in access restrictions to area as well as visual impacts created by the presence of the facilities and maintenance activities.</p>	<p>Same as those common across construction projects (see Section 3.9.5).</p> <p>Solar facilities should be sited and designed to ensure that glint and glare do not have significant effects on nearby recreational users. Popular recreation areas are listed in Appendix A of the State Comprehensive Outdoor Recreation Plan (DLNR 2009).</p>

Table 6-8. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – PV Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	Potential impacts to nearby recreation areas from panels and other components that reflect and result in glinting, glare, and other visual effects.	
Land and Marine Transportation		
	None; installation and operation of a utility-scale PV system would not impact land or marine transportation.	N/A
Airspace Management		
	Potential hazards to aircraft and pilots from sunlight reflection; dependent on the magnitude of reflection (glint and glare) from solar power systems.	The Federal Aviation Administration and the Hawai‘i Department of Transportation, Airports Division requires review of all PV projects sited near active airports to ensure panel glare does not interfere with nearby aircraft.
Noise and Vibration		
	General impacts during construction and operation (see Section 3.12.5).	Same as those common across construction projects (see Section 3.12.6).
Utilities and Infrastructure		
	General construction impacts (see Section 3.13.3.1). Potential minimal impacts to electric utilities (site-specific).	Same as those common across construction projects (see Section 3.13.4).
Hazardous Materials and Waste Management		
Hazardous Materials	General impacts during construction and operation (see Section 3.14.4). Potential exposure to trace amounts of hazardous materials (i.e., cadmium, selenium, arsenic) if panels were broken.	Same as those common across construction projects (see Section 3.14.5). Hazardous materials must be stored, handled, and disposed of at the appropriate hazardous waste facility.
Waste Management	General impacts during construction and operation (see Section 3.14.4). Potential hazardous waste impacts resulting from trace amounts of cadmium, selenium, or arsenic if solar panels are broken and/or during solar panel decommissioning/disposal.	Same as those common across construction projects (see Section 3.14.5). To the extent feasible, recover and reuse components of PV modules, such as glass, aluminum, and semiconductor materials, either for new PV modules or other products.

Table 6-8. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – PV Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Wastewater	Potential impacts from wastewater discharge resulting from disposal of PV modules at their end-life, particularly from potential leaching or contamination from cadmium containing materials.	Solar modules would require proper handling and transport for disposal at the appropriate hazardous waste facility to ensure that no hazardous wastes are disposed of at landfills nor enter the waste stream.
Socioeconomics		
	Very small socioeconomic impacts; minimal job and population effects.	None.
Environmental Justice		
	Small potential impacts to the general population. Site-specific evaluation of impacted populations required.	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.
Health and Safety		
	General construction and operation impacts (see Section 3.17.3).	Same as those common across construction project (see Section 3.17.5).

6.6.1 GEOLOGY AND SOILS

6.6.1.1 Potential Impacts

Effects on geology and soils from construction of a 5-megawatt solar photovoltaic (PV) would be the same as those expected for common construction actions as described in Section 3.1.3. Since the amount of land disturbed would be well over one acre, the permitting requirements described in Section 3.1.3 would be fully applicable.

Operation of the PV facility would not involve activities that would have the potential to affect geology and soils of the area.

6.6.1.2 Best Management Practices and Mitigation Measures

During construction, precautionary measures should be implemented (for example, response plans, cleanup equipment, secondary containment, etc.) to minimize the potential for on- or offsite soil contamination.

6.6.2 CLIMATE AND AIR QUALITY

6.6.2.1 Potential Impacts

6.6.2.1.1 Air Quality

This technology could result in impacts commonly associated with general construction activities, which are addressed in Section 3.2.4.

Operation of a photovoltaic project would not be a source of criteria pollutant emissions.

6.6.2.1.2 Climate Change

Operation of a photovoltaic project would not be a source of greenhouse gas emissions. Assuming a 20 percent capacity factor, the project would generate about 8,800 megawatt-hours per year and could replace electricity requirements from the existing baseline electrical grid by that same amount. A replacement of 8,800 megawatt-hours of electricity per year from the baseline electrical grid would reduce oil consumption from electricity generation by about 580,000 gallons. On O‘ahu, the annual replacement of 8,800 megawatt-hours of electricity would correspond with an annual reduction in greenhouse gas emissions of about 6,400 metric tons CO₂ equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid; EPA 2012a>). On other islands by comparison, an annual replacement of 8,800 megawatt-hours of electricity usage would see an annual reduction in greenhouse gas emissions of about 5,400 metric tons CO₂ equivalent due to a cleaner mix of technologies used to produce electricity on the other islands.

6.6.2.2 Best Management Practices and Mitigation Measures

The common BMPs for air quality are identified in Section 3.2.5.

6.6.3 WATER RESOURCES

6.6.3.1 Potential Impacts

This section addresses potential environmental consequences to water resources from construction and operation of a utility-scale PV project. Potential impacts are addressed in terms of surface water, groundwater, and floodplains and wetlands.

6.6.3.1.1 Surface Water

Effects on surface water during construction of the PV project would be the same as those expected for common construction actions as described in Section 3.3.5.

During operations of the PV facility there would be no activities that would have the potential to affect surface waters other than possibly changing the quantities of stormwater runoff from the site as a result of changes in the characteristics of the surface areas. Whether the constructed site would include more or less impermeable surfaces would depend on the nature of the pre-construction site. If the runoff volume were increased, its management would depend on the nature of the specific site (for example, whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns.

6.6.3.1.2 Groundwater

Effects on groundwater during construction of the PV project would be the same as those expected for common construction actions as described in Section 3.3.5.

During operations of the PV facility there would be no activities that would have the potential to affect groundwater other than possible changes in runoff from the site (as described previously) and potentially an associated change in groundwater recharge. However, the area involved is relatively small and, depending on where runoff from the facility goes or how it is managed, the action may simply represent a change in where water soaks into the ground and possibly provides recharge.

6.6.3.1.3 Floodplains and Wetlands

The proponent of a utility-scale, PV project would be expected to avoid floodplain and wetland areas if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

6.6.3.2 Best Management Practices and Mitigation Measures

Consideration of sensitive locations or receptors with regard to construction and operations of a PV facility would be the same as described for common construction projects in Section 3.3.5. Common BMPs for the protection of water resources are identified in Section 3.3.6.

6.6.4 BIOLOGICAL RESOURCES

This section addresses environmental consequences to biological resources. Potential impacts are addressed in terms of terrestrial vegetation and wildlife habitat, threatened and endangered plant and animal species, designated critical habitat, and high value biological resources such as wetlands and protected land areas considering the type, intensity, duration and physical extent of potential impacts.

6.6.4.1 Potential Impacts

Installation of a solar PV power plant would require clearing approximately 5 acres for each megawatt of capacity. A representative 5-megawatt capacity plant would require clearing approximately 25 acres to install the panels of PV cells and associated infrastructure. The amount of land required for larger capacity plants would increase proportionally. The primary impact to biological resources would be from clearing of vegetation and loss of wildlife and their habitat. Photovoltaic projects are best installed in areas with relatively flat terrain and abundant solar radiation. Those conditions are generally found at lower elevations, and particularly on the leeward side of the islands. Therefore, most of the native vegetation, threatened and endangered species, and protected land areas, including critical habitat that are found at mid- to upper elevation areas where topography is generally steeper and solar radiation is lower would be avoided. However, important biological resources occur at lower elevations and depending on specific project locations, impacts from habitat loss could occur to migratory birds, threatened and endangered plant and animals, critical habitat, protected land areas, and wetlands from site development. Project locations near the ocean may also include marine anchialine pools that may occur several hundred meters inland.

6.6.4.2 Best Management Practices and Mitigation Measures

During project siting, known locations of sensitive biological areas or high value habitats should be avoided to reduce potential impacts to biological resources. Common BMPs for biological resources are identified in Section 3.4.6.1.

6.6.5 LAND AND SUBMERGED LAND USE

This section discusses the potential environmental consequences to land use from a utility-scale photovoltaic system.

6.6.5.1 Potential Impacts

6.6.5.1.1 Land Use

The 5-megawatt representative project would require approximately 25 acres to be cleared and prepared for the installation of the solar panels. A utility-scale PV facility may include the following: an administration building, maintenance building, component assembly building, guardhouse, and other small structures. In some cases, some of the buildings could be located offsite. The site could also need road access, if not existing. There would also be a need for a corridor to tie-in the solar farm to the existing transmission grid. This representative project assumes no energy storage technologies are required.

Land use impacts would include the amount of land disturbed, and the possible conversion of undeveloped land and land in other current use to an energy generating facility. Land ownership patterns could also change or land use easements could be required for the solar site, access roads, and corridors to the nearest electrical grid.

State land use designations and county overlay zones would be considered in locating the facility.

6.6.5.1.2 Submerged Land Use

There would be no impacts to submerged land use.

6.6.5.2 Best Management Practices and Mitigation Measures

None noted.

6.6.6 CULTURAL AND HISTORIC RESOURCES

6.6.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operational phases of a utility scale, PV power project if effective conservation and BMPs are not implemented. During construction, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on

sensitive cultural and historic resources, landscapes, vistas, hunting locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6. Any solar PV facility site selection process would include a detailed environmental impact study, which would include a more detailed evaluation of potential impacts to cultural and historic resources.

6.6.6.2 Best Management Practices and Mitigation Measures

Associated BMPs to reduce potential impacts to cultural, historic, and related natural resources during construction and operation are discussed in Section 3.6.7.

6.6.7 COASTAL ZONE MANAGEMENT

6.6.7.1 Potential Impacts

Development of a solar PV energy project could require a Federal consistency review to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program. Impacts to special management areas, shorefront access, and shoreline erosion would depend on the location of the solar photovoltaic project. However, these potential impacts would be evaluated and reviewed during the Federal consistency review.

6.6.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

6.6.8 SCENIC AND VISUAL RESOURCES

6.6.8.1 Potential Impacts

For the 5-megawatt representative project, approximately 25 acres would be cleared and prepared. Potential impacts to visual resources from construction activities are discussed in Section 3.8.3.

Long-term visual impacts would result from the solar arrays covering approximately 25 acres of land. PV facilities do not require infrastructure associated with heating, transporting, boiling, and cooling water and other heat transfer fluids. However, a utility-scale PV facility may include one or more of the following: administration building, maintenance building, component assembly building, guardhouse, and other small structures. In some cases, these buildings may be located offsite. PV modules are not designed to reflect light and therefore have less potential for glint and glare than the mirrored surfaces of parabolic troughs (see [Section 6.7.7](#)). However, the arrays and other components would reflect light that may result in glinting, glare, and other visual effects that would vary depending on module orientation, sun angle, viewing angle, viewer distance, and other visibility factors.

Geometric patterns of reflected light can be caused by simultaneous reflection of sunlight from regularly spaced metal surfaces in the gaps between the PV modules. These reflections would not be bright enough to cause discomfort; however they may cause visual contrast and change as the observer moves ([Sullivan](#)

[et al. 2012](#)). The degree of contrast would be dependent on viewer position with respect to the facility, lighting, and sun angle. The arrays of PV facilities have appeared black, through a range of blues, to white. These color shifts can cause increases in visual contrast ([Sullivan et al. 2012](#)). The degree of contrast has also been found to be much greater from elevated viewpoints. Because the arrays generally have very low vertical profiles, when viewed from the valley floor or other low-elevation viewpoints, the arrays may blend in with the typically strong horizon line ([Sullivan et al. 2012](#)). In general, PV projects have lower visual impacts than other solar technologies because of the low profile of the arrays and the lower reflectivity of the PV panels compared to the highly reflective mirrors used by other technologies, for example, parabolic troughs (see [Section 6.7.8](#)).

Long-term visual impacts would also occur from routine maintenance activities, such as washing the solar module surfaces, road and building maintenance, and repairs. Washing the surfaces could occur at night and may require vehicle-mounted lights.

Viewer sensitivity to the solar panels would likely depend on the individual. Individuals that view solar power and renewable energy favorably would be less likely to view the impacts of the project in a negative manner.

Short-term and long-term visual impacts for a project larger than the representative project would be as described above for but would be in a larger area in proportion to the increase in size of the project. The visual impacts of glinting, glare, geometric patterns, color shifts, and visual contrast would be of greater magnitude with the larger area of solar panels.

6.6.8.2 Best Management Practices and Mitigation Measures

Solar facilities should be sited and designed to ensure that glint and glare do not have significant effects on roadway users, nearby residences, commercial areas, or other highly sensitive viewing locations. Sensitive viewing locations include areas with historic significance where aesthetics play an important role in an area's long-established character and areas valued for their lack of man-made intrusions, such as National and State parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves.

BMPs to minimize impacts to visual resources are addressed in Section 3.8.4. The Bureau of Land Management has outlined the following measures as BMPs to minimize the visual impacts from utility-scale PV systems ([BLM 2013](#)):

- Site and operate the modules to avoid offsite glare
- Screen solar modules to avoid offsite glare with fencing, berms, or vegetation
- Use and maintain non-reflective or color-treated backs and support structures to decrease visual contrast
- Avoid complete removal of vegetation beneath the modules or consider revegetation consistent with facility operations and safety considerations
- Prohibit commercial messages and symbols on the modules

In addition, the Federal Aviation Administration and the Hawai'i Department of Transportation, Airports Division requires review of all PV projects sited near active airports to ensure panel glare does not interfere with nearby aircraft.

6.6.9 RECREATION RESOURCES

6.6.9.1 Potential Impacts

For the 5-megawatt representative project, approximately 25 acres would be cleared and prepared. Potential impacts to recreation resources from construction activities are discussed in Section 3.9.4.

Long-term impacts to recreation resources could result from the arrays covering approximately 25 acres of land, from access restrictions to the area, and as visual impacts created by the presence of the facilities and maintenance activities. PV panels are not designed to reflect light and therefore have less potential for glint and glare than the mirrored surfaces of parabolic troughs (see [Section 6.7.8](#)). However, the panels and other components would reflect light that may result in glinting, glare, and other visual effects that could affect nearby recreation areas. Impacts would vary depending on panel orientation, sun angle, viewing angle, viewer distance, and other visibility factors.

6.6.9.2 Best Management Practices and Mitigation Measures

Solar facilities should be sited and designed to ensure that glint and glare do not have significant effects on nearby recreational users. Popular recreation areas are listed in Appendix A of the *State Comprehensive Outdoor Recreation Plan* ([DLNR 2009](#)).

BMPs to minimize impacts to recreation resources are addressed in Section 3.9.5.

6.6.10 LAND AND MARINE TRANSPORTATION

As identified in [Table 6-8](#), there would be no potential impacts to land or marine transportation from the representative utility-scale PV project.

6.6.11 AIRSPACE MANAGEMENT

6.6.11.1 Potential Impacts

Solar PV power systems are low in profile and do not pose an obstruction hazard to airspace. Sunlight reflection (glint and glare) from solar power systems is a potential hazard to aircraft and their pilots. The potential impact is related to the magnitude of the reflection. Solar photovoltaic panels typically have a low reflection because they are designed to absorb as much sunlight as possible for conversion into electricity. Therefore, impacts to airspace from the development of solar photovoltaic power plants are expected to be minor.

6.6.11.2 Best Management Practices and Mitigation Measures

Proponents should coordinate with the FAA during the siting process to ensure that any potential impacts to nearby airports or flight paths are minimized.

6.6.12 NOISE AND VIBRATION

6.6.12.1 Potential Impacts

Construction of the representative PV project could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

Long-term noise and vibration impacts from operation of photovoltaic would be minimal and limited to maintenance activities.

6.6.12.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation. See Section 3.12.6.

6.6.13 UTILITIES AND INFRASTRUCTURE

6.6.13.1 Potential Impacts

Potential impacts on each island's electric utilities would typically be small from the addition of 5 megawatts of power generation to any island's overall power grid. For O'ahu, with largest island net capacity of 1,756 megawatts, the change would be about 0.3 percent and for Kaua'i with a net capacity of 125 megawatts the change would be about 4 percent (see section 3.13.1). Higher percentage change increases the likelihood that the affected island utility would need to adjust management of power on the grid and overall power production. For the smaller grids, such as Lāna'i or Molokai, a 5 megawatt project would be large and a smaller project should be considered. Impacts from connection to utilities for construction and operation of this representative project would be the same as those described in Section 3.13.3.1, as applicable. Because of the lower capacity factors for solar power (approximately 20%), utilities would need to also implement energy storage technologies or arrange for other base load power sources in times when solar power is not being generated (e.g., night).

6.6.13.2 Best Management Practices and Mitigation Measures

BMPs for construction would be expected to be implemented to avoid conflicts with existing utilities (see Section 3.13.4).

6.6.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

6.6.14.1 Potential Impacts

6.6.14.1.1 Hazardous Materials

General hazardous material impacts that could occur prior to and during the installation of a PV system are discussed in Section 3.14.4.

Project operations are not anticipated to require hazardous materials that could be spilled or released to the environment. Some solar panels may contain trace amounts of cadmium, selenium, and arsenic which could be hazardous if broken. As such, these hazardous materials must be stored, handled, and disposed of at the appropriate hazardous waste facility. Hazardous materials exposure impacts may result at the end-of-life of the photovoltaic system during disposal. However, these would be secondary waste management impacts.

6.6.14.1.2 Waste Management

General waste management impacts that could occur prior to and during the installation of a PV system are discussed in Section 3.14.4.

Project operations are not anticipated to result in waste management impacts. Some solar panels may contain trace amounts of cadmium, selenium, and arsenic which could be hazardous if broken. Such panels would be deemed hazardous and would need to be handled and disposed of at the appropriately permitted hazardous waste facility.

Potential impacts would result from the disposal of the photovoltaic system at its end-life. As discussed in Section 4.3, Solar Water Heating, it is anticipated that most components of PV modules such as glass, aluminum, and semiconductor materials would be successfully recovered and reused either for new PV modules or other products. However, some PV systems may need to be managed and disposed of as hazardous waste resulting in potential impacts. In particular, the manufacturing, decommissioning and disposal of some PV modules (some thin film PV products) may involve cadmium. Cadmium is a heavy metal that is considered a probable carcinogen in humans and animals and can accumulate in plant and animal tissues. While cadmium does not pose health risks when a PV module is in operation, the production of some PV modules can result in waste sludge¹ and cadmium contaminated wastewater which would need to be properly disposed of at the appropriate hazardous waste facility. Although PV modules are not anticipated to be manufactured in the State, proper disposal of some PV modules at the appropriate hazardous waste facility would be required at its end-life, to ensure no leaching or contamination from cadmium occurs.²

6.6.14.1.3 Wastewater

Minimal to no wastewater impacts would be expected from the installation and operation of a solar farm. Some wastewater may be produced during maintenance from personnel and machinery operations. However these would be minor and limited. Industrial wastewater discharge would be regulated by NPDES wastewater discharge permit requirements.

Potential impacts may result during the production of the PV modules as the production of some PV modules can result in cadmium contaminated wastewater which would need to be properly disposed of at the appropriate hazardous waste facility. Although PV modules are not anticipated to be manufactured in the State, proper disposal of some PV modules at the appropriate hazardous waste facility would be required at its end-life, to ensure no leaching or contamination from cadmium occurs. As such, solar modules would require proper handling and transport for disposal at the appropriate hazardous waste facility to ensure that no hazardous wastes are disposed of at landfills and that hazardous wastes do not enter the waste stream.

6.6.14.2 Best Management Practices and Mitigation Measures

BMPs for hazardous materials, waste management, and wastewater are discussed in Section 3.14.5.

¹ Sludge is defined by the EPA as a semisolid residue from air or water treatment processes (Source: Risk Assessment Glossary, Available online at: <http://www.epa.gov/oswer/riskassessment/glossary.htm>; EPA 2012b). During the production of PVs, toxic sludge can be created when metals and other toxins are removed from the water used during the manufacturing process, and is classified as hazardous waste.

² In order to be deemed ‘hazardous’ by regulators, decommissioned or defective solar panels must fail to meet the US Environmental Protection Agency (EPA) Toxicity Characteristic Leaching Procedures (TCLP) standards in accordance with the RCRA.

6.6.15 SOCIOECONOMICS

6.6.15.1 Potential Impacts

Socioeconomic impacts in Hawai‘i arising from the installation of PV modules to generate 5 megawatts of utility-scale electricity would be very small. Jobs directly associated the installation of the PV modules and the maintenance of the system would be very small. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and county government sector; to rental housing; and to personal income would be very small.

6.6.15.2 Best Management Practices and Mitigation Measures

None noted.

6.6.16 ENVIRONMENTAL JUSTICE

6.6.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the PV system are expected to be small. The potential for environmental justice impacts also would be small.

6.6.16.2 Best Management Practices and Mitigation Measures

Any utility-scale PV project site selection process would include a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

6.6.17 HEALTH AND SAFETY

6.6.17.1 Potential Impacts

Common health and safety impacts for typical construction and operations activities are identified in Section 3.17.3. There are no additional potential health and safety risks that would be unique to PV projects.

6.6.17.2 Best Management Practices and Mitigation Measures

Common health and safety BMPs for typical construction and operations activities are identified in Section 3.17.5.

6.7 Solar Thermal Systems

The representative solar thermal project would be a parabolic trough facility with 5-megawatt capacity on 30 to 50 acres of land (see Section 2.3.3.8.4). The construction and operation of solar modules and support structures would be confined to that acreage and spaced to avoid shading the panels.

[Table 6-9](#) present a summary of the potential environmental impacts for the representative solar thermal project, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts;. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 6-9. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Solar Thermal Systems

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	<p>General construction impacts from land disturbance (see Section 3.1.3).</p> <p>Potential for soil contamination in the event of a leak or accidental release of the heat transfer fluids (such as synthetic oil or even molten salt) used in the system.</p>	<p>Same as those common across construction projects (see Section 3.1.4).</p> <p>Monitor during operations to quickly identify and respond to any leaks or accidental releases of heat transfer fluids, including stopping the spill or release and cleaning up any soil contamination.</p>
Climate and Air Quality		
Air Quality	<p>General construction impacts (see Section 3.2.4).</p> <p>No operational impacts.</p>	<p>Same as those common across construction projects (see Section 3.2.5).</p>
Climate Change	<p>Potential greenhouse gas emissions reduction from a mix of different technologies used to produce electricity.</p>	<p>None.</p>
Water Resources		
Surface Waters	<p>General construction impacts (see Section 3.3.5).</p> <p>Potential stormwater runoff contamination in the event of leaks or accidental releases of the heat transfer fluids (such as synthetic oil or even molten salt) used in the system.</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p> <p>Management of stormwater runoff may be included in project design as needed, including but not limited to collection ditches or stormwater detention ponds to control the rate of flows from the site.</p> <p>Monitor during operations to quickly identify and respond to any leaks or accidental releases of heat transfer fluids, including stopping the spill or release and cleaning up any soil contamination.</p>
Groundwater	<p>Minor groundwater impacts during construction (see Section 3.3.5).</p> <p>Potential changes in runoff to the site and potential associated change in groundwater recharge.</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p> <p>If necessary, the project should include onsite measures such as a stormwater detention pond to control the rate at which stormwater leaves the site.</p>
Floodplains and Wetlands	<p>Potential impacts during construction and operations (site-specific) (see Section 3.3.5).</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p> <p>To the extent feasible, the project shall avoid floodplains and wetlands areas during project siting.</p>

Table 6-9. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Solar Thermal Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Biological Resources		
	<p>General construction impacts (see Section 3.4.5).</p> <p>Potential impacts to biological resources including migratory birds, threatened and endangered plants and animals, critical habitat, protected land areas, and wetlands) from habitat loss during site development (site-specific). For locations near the ocean, potential impacts may occur to marine anchialine pools.</p>	<p>Same as those common across construction projects (see Section 3.4.6).</p> <p>Site selection that avoids known locations of sensitive biological resources or high value habitats should be considered to reduce potential impacts.</p>
Land and Submerged Land Use		
Land Use	<p>Potential change in land ownership patterns through purchase and or land use leases for both the solar thermal project site and any linear corridors required to tie in to the existing electrical grid.</p> <p>Potential impacts to undeveloped land or land currently used for other uses could be converted to energy uses.</p>	Consider State land use designations and county overlay zones in locating the project site.
Submerged Land Use	None; solar thermal projects would be land-based and not impact submerged land uses.	N/A
Cultural and Historic Resources		
	<p>Common construction and operation impacts to cultural resources (see Section 3.6.6).</p> <p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	Common construction and operation BMPs for cultural resources (see Section 3.6.7).

Table 6-9. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Solar Thermal Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Coastal Zone Management		
	<p>Potential impacts to designated special management areas, shorefront access, and shoreline erosion (site-specific); Potential for adverse impacts to those locations near the shoreline.</p> <p>Potential for increase in runoff and sedimentation and impacts to coastal water habitats from land clearing.</p>	<p>Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.</p>
Scenic and Visual Resources		
	<p>General visual impacts during construction (see Section 3.8.3).</p> <p>Potential long-term dynamic visual impacts from parabolic troughs/mirrors (glare/reflected light), thermal storage tanks, steam condenser, cooling towers (plumes) and generator as well as road access, parking, maintenance facilities, and transmission line tie-in.</p> <p>Potential for individual discomfort from glare effects, depending on viewer sensitivity, viewer location, viewer movement, and time of day.</p> <p>Potential increase in light pollution impacts (skyglow, light trespass, and glare) from security lighting and other exterior lighting around buildings, parking areas, work areas and during maintenance activities (vehicle-mounted lights).</p>	<p>Same as those common across construction projects (see Section 3.8.4).</p> <p>During project siting, the project shall consider sensitive locations.</p> <p>The facility should be sited away from roads and trails to avoid causing offsite glare that may cause annoyance and visual discomfort.</p> <p>The project shall consider effects on views from nearby mountains, where elevated observation points would afford open views of solar module fields, as well as potential impacts on the dark night skies that are valued scenic and tourist resources.</p> <p>The Bureau of Land Management has outlined the following measures as BMPs to minimize the visual impacts from utility-scale solar projects (BLM 2013):</p> <ul style="list-style-type: none"> • Use dry cooling technology to avoid water vapor plumes • Site and operate the modules to avoid offsite glare. • Screen solar modules to avoid offsite glare with fencing, berms, or vegetation. • Use and maintain non-reflective or color-treated backs and support structures to decrease visual contrast. • Avoid complete removal of vegetation beneath the modules or consider revegetation consistent with facility operations and safety considerations. • Prohibit commercial messages and symbols on the modules.

Table 6-9. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Solar Thermal Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
		<p>Give consideration to each of the six islands general land use plans and associated implementation tools such as zoning ordinances and development standards related to protecting and maintaining open space and scenic resources.</p> <p>The Federal Aviation Administration and the Hawai‘i Department of Transportation, Airports Division requires review of all solar projects sited near active airports to ensure glare does not interfere with nearby aircraft.</p>
Recreation Resources		
	<p>General construction impacts (see Section 3.9.4).</p> <p>Potential long-term impacts to recreation resources from access restrictions to the site and visual impacts associated with the new facilities. See Section 6.7.8 regarding visual effects of solar thermal facilities.</p> <p>Potential impacts to recreation resources from light pollution, particularly those areas where a dark night sky is valued (i.e., campgrounds).</p>	<p>Same as those common across construction projects (see Section 3.9.5).</p> <p>Sensitive locations such as recreation areas listed in Appendix A of the State Comprehensive Outdoor Recreation Plan should be considered when locating a utility-scale solar thermal system (DLNR 2009).</p> <p>The project shall consider effects on views from nearby mountains, where elevated observation points afford open views of solar module fields, as well as potential impacts on the dark night skies that are valued recreation resources (for example, camping) during project development.</p>
Land and Marine Transportation		
Land Transportation	Potential short-term transportation impacts associated with construction traffic.	None.
Marine Transportation	None; installation and operation of a solar thermal system would not have any marine transportation impacts as it would be totally land-based.	N/A
Airspace Management		
	<p>Potential hazards to both military and civilian aircraft from reflections of the concentrated solar power (CSP) facility.</p> <p>Potential air turbulence hazards to both military and civilian aircraft (likely limited to low altitude aircraft i.e., helicopters or during take-offs and landings) from CSP plants employing a dry cooling system.</p>	Project locations should be evaluated in relation to surrounding airspace to minimize potential hazards to both military and civilian aircraft.

Table 6-9. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Solar Thermal Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Noise and Vibration		
	General impacts during construction and operation (see Section 3.12.5).	Same as those common across construction projects (see Section 3.12.6).
Utilities and Infrastructure		
	General construction impacts (see Section 3.13.3.1). Potential minimal impacts to electric utilities (site-specific).	Same as those common across construction projects (see Section 3.13.4).
Hazardous Materials and Waste Management		
Hazardous Materials	General construction impacts (see Section 3.14.4).	Same as those common across construction projects (see Section 3.14.5).
Waste Management	General construction impacts (see Section 3.14.4).	Same as those common across construction projects (see Section 3.14.5).
Wastewater	General construction impacts (see Section 3.14.4).	Same as those common across construction projects (see Section 3.14.5).
Socioeconomics		
	Very small socioeconomic impacts; minimal job and population effects.	None.
Environmental Justice		
	Minimal potential for environmental justice impacts due to small environmental impacts to general population.	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.
Health and Safety		
	General construction and operation impacts (see Section 3.17.3).	Same as those common across construction projects (see Section 3.17.5).

6.7.1 GEOLOGY AND SOILS

6.7.1.1 Potential Impacts

The representative project would require approximately 1 mile of onshore transmission lines to reach the nearest grid connection, but potential impacts associated with such an action are addressed under the On Island Electrical Transmission technology in Section 8.1 and are not repeated here.

Potential effects on geology and soils from construction of a 5-megawatt solar thermal facility would be the same as those expected for common construction actions as described in Section 3.1.3. Since the amount of land disturbed would be well over one acre, the permitting requirements described in Section 3.1.3 would be fully applicable.

Operation of the solar thermal facility would not normally involve activities that would have the potential to affect geology and soils of the area. However, the heat transfer fluids (such as synthetic oil or even molten salt) used in the system could cause soil contamination were there to be leaks or accidental releases. Normal operational monitoring would be expected to quickly identify and respond to any such incidents, including stopping the spill or release and cleaning up any soil contamination.

6.7.1.2 Best Management Practices and Mitigation Measures

Sensitive geology and soil related locations or receptors should be considered during the siting of a solar thermal facility. The common BMPs for construction are identified in Section 3.1.4.

6.7.2 CLIMATE AND AIR QUALITY

6.7.2.1 Potential Impacts

Solar thermal energy technology converts solar energy into heat energy that can be used to generate electricity. A representative utility-scale 5-megawatt facility would consist of the required hardware (which varies depending on the technology chosen) operating on 30 to 50 acres. Capacity factors range from 25 percent to 40 percent, or more, depending on the technology. The parabolic trough facility used in the representative project has a capacity factor of 25 percent, so the project could provide base load electricity of 11,000 megawatt-hours per year and could replace electricity requirements from the existing baseline electrical grid by that same amount.

6.7.2.1.1 Air Quality

This technology could result in impacts commonly associated with general construction activities, which are addressed in Section 3.2.4.

Operation of a solar thermal project would not be a large source of criteria pollutant emissions.

6.7.2.1.2 Climate Change

Operation of a solar thermal project would not be a large source of greenhouse gas emissions. A replacement of 11,000 megawatt-hours of electricity per year from the existing baseline electrical grid would reduce oil consumption from electricity generation by about 730,000 gallons per year. On O'ahu, the annual replacement of 11,000 megawatt-hours of electricity would correspond with an annual reduction in greenhouse gas emissions of about 8,000 metric tons CO₂ equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid>; EPA 2012a). On other islands by comparison, an annual replacement of 11,000 megawatt-hours of electricity usage would see an annual reduction in greenhouse gas emissions of about 6,700 metric tons CO₂ equivalent due to a different mix of technologies used to produce electricity on the other islands.

6.7.2.2 Best Management Practices and Mitigation Measures

Common BMPs for construction activities are identified in Section 3.2.5.

6.7.3 WATER RESOURCES

6.7.3.1 Potential Impacts

This section addresses potential environmental consequences to water resources from construction and operation of a solar thermal energy facility. Potential impacts are addressed in terms of surface water, groundwater, and floodplains and wetlands. The representative project is assumed to require approximately 1 mile of onshore transmission lines to reach the nearest grid connection, but potential impacts associated with such an action are addressed under the On Island Electrical Transmission technology in Section 8.1.3 and are not repeated here.

6.7.3.1.1 Surface Water

Effects on surface water from construction of a 5-megawatt solar thermal facility would be the same as those expected for common construction actions as described in Section 3.3.5.

During operations of the solar thermal facility there would be no activities that would have the potential to affect surface waters other than possibly changing the quantities of stormwater runoff from the site as a result of changes in the characteristics of the surface areas. Whether the constructed site would include more or less impermeable surfaces would depend on the nature of the pre-construction site. If the runoff volume were increased, its management would depend on the nature of the specific site (for example, whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns. As noted in [Section 6.7.1.1](#), there could be leaks or accidental releases of the heat transfer fluids (such as synthetic oil or even molten salt) used in the system, which could contaminate stormwater runoff and possibly reach surface waters. Normal operational monitoring would be expected to quickly identify and respond to any such incidents, including stopping the spill or release and cleaning up any soil contamination before stormwater could be affected.

6.7.3.1.2 Groundwater

Effects on groundwater from construction of a 5-megawatt solar thermal facility would be the same as those expected for common construction actions as described in Section 3.3.5.

During long-term operations of the solar thermal facility, impacts to groundwater would be limited primarily to the water needs to operate the facility. Water demand for the facility is estimated at about 600,000 gallons per year, which is only about 1,600 gallons per day. This water demand is assumed to include that necessary to support routine washing of the concentrators in order to maintain their efficiency as well as other facility and personnel needs. This amount of additional groundwater demand is very minor in comparison to the State's total groundwater sustainable yield, which is estimated at about 3.6 billion gallons per day. Accordingly, the water needed for the long-term operation of the system would not be expected to result in water availability issues, but would have to be evaluated on a site-specific basis taking into consideration the groundwater sustainable yield for the applicable Aquifer System Area and the existing groundwater demand from that area.

The operations could be associated with changes in runoff from the site and potentially an associated change in groundwater recharge. However, the area involved is relatively small and, depending on where runoff from the facility goes or how it is managed, the action may simply represent a change in where water soaks into the ground and possibly provides recharge.

6.7.3.1.3 Floodplains and Wetlands

The proponent of a utility-scale, solar thermal energy project would be expected to avoid floodplain and wetland areas if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

6.7.3.2 Best Management Practices and Mitigation Measures

As discussed above, the facility could include onsite measures such as a stormwater detention pond to control stormwater runoff rates as part of the project design to reduce impacts to surface waters. In addition, it is anticipated that the project would implement normal operational monitoring to quickly identify and respond to any such incidents, including stopping the spill or release and cleaning up of any soil contamination from heat transfer fluids during project operations.

To avoid impacts to floodplains and wetlands, it is recommended that floodplains and wetlands be avoided during project siting.

6.7.4 BIOLOGICAL RESOURCES

This section addresses environmental consequences to biological resources from the development of a utility-scale solar thermal power plant. Potential impacts are addressed in terms of terrestrial vegetation and wildlife habitat, threatened and endangered plant and animal species, designated critical habitat, and high value biological resources such as wetlands and protected land areas considering the type, intensity, duration and physical extent of potential impacts.

6.7.4.1 Potential Impacts

Installation of a solar thermal power plant would require clearing 6 to 10 acres for each megawatt of capacity. A representative 5-megawatt capacity plant would require clearing approximately 30 to 50 acres to install the solar heat collectors and associated infrastructure. The amount of land required for larger capacity plants would increase proportionally. The primary impact to biological resources would be clearing and removal of vegetation and loss of wildlife and their habitat. Solar thermal projects are best installed in areas with relatively flat terrain and abundant solar radiation. Those conditions are generally found at lower elevations, particularly the leeward side of the islands. Therefore, native vegetation, threatened and endangered species, and protected land areas, including critical habitat that are found at mid- to upper elevation areas where topography is generally steeper and solar radiation is lower would be avoided. However, important biological resources also occur at lower elevations and depending on specific project locations, impacts from habitat loss could occur to migratory birds, threatened and endangered plant and animals, critical habitat, protected land areas, and wetlands from site development. Project locations near the ocean may also have marine anchialine pools that may occur several hundred meters inland. Site selection that avoids known locations of threatened and species, critical habitat, wetlands, and sensitive biological areas would reduce potential impacts.

6.7.4.2 Best Management Practices and Mitigation Measures

As noted above, during project siting, locations of threatened and species, critical habitat, wetlands, and sensitive biological areas should be avoided to reduce potential impacts to biological resources. Common BMPs for terrestrial environments are identified in Section 3.4.6.

6.7.5 LAND AND SUBMERGED LAND USE

This section describes the potential environmental impacts to land use from solar thermal projects.

6.7.5.1 Potential Impacts

6.7.5.1.1 Land Use

A 5-megawatt solar thermal facility could require approximately 30 to 50 acres of land as well as road access, parking, maintenance facilities, and a potential 1-mile transmission line. The installation of a solar thermal project could result in changed ownership patterns through purchase or land use leases for both the solar thermal project site and any linear corridors required to tie-in to the existing electrical grid. Undeveloped land or land currently used for other uses could be converted to energy uses.

The State land use designations and county overlay zoning criteria would be considered.

6.7.5.1.2 Submerged Land Use

As identified in [Table 6-9](#), there would be no potential impacts to submerged land use from the representative solar thermal project.

6.7.5.2 Best Management Practices and Mitigation Measures

None identified.

6.7.6 CULTURAL AND HISTORIC RESOURCES

6.7.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operational phases of a utility scale, solar thermal power project if effective conservation and BMPs are not implemented. During construction, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6. Any solar thermal facility site selection process would include a detailed environmental impact study, which would include a more detailed evaluation of potential impacts to cultural and historic resources.

6.7.6.2 Best Management Practices and Mitigation Measures

Associated BMPs to reduce potential impacts to cultural, historic, and related natural resources during construction and operation are discussed in Section 3.6.7.

6.7.7 COASTAL ZONE MANAGEMENT

6.7.7.1 Potential Impacts

Development of a solar thermal energy project could require a Federal consistency review to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program. Impacts to special management areas, shorefront access, and affect shoreline erosion would depend on location of the project. Locations near the shoreline would potentially have the most impact. Land clearing could potentially increase runoff and sedimentation with potential impacts on coastal water and habitats.

6.7.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

6.7.8 SCENIC AND VISUAL RESOURCES

6.7.8.1 Potential Impacts

Any proposed project site would experience land clearance activities and require lay-down yards. Depending on efficiency and tracking requirements, a solar thermal facility would require 6 to 10 acres to generate one megawatt of power ([NREL 2013](#)). Therefore, for a 5-megawatt facility, 30 to 50 acres of land would be required. Construction would take approximately 1 year. Potential impacts to visual resources from construction activities are described in Section 3.8.3.

Long-term visual impacts would result from the new facilities that would include parabolic troughs, thermal storage tanks, steam condenser, and a generator as depicted on Figure 2-32. In addition, road access, parking, maintenance facilities, and a transmission tie-in of a least 1 mile would be required. Visual impacts from parabolic trough facilities include glare from heat transfer fluid tubes or related components, geometric patterns of reflected light that create strong scintillations, plumes associated with cooling towers, and reflections from mirror supports and ancillary facilities. A study performed by Argonne National Laboratory's Environmental Science Division found that parabolic trough facilities were found to be easily visible at long distances in both daytime and nighttime observations. In some cases, glare was bright enough to cause strong visual discomfort and temporary after images when observed at distances as far as several miles ([Sullivan et al. 2012](#)). Some observers experienced discomfort from glare at distances of up to 4 miles from an elevated viewpoint. The study concluded that it is likely that glare may have been observable at even longer distances, but it could not be verified because of road access limitations ([Sullivan et al. 2012](#)).

Other visual effects observed included dramatic and rapid changes in the apparent colors and/or reflectivity of the solar collector arrays, depending on the time of day, viewer location, and viewer movement. The parabolic trough facilities exhibited a range of colors from black to silvery white and included blues, grays, browns, and greens. These large color shifts can cause dramatic increase in the visual contrast from the facility. In some cases the color shifts may make the facility blend in with the background more effectively, or make it appear to mimic a natural feature, such as a lake ([Sullivan et al. 2012](#)).

The study found that because of their large size, reflective surfaces, and regular geometry --- under favorable viewing conditions --- even relatively small solar facilities may be visible for long distances, in excess of 20 miles; however, they generally cannot be recognized as solar facilities at these distances and may sometimes blend in with the surrounding landscape. A major conclusion of the study was that the visual experience of the facilities is very dynamic, primarily because of the large number of reflective surfaces. The appearance varies substantially, depending on the horizontal and vertical viewing angle and distance, as well as the time of day, and it may change dramatically as the observer moves, e.g., driving by in a vehicle, or as even short stretches of time elapse ([Sullivan et al. 2012](#)).

Security and other exterior lighting around buildings, parking areas, and other work areas could contribute to light pollution. Maintenance activities conducted at night, such as mirror washing, might require vehicle-mounted lights, which could also contribute to light pollution. Light pollution impacts associated with utility-scale solar facilities include skyglow, light trespass, and glare ([BLM 2013](#)).

6.7.8.2 Best Management Practices and Mitigation Measures

Sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the four designated scenic byways (three on Hawai‘i and one on Kaua‘i); State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System should be considered and avoided when locating a utility-scale solar thermal system. The facility should be sited away from roads and trails to avoid causing offsite glare that may cause annoyance and visual discomfort. Effects on views from nearby mountains, where elevated observation points would afford open views of solar collector fields, as well as potential impacts on the dark night skies that are valued scenic and tourist resources should also be considered.

In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards. Some of the counties’ plans include more detail than others, but all include objectives related to protecting and maintaining open space and scenic resources consistent with the State’s land use designations.

BMPs to minimize impacts to visual resources during construction are addressed in Section 3.8.4. The Bureau of Land Management has outlined the following measures as BMPs to minimize the visual impacts from utility-scale solar projects ([BLM 2013](#)):

- Use dry cooling technology to avoid water vapor plumes
- Site and operate the collectors to avoid offsite glare
- Screen solar collectors to avoid offsite glare with fencing, berms, or vegetation
- Use and maintain non-reflective or color-treated backs and support structures to decrease visual contrast
- Avoid complete removal of vegetation beneath the collectors or consider revegetation consistent with facility operations and safety considerations
- Prohibit commercial messages and symbols on the collectors

In addition, the Federal Aviation Administration and the Hawai‘i Department of Transportation, Airports Division requires review of projects sited near active airports to ensure glare does not interfere with nearby aircraft.

6.7.9 RECREATION RESOURCES

6.7.9.1 Potential Impacts

As mentioned above, any proposed site would undergo land clearing. Potential impacts to recreation resources from construction activities are described in Section 3.9.4.

Long-term impacts to recreation resources would result from access restrictions to the site and potential visual impacts of the new facilities as depicted on Figure 2-32. In addition, road access, parking, maintenance facilities, and a transmission tie-in of a least 1 mile would be required. Visual impacts of solar thermal facilities are described in more detail in [Section 6.7.8](#).

Security and other exterior lighting around buildings, parking areas, and other work areas could contribute to light pollution. Maintenance activities conducted at night, such as mirror washing, might require vehicle-mounted lights, which could also contribute to light pollution. Light pollution impacts could affect nearby recreation areas where a dark night sky is valued, such as campgrounds. This could impact or remove land from current recreational uses.

6.7.9.2 Best Management Practices and Mitigation Measures

Sensitive locations such as recreation areas listed in Appendix A of the *State Comprehensive Outdoor Recreation Plan* should be considered when locating a utility-scale solar thermal system ([DNLR 2009](#)). The facility should be sited away from roads and trails to avoid causing offsite glare that may cause annoyance and visual discomfort. Effects on views from nearby mountains, where elevated observation points would afford open views of solar collector fields, as well as potential impacts on the dark night skies that are valued recreation resources (for example, camping) should also be considered.

BMPs to minimize impacts to recreation resources are addressed in Section 3.9.5. BMPs to minimize impacts to visual resources from utility-scale solar thermal systems are addressed in [Section 6.7.8.2](#) and can minimize impacts to recreation resources where scenic quality is important.

6.7.10 LAND AND MARINE TRANSPORTATION

6.7.10.1.1 Land Transportation

As identified in [Table 6-9](#), there would be no impacts to land transportation from the representative solar thermal project.

6.7.10.1.2 Marine Transportation

As identified in [Table 6-9](#), there would be no potential impacts to marine transportation from the representative solar thermal project.

6.7.11 AIRSPACE MANAGEMENT

6.7.11.1 Potential Impacts

Parabolic trough technology uses relatively low profile equipment that would not create an obstruction to airspace. Contrary to solar PV panels, mirrors and reflectors in concentrated solar power (CSP) facilities are designed for maximum reflection. Reflection from a CSP system could be a potential hazard to both

military and civilian aircraft. Project locations would have to be evaluated in relation to surrounding airspace.

CSP plants that employ a dry cooling system (i.e., air cooled condenser) with large fans that blow air up across the condensers to enhance cooling could produce air turbulence that could be hazardous to aircraft. The potential impact depends on the size of the cooling system and location relative to air traffic. Impacts would likely be limited to low altitude aircraft such as helicopters or take-offs and landings and could be mitigated by appropriately locating facilities.

6.7.11.2 Best Management Practices and Mitigation Measures

As noted above, as part of BMPs, project locations should be evaluated in relation to surrounding airspace to minimize potential hazards to both military and civilian aircraft.

6.7.12 NOISE AND VIBRATION

6.7.12.1 Potential Impacts

Construction of the representative solar thermal project could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

It is not expected that operation of the representative solar thermal project would generate noise that exceeds the acceptable noise levels beyond the site boundaries ([State of Hawai‘i 2011](#)). Long-term noise and vibration impacts from operation of solar thermal systems would be minimal.

6.7.12.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation. See Section 3.12.6.

6.7.13 UTILITIES AND INFRASTRUCTURE

6.7.13.1 Potential Impacts

Effects on each island’s electric utilities typically be small from the addition of 5 megawatts of power generation to any island’s overall power grid. For O‘ahu, with largest island net capacity of 1,756 megawatt, the change would be about 0.3 percent and for Kaua‘i with a net capacity of 125 megawatts the change would be about 4 percent (see Section 3.13.1). Higher percentage change increases the likelihood that the affected island utility would need to adjust management of power on the grid and overall power production. For the smaller grids, such as Lāna‘i or Molokai, a 5 megawatt project would be large and a smaller project should be considered. Impacts from connection to utilities for construction and operation of this representative project would be the same as those described in Section 3.13.3.1. Because of the lower capacity factors for solar power (approximately 20 percent), utilities would need to also implement energy storage technologies or arrange for other base load power sources in times when solar power is not being generated (e.g., night).

6.7.13.2 Best Management Practices and Mitigation Measures

As noted above, for the smaller grids, such as Molokai or Lāna‘i, a 5-megawatt project would be a 40 percent to 50 percent addition and would require the utility to adjust or consider a smaller project. BMPs

for construction would be expected to be implemented to avoid conflicts with existing utilities (see 3.13.4).

6.7.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

6.7.14.1 Potential Impacts

6.7.14.1.1 Hazardous Materials

General hazardous material exposure impacts that could occur prior to and during the installation of a solar thermal system are discussed in Section 3.14.4.

During project operations and maintenance, small quantities of hazardous materials may be periodically used, transported, and disposed of. These hazardous materials would mostly consist of small amounts of fuels, oils, coolants and various other chemicals. In the event of a spill or an accident, minor releases may occur.

6.7.14.1.2 Waste Management

General waste management impacts that could occur prior to and during the installation of a solar thermal system are discussed in Section 3.14.4.

Project operations from concentrated solar power (CSP) technologies such as the parabolic trough may generate substantial amounts of heat transfer fluids (HTFs) and some industrial wastes, such as lubricating oils, compressor oils, dielectric fluids, and hydraulic fluids. As such, proper handling, transport and disposal waste at the appropriately permitted hazardous waste facility would be required for such waste to ensure that no hazardous materials are disposed of at landfills and that hazardous materials do not enter the waste stream.

6.7.14.1.3 Wastewater

Wastewater impacts resulting from the construction and operation of solar thermal collectors would be minimal as most water utilized by the project would be converted into steam to power engine/turbines and generate electricity. Minimal wastewater would be generated from personnel and machinery operations and maintenance. In addition, the project would be required to comply with NPDES wastewater discharge permit requirements during construction and facility operations to regulate facility wastewater discharges.

6.7.14.2 Best Management Practices and Mitigation Measures

BMPs for hazardous materials, waste management, and wastewater services are discussed in Section 3.14.5.

6.7.15 SOCIOECONOMICS

6.7.15.1 Potential Impacts

Socioeconomic impacts in Hawai'i arising from construction and operating a 5-megawatt solar thermal facility would be very small. The solar collectors and associated apparatus could be manufactured in Hawai'i and hence, the economic benefits associated with the manufacturing would accrue within the State. The number of jobs associated with the manufacture of the solar collectors, the construction of the facility, and the number of jobs to operate and maintain the plant would be very small. Approximately 10

temporary construction workers would be needed for a period up to twelve months and 10-15 positions would be created to operate the facility. Jobs directly associated with the manufacture of the solar collectors, construction of the solar thermal facility, and operation of the facility would be likely filled by individuals residing within the area of influence (the State of Hawai'i) and not by workers migrating to the State to fill those positions. The representative project would not create many new net jobs. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and county government sector; to rental housing; and to personal income would be very small.

6.7.15.2 Best Management Practices and Mitigation Measures

None noted.

6.7.16 ENVIRONMENTAL JUSTICE

6.7.16.1 Potential Impacts

The potential environmental impacts to the general population associated with a 5-megawatt solar thermal facility are expected to be small. The potential for environmental justice impacts also would be small.

6.7.16.2 Best Management Practices and Mitigation Measures

Any solar thermal facility site selection process would include a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

6.7.17 HEALTH AND SAFETY

6.7.17.1 Potential Impacts

Common health and safety impacts for typical construction and operations activities are identified in Section 3.17.3. There would not be any unique hazards or accident scenarios associated with solar thermal energy projects.

6.7.17.2 Best Management Practices and Mitigation Measures

Common health and safety BMPs for typical construction and operations activities are identified in Section 3.17.3.

6.8 Wind (Land-Based)

The representative utility-scale, onshore wind project is the construction and operation of a 25-megawatt facility consisting of ten 2.5-megawatt wind turbines (see Section 2.3.3.9.4). If the scope of the representative project were scaled smaller or larger, the number of wind turbines would decrease or increase by the same factor.

[Table 6-10](#) present a summary of the potential environmental impacts for the representative utility-scale, onshore wind project, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology; and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 6-10. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Land-Based) Systems

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	General construction impacts from land disturbance/soil erosion (see Section 3.1.3). No operational impacts.	Same as those common across construction projects (see Section 3.1.4).
Climate and Air Quality		
Air Quality	General construction impacts (see Section 3.2.4). No operational impacts.	Same as those common across construction projects (see Section 3.2.5).
Climate Change	Potential greenhouse gas emissions reduction from a mix of cleaner technologies used to produce electricity.	None.
Water Resources		
Surface Waters	General construction impacts (see Section 3.3.5). Potential impacts from power pole installation to the nearest electrical grid are discussed in Section 8.1.3, On Island Electrical Transmission. Potential for increased stormwater runoff as a result of increased impermeable surfaces (wind turbine foundations, electrical support buildings, and paved roads or parking areas) – (site-specific).	Same as those common across construction projects (see Section 3.3.6).
Groundwater	General construction impacts (see Section 3.3.5).	Same as those common across construction projects (see Section 3.3.6).
Floodplains and Wetlands	General construction impacts (site-specific) (see Section 3.3.5).	Same as those common across construction projects (see Section 3.3.6).

Table 6-10. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Land-Based) Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Biological Resources		
	<p>General construction and operation impacts (see Section 3.4.5).</p> <p>Potential impacts to biological resources including loss of vegetation and wildlife (migratory birds, threatened and endangered plants and animals, critical habitat, and other high value areas such as wetlands and native plant communities) from site development (site-specific).</p> <p>Potential for mortality of avian species and bats (site-specific).</p> <p>Potential impacts to seabirds by attracting/disorienting them from onsite lighting.</p>	<p>General construction and operation BMPs (see Section 3.4.6).</p> <p>Minimize lighting during construction and operations.</p> <p>Avoidance of sites with threatened and endangered species and critical habitat, areas of high bird or bat concentrations such as nesting sites or roost trees, and landscape positions along flight paths would reduce additional mitigation actions.</p> <p>Re-vegetation of construction disturbances and controlling invasive species as necessary.</p> <p>Adjust the cut-in speed to reduce blade rotation at low wind speeds and reduce the probability of mortalities.</p> <p>Develop a Bird and Bat Conservation Strategies (BBCS) or alternatively a HCP if required under the applicable regulations.</p>
Land and Submerged Land Use		
Land Use	<p>Potential land use impacts including land disturbance during site preparation and turbine installation, as well as access road construction and support structures.</p> <p>Potential conversion of undeveloped land or land with other current land uses for energy use.</p> <p>Potential landownership changes and obtainment of land use easements.</p>	<p>Turbines would be sited in locations that do not have obstructions to the blades.</p> <p>Nearby homes, commercial property; and other land uses would be located outside the fall zone.</p>
Submerged Land Use	None; land-based wind turbines would have no potential effects to submerged land use.	N/A

Table 6-10. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Land-Based) Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Cultural and Historic Resources		
	<p>Common construction and operation impacts to cultural resources (see Section 3.6.6).</p> <p>The visual impact of wind turbines may be unacceptable near cultural and historic areas.</p> <p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	<p>Common construction and operation BMPs for cultural resources (see Section 3.6.7).</p>
Coastal Zone Management		
	<p>Potential impacts to designated special management areas, shorefront access, and shoreline erosion (site-specific).</p>	<p>Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.</p>
Scenic and Visual Resources		
	<p>General short-term visual impacts during construction including site preparation activities such as clearing, construction of access and onsite roads, equipment laydown areas, installation of turbine foundations, erection of turbines, and connection to the grid (see Section 3.8.3).</p> <p>Potential long-term visual impacts from wind turbine operations including the presence of the wind turbines, movement of the rotor blades, shadow flicker, blade glinting, flashing aviation warning lights (nighttime in particular), roads, vehicles,</p>	<p>Same as those common across construction projects (see Section 3.8.4).</p> <p>Aviation warning lights (usually red flashing lights) are required for towers taller than 200 feet tall.</p> <p>Sensitive locations should be considered when locating a wind turbine project.</p> <p>Each of the islands' general land use plans and associated implementation tools such as zoning ordinances and development standards should be taken into consideration during project siting.</p>

Table 6-10. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Land-Based) Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	<p>and workers conducting maintenance activities.</p> <p>Depending on viewer sensitivity, potential for long-term impacts to viewers nearby due to the strong vertical lines/large sweep of turbines/moving blades that can dominate views or command visual attention.</p> <p>Depending on viewer sensitivity, potential for long-term shadow flicker impacts for viewers close enough to fall within the shadows cast by the turbines.</p>	<p>The Bureau of Land Management has outlined the following measures as BMPs to minimize visual impacts of wind energy facilities (BLM 2013):</p> <ul style="list-style-type: none"> • Consider topography when siting turbines • Cluster or group turbines to break up overly long lines of turbines • Create visual order and unity among clusters • Site turbines to minimize shadow flicker • Use audio visual warning system technology to reduce night sky impacts from red warning lights • Create visual uniformity in shape, color, and size • Use fewer, larger turbines • Use non-reflective coatings on turbines and other facility components • Prohibit commercial messages and symbols on wind turbines • Keep wind turbines in good repair • Clean nacelles and towers • Consult with any National Park System units within the viewshed of the proposed project. • Complete a thorough viewshed analysis to minimize potential impacts to scenic resources. • Conduct local community outreach for wind turbines given Hawai‘i’s scenic beauty and limited landscapes that increase wind farm visibility. • Consider the appropriate color for the wind turbines based on the specific project location. • Consider placing aviation lighting on the ends of a series of towers, as opposed to every individual tower. Slower pulsing or constant marker lighting should be avoided. • New technology that triggers beacons by radar when aircraft is in the vicinity should be considered.

Table 6-10. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Land-Based) Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Recreation Resources		
	<p>General recreation resource impacts during construction (see Section 3.9.4).</p> <p>Potential long-term recreational resource impacts such as access restrictions due to the presence of wind-turbines, movement of the rotor blades, shadow flicker, blade glinting, aviation warning lights, roads, vehicles, and workers conducting maintenance activities.</p> <p>Potential impacts to nearby recreation areas from strong vertical lines of the turbines dominating views and large sweep of moving blades commanding visual attention.</p> <p>Potential intrusion to the natural scenery and viewshed depending on the viewer sensitivity.</p> <p>Potential impacts to the night sky for nearby recreation areas (i.e., campgrounds) from aviating warning lights.</p>	<p>Same as those common across construction projects (see Section 3.9.5).</p> <p>Sensitive locations such as recreation areas in Appendix A of the State Comprehensive Outdoor Recreation Plan (DLNR 2009) should be considered when locating a wind turbine project. Recreation areas that value a dark night sky should also be considered.</p> <p>Each of the six islands general land use plans and associated implementation tools such as zoning ordinances and development standards should be considered during project siting.</p> <p>The proponent should complete a thorough viewshed analysis to minimize potential impacts to recreation resources.</p>
Land and Marine Transportation		
Land Transportation	Potential short-term impacts on roadway traffic during project development (i.e., transportation of wind turbine components such as the blades and turbines to the construction site).	Coordinate transportation of large equipment with local authorities.
Marine Transportation	Minor impacts on marine transportation from shipment via marine cargo ship.	None.
Airspace Management		
	<p>Potential hazards to airspace navigation, both military (training and operations) and civilian (including tourist industry helicopters/fix-winged).</p> <p>Potential impacts to aviation navigation and communication systems such as radar.</p> <p>Potential hazards to aircrafts downwind of rotor-induced turbulence.</p>	<p>During project siting, evaluate project locations relative to defined airspace and relative to radar and other communication systems to identify and mitigate potential impacts.</p> <p>Maintain separation distances and obstacle avoidance to reduce potential hazards to aircraft.</p>

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Environmental Justice		
	Potential environmental justice impacts depending upon siting location.	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.
Health and Safety		
	General construction and operation impacts (see Section 3.17.3).	Same as those common across construction projects (see Section 3.17.5).

6.8.1 GEOLOGY AND SOILS

6.8.1.1 Potential Impacts

Effects on geology and soils from construction/installation of 10 utility-scale wind turbines would be the same as those expected for common construction actions as described in Section 3.1.3. Since the amount of land disturbed would be well over one acre, the permitting requirements described in Section 3.1.3 would be fully applicable.

Construction of a scaled, smaller or larger, wind farm would involve disturbance of a proportionally smaller or greater area of land. The project would be required to obtain a storm water discharge permit, and the same type of BMPs would be implemented independent of the size of the disturbed area and the measures would be equally protective. For a larger project, the longer construction period and the increased number of construction equipment may be associated with a higher probability for spills or leaks of fuel and lubricants from equipment, but the types of precautions normally implemented (for example, response plans, cleanup equipment, secondary containment, etc.) would keep potential for on- or offsite soil contamination at a minimum.

Operation of 10 wind turbines or a greater number of wind turbines would not involve activities that would have the potential to affect geology and soils of the area.

6.8.1.2 Best Management Practices and Mitigation Measures

Consideration of sensitive geology and soil related locations or receptors for construction and operations of a wind farm would be the same as described for common construction projects in Section 3.1.3.

6.8.2 CLIMATE AND AIR QUALITY

6.8.2.1 Potential Impacts

Wind turbines convert the kinetic energy of the wind to mechanical power. A representative utility-scale 25-megawatt facility would consist of ten 2.5-megawatt wind turbines. Capacity factors for several Hawai‘i wind farms range from 45 to 65 percent ([DBEDT 2013](#)). Assuming a 50 percent capacity factor,

the project would provide base load electricity of about 110,000 megawatt-hours per year and could replace electricity requirements from the baseline electrical grid by that same amount.

6.8.2.1.1 Air Quality

This technology could result in impacts commonly associated with general construction activities, which are addressed in Section 3.2.4.

6.8.2.1.2 Climate Change

A replacement of 110,000 megawatt-hours of electricity per year from the baseline electrical grid would reduce oil consumption from electricity generation by about 7.3 million gallons. On O‘ahu, the annual replacement of 110,000 megawatt-hours of electricity would correspond with an annual reduction in greenhouse gas emissions of about 80,000 metric tons CO₂ equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid; EPA 2012a>). On other islands by comparison, the same annual replacement of electricity usage would see an annual reduction in greenhouse gas emissions of about 67,000 metric tons CO₂ equivalent due to a different mix of technologies used to produce electricity on the other islands ([EPA 2012a](http://www.epa.gov/egrid; EPA 2012a)).

Scaled versions of a utility-scale wind turbine project would produce linearly scaled impacts to air quality. For instance, a 50-megawatt wind turbine project would replace electricity usage from the baseline grid by two times that of a 25-megawatt project. The corresponding reduction in greenhouse gases also would be two times that of a 25-megawatt project. Air emissions during construction would also be proportional.

6.8.2.2 Best Management Practices and Mitigation Measures

None noted.

6.8.3 WATER RESOURCES

6.8.3.1 Potential Impacts

6.8.3.1.1 Surface Water

Effects on surface water from construction/installation of ten utility-scale wind turbines would be the same as those expected for common construction actions as described in Section 3.3.5. Effects of installing power poles over a mile distance to the nearest connection to the existing electrical grid would be the same as addressed under the On Island Electrical Transmission technology in Section 8.1.3.

During operations there would be no activities that would have the potential to affect surface waters other than possibly increasing storm water runoff from the site as a result of the new impermeable surfaces (wind turbine foundations, electrical support buildings, and paved roads or parking areas if applicable) that would be at the site. If the pre-construction project site was agricultural land or land with natural vegetation, the completed project site (with concrete pads for the turbine bases and new access roads) could have a higher percentage of impermeable surfaces and accordingly could generate more storm water runoff. Management of this increased volume of runoff would depend on the nature of the specific site (for example, whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns.

Potential impacts to surface waters during construction of a smaller or larger scaled project, would be similar to that of the representative project. The amount of land disturbed would decrease or increase, but the same requirements would be applicable and the same types of BMPs to control storm water discharge would be equally effective. For a larger project, the longer construction period and the increased number of construction equipment may be associated with a higher probability for spills or leaks of fuel and lubricants from equipment, but the types of precautions normally implemented (for example, response plans, cleanup equipment, secondary containment, etc.) would minimize the potential for contaminants to reach surface water. During operations a greater amount of impermeable surfaces associated with a larger wind farm would tend to generate more runoff, but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns. Also, with the amount of open space required between wind turbines, the area would still be largely unchanged from its preconstruction condition.

6.8.3.1.2 Groundwater

Effects on groundwater from construction/installation of ten utility-scale wind turbines would be the same as those expected for common construction actions as described in Section 3.3.5.

During long-term operations of the wind turbines there would be no, or negligible demands for water. The operations would be associated with increased runoff (as described previously) and potentially an associated decrease in groundwater recharge. However, the area involved is relatively small and, depending on where runoff from the facility goes or how it is managed, the action may simply represent a change in where water soaks into the ground and possibly provides recharge.

Potential impacts to groundwater during construction would be as described above for the representative project. More water would be required to support a larger construction effort, but the demand would still be limited primarily to dust suppression and soil compaction uses, so it would be minor.

6.8.3.1.3 Floodplains and Wetlands

The proponent of a utility-scale, wind turbine project would be expected to avoid floodplains and wetlands areas if only to reduce costs and minimize regulatory requirements. This is particularly true of wetland areas since there would likely be an increased occurrence of birds in such areas. However, if they could not be avoided, construction considerations would be the same as described for common construction actions discussed in Section 3.3.5. This is independent of project size and would apply equally to a scaled project.

6.8.3.2 Best Management Practices and Mitigation Measures

As noted above and as part of BMPs, during project siting, it is recommended that floodplains and wetlands be avoided.

6.8.4 BIOLOGICAL RESOURCES

This section addresses environmental consequences to biological resources from the development of utility-scale wind energy. Potential impacts are addressed in terms of terrestrial vegetation and wildlife habitat, threatened and endangered plant and animal species, designated critical habitat, and high value biological resources such as wetlands and protected land areas considering the type, intensity, duration and physical extent of potential impacts.

6.8.4.1 Potential Impacts

Common potential impacts from typical construction and operations activities are identified in Section 3.4.5. The primary impacts to biological resources from developing utility-scale wind energy would be clearing of vegetation for construction of wind turbines and access roads and potential mortality of wildlife species from collisions with the turbine blades. The amount of land required is about 10 acres per megawatt of installed capacity. The actual vegetation temporarily disturbed during construction is approximately 1.7 acres per megawatt and 0.7 acre of permanently disturbed vegetation. A representative project of ten 2.5-megawatt wind turbines (25-megawatt project) would require approximately 250 acres but disturb approximately 43 acres during construction with permanent loss of about 18 acres from project development. These estimates are approximate values and the amount land disturbed will depend on specific site conditions. For example, some locations may have steeper topography between towers and require longer or separate access routes. Some additional clearing of vegetation may occur around the turbine towers to assist in impact monitoring (i.e., surveying for bird or bat mortalities). Potential impacts from the land disturbances on vegetation, wildlife, threatened and endangered plant and animal species, critical habitat, and other high value areas such as wetlands and native plant communities would be a function of the specific project location and the biological resources located on and near the project site. Appropriate evaluations and mitigation would have to be developed on a site specific basis as each potential project site may have different resources.

Mortality of avian species and bats is a primary concern for large utility-scale wind projects. The fauna of Hawai‘i is rich in bird diversity. Different groups of birds have different risks of collision with turbine blades based on individual behavior such as flight height, time of flight (day versus night), and frequency of flight. Project location is an important factor and must be considered from two perspectives. First, the vegetation or habitat surrounding the wind turbines would influence species at risk of mortality. Secondly, the landscape in the region surrounding the project may include habitats (e.g., wetlands, native vegetation communities, critical habitat, seabird nesting colonies) and landscape features (e.g., ridges, cliffs, beaches) that may increase the likelihood that a particular species or group of birds would cross the project site. For example, seabirds frequently fly between nesting colonies and ocean foraging sites. Water birds may fly between ponds and wetlands. The Hawaiian hoary bat moves between roosting trees and foraging areas. Migratory birds may arrive from northern breeding ranges along the northern coasts of the islands.

The USFWS has prepared onshore wind energy guidelines to assist with developing wind projects and minimizing potential impacts to birds and bats ([USFWS 2012](#)). The guidelines use a tiered approach for assessing potential adverse effects to species of concern and their habitats. The tiered approach is an iterative decision-making process for collecting information in increasing detail; quantifying the possible risks of proposed wind energy projects to species of concern and their habitats; and evaluating those risks to make siting, construction, and operation decisions.

6.8.4.2 Best Management Practices and Mitigation Measures

Common BMPs for typical construction and operations activities are identified in Section 3.4.6. Potential impacts from the land disturbances on vegetation, wildlife, threatened and endangered plant and animal species, critical habitat, and other high value areas such as wetlands and native plant communities would be function of the specific project location and the biological resources located on and near the project site. Avoidance of sites with threatened and endangered species and critical habitat, areas of high bird or bat concentrations such as nesting sites or roost trees, and landscape positions along flight paths would reduce potential mitigation actions.

Re-vegetation of construction disturbances and controlling invasive species are additional mitigation actions that reduce potential impacts. The location of the project in relation to these regional habitats and landscape feature may influence the potential risk of turbine collisions. Adjusting the cut-in speed to reduce blade rotation at low wind speeds may reduce the probability of mortalities. Onsite lighting could attract and disorient seabirds. Minimizing operational lighting and night-time lighting during construction would mitigate these potential impacts. The project could develop a Bird and Bat Conservation Strategies (BBCS) or alternatively a HCP if required under the applicable regulations. A wind energy project-specific BBCS is an example of a document or compilation of documents that describes the steps a developer could or has taken to apply the wind energy guidelines to mitigate for adverse impacts and address the post-construction monitoring efforts the developer intends to undertake. A developer may prepare a BBCS in stages, over time, as analysis and studies are undertaken and more information is obtained ([USFWS 2012](#)).

6.8.5 LAND AND SUBMERGED LAND USE

6.8.5.1 Potential Impacts

6.8.5.1.1 Land Use

The representative project would be to construct and operate a 25-megawatt facility comprised of ten 2.5-megawatt wind turbines. Each turbine would be on a horizontal axis unit, with a 390-foot rotor (the blade lengths are about 190 feet). The rotors would be mounted on a 360-foot monopole.

The land required for the entire project would be about 250 acres. Within the 250 acres, the land that would be permanently disturbed (under turbine areas, roads, and other structure footprints) is about 17.5 acres. The site would be disturbed during site preparation and turbine installation, as well as access road construction, and support structures. The turbines would need to be sited in locations that do not have obstructions to the blades.

Undeveloped land or land with other current land uses would be converted to energy uses. A tie-in to the existing transmission grid is assumed to be 1 mile. Landownership changes could be possible as well as obtaining land use easements.

6.8.5.1.2 Submerged Land Use

As identified in [Table 6-10](#), there would be no potential impacts to submerged land use from the representative utility-scale, onshore wind project.

6.8.5.2 Best Management Practices and Mitigation Measures

Common BMPs for typical construction activities are identified in Section 3.5.3. Nearby homes, commercial property; and other land uses would be required to be outside the fall zone. The fall zone is an area in which a turbine could conceivably land if it were to topple.

6.8.6 CULTURAL AND HISTORIC RESOURCES

6.8.6.1 Potential Impacts

Adverse impacts could potentially occur to cultural, historic, and related natural resources during construction and operation of the representative utility-scale, onshore wind power project if effective conservation and BMPs are not implemented. Of particular importance in Hawai‘i is the potential visual

impact of wind turbines that might be unacceptable near cultural and historic areas where the historic integrity (setting, feeling, association, viewsheds) plays an important role in the value of the resource.

During construction, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6. Any land-based wind facility site selection process would include a detailed environmental impact study, which would include a more detailed evaluation of potential impacts to cultural and historic resources.

6.8.6.2 Best Management Practices and Mitigation Measures

Associated BMPs to reduce potential impacts to cultural, historic, and related natural resources during construction and operation are discussed in Section 3.6.7.

6.8.7 COASTAL ZONE MANAGEMENT

6.8.7.1 Potential Impacts

Development of a utility-scale wind energy project could require a Federal consistency review to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program. Impacts to special management areas, shorefront access, and affect shoreline erosion would depend on project location.

6.8.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

6.8.8 SCENIC AND VISUAL RESOURCES

6.8.8.1 Potential Impacts

Approximately 250 acres of land would be required for the 25-megawatt facility consisting of ten 2.5-megawatt wind turbines. Short-term visual impacts during construction would include site preparation activities such as clearing; construction of access and onsite roads; equipment laydown areas; installation of turbine foundations; erection of the turbines; and connection to the grid at a distance of 1 mile from the edge of the 50-acre property. Potential impacts to visual resources from construction activities are addressed in Section 3.8.3.

Long-term visual impacts associated with operations include the presence of the wind turbines, movement of the rotor blades, shadow flicker, blade glint or glare, aviation warning lights, roads, vehicles, and workers conducting maintenance activities. The ten turbines would be horizontal axis units, with a 390-foot rotor diameter (the blade lengths are about 190 feet), and would be mounted on monopoles, 360 feet tall. Aviation warning lights would be required because the towers are more than 200 feet tall. Normally these are red flashing lights and are not required on every turbine. For nearby viewers, the strong vertical lines of the turbines could dominate views and the large sweep of the moving blades may command visual attention. The visual impact of a wind turbine depends, to some extent, on the sensitivity of the viewer. Some individuals consider the aerodynamic design of the turbines graceful and modernistic, while others feel they are an unnatural intrusion to the natural scenery and viewshed.

Shadow flicker zones occur when the blades of a wind turbine cast a rapidly moving shadow on a residence or other structure. Shadow flicker zones vary by time of day and by season as the sun angle changes in relation to the wind turbine. Because of the low sun angle at dawn and dusk, shadows can extend over longer distances in the morning and evening. Rapidly moving shadows or flickering shadows can create an unpleasant indoor environment for those nearby and may be considered a nuisance when cast upon sensitive receptors including residences, schools, or hospitals. The type of turbine, landscape features, latitude, weather, and wind energy generation facility layout are all factors that would impact shadow flicker and blade glint and glare ([Fortin et al. 2013](#)).

Short- and long-term impacts for a larger project would be similar to those above but greater in magnitude. If the scope were increased by some factor, the number of wind turbines, the land required for the entire project, the land permanently disturbed, and the land temporarily disturbed would all increase by about the same order of magnitude. The strong vertical lines of the towers and the movement of the blades of more turbines would be more likely to command visual attention. In addition, the red warning lights on a greater number of turbines would cause greater visual impacts as compared to fewer blinking lights for a smaller project. However, typically lights are not required on every turbine in a wind farm or installation. The number of lighted turbines would depend on the arrangement of the turbines.

6.8.8.2 Best Management Practices and Mitigation Measures

As part of BMPs, sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the four designated scenic byways (three on Hawai‘i and one on Kaua‘i); State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System should be considered and avoided when locating a wind turbine project.

In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards. Some of the counties’ plans include more detail than others, but all include objectives related to protecting and maintaining open space and scenic resources consistent with the State’s land use designations.

The Bureau of Land Management has outlined the following measures as BMPs to minimize visual impacts of wind energy facilities ([BLM 2013](#)):

- Consider topography when siting wind turbines
- Cluster or group turbines to break up overly long lines of turbines
- Create visual order and unity among turbine clusters
- Site wind turbines to minimize shadow flicker
- Relocate turbines to avoid visual impacts
- Use audio visual warning system technology to reduce night sky impacts from red warning lights

- Create visual uniformity in shape, color, and size
- Use fewer, larger turbines
- Use non-reflective coatings on turbines and other facility components
- Prohibit commercial messages and symbols on wind turbines
- Keep wind turbines in good repair
- Clean nacelles and towers

Other BMPs specific to wind energy facilities include:

- Consult with any National Park System units within the viewshed of the proposed project.
- Complete a thorough viewshed analysis to minimize potential impacts to scenic resources. Local community outreach is also a priority for wind turbines, given Hawai‘i’s scenic beauty and limited landscapes that increase wind farm visibility. Proper outreach includes providing accurate visual simulations of the project to local community groups, leaders, and neighborhood boards. Developers may need to adjust their project. This could include visuals for night and day operations, as the required aviation safety (red) lighting has been described as an environmental impact. Thorough viewshed analysis may also include additional simulations and mapping at distances farther than the standard 5-mile and 10-mile potential impact radius. A 20-mile radius or larger may be required for visual simulations and visibility mapping for areas visible from NPS units. Mapping radii and visual simulation distances should be decided in consultation with NPS and other Federal agencies.
- Consider the appropriate color for the wind turbines based on the specific project location. White can be visually intrusive in some locations; a muted gray or other color may be better to help blend the turbines into the sky or surroundings.
- Consider placing aviation lighting on the ends of a series of towers, as opposed to every individual tower. Lower intensity or density lighting on the intervening towers may also be an option in lieu of the highest intensity lighting on each tower. Slower pulsing or constant marker lighting should be avoided. New technology that triggers beacons by radar when aircraft is in the vicinity should be considered.

6.8.9 RECREATION RESOURCES

6.8.9.1 Potential Impacts

Approximately 250 acres of land would be required for a 25-megawatt facility consisting of ten 2.5-megawatt wind turbines. Potential impacts to recreation resources from construction activities are addressed in Section 3.9.4.

Long-term impacts to recreation resources associated with operations include access restrictions due to the presence of the two wind turbines, movement of the rotor blades, shadow flicker, blade glinting, aviation warning lights, roads, vehicles, and workers conducting maintenance activities. For nearby recreation users, the strong vertical lines of the turbines could dominate views and the large sweep of the moving blades may command visual attention. Shadow flicker could occur for those individuals close enough to fall within the shadows cast by the turbines. Some recreation users may feel that the wind turbines are an unnatural intrusion to the natural scenery and viewshed. Aviation warning lights would impact the night sky for nearby recreation areas, such as campgrounds.

Short- and long-term impacts for scaled larger project would be similar to those above but greater in magnitude. If the scope were increased by some factor, the number of wind turbines, the land required for the entire project, the land permanently disturbed, and the land temporarily disturbed would all increase by about the same order of magnitude. The strong vertical lines of the towers and the movement of the blades of more turbines would be more likely to command visual attention. In addition, a greater number of red warning lights would be required for more turbines. However, not all wind turbines within an installation or farm need to be lighted. The number of lighted turbines would depend on the arrangement of the turbines. These blinking lights would cause impacts to the night sky for nearby recreation areas, such as campgrounds.

6.8.9.2 Best Management Practices and Mitigation Measures

Sensitive locations such as recreation areas in Appendix A of the *State Comprehensive Outdoor Recreation Plan (DLNR 2009)* should be considered when locating a wind turbine project. Recreation areas that value a dark night sky should also be considered. In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards.

BMPs to minimize impacts to recreation resources are addressed in Section 3.9.5. In addition the BMPs for visual impacts in [Section 6.8.8.2](#) should be implemented. The proponent should complete a thorough viewshed analysis to minimize potential impacts to recreation resources. Local community outreach is also a priority for wind turbines, given Hawai'i's scenic beauty and limited landscapes that increase wind farm visibility. Proper outreach includes providing accurate visual simulations of the project to local community groups, leaders, and neighborhood boards. Developers may need to adjust their project. This could include visuals for night and day operations, as the required aviation safety (red) lighting has been described as an environmental impact. Thorough viewshed analysis may also include additional simulations and mapping at distances farther than the standard 5-mile and 10-mile potential impact radius. A 20-mile radius or larger may be required for visual simulations and visibility mapping for areas visible from NPS units. Mapping radii and visual simulation distances should be decided in consultation with NPS and other Federal agencies. In addition, consultation should be conducted for site-specific wind energy development with any National Park System units within the viewshed of the proposed site.

6.8.10 LAND AND MARINE TRANSPORTATION

6.8.10.1 Potential Impacts

6.8.10.1.1 Land Transportation

Development of utility-scale wind energy on the islands would have minimal impact on land transportation. Transportation of wind turbine components such as the blades and turbines to the construction site would have short-term impacts on road traffic.

6.8.10.1.2 Marine Transportation

Development of utility-scale wind energy on the islands would have minimal impact on marine transportation. Wind turbine components would likely be shipped via marine cargo ship. The amount of added cargo handling created by wind turbine components would not substantially impact the marine transportation system or harbor operations.

6.8.10.2 Best Management Practices and Mitigation Measures

None noted.

6.8.11 AIRSPACE MANAGEMENT

6.8.11.1 Potential Impacts

Utility-scale wind turbines, towers, and rotor blades often exceed 200 feet and would require an FAA obstruction to navigation determination. Because of their height, wind turbines are a potential hazard to airspace navigation, both military and civilian. Hawai‘i also has an abundance of lower altitude aviation associated with the tourist industry (both helicopter and fix-winged) and military training and operations (helicopters) that could be impacted by wind turbines. Project locations relative to defined airspace will be important in mitigating potential impacts.

Wind turbines could also impact aviation navigation and communication systems such as radar. This impact is a concern for both civilian and military aviation operations. Location of wind turbines relative to radar and other communication systems may require evaluation to identify and mitigate any potential impacts.

Rotor-induced turbulence downwind from a wind turbine could pose a hazard to aircraft. However, the turbulence would likely not be any different than from other large structures such as buildings and could be mitigated by maintaining separation distances and obstacle avoidance.

6.8.11.2 Best Management Practices and Mitigation Measures

As noted above, the project’s location relative to defined airspace will be important in mitigating potential impacts. In addition, as part of BMPs, the project would require an FAA obstruction to navigation determination to minimize potential hazards to both military and civilian airspace navigation.

6.8.12 NOISE AND VIBRATION

6.8.12.1 Potential Impacts

Short-term noise and vibration impacts would result from construction of ten 2.5-megawatt utility-scale wind turbines. Construction would last about one year.

Wind turbines operate when wind conditions are favorable, day or night. Wind turbines generate both aerodynamic sounds (generated by the blades passing through the air) and mechanical noise (generated from the turbine’s internal gears). Depending on the wind turbine design and wind speed, the aerodynamic noise produces a repetitive sound that may seem like a buzzing, whooshing, or pulsing. Wind turbine noise is present at all frequencies, which includes infrasound (low frequency sound inaudible to the human ear), frequencies in the audible range for humans, and high frequencies. Infrasound is inaudible to the human ear and its effects on humans are not well understood ([NRC 2007](#)). This unheard sound may cause human annoyance, sensitivity, disturbance, and disorientation, and the effects on birds, bats, and other wildlife may be more profound ([USFWS 2011](#)). Frequency varies with wind speed, blade pitch, and blade speed, and wind turbines can have different acoustics on different days even at the same wind speed ([NREL 2012](#)). Additionally, the noise the human ear can detect from a wind turbine is dependent on background noise levels. Noise would be more audible at lower levels in rural areas compared to urban areas. As wind speed increases, the wind itself masks the increasing turbine noise ([BLM 2005](#)).

Operational noise levels produced by each 2.5-megawatt utility-scale wind turbine would be 106 dBA at the source at standard power. Combined noise levels from multiple turbines should be estimated. Different arrangements of multiple wind turbines (for example, in a line or in clusters) would result in different noise levels; however, the resultant noise levels would not vary by more than 10 dB ([BLM 2005](#)). Continuous and long-term noise levels in excess of 65 dBA are normally unacceptable for noise-sensitive land uses such as residences, schools, churches, and hospitals (see Section 3.12). Long-term noise and vibration impacts would depend on the location of the wind turbine and compatibility with the existing land uses.

6.8.12.2 Best Management Practices and Mitigation Measures

Nearby sensitive receptors for noise and vibration near proposed sites for a new utility-scale wind farm should be considered to avoid potential impacts to these locations.

Noise and vibration impacts should be considered when siting a utility-scale wind farm. Developers must comply with Federal, State, and county noise regulations and ordinances. Available noise and vibration data should be referenced and noise studies are recommended to develop expectations regarding operational noise levels before installation. Conduct wind study to determine if predicted noise levels would be masked by wind noise.

Manufacturers may also mitigate noise levels through the use of noise reduction materials and soundproofing techniques when designing and retrofitting wind turbines and wind farms. Mitigation through design for mechanical sounds can include special finishing of gear teeth, using low-speed cooling fans and mounting components in the nacelle instead of at ground level, adding baffles and acoustic insulation to the nacelle, using vibration isolators and soft mounts for major components, and designing the turbine to prevent sounds from being transmitted into the overall structure. Efforts to reduce aerodynamic sounds include the use of lower tip speed ratios, lower blade angles of attack, upwind rotor designs, variable speed operation and most recently, the use of specially modified blade trailing edges.

6.8.13 UTILITIES AND INFRASTRUCTURE

6.8.13.1 Potential Impacts

Effects on each island's electric utilities would typically be small from the addition of 25 megawatt of power generation to any island's overall power grid. For O'ahu, with largest island net capacity of 1,756 megawatt, the change would be about 1.4 percent (see Section 3.13.1). For islands with a smaller net capacity, the project would need to be sized to match the particular needs. Impacts from connection to utilities for construction and operation of this representative project would be the same as those described in Section 3.13.3.1, as applicable.

6.8.13.2 Best Management Practices and Mitigation Measures

BMPs for construction would be expected to be implemented to avoid conflicts with existing utilities (see Section 3.13.4).

6.8.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

6.8.14.1 Potential Impacts

6.8.14.1.1 Hazardous Materials

As indicated in [Table 6-10](#), the representative onshore wind project would not result in hazardous material exposure impacts other than those associated with general construction activities. Additional discussion is provided in Section 3.14.4.

Potential hazardous material exposure impacts may occur from the use of batteries for energy storage, which is discussed in Section 8.5.14.

6.8.14.1.2 Waste Management

As indicated in [Table 6-10](#), the representative onshore wind project would result in minimal impacts to waste management as a result of general construction activities. Additional discussion is provided in Section 3.14.4.

Potential waste management impacts may occur from the decommissioning of the wind turbines and during the disposal of the batteries used for energy storage. Consideration should be given to those landfills currently at capacity or are pending expansion—particularly on the islands of O‘ahu and Hawai‘i. Additional discussion is provided in Section 3.14.4.

Waste management impacts from the disposal of the batteries used for energy storage are provided in Section 8.5.14.

6.8.14.1.3 Wastewater

As indicated in [Table 6-10](#), the representative onshore wind energy project would not result in impacts to wastewater services. Water use would be relatively minor (for dust control measures and that used in the formulation of concrete for footings).

6.8.14.2 Best Management Practices and Mitigation Measures

BMPs for hazardous materials, waste management, and wastewater are discussed in Section 3.14.5.

6.8.15 SOCIOECONOMICS

6.8.15.1 Potential Impacts

Socioeconomic impacts in Hawai‘i arising from ten 2.5-megawatt land based wind turbines on a scale utilized by an electric utility company would be very small. The turbines, rotor and blades, and mounting poles would likely be manufactured outside the State and, if so, economic benefits associated with the manufacturing would accrue elsewhere. The number of temporary jobs associated with the installation of the units and the numbers of jobs to monitor, operate, and maintain the units would be very small. Jobs directly associated with the project likely would be filled by individuals residing within the area of influence (the State of Hawai‘i) and not by workers migrating to the State to fill those positions. The representative project would not create many new net jobs. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and county government sector; to rental housing; and to personal income would be very small.

Possible changes to electrical rates for residential, commercial, and industrial users and changes in the consumption of electricity that could occur from changes in rates associated with utility land based wind turbines were not evaluated.

Similar to the representative project, a scaled project would also result in relatively few new jobs and therefore would not result in any noticeable socioeconomic impacts.

6.8.15.2 Best Management Practices and Mitigation Measures

None noted.

6.8.16 ENVIRONMENTAL JUSTICE

6.8.16.1 Potential Impacts

The representative utility-scale, land-based wind energy project could result in a higher potential for environmental justice impacts due to the larger-scale aspect of the facility and the possibility that the facility could be located in a rural area considered important to minority or low-income populations (especially Native Hawaiians). In order to evaluate the potential environmental justice-related impacts, potential projects would require an understanding of location and scale of facilities, the proximity to minority and low-income populations, and range of potential impacts expected.

6.8.16.2 Best Management Practice and Mitigation Measures

Any utility-scale, onshore wind project site selection process would include a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

6.8.17 HEALTH AND SAFETY

6.8.17.1 Potential Impacts

Workers have the potential to be injured or killed during construction, operation, and decommissioning of wind turbines through industrial accidents such as falls, fires, and dropping or collapsing equipment. Such accidents are uncommon in the wind industry and are avoidable through implementation of proper safety practices and equipment maintenance.

Collapse of a turbine or breakage (and throwing) of one or more turbine blades is possible, but both are very unlikely occurrences. Debris falling from these occurrences would likely be limited to a calculated fall zone, which is defined to approximate the area around the base of the turbine that would likely receive the tower and turbine if it were to fall.

A potential nuisance health effect of operating wind turbines is shadow flicker and blade glint and glare. These terms refer to the phenomenon that occurs when the moving blades of wind turbines cast moving shadows (shadow flicker) or reflections (blade glint or glare) that cause a flickering effect. This can be viewed by observers as either brief changes in brightness in an indoor environment or by moving shadows on the ground in an outdoor environment. The type of turbine, landscape features, latitude, weather, and wind energy generation facility layout are all factors that would impact shadow flicker and blade glint and glare ([Fortin et al. 2013](#)). While studies have found that shadow flicker may result in the potential for epileptic seizures for those suffering from photosensitive epilepsy ([Fortin et al. 2013](#)), the American Wind Energy Association has refuted that finding, noting that “shadow flicker from utility

scale wind turbines occurs much more slowly than the ‘light strobing’ associated with seizures” ([AWEA 2010](#)). [Harding et al. \(2008\)](#) reported that flickers with a frequency greater than 3 hertz, i.e., a light flashing at a rate of more than 3 times per second, could potentially induce photosensitive seizures. A wind turbine with three blades would have to make a full revolution every second (or 60 revolutions per minute) to reach a frequency of 1 hertz, and large wind turbines operate at a much slower rate.

Effects on public safety services from construction and operation of the representative project would be the same as those as described in Section 3.13.3.2.

6.8.17.2 Best Management Practices and Mitigation Measures

Employ safety BMPs to avoid impacts from standard industrial hazards. Consider the fall zone of the individual turbines when siting the facilities and attendant structures.

6.9 Wind (Offshore)

The representative utility-scale, offshore wind project is the construction and operation of a 50-megawatt facility consisting of ten 5-megawatt wind turbines (see Section 2.3.3.10.4). The wind turbines would be deployed over an area of about 3.9 square miles, about 4.3 nautical miles (5 miles) from the shoreline and away from the nearshore environment in water with a depth greater than 200 feet on a floating platform with a semi-submersible design. If the scope of the representative project were increased, the number of wind turbines and the area required for the entire project would all increase by roughly the same factor.

[Table 6-11](#) present a summary of the potential environmental impacts for the representative utility-scale, offshore wind project, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 6-11. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Offshore) Systems

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	General onshore construction impacts from land disturbance/soil erosion (see Section 3.1.3). Potential impacts to marine sediments (i.e., natural migration of sand, etc.) from anchor/mooring devices, undersea cables, and land/sea transition zones (see Section 8.2.1). No operational impacts.	General onshore construction BMPs (see Section 3.1.3). Conduct horizontal directional drilling in areas of good stability.

Table 6-11. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Offshore) Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Climate and Air Quality		
Air Quality	<p>General construction impacts (see Section 3.2.4).</p> <p>Potential increased criteria pollutants from construction equipment including marine vessels (powered by fossil fuels i.e., diesel, or gasoline) during construction.</p> <p>Potential for fugitive dust at nearby onshore construction related areas.</p>	<p>Same as those common across construction projects (see Section 3.2.4).</p>
Climate Change	<p>Potential greenhouse gas emissions reduction from a mix of cleaner technologies used to produce electricity.</p>	<p>None.</p>
Water Resources		
Surface Waters	<p>General construction impacts including horizontal directional drilling for electrical cables and for the construction of a substation (see Section 3.3.5).</p> <p>No potential onshore effects during operations.</p> <p>Potential for increased turbidity at breakout point from drilling mud or slurries used during horizontal directional drilling.</p> <p>Potential impacts to coral or other bottom communities of concern from high turbidity (site-specific).</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p> <p>Devices such as silt curtains could be deployed in specific locations such as the HDD breakout point to help reduce potential impacts.</p> <p>Schedule project activities during seasonal periods when wave, current, and wind are expected to be at lows.</p>
Groundwater	<p>General onshore construction impacts (see Section 3.3.5).</p> <p>No operational impacts.</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p>
Floodplains and Wetlands	<p>General construction impacts (site-specific) (see Section 3.3.5).</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p> <p>To the extent feasible, avoid siting the project location in a floodplain or wetland.</p> <p>Activities involving discharges of dredged or fill materials into the waters of the U.S. require a Section 404 permit (for the placement of the wind turbine anchoring devices and cables on the ocean side of the system and those actions which are conducted within the territorial seas—area within 3 nautical miles of the shore).</p>

Table 6-11. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Offshore) Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Biological Resources		
	<p>General construction impacts (site-specific) (see Section 3.4.5).</p> <p>Potential disturbance impacts to the ocean floor and marine communities/ habitats (i.e., coral reefs, shallow benthic communities, seagrasses, beaches, and possibly marine pools) during installation of anchors, undersea cables (site-specific).</p> <p>Potential impacts to marine animals from temporary construction noise impacts.</p> <p>Potential for increase in marine mammal collisions from ships and boats during construction.</p> <p>Potential increase for hazards to marine mammals congregating in marine subsurface structures.</p> <p>Potential for increased collision hazard for large marine mammals (i.e., whales) from mooring cables.</p> <p>Potential hazards (increased risk for mortalities by rotor blade collision) to seabirds in areas surrounding wind turbines due to potential aggregation of forage fish near submarine structures, tower safety lighting, and potential use of aboveground platform structures as resting areas.</p> <p>Potential introduction of an electromagnetic field into the marine environment along the cable resulting in potential impacts to marine mammals with electrosensory systems.</p>	<p>Same as those common across construction projects (see Section 3.4.6).</p> <p>The project shall install anchor points in locations that avoid high value habitats such as coral reef.</p> <p>Use dedicated observers to minimize potential for marine mammal collision during construction.</p> <p>Use HDD in the land/sea transition zone to minimize potential impacts to near shore coral reefs, beaches, and marine pools.</p>
Land and Submerged Land Use		
Land Use	<p>Potential change in local landownership patterns.</p> <p>Potential land disturbance during construction of the tie-in to the existing transmission grid.</p>	<p>Use erosion control and sedimentation guidelines to minimize potential surface land use impacts.</p> <p>Consider State land use designations and county overlay zones during project siting.</p>
Submerged Land Use	Potential impacts to sea floor requiring a submerged lands lease (see Section 8.2.5).	Incorporate BMPs associated with undersea cable (see Section 8.2.5).

Table 6-11. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Offshore) Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Cultural and Historic Resources		
	<p>Common construction and operation impacts to cultural resources (see Section 3.6.6).</p> <p>The visual impact of wind turbines may be unacceptable near cultural and historic areas.</p> <p>Potential direct impacts from onshore and offshore construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities. Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	<p>Common construction and operation BMPs for cultural resources (see Section 3.6.7).</p>
Coastal Zone Management		
	<p>Potential impacts to designated special management areas, shorefront access, and shoreline erosion (site-specific).</p>	<p>Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.</p>
Scenic and Visual Resources		
	<p>Potential long-term visual impacts from wind turbine operations including the presence of the wind turbines, the sweeping movement of the blades, lighting for the marine and aviation navigation, and the land/sea transition site.</p> <p>Depending on viewer sensitivity, potential for long-term impacts to viewers due to the strong vertical lines/large sweep of turbines/moving blades that can dominate views or command visual attention.</p>	<p>Same as those common across construction projects (see Section 3.8.4).</p> <p>Conduct local community outreach for wind turbines, given Hawai‘i’s scenic beauty and limited landscapes that increase wind farm visibility. Proper outreach includes providing accurate visual simulations of the project to local community groups, leaders, and neighborhood boards. Developers may need to adjust their project. This could include visuals for night and day operations, as the required aviation safety (red) lighting has been described as an environmental impact.</p>

Table 6-11. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Offshore) Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
		<p>Consider placing aviation lighting on the ends of a series of towers, as opposed to every individual tower. Lower intensity or density lighting on the intervening towers may also be an option in lieu of the highest intensity lighting on each tower. Slower pulsing or constant marker lighting should be avoided.</p> <p>Consider new technology that triggers beacons by radar when aircraft is in the vicinity.</p>
Recreation Resources		
	<p>General recreation resource impacts during construction (see Section 3.9.4).</p> <p>Potential long-term recreational resource impacts including access restrictions due to the presence of the wind turbines, the sweeping movement of the rotor blades, lighting for marine and aviation navigation, and the land/sea transition site.</p>	<p>Same as those common across construction projects (see Section 3.9.5).</p> <p>The proponent should complete a thorough viewshed analysis to minimize potential impacts to recreation resources.</p> <p>To reduce seascape impacts, the project facilities must be sited away from recreation resource areas and viewing locations.</p> <p>Consultation should be conducted for site-specific wind energy development with any National Park System units within the viewshed of the proposed offshore location.</p>
Land and Marine Transportation		
Land Transportation	Potential short-term impacts on roadway traffic during project development (i.e., transportation of wind turbine components such as the blades and turbines to the harbor for transport to the construction site).	Coordinate transfer of larger pieces of equipment with local authorities.
Marine Transportation	Potential navigation hazards to domestic and military marine transportation including to military submarine operations from undersea structures (mooring cables and power lines extending down to the ocean floor)	<p>Review and mark offshore wind platforms under the U.S. Coast Guards Aids to Navigation program.</p> <p>During project siting, locate structures and cables away from major marine shipping routes to minimize potential navigational hazards.</p>

Table 6-11. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Offshore) Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Airspace Management		
	<p>Potential hazards to airspace navigation, both military (military training and operations) and civilian (including tourist industry helicopters/fix-winged aircraft).</p> <p>Potential impacts to aviation navigation and communication systems such as radar.</p> <p>Potential hazards to aircrafts downwind of rotor-induced turbulence.</p>	<p>During project siting, evaluate project locations relative to defined airspace and relative to radar and other communication systems to identify and mitigate potential impacts.</p> <p>Maintain separation distances and obstacle avoidance to reduce potential hazards to aircraft.</p>
Noise and Vibration		
	<p>Short-term noise and vibration impacts to sensitive noise receptors, including potential impacts to marine mammals and sea turtles.</p>	<p>Avoid sensitive receptors for noise and vibration (identified in Section 3.12).</p> <p>Noise avoidance and mitigation measures may be imposed directly as conditions of noise permit issuance.</p> <p>Establish an exclusion zone and soft-start, shutdown, and delay procedures during construction (if a marine mammal or sea turtle approaches or enters an exclusion zone).</p> <p>Conduct visual monitoring during construction.</p> <p>Adhere to temporal restrictions.</p> <p>Use maintained equipment with sound-control devices.</p> <p>Place hydrodynamic foils on the upper half of the mooring line.</p> <p>Requests for Incidental Harassment Authorization must include monitoring and reporting plans.</p> <p>In order to decrease the strum effect, place hydrodynamic foils on the upper half of mooring lines.</p> <p>Manufacturers may also mitigate noise levels through the use of noise reduction materials and soundproofing techniques when designing wind turbines.</p>

Table 6-11. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Wind (Offshore) Systems (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Utilities and Infrastructure		
	<p>General construction impacts (see Section 3.13.3.1).</p> <p>Potential impacts to electric utilities (site-specific) (see Section 3.13.3.1).</p>	<p>For information, see Section 3.13.4.</p>
Hazardous Materials and Waste Management		
Hazardous Materials	<p>General construction impacts (see Section 3.14.4).</p> <p>Potential hazardous materials exposure impacts associated with construction from MRS sites (see Section 8.2.14).</p>	<p>Same as those common across construction projects (see Section 3.14.5).</p>
Waste Management	<p>General construction impacts (see Section 3.14.4).</p> <p>Minimal construction and demolition waste.</p> <p>Potential impacts during the decommissioning and dismantling of the wind turbine as result of turbine removal, and etc.</p>	<p>Same as those common across construction projects (see Section 3.14.5).</p>
Wastewater	<p>Minor and limited wastewater impacts from construction and during operations/maintenance activities from personnel and machinery operations.</p>	<p>None.</p>
Socioeconomics		
	<p>Very small socioeconomic impacts; minimal job and population effects.</p>	<p>None.</p>
Environmental Justice		
	<p>Small potential for environmental justice impacts.</p>	<p>During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.</p>
Health and Safety		
	<p>General construction impacts (see Section 3.17.3).</p> <p>Potential for public health and safety impacts including to boats, both civilian and military marine vessels, and to the public onshore in the unlikely event the device were destroyed, damaged or if the loss of mooring/spatial stabilization were to occur.</p>	<p>Same as those common across construction projects (see Section 3.17.5).</p>

6.9.1 GEOLOGY AND SOILS

The representative utility-scale, offshore wind project would require approximately 1 mile of onshore transmission lines to reach the nearest grid connection, but potential impacts associated with such an action are addressed under the On Island Electrical Transmission technology in Section 8.1.1 and are not repeated here.

6.9.1.1 Potential Impacts

Onshore Activities

Onshore activities for construction of the representative project would consist of horizontal directional drilling to bring the electrical cable from the offshore wind farm in through the sea-to-land transition area. It would also involve construction of a small substation at or near the HDD setup site to condition the power for relay to the electrical grid. Alternatively, the substation could be included on one of the wind turbine platforms. Effects on geology and soils from these actions would be the same as those expected for common construction actions as described in Section 3.1.3.

There would be no impacts to onshore geology or soils during operation of the offshore wind turbine.

Offshore Activities

The ocean-side elements of the offshore wind power project would not involve potential soil-related impacts because of their marine location, but there would be corresponding effects on the marine sediments. For example, anchor devices would be expected to have impacts on the natural migration of sand. Potential impacts to marine sediments from an offshore wind power project would basically be the same as described in Section 8.2.1 for placement of undersea cables and the associated land-sea transition zones for those cables.

Operation of the offshore wind turbines would not be expected to have further impacts on marine sediments beyond those initiated during construction.

6.9.1.2 Best Management Practices and Mitigation Measures

HDD operations that would be involved in installing cables in the land-sea transition zones require an area of good stability. However, a basic premise of the HDD technology (that is, tunneling under areas where surface actions are to be avoided) provides a mechanism to avoid areas that would present difficulties for drilling and subsequent construction.

6.9.2 CLIMATE AND AIR QUALITY

6.9.2.1 Potential Impacts

Wind turbines convert the kinetic energy of the wind to mechanical power. Offshore wind turbines tend to have larger capacities than onshore turbines. A representative utility-scale 50-megawatt facility would consist of ten 5-megawatt wind turbines deployed 4.3 nautical miles from shore and mounted on a 280-foot-long monopole. Assuming a 40 percent capacity factor (Chapter 2), the project would provide base load electricity of about 180,000 megawatt-hours per year and would replace electricity requirements from the baseline electrical grid by that same amount.

6.9.2.1.1 Air Quality

Air quality impacts associated with construction of an offshore utility-scale wind turbine project would be short term, intermittent, and limited to the duration of the construction project. Off-shore installation of wind turbines would not generate fugitive dust at the site of installation, but the construction project could result in land disturbances and related fugitive dust at nearby onshore construction-related areas, including locations where the offshore electrical lines connect with the onshore regional electric grid. Construction equipment, including marine vessels, which are powered by fossil fuels, such as diesel or gasoline, would emit criteria pollutants, small amounts of hazardous air pollutants, and greenhouse gases during the duration of the construction project. These common construction-related impacts to air quality are discussed in Section 3.2.4.

6.9.2.1.2 Climate Change

It is projected that a 50-megawatt offshore wind project would not produce as much electricity per year as a 50-megawatt onshore wind project due to a capacity factor of 40 percent for offshore turbines compared with a capacity factor of between 45 and 65 percent for onshore projects. Consequently, the replacement of electricity from the baseline electrical grid would be less for offshore wind turbines.

A replacement of 180,000 megawatt-hours of electricity per year from the baseline electrical grid would reduce oil consumption from electricity generation by about 12 million gallons per year. On O‘ahu, the annual replacement of 180,000 megawatt-hours of electricity would correspond with an annual reduction in greenhouse gas emissions of about 130,000 metric tons CO₂ equivalent based on EPA eGrid2012 emission factors for estimating greenhouse gas emissions from electricity generation (<http://www.epa.gov/egrid>; EPA 2012a). On other islands by comparison, a similar annual replacement of electricity usage would see an annual reduction in greenhouse gas emissions of about 110,000 metric tons CO₂ equivalent due to a different mix of technologies used to produce electricity on the other islands.

6.9.2.2 Best Management Practices and Mitigation Measures

BMPs for climate and air quality would be the same as those for common construction and operations projects (see Section 3.2.5).

6.9.3 WATER RESOURCES

This section addresses potential environmental consequences to water resources from installation and operation of offshore wind turbines. Potential impacts are addressed in terms of surface water, groundwater, and floodplains and wetlands. The representative project is assumed to require approximately 1 mile of onshore transmission lines to reach the nearest grid connection, but potential impacts associated with such an action are addressed under the On Island Electrical Transmission technology in Section 8.1.3 and are not repeated here.

6.9.3.1 Potential Impacts

6.9.3.1.1 Surface Water

Onshore Activities

Onshore activities for construction of the representative project would consist of horizontal directional drilling to bring the electrical cable from the wind turbine in through the sea-to-land transition area. It would also involve construction of a small substation at or near the HDD setup site to condition the power for relay to the electrical grid. Alternatively, the substation could be included on one of the wind turbine

platforms. Effects on (non-marine) surface water from these actions would be the same as those expected for common construction actions as described in Section 3.3.5.

During operations there would be no activities that would have the potential to affect surface waters. Areas disturbed during construction would be restored to pre-disturbance condition so any long-term changes in runoff quantities would not be expected.

Offshore Activities

At the locations where the HDD would breakout on the ocean floor, the wind turbines would be anchored to the ocean floor, and electrical cables or other conduits were buried between the wind turbines and into the shore, ocean sediments would be disturbed and dispersed to some degree. The drilling mud or slurries used in the HDD could also be released at the breakout point. These dispersed sediments increase turbidity for at least some period of time and, depending on the currents or wave actions at the site, would settle out in different locations, possibly in areas of coral or other bottom communities of concern. Potential impacts to such communities would not only depend on whether they are present near wind turbine deployment sites and the cable installation paths, but also whether they are periodically subjected to naturally occurring high turbidity. Devices such as silt curtains could be deployed in specific locations such as the HDD breakout point to help reduce potential impacts. However, devices such as silt curtains often have limited effects, particularly if wave or current action is high at the site. Correspondingly, another mitigation measure normally considered would be to schedule such project activities during seasonal periods when wave, current, and wind would be expected to be at lows. These potential impacts to marine waters actions are very similar to those described in Section 8.2.3 for placement of undersea cables and the associated land-sea transition zones for those cables.

There would be no expected impacts to marine water quality during operation of the wind turbines.

6.9.3.1.1 Groundwater

Onshore Activities

Effects on groundwater from onshore construction activities would be the same as those expected for common construction actions as described in Section 3.3.5.

During long-term operations of the offshore wind turbines, no impacts to groundwater would be expected.

Offshore Activities

No groundwater impacts would be expected from the offshore activities associated with deployment or operation of the wind turbines.

6.9.3.1.2 Floodplains and Wetlands

Onshore Activities

It is reasonable to assume that the proponent of an offshore wind turbine project would avoid onshore construction in a floodplain or wetland if at all possible, if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

Offshore Activities

A Section 404 permit from the Corps of Engineers would likely be required for the placement of the wind turbine anchoring devices and cables on the ocean side of the system; that is, to the extent such actions are done within the territorial seas (the area within about 3 nautical miles of the shore). Activities involving discharges of dredged or fill materials into the Waters of the U.S. require a Section 404 permit. The

breakout point for the lines (from the HDD) could require placement of fill material to stabilize the location and be subject to a Section 404 permit. Depending on how it was to be performed, the action of burying cables along the ocean floor might be considered excavation and filling all in a single action rather than a discharge of dredged or fill materials, so the Corps may not consider it to be subject to 404 permitting ([Sharples 2011](#)). If there was any question about the applicability of a Section 404 permit, discussion with the Corps of Engineers would be the appropriate course of action.

6.9.3.2 Best Management Practices and Mitigation Measures

BMPs to prevent or minimize impacts to water resources from construction activities are described in Section 3.3.6.

6.9.4 BIOLOGICAL RESOURCES

6.9.4.1 Potential Impacts

Common potential impacts from typical construction and operations activities are identified in Section 3.4.5. Installation of ten large-scale (280 foot tower, 205 foot turbine blades) floating 5-megawatt wind turbines approximately five miles offshore could impact seabirds and the marine environment. The floating platforms would be tethered to the ocean floor with mooring cables and anchors. Installation of anchors would create a small disturbance on the ocean floor during installation. If the three anchor points avoid high value habitats such as coral reefs and are anchored in mud sediments, the potential disturbance impact on the seafloor would be reduced. Potential construction impacts from noise could cause temporary avoidance behavior by marine animals. Many marine species have well developed acoustical communication and may be sensitive to introduced sound. Ships and boats used during construction could temporarily increase potential collisions with marine mammals but could be effectively mitigated using dedicated observers.

The semi-submersible turbine platform structure, cabling, and seafloor anchors would serve as potential surfaces for biofouling organisms, effectively acting as artificial reefs. The subsurface wind turbine structures could serve as fish aggregation devices that attract marine animals. The mooring cables are a potential collision hazard for large marine mammals such as whales. However, the probability of a collision would be low but could increase if marine mammals congregate in the vicinity of the subsurface structures. Tension on the mooring lines would be sufficient to prevent looping and creating an entanglement hazard. The ten turbines would be distributed over approximately four square miles (about one turbine per 250 acres). Collectively as a group the turbine structures could create an area of increased marine activity; increased production of substructures (biofouling), attraction of fish, and then possibly marine mammals. Cable mooring lines could impact marine mammal migration corridors and habitats used for breeding, feeding, resting, and raising young. However, the potential impacts would depend on specific project locations in relation to migration corridors and habitats used for specific life history functions which should be considered during project site selection and evaluated in more detail during project development.

Above water, little is known about the flight patterns and behavior of seabirds at sea and therefore, the probability of mortality by collision with turbine blades is not known. Of concern would be the potential of seabirds to be attracted to the region surrounding the wind turbines because of possible aggregation of forage fish near the turbine submarine structures. Tower safety lighting could be an attractant to seabirds. Following lighting guidelines similar to those for onshore wind turbines could help minimize potential effects. Seabirds are well adapted to life at sea, and it is not known whether seabirds would use aboveground platform structures as resting areas. Any change in the marine environment that would

increase the probability of seabirds flying in the vicinity of the wind turbines could potentially increase the risk of mortalities by rotor blade collisions.

An offshore wind turbine would require an undersea power cable to transmit electricity to shore. Installation of the power cable would disturb marine habitats including coral reefs, shallow benthic communities, seagrasses, beaches, and possibly marine pools. The potential impacts would depend on specific project location and the cable route selected. An HDD would be used in the land/sea transition zone and would minimize potential impacts to near shore coral reefs, beaches, and marine pools. An undersea power cable could introduce an electromagnetic field (EMF) into the marine environment along the cable. Although potential impacts to and responses of marine organisms to EMFs are not fully understood, many marine species such as sharks, marine mammals, sea turtles, and some bony fishes have well developed electrosensory systems that may be involved in orientation, homing, and navigation or life functions such as detection of prey and predators ([Normandeau et al., 2011](#)). The potential strength of the EMF surrounding the cable is a function of the voltage, cable shielding, and whether the cable is buried or laid along the ocean floor. However, the EMF is attenuated fairly quickly with distance from the cable (5 meters) and the potential impact is likely to be negligible ([Normandeau et al., 2011](#)).

6.9.4.2 Best Management Practices and Mitigation Measures

Common BMPs from typical construction and operations activities are identified in Section 3.4.5. BMPs associated with the undersea cable connecting the offshore wind farm to the electrical grid are discussed in Section 8.2.4. BMPs and mitigation measures identified for the off-shore wind include:

- Use dedicated observers during construction to reduce potential collisions between ships and boats and marine mammals
- Follow lighting guidelines similar to those for onshore wind turbines to minimize potential effects to seabirds.
- Use HDD in the land/sea transition zone to minimize potential impacts to near shore coral reefs, beaches, and marine pools.
- During project siting, select an undersea cable route to minimize potential disturbance to marine habitats including coral reefs, shallow benthic communities, seagrasses, beaches, and possible marine pools.

6.9.5 LAND AND SUBMERGED LAND USE

6.9.5.1 Potential Impacts

6.9.5.1.1 Land Use

Onshore land would be acquired through purchase or easement for the tie-in to the existing transmission grid; this could result in a change in local landownership patterns. There would be land disturbance during construction of the tie-in to the grid.

6.9.5.1.2 Submerged Land Use

The installation of mooring lines and the electrical cable to the shoreline would have impacts to the sea floor and local marine habitat.

Regarding the shoreline interface, State land use designations and county overlay zoning would be considered, along with Coastal Zone Management guidelines. A submerged lands lease would be required.

Section 8.2.5 Undersea Cable Corridors, provides additional information on the potential environmental impacts to land and submerged land use.

6.9.5.2 Best Management Practices and Mitigation Measures

Routing of any undersea power cable to connect to the offshore wind facility should avoid or minimize the crossing of existing or planned telecommunication cables. The waters around the islands, especially O‘ahu, also have dumps of subsurface munitions and chemical weapons, which should be avoided. Additional bathymetry studies can assist in defining environmentally sensitive and important areas.

With regard to the potential temporary surface land use impacts, land disturbances would be minimized through the use of erosion control and sedimentation guidelines and the use of HDD. Siting of the sea/land transition sites would also consider State land use designations and county overlay zones.

If there is a need for undersea cables to cross seabed obstructions, especially in areas that are congested with pipelines and/or telecommunication cables, two methods are available for mitigation: 1) concrete mattresses to support the cable above obstructions, and 2) use of protective sleeves over the obstructions.

6.9.6 CULTURAL AND HISTORIC RESOURCES

6.9.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operational phases of a utility scale, floating platform, semi-submersible designed, offshore wind turbine and associated onshore ancillary facilities if effective conservation and BMPs are not implemented. Of particular importance in Hawai‘i is the potential visual impact of wind turbines that might be unacceptable near cultural and historic areas where the historic integrity (setting, feeling, association, viewsheds) plays an important role in the value of the resource.

During construction in onshore, nearshore, and offshore locations, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting and fishing locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6. Any offshore wind facility site selection process would include a detailed environmental impact study, which would include a more detailed evaluation of potential impacts to cultural and historic resources.

6.9.6.2 Best Management Practices and Mitigation Measures

Associated BMPs to reduce potential impacts to cultural, historic, and related natural resources during construction and operation are discussed in Section 3.6.7.

6.9.7 COASTAL ZONE MANAGEMENT

Impacts to coastal zones were evaluated based on the extent to which a project would conflict with the policies of the Hawai'i Coastal Zone Management Program and potentially affect special management areas, shorefront access, and shoreline erosion.

6.9.7.1 Potential Impacts

Development of the utility-scale offshore wind energy project could require a Federal consistency review to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program. The project would require a power cable from the floating turbine platform to land. Depending on the location where the cable crosses the shoreline, the project could impact designated special management areas, restrict shorefront access, and affect shoreline erosion.

6.9.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

6.9.8 SCENIC AND VISUAL RESOURCES

6.9.8.1 Potential Impacts

Ten 5-megawatt wind turbines, with 420-foot rotor diameter (the blade lengths are about 205 feet), would be mounted on 280-foot-long monopoles. The wind turbines would be about 5 miles from the shoreline on floating platforms with a semi-submersible design. The area required for the entire project is assumed to be 3.9 square miles. Connection to the electrical grid would be approximately 1 mile from the nearest shoreline. A land/sea transition zone would be required. Section 8.2 analyzes the potential impacts of land/sea cable transition sites and the undersea cable.

Long-term visual impacts include the turbines themselves, the sweeping movement of the blades, lighting for marine and aviation navigation, and the land/sea transition site. Argonne National Laboratory's Environmental Science Division and the University of Arkansas Center for Advanced Spatial Technology conducted a preliminary assessment of the visibility of offshore wind facilities in the United Kingdom. The facilities studied ranged in size from 25 to 140 turbines ([Sullivan et al. 2012](#)).

Results showed that under favorable viewing conditions, small to moderately sized facilities were visible to the unaided eye at distances greater than 26 miles, with turbine blade movement visible up to 24 miles. At night, aviation navigation lighting was visible at distances greater than 24 miles. The observed wind facilities were judged to be a major focus of visual attention at distances up to 10 miles, were noticeable to casual observers at distances of almost 18 miles, and were visible with extended or concentrated viewing at distances beyond 25 miles ([Sullivan et al. 2012](#)).

[Sullivan et al. \(2012\)](#) also reported that the synchronized sweeping movement of the massive blades during the day and the synchronized flashing of the lighting at night contribute to the facilities' visibility over very long distances. The study showed that even small offshore wind facilities of a few dozen

turbines can be seen easily at distances exceeding 15 miles and that moderately sized facilities of 100 turbines are seen easily at distances of 22 miles or even farther, in a variety of weather and lighting conditions. At distances of 9 miles or less, even isolated, small facilities will likely be a major focus of visual attention in seaward views, again in a variety of weather and lighting conditions. Based on this study, it is likely that 10 wind turbines located 4 miles offshore would be a focus of visual attention. As with onshore wind systems, some individuals would view the turbines in a positive manner, while others would feel they are an unnatural intrusion into the seascape.

Short- and long-term visual impacts of a larger offshore wind facility would be of greater magnitude. The number of wind turbines and the area required for the entire project would all increase by the same order of magnitude. A larger array of wind turbines would provide power that would be collected at one of the platforms where a substation would be located, allowing the run of a single cable (or group of cables placed together) to shore.

6.9.8.2 Best Management Practices and Mitigation Measures

Sensitive locations such as designated scenic byways; State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System should be considered and avoided when locating an offshore wind facility.

Consultation should be conducted for site-specific wind energy development with any National Park System units within the viewshed of the proposed siting location. In addition, a thorough viewshed analysis should be completed to minimize the impacts to scenic resources. Thorough viewshed analysis may include additional simulations and mapping at distances farther than the standard 5-mile and 10-mile potential impact radius. A 20-mile radius or larger may be required for visual simulations and visibility mapping for areas visible from NPS units. Mapping radii and visual simulation distances should be decided in consultation with NPS and other Federal agencies.

Visual impacts of offshore wind turbines would be extremely difficult to mitigate; therefore, to reduce the impacts in a seascape, the facilities must be sited away from sensitive visual resource areas and viewing locations. To minimize impacts from aviation lighting, consider placing lighting on the ends of a series of towers, as opposed to every individual tower. Lower intensity or density lighting on the intervening towers may also be an option in lieu of the highest intensity lighting on each tower. Slower pulsing or constant marker lighting should be avoided. New technology that triggers beacons by radar when aircraft are in the vicinity could be considered.

6.9.9 RECREATION RESOURCES

6.9.9.1 Potential Impacts

The 10 5-megawatt wind turbines would be about 5 miles from the shoreline on floating platforms with a semi-submersible design. Section 8.2 analyzes the potential impacts of land/sea cable transition sites.

Long-term impacts to recreation resources include potential access restrictions to the site of the facility and potential visual impacts of the turbines themselves, the sweeping movement of the blades, lighting for marine and aviation navigation, and the land/sea transition site. Some foundations act as artificial reefs which could enhance recreational fishing.

The synchronized sweeping movement of the massive blades during the day and the synchronized flashing of the lighting at night contribute to the facilities' visibility over very long distances. Potential

visual impacts of offshore wind facilities that could impact recreation resources are described in more detail in [Section 6.9.8](#).

6.9.9.2 Best Management Practices and Mitigation Measures

Sensitive locations such as recreation areas listed in Appendix A of the *State Comprehensive Outdoor Recreation Plan* ([DLNR 2009](#)) should be considered when locating an offshore wind facility. In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards. Visual impacts of offshore wind turbines would be extremely difficult to mitigate, therefore to reduce the impacts in a seascape, the facilities must be sited away from recreation resource areas and viewing locations.

Consultation should be conducted for site-specific wind energy development with any National Park System units within the viewshed of the proposed siting location. In addition, a thorough viewshed analysis should be completed to minimize the impacts to recreation resources. Thorough viewshed analysis may include additional simulations and mapping at distances farther than the standard 5-mile and 10-mile potential impact radius. A 20-mile radius or larger may be required for visual simulations and visibility mapping for areas visible from NPS units. Mapping radii and visual simulation distances should be decided in consultation with NPS and other Federal agencies.

6.9.10 LAND AND MARINE TRANSPORTATION

6.9.10.1 Potential Impacts

6.9.10.1.1 Land Transportation

During project construction, the project would likely result in short-term impacts on roadway traffic during project development (i.e., transportation of wind turbine and transmission line components such as the blades and turbines to the harbor for transport to the construction site).

6.9.10.1.2 Marine Transportation

Development of offshore utility-scale wind energy would create a potential navigation hazard to domestic and military marine transportation. Offshore wind platforms would require review and marking under the U.S. Coast Guards Aids to Navigation program. The undersea structures including the mooring cables and power line extending down to the ocean floor are potential obstacles and hazards to military submarine operations. Locations away from major marine shipping routes would minimize potential navigational hazards.

6.9.10.2 Best Management Practices and Mitigation Measures

Any movement or transport of the large pieces of equipment associated with the offshore wind turbines (either on land or by sea) should be coordinated with the proper authorities to ensure that any traffic issues are minimized.

6.9.11 AIRSPACE MANAGEMENT

6.9.11.1 Potential Impacts

The types of potential impacts to airspace for offshore wind turbines would be similar to those for onshore turbines (see [Section 6.8.11](#)). An FAA obstruction to navigation evaluation would be required.

However, depending on offshore locations, offshore airspace may require evaluation to determine if any airspace classification would be affected. The wind turbines could be a hazard to low elevation aviation such as civilian and non-civilian helicopters and small fixed-wing aircraft. An evaluation also may be required to evaluate potential impacts to radar and communication systems.

6.9.11.2 Best Management Practices and Mitigation Measures

As noted above, as part of BMPs, an FAA obstruction to navigation evaluation would be required as well as an evaluation of potential impacts to radar and communication systems.

6.9.12 NOISE AND VIBRATION

6.9.12.1 Potential Impacts

Short-term noise and vibration impacts would result from construction of ten 5-megawatt offshore wind turbines. Undersea cables would connect the offshore wind facility to a land/sea cable transition site (see Section 8.2.12). Construction noise from equipment and vessels, and vibration caused by pile-driving, could exceed regulatory levels. The large majority of the noise would be attributable to on-shore development including the HDD for the cable and the land/sea transition site. Construction noise could indirectly impact scenic and visual resources, recreation resources, cultural resources, worker health and safety, and possibly public health. Further, according to the Incidental Harassment Authorization ([77 FR 43259, July 24, 2012](#)) exposure to elevated sound levels from vibratory and impact pile driving may result in temporary impacts to marine mammal hearing and behavior. However, in its Biological Opinion, the NMFS stated that it does not expect any takes of marine mammals by injury, serious injury, or mortality ([NMFS 2012](#)). Marine mammal prey species, such as fish, and sea turtles may also be temporarily impacted.

Wind turbines operate when wind conditions are favorable, day or night. Wind turbines generate both aerodynamic sounds (generated by the blades passing through the air) and mechanical noise (generated from the turbine's internal gears). Depending on the wind turbine design and wind speed, the aerodynamic noise produces a repetitive sound that may seem like a buzzing, whooshing, or pulsing. Wind turbine noise is present at all frequencies, which includes infrasound (low frequency sound inaudible to the human ear), frequencies in the audible range for humans, and high frequencies. Infrasound is inaudible to the human ear and its effects on humans are not well understood ([NRC 2007](#)). This unheard sound can cause human annoyance, sensitivity, disturbance, and disorientation, and the effects on seabirds and other wildlife may be more profound ([USFWS 2011](#)). Frequency varies with wind speed, blade pitch, and blade speed, and wind turbines can have different acoustics on different days even at the same wind speed ([NREL 2012](#)). Additionally, the noise the human ear can detect from a wind turbine is dependent on background noise levels. Noise would be more audible at lower levels in rural areas compared to urban areas. As wind speed increases, the wind itself masks the increasing turbine noise ([BLM 2005](#)).

Operation of a utility-scale offshore wind project could potentially result in long-term noise and vibration impacts. Each of the ten representative 5-MW floating wind turbines would produce a noise level of 108 dBA at the source at standard power. Combined noise levels from multiple turbines should be estimated. Different arrangements of multiple wind turbines (for example, in a line or in clusters) would result in different noise levels. At a distance of 5 miles from shore, noise from operation of the wind turbine would decrease to a level that would likely not be detectable or would be barely audible to people on shore. In addition, the turbine noise would be masked by ambient noise (such as wind and waves) and during calm periods, the turbine would spin less or not all, resulting in less or no noise. Each of the ten floating platforms for the wind turbines would be held in place by three freely hanging mooring lines. Mooring

lines create what is called a “strum effect” from the current rushing past the mooring line and causing it to vibrate and hum ([BOEM 2012](#)).

6.9.12.2 Best Management Practices and Mitigation Measures

Noise and vibration impacts should be considered when siting a utility-scale offshore wind project. These BMPs take into account the potential noise associated with the land-sea transition site. The following recommended BMPs could reduce the potential disturbances from noise and vibration ([NMFS 2012](#)):

- temporal restrictions (such as not conducting vibratory pile driving during peak humpback whale season in Hawai‘i);
- establishment of an exclusion zone (a buffer to prevent harassment [injury] of any marine mammal species or sea turtles) during construction and shutdown and delay procedures (if a marine mammal or sea turtle approaches or enters an exclusion zone);
- soft-start procedures during construction (a technique that allows marine mammals or sea turtles to leave the immediate area before sound sources reach maximum noise levels);
- in-situ underwater sound monitoring (sound monitoring during sheet pile and test pile driving);
- visual monitoring (an onsite, biologically trained individual approved in advance to monitor sound during construction); and
- per Marine Mammal Protection Act implementing regulations at [50 CFR § 216.104 \(a\)\(13\)](#), requests for Incidental Harassment Authorization must include monitoring and reporting plans.

Additional BMPs include the following:

- Developers must comply with Federal, State, and county noise regulations and ordinances. Noise permits would be required if noise levels exceed regulatory limits. A noise permit variance would be necessary when permitted noise limits would be exceeded. Noise avoidance and mitigation measures may be imposed directly as conditions of permit issuance.
- In order to decrease the strum effect, place hydrodynamic foils on the upper half of mooring lines.
- Manufacturers may also mitigate noise levels through the use of noise reduction materials and soundproofing techniques when designing wind turbines.

6.9.13 UTILITIES AND INFRASTRUCTURE

This section addresses potential environmental consequences to utilities and infrastructure from construction and operation of a 50-megawatt offshore wind project located 5 miles offshore.

6.9.13.1 Potential Impacts

Effects on each island’s electric utilities would typically be small from the addition of 50 megawatt of power generation to any island’s overall power grid. For O‘ahu, with largest island net capacity of 1,756 megawatts, the change would be about 3 percent (see Section 3.13.1). For islands with a smaller net capacity, the project would need to be sized to match the particular needs. Impacts from connection to

utilities for construction and operation of this representative project would be the same as those described in Section 3.13.3.1, as applicable.

6.9.13.2 Best Management Practices and Mitigation Measures

BMPs for construction would be expected to be implemented to avoid conflicts with existing utilities (see Section 3.13.4).

6.9.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

6.9.14.1 Potential Impacts

6.9.14.1.1 Hazardous Materials

During construction activities, the potential exists for the project to encounter hazardous materials including Munition Response Sites (MRSs) offshore. MRS sites pose safety and hazardous risks as MRS sites include munitions and explosives of concern, unexploded ordnance and discarded military munitions. Additional information regarding the locations/ or potential locations of these sites can be found in Section 3.14. While DoD is currently in the process of citing and cleaning up these sites, not all sites have currently been identified. As such, the project would be required to implement BMPs during project siting to minimize potential safety and hazardous materials risks associated with MRS sites. Additional discussion is also provided in Section 8.2.14.

Construction activities may involve the use of hazardous materials such as fuels, oils, solvents, and glues. In addition, inadvertent spills could occur during onsite fueling of equipment or by accident (e.g., puncture of a fuel tank through operator error or slope instability). Therefore, the use of hazardous materials would be required to comply with developed site-specific BMPs related to fueling, vessel washing and handling, use, and storage of chemicals to minimize any risk to workers or the public. In addition, to minimize the potential for release of oil and other contaminants into surface water or groundwater, the project would be required to provide a Safety Response Plan, which would contain a spill prevention control and countermeasures plan (SPCCP detailing procedures to minimize and mitigate any spills of hazardous materials. All hazardous materials would be disposed of appropriately at an offsite permitted facility. Additional discussion is provided in [Section 6.9.14.1.2 Waste Management](#).

The operation and maintenance of the wind turbines may require the use of chemicals such as lubricating oils, hydraulic fluids, battery electrolytes, dielectric fluids, coolants, solvents, purging solutions, and cleaning agents. Most of these fluids would be contained within the equipment. However, during maintenance, the potential for a spill or accidental release into the marine environment could occur. As such, these hazardous materials or substances would be handled, stored, transported and disposed of at the appropriate permitted facility, in accordance with Federal, State, and county laws and regulations to ensure that hazards are not released into the environment. Additional discussion regarding disposal of this waste is discussed in the section that immediately follows, in Waste Management. In the event of a spill or if an accidental release occurs, appropriate safety precautionary measures and rapid response would be taken including following procedures outlined in spill and safety response plans, EPA materials safety data sheets, BOEM requirements, OSHA requirements, and notifying the appropriate authorities including the State DOH and first responders (as necessary). Spills offshore are also subject to the Clean Water Act. For potential impacts regarding water resources please refer to [Section 6.9.3](#). For potential impacts regarding toxicity to marine life please refer to [Section 6.9.4](#).

6.9.14.1.2 Waste Management

The representative project would install ten 5-megawatt wind turbines approximately five miles offshore and would require the construction and development of floating platforms and substations. Most of the materials used for the facility would arrive pre-fabricated, rather than built onsite. Therefore, the amount of construction and demolition waste generated would likely be minimal. For example, the large structural components such as the turbine rotors, generators, floating semi-submersible platform, and electric cables are already pre-built. In addition it is anticipated that the nominal amount of waste generated onsite would be minimized through recycling efforts and resultant diversion of generated wastes. During design and construction phases, consideration should be given to development and implementation of a recycling plan. In addition, a recycling program would effectively recover building materials that could contain potentially hazardous substances (e.g., liquid wastes, paints, oil, or solvents).

Typically, whenever machinery is used and equipment using hydraulic power is used on construction projects, there is the potential for generation of waste oil and fluids resulting from maintenance and repair activities on the machinery and equipment. Proper handling, transport, and disposal of hazardous materials or substances would be required to comply with State and Federal OSHA, and county requirements. This includes proper handling and transport for disposal at the appropriate hazardous material facility to ensure that no hazardous materials are disposed of at landfills and that no hazardous materials enter the waste stream.

The operation and maintenance of the wind turbines may require the use of industrial wastes such as lubricating oils, hydraulic fluids, battery electrolytes, dielectric fluids, coolants, solvents, purging solutions, and cleaning agents. These would be handled, stored, in accordance with Federal, State, and county laws and disposed of at the appropriate permitted offsite disposal facility to ensure that no hazardous materials are disposed of at landfills and that hazardous materials do not enter the waste stream.

Potential impacts could also occur during the decommissioning and dismantling of the wind turbine as result of turbine removal, and etc. However, much of the solid material could be recycled and sold as scrap or used in road building or bank re-stabilization projects. The remaining nonhazardous waste would be sent to permitted disposal facilities.

Potential impacts may result to the existing landfills pending resolution of new landfills siting, particularly in the island of O‘ahu and Hawai‘i. Additional discussion is provided in Section 3.14.4.

6.9.14.1.3 Wastewater

As indicated in [Table 6-11](#), the representative offshore wind project would not result in impacts to wastewater services. Water use would be minor.

6.9.14.2 Best Management Practices and Mitigation Measures

BMPs for hazardous materials, waste management, and wastewater would be the same as those for common construction and operations projects. See Section 3.14.5.

6.9.15 SOCIOECONOMICS

6.9.15.1 Potential Impacts

Socioeconomic impacts in Hawai‘i arising from a 50-megawatt offshore wind energy project would be very small. The turbine, rotor and blades, and mounting pole would likely be manufactured outside the State and, if so, economic benefits associated with the manufacturing would accrue elsewhere. The number of temporary jobs associated with the installation of the units, perhaps several dozen, and the numbers of jobs to monitor, operate, and maintain the turbines, about 3 positions, would be very small. Jobs directly associated the project would be likely filled by individuals residing within the area of influence (the State of Hawai‘i) and not by workers migrating to the State to fill those positions. The representative project would not create many new net jobs. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and county government sector; to rental housing; and to personal income would be very small.

6.9.15.2 Best Management Practices and Mitigation Measures

None noted.

6.9.16 ENVIRONMENTAL JUSTICE

6.9.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the representative offshore wind farm are expected to be small. The potential for environmental justice impacts also would be small.

6.9.16.2 Best Management Practices and Mitigation Measures

A utility-scale offshore wind turbine project site selection process should include a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

6.9.17 HEALTH AND SAFETY

6.9.17.1 Potential Impacts

Common health and safety impacts from typical construction and operations activities are identified in Section 3.17.3. As discussed in [Section 6.4.17](#), the representative project may present public health and safety concerns to boats, both civilian and military marine vessels, and to the public onshore in the event a device were destroyed, damaged or if the loss of mooring/spatial stabilization were to occur. Such events likely occur as a result of rough seas and breaking waves associated with 50 and 100-year storms (particularly in shallow water) or in the event of natural disasters including a tsunami. Potential hazards and safety risks may occur as a result of accidents.

6.9.17.2 Best Management Practices and Mitigation Measures

Common health and safety BMPs from typical construction and operations activities are identified in Section 3.17.5.

7 ENVIRONMENTAL IMPACTS FROM ALTERNATIVE TRANSPORTATION FUELS AND MODES

This chapter presents the potential environmental impacts that could be expected for activities and technologies from alternative transportation fuels and modes. These activities and technologies were presented in Chapter 2, Section 2.3.4. For each activity/technology evaluated in this chapter, there is a representative project that aids the PEIS in presenting and characterizing the potential environmental impacts. These representative projects are described in detail in Section 2.3.4 and are summarized again here for each activity/technology. The potential impacts are presented for each environmental resource area. As was described in Chapter 3, many of the activities and technologies could result in environmental impacts that would be common of typical construction projects and may not be unique to the specific activity or technology. In these cases, the presentation of potential impacts in this chapter refers the reader to the appropriate section in Chapter 3 that presents these common impacts for that resource area. Therefore, the details in this chapter deal primarily with those impacts that would be unique to the specific activity or technology being evaluated.

Where feasible, common representative projects were developed to assess the potential impacts (positive and negative) of the alternative transportation fuels and modes technology options. For the representative projects, the objective was to reduce annual petroleum production by 20 million gallons of gasoline or diesel by 2030, consistent with the HCEI goal. Some of the technologies and activities could easily scale up to commercial production thereby reducing annual petroleum by more than 20 million gallons; however, the lower volume represents a more realistic project for comparison in the State of Hawai‘i.

Each of the sections below includes a summary table of the potential environmental impacts and best management practices (BMPs) for that activity or technology. Not all technologies have the potential to impact all environmental resource areas analyzed in this document. Therefore, the summary table also identifies and screens those resource areas that are not expected to be impacted by the technology. This approach is consistent with DOE’s sliding scale approach to the preparation of NEPA analyses.

7.1 Biofuels

As discussed in Section 2.3.4.1, due to the uncertainty of biofuel technology readiness, it is difficult to describe with any accuracy what a representative project might look like, which would ultimately depend on the type of biofuel technology selected. For purposes of this PEIS, this section considers the range of potential biofuel feedstocks identified in Section 2.3.4.1.2 that addresses potential impacts from development and utilization of biofuels in Hawai‘i. Aspects of the representative project are discussed in more detail in the sections that follow.

[Table 7-1](#) presents a summary of the potential environmental impacts for biofuels, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 7-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Biofuels

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	<p>Construction impacts would be similar for any of the biofuel technologies and would be consistent with those expected for common construction actions as described in Section 3.1.3.</p> <p>During operation, potential impacts on geology and soils could vary greatly depending on the biofuel technology and feedstock: potential impacts include soil nutrient depletion; contamination from over-application of pesticides; and increased risk of erosion following crop harvest.</p>	<p>Employ standard best agricultural practices to keep soil contamination and erosion to a minimum.</p>
Climate and Air Quality		
Air Quality	<p>General construction and operation impacts (see Section 3.2.4).</p> <p>The production of the biomass required to produce the biofuels and the operation of facilities to produce biofuels would emit criteria pollutants during the production process. These emissions are addressed in Section 6.1.2 for utility-scale biomass projects.</p>	<p>Same as those common across construction and operation projects (see Section 3.2.5).</p>
Climate Change	<p>The production of the biomass required to produce the biofuels and the operation of facilities to produce biofuels would emit greenhouse gases during the production process. These emissions are addressed in Section 6.1.2 for utility-scale biomass projects.</p> <p>Gasoline replacement would result in annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent.</p>	<p>None.</p>

Table 7-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Biofuels (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Water Resources		
Surface Water	<p>General construction impacts to surface water (see Section 3.3.5).</p> <p>Minimal operational impacts of a biofuel processing plant other than possibly increasing storm water runoff from the site.</p> <p>Potential water use impacts associated with feedstock crops. See Section 6.1.</p> <p>Potential impacts from runoff contamination during feedstock/agricultural production as a result of fertilizer or pesticide applications.</p> <p>No impacts to surface water resources from use of biofuel as a supplement to, or replacement for gasoline.</p>	<p>Evaluate water needs for a dedicated biofuel crop on a site-specific basis.</p> <p>Ensure agricultural materials used are appropriately approved or licensed for the intended use and handled, stored, and applied in accordance with the manufacturer guidelines and the chemical-specific material safety data sheets.</p>
Groundwater	<p>General construction impacts on groundwater during construction (see Section 3.3.5).</p> <p>Long-term operational impacts of biofuel processing plant to groundwater would be limited primarily to the water needs to operate the facilities.</p> <p>Potential operational impact of biofuel agricultural activities due to contamination from fertilizer or pesticide applications reaching groundwater either via runoff or local recharge.</p> <p>Use of biofuel as a supplement to, or replacement for gasoline would not be expected to have any impact on groundwater resources.</p>	<p>Evaluate water needs for a biofuel production plant on a site-specific basis.</p> <p>Ensure agricultural materials used are appropriately approved or licensed for the intended use and handled, stored, and applied in accordance with the manufacturer guidelines and the chemical-specific material safety data sheets.</p>
Floodplains and Wetlands	<p>Potential effects to floodplain and wetland areas during construction if floodplains and wetlands were not avoided.</p>	<p>Same as those common across construction and operation projects (see Section 3.3.5).</p>

Table 7-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Biofuels (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Biological Resources		
	<p>Impacts common to construction and operations activities are identified in Section 3.4.5.</p> <p>Impacts to terrestrial wildlife and protected plants and animals from construction of the biofuel production plant and local infrastructure (i.e., access roads, water lines, electrical lines) are expected to be relatively minor.</p> <p>Potential impacts associated with agricultural production of some feedstocks posing invasive risk.</p> <p>Minimal potential impacts associated with conversion of land to feedstock production as there is readily available surplus of arable land previously used in agricultural production.</p> <p>Biomass crops may become habitat for protected species, which would restrict the ability to harvest, particularly during birthing seasons.</p>	<p>BMPs common to construction and operations activities are identified in Section 3.4.6.</p> <p>Site selection for the biofuel plant important in reducing potential impacts.</p> <p>Evaluate biomass production lands in proximity to areas with critical habitat and other high value habitats such as wetlands, areas of native vegetation, and protected land areas to ensure that potential impacts to wildlife or protected plant species are minimized or avoided.</p>
Land and Submerged Land Use		
Land Use	<p>Impacts common to construction and operations activities are identified in Section 3.5.4</p> <p>Land use impacts could occur from the construction and operation of new production facilities required to generate the biofuels and the infrastructure required to distribute it as an alternative transportation fuel source.</p>	<p>BMPs common to construction and operations activities are identified in Section 3.5.5.</p>
Submerged Land Use	<p>Potential submerged land use impacts if feedstock used to produce the biofuels were harvested offshore (i.e., algae).</p>	<p>None.</p>
Cultural and Historic Resources		
	<p>General construction and operation impacts (see Sections 3.6.6).</p>	<p>Same as those common across construction and operational projects (see Section 3.6.7).</p>

Table 7-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Biofuels (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Coastal Zone Management		
	Potential impacts if development of harbor facilities for handling and distributing biofuels between islands is required. The harbor facilities could impact designated special management areas and affect shorefront access; development likely to occur in areas of similar existing facilities and compatible uses.	Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.
Scenic and Visual Resources		
	<p>Potential visual impacts from constructing and operating biofuel processing plant described in Section 6.1.8.</p> <p>Minimal long-term visual impacts typical of agricultural activity, including presence of workers and equipment; lands zoned for agricultural use.</p> <p>Minimal visual impacts associated with truck traffic delivering biomass to processing plant.</p>	<p>General construction BMPs (see Section 3.8.4).</p> <p>Sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the four designated scenic byways (three on Hawai‘i and one on Kaua‘i); State, National, and National Historical Parks; National Historic Trails and Landmarks; National Natural Landmarks; and reserves protected by the Natural Area Reserves System should be considered and avoided when locating a power generating plant.</p> <p>Consideration should be given to general land use plans and associated implementation tools such as zoning ordinances and development standards to protect and maintain open space and scenic resources, consistent with the State’s land use designations.</p>
Recreation Resources		
	<p>General construction impacts (see Section 3.9.4).</p> <p>Minimal long-term impacts of feedstock production due to existing agricultural character of the area potentially included in the growing of feedstock and likelihood of growing feedstock in land zoned for agricultural uses as opposed to recreation uses.</p>	<p>Consider distance to popular recreation areas identified in Appendix A of the <i>State Comprehensive Outdoor Recreation Plan (DLNR 2009)</i>.</p> <p>Same as those common across construction and operation projects (see Section 3.9.5).</p>

Table 7-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Biofuels (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Land and Marine Transportation		
Land Transportation	<p>Increased truck and employee traffic around processing facilities.</p> <p>Minor increase in truck traffic near biomass collection points.</p> <p>Repeated truck traffic could increase wear and tear on road pavement and increase the frequency of road maintenance.</p>	Same as those common across construction and operation projects (see Section 3.10.4).
Marine Transportation	<p>Potential impacts on operation of the harbor systems, harbor infrastructure, primary shipping routes between islands, general marine transportation around the islands (tourism, fishing), and military marine surface and subsurface operations.</p> <p>Potential impact to harbor system if new liquid bulk handling facilities are required.</p>	None.
Airspace Management		
	None; interference with safe air traffic would not occur as a result of the development or use of biofuels.	N/A
Noise and Vibration		
	<p>General impacts during construction (see Section 3.12.5).</p> <p>Potential long-term impacts to existing noise and vibration levels, depending on the location of facilities and compatibility with existing noise levels and land uses.</p>	Same as those common across construction and operation projects (see Section 3.12.6).
Utilities and Infrastructure		
	Potential impact to local energy utilities by bringing large production facilities online which could affect their load capacity.	None.
Hazardous Materials and Waste Management		
Hazardous Materials	<p>Potential impacts from exposure to hazardous materials could result from chemical application (herbicides, pesticides, soil amendments) related to feedstock production.</p> <p>Potential impacts from exposure to hazardous materials associated with biofuel processing (see Section 6.1.14).</p> <p>Potential impacts from exposure to hazardous materials from accidents and spills during handling, storage, and transport of biofuels to fuel stations.</p>	Handling, storage, and transport of biofuels may require more stringent safety measures due to the potential corrosive properties of other fuels such as E85. Compliance with EPA, OSHA, USDOT, and the State’s DOH and DOT requirements during the handling, storage, and transport of the biofuel to ensure compliance with Federal, State, and local safety procedures.

Table 7-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Biofuels (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Waste Management	Minimal waste management impacts from feedstock production and processing. Potential impacts would occur during the construction and operation of the processing facilities to produce biofuels (see Section 6.1.14).	None.
Wastewater	Refer to surface water impacts.	None.
Socioeconomics		
	The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income would be very small.	None.
Environmental Justice		
	Small environmental justice impacts. Site-specific evaluation of impacted populations required.	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically, Native Hawaiians.
Health and Safety		
	The use of biofuels would not introduce any unique health hazard beyond that already addressed as a function of air quality or standard industrial hazards. Health risks from the use of pesticides, herbicides, and fertilizers in the growth of biomass. Additional risks of traffic accidents associated with the transport of biomass materials.	See related sections on transportation and hazardous materials

7.1.1 GEOLOGY AND SOILS

7.1.1.1 Potential Impacts

The representative project to be considered in this case is a range of potential applications of biofuel technologies. Implementation of any of the biofuel technologies would be expected to involve construction actions for processing plants, distribution infrastructure, and other support facilities. Potential impacts to geology and soils from such construction actions primarily would be associated with controlling soil erosion and preventing soil contamination. These impacts would be similar for any of the biofuel technologies and would be consistent with those expected for common construction actions as

described in Section 3.1.3. Construction actions would be expected to involve disturbance of more than one acre of land, so the permitting requirements described in Section 3.1.3 would be fully applicable.

During operations, potential effects on geology and soils could vary greatly depending on the biofuel technology. For example, some technologies may involve a greater number of hazardous materials than others, but the same type of precautions would be implemented to prevent spills or leaks to soils. Possibly the technologies with the greatest potential to affect soils would be those requiring large agricultural operations to generate feedstocks. Large-scale agricultural actions would pull nutrients from the soils that would likely have to be replenished over time through addition of soil supplements and fertilizers consistent with standard agricultural practices. Pesticides would likely be used as necessary to maintain the crop value. Supplements, fertilizers, and pesticides might all be considered soil contaminants if misused, including overuse such that the materials could be carried off the site in runoff. Also, as crops were harvested, there would be periods when soils would be more susceptible to erosion. These periods would be dependent on the type of biomass used; crops such as sugarcane are harvested every 1 to 2 years, whereas trees might be harvested every 7 to 12 years.

Use of the biofuel as a supplement to, or replacement for gasoline would not be expected to have any impact on geology or soils.

7.1.1.1 Best Management Practices and Mitigation Measures

Standard best management agricultural practices would keep soil contamination and erosion to a minimum. Additional BMPs can be found in Section 3.1.3.

7.1.2 CLIMATE AND AIR QUALITY

7.1.2.1 Potential Impacts

7.1.2.1.1 Air Quality

Impacts on air quality from the representative project would be the same as those expected for common construction actions described in Section 3.2.4. The production of the biomass required to produce the biofuels and the operation of facilities to produce biofuels would emit criteria pollutants during the production process. See in Section 6.1.2 for utility-scale biomass projects.

Depending on the type of biofuel technology chosen, the biofuel would likely be slowly integrated into the State's alternative fuel mix. Some of these fuels may be incorporated as a blend or provided at fueling stations on their own if the infrastructure were built to support it. As these fuels would initially be blended with gasoline, air emissions from vehicles would still occur, albeit reduced.

7.1.2.1.2 Climate Change

Biofuels are fuels derived from biomass or waste feedstocks. If biofuel technology can replace 20 million gallons of gasoline and diesel from being burned in vehicles, that would correspond with an annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent. The greenhouse gas reduction occurs because of the concept that burning biofuels would be carbon neutral. Refer to Section 5.1.2.1.2 for a brief discussion of carbon neutrality and how it is an unsettled issue that is under litigation. The premise of carbon neutrality is that as long as biomass resources are managed sustainably (that is, the annual amount of biomass resources grown are greater or equal to the annual amount used), the combustion of harvested materials presents no net increase of carbon to the ongoing carbon cycle. Therefore, the burning of biofuels should not be considered an increase in greenhouse gas

emissions. By comparison, the combustion of fossil fuels such as oil emits carbon that has been out of the current carbon cycle for millennia and therefore does contribute to an increase in greenhouse gas emissions.

As noted above, the production of the biomass required to produce the biofuels and the operation of facilities to produce biofuels would emit criteria pollutants and subsequently greenhouse gases during the production process. These emissions are addressed in Section 6.1.2 for utility-scale biomass projects.

7.1.2.2 Best Management Practices and Mitigation Measures

None noted.

7.1.3 WATER RESOURCES

7.1.3.1 Potential Impacts

7.1.3.1.1 Surface Water

Potential impacts to surface water would primarily concern controlling construction materials and storm water runoff such that sediments or other contaminants were not carried offsite to receiving waters. These impacts would be similar for any of the biofuel technologies and would be consistent with those expected for common construction actions as described in Section 3.3.5.

During operation of a biofuel processing plant, there likely would be no routine activities that would have the potential to affect surface waters other than possibly increasing storm water runoff from the site. Management of this increased volume of runoff would depend on the nature of the specific site (for example, whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns. The potential for spills or leaks of hazardous substances is always a concern for industrial facilities, but normal procedures, structures, and equipment for preventing such incidences and for response actions should they ever occur, would minimize the potential for contaminants to reach surface waters. Depending on the nature of the processing plant, there could be wastewaters generated that would have to be disposed of. Such wastewaters might be appropriate for discharge to a sanitary sewer or even as use for crop irrigation. They would not, however, be authorized for discharge to any surface water without a permit, which would require that the water quality of the receiving water not be adversely impacted.

Possibly the greatest potential effect during biofuel operations would be the water demand to support large agricultural operations needed to generate feedstocks for some of the technologies. It is likely such a demand would have to come from surface water sources. The biomass projects evaluated in Section 6.1 include a direct combustion project with a dedicated crop that required 12 to 17 million gallons per day and another dedicated crop to support a biodiesel plant that would require 21 to 40 million gallons per day even after accounting for contribution from precipitation (see Section 6.1.3.1.1). It is reasonable to assume that agricultural activities to support a large biofuel project would have water demands of a similar order of magnitude. Although 800 million gallons of surface water was used each day by the sugar industry in 1920, the amount of surface water used in irrigation over the entire State was down to about 74 million gallons per day in 2005 (see Section 3.3.1.1.4). Accordingly, a water demand in the region of 10 to 40 million gallons per day that might be needed to support a biofuel project would be a large increase in demand for irrigation water, particularly if it would be in a localized area. The water need is

small in comparison to the average amount of runoff from rain created from the islands each day, which is estimated at 10 to 40 percent of 21 billion gallons per day (see Section 3.3.2.1.2), but there would be existing competing water uses on every island, even if it were only to maintain stream habitat. On a Statewide basis, the water need may appear to be well within the carrying capacity of the resource, but water needs for a dedicated biofuel crop would have to be evaluated further on a site-specific basis. Water in Hawai'i is a precious and limited public resource owned by the people of Hawai'i. Its use for private commercial enterprises is regulated by the Commission on Water Resource Management, which dictates the amount of water allocated to private entities.

Operation of the dedicated biofuel crop would also represent potential for runoff contamination from the fields as a result of fertilizer or pesticide applications. This runoff could then reach surface water resources. Depending on their characteristics and concentrations, fertilizer and pesticide chemicals can produce adverse environmental impacts if they reach surface waters. The potential for such impacts is minimized if the materials used are appropriately approved or licensed for the intended use and they are handled, stored, and applied in accordance with the manufacturer guidelines and the chemical-specific material safety data sheets.

Use of the biofuel as a supplement to, or replacement for gasoline would not be expected to have any impact on surface water resources.

7.1.3.1.2 Groundwater

Effects on groundwater during construction associated with any of the biofuel technologies would be the same as those expected for common construction actions as described in Section 3.3.5.

During long-term operations of a biofuel processing plant, impacts to groundwater would be limited primarily to the water needs to operate the facilities. These water demands would not be expected to be prohibitive, but as described for surface water, groundwater is a valuable resource and the needs to support a biofuel plant would have to be evaluated further on a site-specific basis.

Operation of biofuel agricultural activities would also represent potential for contamination from fertilizer or pesticide applications to reach groundwater either via runoff or local recharge. Fertilizer and pesticide chemicals potentially can be carried down by infiltrating water and result in groundwater areas where drinking water standards are threatened or even exceeded. The potential for such impacts is minimized if the materials used are appropriately approved or licensed for the intended use and they are handled, stored, and applied in accordance with the manufacturer guidelines and the chemical-specific material safety data sheets.

Use of the biofuel as a supplement to, or replacement for gasoline would not be expected to have any impact on groundwater resources.

7.1.3.1.3 Floodplains and Wetlands

The proponent of a large-scale, biofuel project would be expected to avoid floodplain and wetland areas if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

7.1.3.2 Best Management Practices and Mitigation Measures

If it is assumed the biofuel processing plant would have access to a sewer system, there would be no sanitary or process wastewater issues associated with facilities' operation and there would be no sensitive water resource locations or receptors that should be given special consideration. With regard to water resources to support the operation's water needs, most of O'ahu and all of Molokai have been designated Groundwater Management Areas (see Sections 3.3.2.3 and 3.3.2.4) because of concerns over the long-term availability of groundwater. This designation authorizes the State to manage groundwater through a permitting process. This does not mean the project could not be implemented on either island due to lack of water, but it does identify a heightened level of concern that would have to be evaluated for a proposed action that involved any water demand. Also, Lāna'i has no surface water resources that could be used to support irrigation of a dedicated biomass crop and groundwater resources are very limited.

Standard BMPs to protect water resources are identified in Section 3.3.6.

7.1.4 BIOLOGICAL RESOURCES

7.1.4.1 Potential Impacts

Common impacts to biological resources from typical construction and operation activities are identified in Section 3.4.5.

Potential impacts to biological resources from the development of a biofuel industry would occur primarily during the biomass production and harvesting process and construction and operation of the biofuel production plant. The amount of land area disturbed (i.e., cleared of vegetation) for construction of the biofuel plant would depend on the production capacity of the plant. Some of the land disturbed during construction would be landscaped after construction. It is assumed that the production facility would be located in elevations and terrain suitable for growing the type of feedstock selected. Impacts to terrestrial wildlife and protected plants and animals from construction of the biofuel production plant and local infrastructure (i.e., access roads, water lines, electrical lines) are expected to be relatively minor. Site selection for the biofuel production plant would be important in reducing potential impacts. Locations in areas with native vegetation, near wetland habitats, or protected land areas, including critical habitat, would potentially have the most impact. Use of previously disturbed areas or lands with highly modified vegetation such as existing arable agriculture would minimize impacts. Facility lighting during operation of the biofuel plant could have potential impacts on flights of marine birds, such as shearwaters and petrels, depending on the project location. Lighting designs and operation routines to minimize lighting needs could be used to avoid or reduce this potential impact.

The biomass production process would require the most land area, approximately 15,000 acres. Biomass feedstock would be produced from either existing agricultural cropland or former cropland. Because of recent declines in agriculture production throughout the islands, existing fallow arable land is available for the production of biomass crops. However, some former crop land may now contain vegetation that has sufficiently recovered to provide some value as wildlife habitat. Impacts to threatened and endangered species could occur as some species use both native and non-native vegetation. Biomass production lands in proximity to areas with critical habitat and other high value habitats such as wetlands, areas of native vegetation, and protected land areas would require evaluation to ensure that potential impacts to wildlife or protected plant species are minimized or avoided. Some biomass crop species, such as banagrass, are potential risks as invasive species, particularly in areas close to protected areas and high value habitats.

7.1.4.2 Best Management Practices and Mitigation Measures

As discussed above, site selection for the biofuel production plant is important in reducing potential impacts to biological resources. Biomass production lands in proximity to areas with critical habitat and other high value habitats such as wetlands, areas of native vegetation, and protected land areas would require evaluation. BMPs would be the same as those common across projects for construction and operation (see Section 3.4.6).

7.1.5 LAND AND SUBMERGED LAND USE

7.1.5.1 Potential Impacts

7.1.5.1.1 Land Use

Land use impacts could occur from the construction and operation of new production facilities required to generate the biofuels and the infrastructure required to distribute it as an alternative transportation fuel source. Common impacts to land use from typical construction and operation activities are identified in Section 3.5.4.

7.1.5.1.2 Submerged Land Use

Submerged land use impacts could occur from the feedstock required to generate the biofuels (i.e., if algae were to be used) as some feedstock may need to be harvested offshore.

7.1.5.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation (see Section 3.5.5).

7.1.6 CULTURAL AND HISTORIC RESOURCES

7.1.6.1 Potential Impacts

Impacts to cultural and historic resources from the representative biofuels project would be consistent with those expected for common construction and operation actions as described in Section 3.6.6.

Impacts would also be similar to those identified in Section 6.1.6.1 for utility-scale biomass projects.

7.1.6.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures associated with the development and utilization of biofuels are discussed in Section 3.6.7.

7.1.7 COASTAL ZONE MANAGEMENT

7.1.7.1 Potential Impacts

Development of biofuels production could eventually require development of harbor facilities for handling and distributing biofuels between islands. The harbor facilities could impact designated special management areas and affect shorefront access. However, these facilities would likely be developed in an area with similar existing facilities and would most likely be consistent with current uses. These potential

impacts could require evaluation through a Federal consistency review under the Coastal Zone Management Program.

Operation of the biofuel vehicles supported by the representative project would not be expected to have any impact on coastal zone management areas.

7.1.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

7.1.8 SCENIC AND VISUAL RESOURCES

7.1.8.1 Potential Impacts

The biofuel for the representative project would be produced in a utility-scale biomass processing plant. Potential visual impacts from constructing and operating a biomass processing plant are described in Section 6.1.8. This section evaluates potential visual impacts of the production of the crops to support biofuels production and those fuel-specific vehicles that use the new fuel source.

The amount of land required would depend on the particular crop. Long-term visual impacts would be typical of agricultural activity, including the presence of workers and equipment. Because these lands are zoned for agricultural use, planting and harvesting these crops would be compatible uses of the land and therefore, visual impacts would not be significant. Visual impacts would also be caused by truck traffic to deliver the feedstock to the processing plant.

Operation of fuel-specific vehicles would not cause visual impacts. The transition to biofuels would require integration into the existing petroleum and fuel distribution infrastructure already present in the State to reduce costs and efficiently utilize the existing built-in infrastructure or may require the construction of new infrastructure and distribution systems. Short and long-term visual impacts could occur from construction and operation of new infrastructure and distribution systems. Short-term visual impacts would be typical of construction activities described in Section 3.8.3. Long-term visual impacts would depend on the locations of new infrastructure and their compatibility with the existing environment.

7.1.8.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation. See Section 3.8.4. Additionally, the BMPs identified for biomass projects in Section 6.1.8 would also be applicable.

7.1.9 RECREATION RESOURCES

7.1.9.1 Potential Impacts

Potential recreation resource impacts from constructing and operating a biomass processing plant are described in Section 6.1.9. This section evaluates potential recreation impacts of the production of the crops to support biofuels production and those vehicles that may be used for the new fuel source.

Long-term recreation resource impacts would be minimal because of the existing agricultural character of the area potentially included in the biofuels effort.

Operation of flex fuel vehicles would not cause recreation resource impacts. The transition to biofuels would require integration into the existing petroleum and fuel distribution infrastructure already present in the State to reduce costs and efficiently utilize the existing built-in infrastructure, or may require the construction of new infrastructure and distribution systems. Short and long-term recreation resource impacts could occur from construction and operation of new infrastructure and distribution systems. Short-term visual impacts would be typical of construction activities described in Section 3.9.4. Long-term recreation resource impacts would depend on the locations of new infrastructure and their compatibility with the existing land uses.

7.1.9.2 Best Management Practices and Mitigation Measures

Consider distance to popular recreation areas identified in Appendix A of the *State Comprehensive Outdoor Recreation Plan* ([DLNR 2009](#)).

BMPs to minimize potential impacts to recreation resources are provided in Section 3.9.5.

7.1.10 LAND AND MARINE TRANSPORTATION

7.1.10.1 Potential Impacts

7.1.10.1.1 Land Transportation

Minor impacts would be expected around the biofuel processing facilities as a result of truck and employee traffic. Other, more distributed, truck traffic would occur near the various agricultural lands from which the biomass would be collected. Increased heavy truck traffic could increase wear on road pavement and increase the frequency of road maintenance. The use of biofuels as a transportation fuel would have no impact on land transportation (i.e., traffic).

7.1.10.1.2 Marine Transportation

Impacts to marine transportation would include potential effects on operation of the harbor systems, harbor infrastructure, primary shipping routes between islands, general marine transportation around the islands (tourism, fishing), and military marine surface and subsurface operations. These impacts would be applicable if biofuels were generated on one island and transported to other islands, or even the mainland. If biofuels were shipped through the harbor systems, new liquid bulk handling facilities that are separate from those that now handle petroleum-based fuels may be needed because of different fuel characteristics.

7.1.10.2 Best Management Practices and Mitigation Measures

None identified.

7.1.11 AIRSPACE MANAGEMENT

As identified in [Table 7-1](#), there would be no potential impacts to airspace management from the representative biofuels project.

7.1.12 NOISE AND VIBRATION

7.1.12.1 Potential Impacts

The representative biofuels project could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

The representative biofuels project could potentially result in long-term impacts to existing noise and vibration levels. Industrial noise would be produced from feedstock production, operation of biofuel processing facilities, and truck deliveries. If a biofuel production facility and the power plant are not co-located, tanker truck transportation would be required to transport the biofuel from the production facility to the power plant. Such noise could indirectly impact scenic and visual resources, recreation resources, cultural resources, worker health and safety, and possibly public health. Impacts would depend on the location of facilities and compatibility with existing noise levels and land uses. Long-term noise and vibration impacts from operation of fueling infrastructure and biofuel vehicle use would be negligible.

7.1.12.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation (see Section 3.12.6).

7.1.13 UTILITIES AND INFRASTRUCTURE

7.1.13.1 Potential Impacts

The representative biofuels project could impact local energy utilities by bringing large production facilities online which could affect their load capacity. These production facilities would be new, potentially large users of electricity. Since these would be facilities used to produce biofuels for transportation use, the electricity use would not be offset by electricity generation using the biofuels (refer to Section 6.1.17).

Considering that these facilities would be planned and coordinated with the local utilities well in advance of full operations, impacts to the ability of the utility to handle the load would be minimal.

7.1.13.2 Best Management Practices and Mitigation Measures

None noted.

7.1.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

7.1.14.1 Potential Impacts

7.1.14.1.1 Hazardous Materials

The production of biofuels for the representative project likely would result from various feedstocks that could require the use of chemicals such as herbicides, pesticides, and fertilizers to propagate higher yields. Application of these must occur be in accordance with EPA Materials Safety Data Sheets, USDA, USDOT, and State DOA and DOH regulations to ensure the proper handling, transport, and disposal of these chemicals. Certain feedstock, such as sugar cane, already has an established history of commercial production in Hawai'i. As such, the pesticides and herbicides anticipated for use in the representative project could be of similar type and would require similar handling, transport, and disposal. Other

feedstock, such as banagrass and algae, has not been grown in the State for commercial scale production. As such, the representative project would be required to ensure adequate precautions are taken to prevent chemical spills or release from occurring.

After harvesting, the biofuel feedstock would be transported to a biomass conversion facility. For details regarding the potential impacts of a biomass plants, refer to Section 6.1.14.

Upon processing, the biofuel would be distributed to various fueling stations for retail sale. Depending on the biofuel being distributed, the handling, storage, and transport of the biofuel produced by the representative project may require more stringent safety measures due to potentially corrosive properties (i.e., E85). As such, the representative project would require compliance with EPA, OSHA, USDOT, and the State's DOH and DOT requirements during the handling, storage, and transport of the fuel to ensure compliance with Federal, State, and local safety procedures. Safety measures could include the preparation of emergency and safety response plans in accordance with the USDOT's Pipeline and Hazardous Material Safety Administration's regulations and requirements, coordination with the U.S Coast Guard Hazardous Materials Division and National Response Center, and HDOH.

7.1.14.1.2 Waste Management

The feedstock production for biofuels is anticipated to result in minimal generation of waste, as production would likely occur in areas zoned for agricultural production similar to existing practices. This may involve the use of herbicides and pesticides, which would be considered hazardous waste and would need to be stored, handled, and transported offsite for disposal at the appropriate hazardous waste facility.

The processing of feedstock for biofuel conversion would result in some waste generation. These other impacts would occur during the construction and operation of the processing facilities to produce the biofuel. Those impacts would be similar to those that would occur from the representative project discussed in Section 6.1.14.

The distribution of the biofuel is not anticipated to result in waste generation. However, there would be impacts from the import and use of fuel-specific vehicles depending on the type of biofuel used (i.e., E85 would require the use of flex-fuel vehicles). These fuel-specific vehicles may need to be imported into the State. As existing internal combustion engine vehicles would need to be replaced, this would result in an increase in the amount of waste from vehicles that would be disposed of in Hawai'i. It is anticipated that the majority of the vehicles would be disposed of at recycling facilities in the State; however, it is noted that not all car parts or materials may be reused or recycled. Therefore, those non-recyclable car parts or materials may require disposal at one of the various landfills serving the State.

7.1.14.1.3 Wastewater

Primary wastewater impacts resulting from the use of biofuel in vehicles would be minimal to none. Biofuels would likely be integrated into the existing infrastructure, to the extent feasible. However, additional refueling stations or infrastructure may be required, the construction of which may generate minimal wastewater. However, such projects would likely incorporate BMPs including compliance with NPDES wastewater discharge permit requirements.

Secondary impacts could result during the manufacture and processing of biofuels. This is further discussed in Sections 5.1.14 and 6.5.14.

7.1.14.2 Best Management Practices and Mitigation Measures

Prior to planting biomass crops or siting a biofuels facility, parcels would be investigated via the review of public records and the performance of site inspections to identify possible hazardous materials that may be present at development or agricultural locations. In the event that the project location is sited at one of these sites, site remediation would be recommended prior to project development.

Consider current landfill constraints when siting a biofuels processing facility.

7.1.15 SOCIOECONOMICS

7.1.15.1 Potential Impacts

Socioeconomic impacts associated with the development of biofuels to replace gasoline or diesel fuels could necessitate the construction and operation of new infrastructure and distribution systems. New net jobs could be created. Additional jobs in the agriculture sector could also be generated as acreage is devoted to harvesting feedstock. The number of jobs associated with the new infrastructure and/or new agriculture ventures would be very small, perhaps several dozen positions. Jobs directly associated with the project likely would be filled by individuals residing within the State of Hawai‘i and not by in-migrating workers. The representative project would not create many new net jobs. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal would be very small.

7.1.15.2 Best Management Practices and Mitigation Measures

None identified.

7.1.16 ENVIRONMENTAL JUSTICE

7.1.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the development of biofuels are expected to be small. Impacts to minority and low-income populations also would be small.

7.1.16.2 Best Management Practices and Mitigation Measures

Any site selection process would need to include a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

7.1.17 HEALTH AND SAFETY

7.1.17.1 Potential Impacts

Because the representative project for development of biofuels would use dedicated crops as feedstock for the process, the project would include the application of chemicals such as herbicides, fertilizers, and pesticides (see [Section 7.1.14](#)). In the event of an accidental spill or release, the project would be required to comply with a spill and response plan including notifying the proper authorities such as the local fire department and the HDOH to minimize risks to workers and to the public. With incorporation of precautionary safety measures and compliance with Federal, State, and local regulations, it is not anticipated that chemicals spills or release would occur and project impacts would be minimal.

Effects on island public safety services would be small since the workers to construct and to operate the biofuels facility and to work the agricultural positions would be expected to come from the island’s existing work force. Police, fire, and medical services would not be adversely affected with this small change.

7.1.17.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across construction and operation projects (see Section 3.17.5).

7.2 Plug-In Electric Vehicles (PEVs)

The representative PEV project would increase the light-duty (i.e., passenger car) electric vehicle population to avoid the use of 20 million gallons of gasoline fuel by 2030 (see Section 2.3.4.2.5). The representative project assumes that the statewide vehicle mix remains 50 percent passenger cars and 50 percent light trucks, and that only passenger cars will transition to electric vehicles (i.e., no light trucks). The representative project assumes a mixture of battery electric vehicles and different levels of plug-in hybrid-electric vehicles (e.g., PHEV-10, PHEV-20, and PHEV-40) to mimic a potential future fleet mix. Details on these vehicles can be found in Chapter 2.

Table 7-2 presents a summary of the potential environmental impacts for plug-in electric vehicles, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 7-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Plug-in Electric Vehicles

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	Soil disturbances would be limited to instances where minor trenching was required to install chargers at commercial or residential locations.	None.
Climate and Air Quality		
Air Quality	Reduction in air emissions from lowering gasoline usage in passenger vehicles would be partially offset by the amount of air emissions produced from generating electricity.	None.
Climate Change	Reduction in greenhouse gas emissions from lowering gasoline usage in passenger vehicles would be partially offset by the amount of greenhouse gas emissions produced from generating electricity.	None.
Water Resources		
	None; increasing the number of electric vehicles in Hawai‘i would not impact water resources.	N/A
Biological Resources		
	None; increasing the number of electric vehicles in Hawai‘i would not impact surface water.	N/A

Table 7-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Plug-in Electric Vehicles (continued)Error! Bookmark not defined.

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Land and Submerged Land Use		
Land Use	Reduced gasoline demand could result in decreased number of conventional fueling stations; small parcels of land could be converted to other uses and ownership.	None.
Submerged Land Use	None; increasing the number of electric vehicles in Hawai‘i would not impact submerged land use.	N/A
Cultural and Historic Resources		
	None; increasing the number of electric vehicles in Hawai‘i would not impact cultural or historical resources.	N/A
Coastal Zone Management		
	None; increasing the number of electric vehicles in Hawai‘i would not impact coastal zone management.	N/A
Scenic and Visual Resources		
	None; increasing the number of electric vehicles in Hawai‘i would not impact scenic or visual resources.	N/A
Recreation Resources		
	None; increasing the number of electric vehicles in Hawai‘i would not impact recreation resources.	N/A
Land and Marine Transportation		
Land Transportation	Land transportation infrastructure could be affected through decreases in HDOT revenue from reductions in petroleum fuel taxes as the number of plug-in electric vehicles increased.	None.
Marine Transportation	None; increasing the number of electric vehicles in Hawai‘i would not impact marine transportation.	N/A
Airspace Management		
	None; increasing the number of electric vehicles in Hawai‘i would not impact airspace management.	N/A
Noise and Vibration		
	General impacts during construction and operation (see Section 3.12.5).	Same as those common across construction and operation projects (see Section 3.12.6).

Table 7-2. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Plug-in Electric Vehicles (continued)Error! Bookmark not defined.

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Utilities and Infrastructure		
	Potential impacts on the islands’ electric utilities would primarily be an increased power demand of 292 gigawatt-hours per year (equivalent to about 33 megawatts if operated continuously) to operate charging stations for the required number of vehicles to support the reduction of 20 million gallons of gasoline. This increase would need to be met either by offsetting renewable power generators or continued use of existing power facilities. This additional load would ramp up slowly as the penetration of PEVs increased on the islands.	Same as those common across construction and operation projects (see Section 3.13.3). Developers of PEV charging stations and should stay in communication with local utilities to allow accurate forecasting of future power needs.
Hazardous Materials and Waste Management		
Hazardous Materials	Minimal hazardous material exposure impacts from plug-in electric vehicles during operations. Hazardous material exposure impacts may result at the end-life of the vehicle use from batteries (see Section 7.2.14.1.2).	Special treatment is recommended during the disposal of the vehicle battery packs that cannot be recycled, including setting aside these battery packs, and proper handling and transport for disposal at the appropriate hazardous material facility.
Waste Management	Potential waste management impacts at the end-life of electric vehicles or during its disposal. Potential impacts would result from the import and use of plug-in electric vehicles; replacement of existing internal combustion engine vehicles result in an increase in the amount of waste vehicles.	Special treatment is recommended during the disposal of the vehicle battery packs that cannot be recycled, including setting aside these battery packs, and proper handling and transport for disposal at the appropriate hazardous material facility
Wastewater	None; transitioning to a fleet of electric and hybrid electric vehicles would not impact wastewater.	N/A
Socioeconomics		
	The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income would be very small.	None.
Environmental Justice		
	None; transitioning to a fleet of electric and hybrid electric vehicles would not have environmental justice impacts.	N/A
Health and Safety		
	None; transitioning to a fleet of electric and hybrid electric vehicles in Hawai‘i would not introduce any new significant hazards compared with gasoline- or diesel-powered vehicles.	N/A

7.2.1 GEOLOGY AND SOILS

7.2.1.1 Potential Impacts

Increasing the number of electric and hybrid electric vehicles in Hawai'i would be expected to have no substantive impacts on geology or soils. Soil disturbances would be limited to instances where minor trenching was required to install chargers at commercial or residential locations. Where necessary, the amount of trenching required is estimated at 10 to 150 feet per charger. Since the trenching would simply be for the installation of electric cable or conduit, the trenches would not be expected to be very deep or require a wide disturbance. Land disturbance at any single location would not be expected to even approach an acre, so the work would not be performed under a stormwater discharge permit. However, it is reasonable to assume this work would be performed by businesses with trained workers, working under procedures to minimize the potential for any loose soil to be carried away from the site by wind or stormwater. The small size of the trenching action at any site would be expected to translate into a very quick project, with the site being returned to a stable condition in a short time, so there would be a lower probability of encountering runoff or erosion issues than if it were a longer duration project.

During operation of the vehicles or charging stations there would be no activities that would have the potential to affect geology or soils.

7.2.1.2 Best Management Practices and Mitigation Measures

None identified.

7.2.2 CLIMATE AND AIR QUALITY

7.2.2.1 Potential Impacts

7.2.2.1.1 Air Quality

The representative project involves the use of approximately 88,000 electric vehicles being powered by a battery pack. Vehicle charging occurs via plugging into an electrical power source increasing energy demand on the grid. While project operations would result in an annual reduction of 20 million gallons of gasoline, this would be offset by increased energy usage required from existing power plants that are likely generating electricity from oil products. As such, air emissions reduced by the use of plug-in electric vehicles would be partially offset by the increased load required from electrical generating plant. A full reduction in air emissions could be realized if electricity were generated from renewable sources rather than from petroleum.

7.2.2.1.2 Climate Change

The representative project would require approximately 88,000 electric vehicles in the State. An annual reduction of 20 million gallons of gasoline would correspond to an annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent. The reduction in greenhouse gas emissions from lowering gasoline usage in passenger vehicles would be partially offset by the amount of greenhouse gas emissions produced from generating the electricity from oil products that would be required to charge the vehicles. The greater the amount of electricity produced by renewable sources in 2030, the greater the greenhouse gas reductions. A full reduction in greenhouse gases could be realized if electricity were generated from renewable sources rather than from petroleum.

The electric capacity required to charge the 2030 fleet is estimated to be 800,000 kilowatt-hours daily and would require a generation capacity of about 133 megawatts. This demand equates to 5.2 percent of the firm generation power capacity in Hawai‘i for each avoided 20 million gallons of gasoline (Chapter 2).

7.2.2.2 Best Management Practices and Mitigation Measures

None identified.

7.2.3 WATER RESOURCES

7.2.3.1 Potential Impacts

7.2.3.1.1 Surface Water

As identified in [Table 7-2](#), there would be no potential impacts to surface water from the representative PEV project.

7.2.3.1.2 Groundwater

As identified in [Table 7-2](#), there would be no potential impacts to groundwater from the representative PEV project.

7.2.3.1.3 Floodplains and Wetlands

The only construction-related or soil disturbing actions associated with the representative project would be the minor trenching required to install charging stations at some locations. In order for such actions to impact floodplains or wetlands, the applicable commercial or residential facility would have to be located within or immediately adjacent to a floodplain or wetland. Although such a situation could occur, it is reasonable to assume that it would not be the norm. It is also reasonable to assume that in such a location, and deciding where a charging station might be placed, care would be taken to avoid conflicts with floodplains or wetlands if at all possible, if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

7.2.3.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures to reduce potential impacts to water resources are discussed in Section 3.3.6.

7.2.4 BIOLOGICAL RESOURCES

As identified in [Table 7-2](#), there would be no potential impacts to biological resources from the representative PEV project.

7.2.5 LAND AND SUBMERGED LAND USE

7.2.5.1 Potential Impacts

7.2.5.1.1 Land Use

Increasing the number of electric vehicles in Hawai'i would have a minimal impact on land use. In limited instances, minor trenching (10 to 150 feet) may be required to install charging stations at residential, commercial, and tourist areas. However, such disturbances would be small and temporary.

As electric vehicles increase in popularity, the number of gasoline driven vehicles could decrease, reducing the demand for gasoline and diesel fuel. As a result, there could be decreases in the number of conventional fueling stations and small parcels of land could be converted to other uses and ownership.

7.2.5.1.2 Submerged Land Use

As identified in [Table 7-2](#), there would be no potential impacts to submerged land use from the representative PEV project.

7.2.5.2 Best Management Practices and Mitigation Measures

None identified.

7.2.6 CULTURAL AND HISTORIC RESOURCES

7.2.6.1 Potential Impacts

Increasing the number of electric vehicles in Hawai'i would be expected to have no impacts on cultural or historical resources. However, potential adverse impacts could occur to cultural, historical, and related natural resources during trenching if effective conservation and BMPs are not implemented. The potential cultural and historic impacts associated with constructing and operating ancillary support facilities for electric vehicles is discussed in Sections 3.6.6.

During operation of the vehicles or charging stations there would be no activities that would have the potential to affect cultural or historical resources.

7.2.6.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures to reduce potential impacts to cultural and historic resources are discussed in Section 3.6.7.

7.2.7 COASTAL ZONE MANAGEMENT

As identified in [Table 7-2](#), there would be no potential impacts to coastal zone management from the representative PEV project.

7.2.8 SCENIC AND VISUAL RESOURCES

As identified in [Table 7-2](#), there would be no potential impacts to scenic or visual resources from the representative PEV project.

7.2.9 RECREATION RESOURCES

As identified in [Table 7-2](#), there would be no potential impacts to recreation resources from the representative PEV project.

7.2.10 LAND AND MARINE TRANSPORTATION

7.2.10.1 Potential Impacts

7.2.10.1.1 Land Transportation

To support the increase in electrical vehicles, additional charging stations may have to be constructed. Land transportation infrastructure could be affected through decreases in HDOT revenue from reductions in petroleum fuel taxes as the number of electric vehicles increases, which support maintenance of the State road systems. However, this impact would be expected to occur over several years as the number of plug-in electric vehicles increases, allowing opportunity to address this potential impact.

7.2.10.1.2 Marine Transportation

As identified in [Table 7-2](#), there would be no potential impacts to marine transportation from the representative PEV project.

7.2.10.2 Best Management Practices and Mitigation Measures

None identified.

7.2.11 AIRSPACE MANAGEMENT

As identified in [Table 7-2](#), there would be no potential impacts to airspace management from the representative PEV project.

7.2.12 NOISE AND VIBRATION

7.2.12.1 Potential Impacts

There are no PEVs manufactured in Hawai'i, nor are any state-based vendors likely to manufacture home charger stations. Therefore noise and vibration impacts associated with manufacturing would occur elsewhere. Recharging stations and appliances would be constructed and installed. The representative plug-in EV project could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

Noise and vibration levels for operation of plug-in EVs vehicles would be similar to or less than existing levels resulting from operation of traditionally fueled vehicles. The noise that would be expected from operating charging station would be negligible.

7.2.12.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation. See Section 3.12.6.

7.2.13 UTILITIES AND INFRASTRUCTURE

7.2.13.1 Potential Impacts

Potential impacts on the islands electric utilities would primarily be an increased power demand of 292 gigawatt-hours per year (equivalent to about 33 megawatts if operated continuously) to operate charging stations for the required number of vehicles to support the reduction of 20 million gallons of gasoline. This increase would need to be met either by offsetting renewable power generators or continued use of existing power facilities. This additional load would ramp up slowly as the penetration of PEVs increased on the islands. Island utilities are aware of this type of increase and have both renewable energy and continued use plans under consideration to meet this type of increased demand source ([HECO 2013](#)).

7.2.13.2 Best Management Practices and Mitigation Measures

In addition to the common BMPs for utilities and infrastructure identified in Section 3.13.3, developers of PEV charging stations and should stay in communication with local utilities to allow accurate forecasting of future power needs.

7.2.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

7.2.14.1 Potential Impacts

7.2.14.1.1 Hazardous Materials

The representative project assumes the use of 88,000 plug-in electric or hybrid electric vehicles which utilize battery packs, such as lithium-ion batteries to fuel and power an electric powertrain to propel a vehicle. Unlike the lead-acid batteries in traditional motor vehicles, lithium-ion batteries are classified as non-hazardous except in California. As such, the operation of plug-in electric vehicles is not anticipated to result in hazardous material impacts. Hazardous material exposure impacts may result at the end-life of the vehicle use. A detailed discussion of battery disposal impacts is included in [Section 7.2.14.1.2](#).

Prior to charging station installation, proposed project sites are recommended for investigation via the review of public records and the performance of site inspections to identify possible hazardous materials that may be present at development locations.

7.2.14.1.2 Waste Management

Primary waste management impacts resulting from the use of plug-in electrical vehicles would occur at the end-life of electric vehicles or during its disposal. As discussed in 2.3.4.2, PEVs have more components than conventional vehicles (e.g., batteries, electric motors, power electronics, and cabling). Most of these materials are of high value so it is anticipated that these components would be reused and recycled to the extent feasible. Recycling practices and protocols for lithium-ion batteries have been in place for decades and are being further developed to handle the various types of lithium-ion batteries used in hybrid electric vehicles and plug-in electric vehicles. Batteries in electric vehicles are considered to have reached their end-of-life when the battery charge is 80 percent of the new battery capacity. At this point, batteries still have a lot of potential for other “second use” applications, such as providing an energy buffer for solar or wind generation and utility grid support. The likely path for healthy batteries will be to recondition them and redeploy them in service in a non-vehicle application. This approach avoids all of the costs and energy use to produce new batteries and improves batteries’ life cycle emissions and costs because the batteries are kept out of the recycling stream for many years past when they are not fit for use in hybrid electric vehicles and plug-in electric vehicles. Batteries that cannot be

repurposed would likely be recycled and would have the raw materials recaptured to produce new batteries.

As lithium-ion batteries are made out of many materials that can be toxic to humans and animals in chemical reactions (such as water), special treatment is recommended during the disposal of the vehicle battery packs that cannot be recycled. This includes setting aside these battery packs, and proper handling and transport for disposal at the appropriate hazardous material facility. This would ensure that no hazardous materials are disposed of at landfills and that hazardous materials do not enter the waste stream.

Additional impacts may result from the import and use of plug-in electric vehicles. As discussed in Section 2.3.4.2, the representative project would result in the import of approximately 88,000 plug-in electric vehicles in the State. As existing internal combustion engine vehicles would need to be replaced, this would result in an increase in the amount of waste vehicles that would be disposed of in Hawai‘i. It is anticipated that the majority of the vehicles would be disposed of at recycling facilities in the State; however, it is noted that not all car parts or materials may be reused or recycled. Therefore those non-recyclable car parts or materials may require disposal at one of the various landfills serving the State.

7.2.14.1.3 Wastewater

As identified in [Table 7-2](#), there would be no potential impacts to wastewater from the representative PEV project.

7.2.14.2 Best Management Practices and Mitigation Measures

As discussed in Section 3.14, several landfills in the islands of O‘ahu and Hawai‘i are currently at capacity. As such, depending on the proposed project location, the disposal of non-recyclable car parts/materials may add to existing landfill capacity constraints. The resolution of landfill siting and expansion on several islands are pending or are in the process. Therefore, additional waste produced in the islands of O‘ahu and Hawai‘i may result in potential impacts, pending the resolution of existing landfill capacity constraints.

7.2.15 SOCIOECONOMICS

7.2.15.1 Potential Impacts

Socioeconomic impacts associated with transition of conventional, gasoline-powered vehicles to more plug-in electric vehicles would be very small. Some new net jobs could be created, but most new jobs would replace soon-to-be obsolete positions. There are no plug-in electric vehicles manufactured in Hawai‘i, nor are any State-based vendors likely to manufacture home charger stations. Therefore, economic benefits associated with manufacturing would accrue elsewhere. Existing vehicle dealerships, mechanics, and support personnel would likely transform their offerings to meet the emerging plug-in electric vehicle market, but create few new net jobs.

While the need for traditional gasoline service stations would diminish, recharging stations and appliances would be constructed and installed. The number of jobs associated with the construction and installation of new charging infrastructure would be very small. Jobs directly associated with the recomposed vehicle fleet would be likely filled by individuals residing within the area of influence (the State of Hawai‘i), who now perform similar services for conventional vehicles, and not by in-migrating workers. The conversion to a plug-in electric vehicle fleet would not create many new net jobs. The impact to population; to

employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income would be very small.

7.2.15.2 Best Management Practices and Mitigation Measures

None identified.

7.2.16 ENVIRONMENTAL JUSTICE

As identified in [Table 7-2](#), there would be no environmental justice impacts from the representative PEV project.

7.2.17 HEALTH AND SAFETY

As identified in [Table 7-2](#), there would be no health and safety impacts from the representative PEV project.

7.3 Hybrid Electric Vehicles (HEVs)

The representative HEV project would increase the light-duty (i.e., passenger car) hybrid-electric vehicle population to avoid the use of 20 million gallons of gasoline fuel by 2030 (see Section 2.3.4.3.5). As with the PEV project, the HEV representative project assumes that the statewide vehicle mix remains at 50-percent passenger car and 50-percent light truck and that only passenger cars and light trucks will transition to hybrid-electric vehicles. Further, the representative project assumes 60 percent of the hybrids will be micro-hybrids and 25 percent will be full hybrids. Reaching the 20-million-gallon petroleum reduction goal would require roughly 383,000 hybrid-electric vehicles (or roughly 30 percent of all passenger vehicles in 2030). Specific comparisons of miles traveled to fuel consumption are presented in Chapter 2.

[Table 7-3](#) presents a summary of the potential environmental impacts for hybrid electric vehicles, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 7-3 Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Hybrid Electric Vehicles

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	None; increasing the number of HEVs would not impact geology and soils.	N/A
Climate and Air Quality		
Air Quality	Potential reduction in criteria pollutants emitted by internal combustion engine vehicles.	None.
Climate Change	A reduction of 20 million gallons of gasoline would correspond with an annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent.	None.

Table 7-3 Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Hybrid Electric Vehicles (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Water Resources		
	None; increasing the number of HEVs would not impact water resources.	N/A

Health and Safety		
	None; increasing the number of HEVs in Hawai‘i would not introduce any new significant hazards as compared to gasoline- or diesel-powered vehicles	N/A

7.3.1 GEOLOGY AND SOILS

As identified in [Table 7-3](#), there would be no potential impacts to geology and soils from the representative HEV project.

7.3.2 CLIMATE AND AIR QUALITY

7.3.2.1 Potential Impacts

7.3.2.1.1 Air Quality

Hybrid electric vehicles combine an internal combustion engine and an energy storage system to propel the vehicle. Fuel savings is achieved by recovering braking energy and thus decreasing fuel consumption. As the vehicles would result in fuel savings, hybrid electric vehicles would reduce the amount of criteria pollutant emissions emitted by regular vehicles.

7.3.2.1.2 Climate Change

A proposed representative project would increase the light-duty hybrid-electric vehicle population to avoid 20 million gallons of gasoline fuel use by 2030. This would require about 380,000 hybrid-electric vehicles. A reduction of 20 million gallons of gasoline would correspond with an annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent.

7.3.2.2 Best Management Practices and Mitigation Measures

None identified.

7.3.3 WATER RESOURCES

As identified in [Table 7-3](#), there would be no potential impacts to water resources, including surface water, groundwater, wetlands, and floodplains, from the representative HEV project.

7.3.4 BIOLOGICAL RESOURCES

As identified in [Table 7-3](#), there would be no potential impacts to biological resources from the representative HEV project.

7.3.5 LAND AND SUBMERGED LAND USE

As identified in [Table 7-3](#), there would be no potential impacts to land or submerged land use from the representative HEV project.

7.3.6 CULTURAL AND HISTORIC RESOURCES

As identified in [Table 7-3](#), there would be no potential impacts to cultural or historical resources from the representative HEV project.

7.3.7 COASTAL ZONE MANAGEMENT

As identified in [Table 7-3](#), there would be no potential impacts to coastal zone management from the representative HEV project.

7.3.8 SCENIC AND VISUAL RESOURCES

As identified in [Table 7-3](#), there would be no potential impacts to scenic and visual resources from the representative HEV project.

7.3.9 RECREATION RESOURCES

As identified in [Table 7-3](#), there would be no potential impacts to recreation resources from the representative HEV project.

7.3.10 LAND AND MARINE TRANSPORTATION

7.3.10.1 Potential Impacts

7.3.10.1.1 Land Transportation

Land transportation infrastructure could be affected through decreases in HDOT revenue from reductions in petroleum fuel taxes as the number of hybrid electric vehicles increases, which support maintenance of the State road systems. However, this impact would be expected to occur over several years as the number hybrid electric vehicles increases, allowing opportunity to address this impact.

7.3.10.1.2 Marine Transportation

As identified in [Table 7-3](#), there would be no potential impacts to marine transportation from the representative HEV project.

7.3.10.2 Best Management Practices and Mitigation Measures

None identified.

7.3.11 AIRSPACE MANAGEMENT

As identified in [Table 7-3](#), there would be no potential impacts to airspace management from the representative HEV project.

7.3.12 NOISE AND VIBRATION

As identified in [Table 7-3](#), there would be no potential impacts to noise and vibration from the representative HEV project.

7.3.13 UTILITIES AND INFRASTRUCTURE

As identified in [Table 7-3](#), there would be no potential impacts to utilities and infrastructure from the representative HEV project.

7.3.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

7.3.14.1 Potential Impacts

7.3.14.1.1 Hazardous Materials

The representative project assumes the use of about 383,000 hybrid electric vehicles which uses gasoline and battery packs (such as nickel metal hydride or lithium-ion batteries) to fuel and power a vehicle. These vehicles operate similar to conventional vehicles. As mentioned in Section 2.3.4.3, Hybrid Electric Vehicles, all current HEVs in the U.S. are gasoline-fueled; as such, HEVs are fueled in exactly the same way at the same fueling stations that conventional internal combustion engine vehicles are. The servicing of electric vehicles that occur at dealerships would occur in the same manner as conventional vehicles, except that new and unique services are required for hybrid system components. Many vehicle manufacturers already have hybrids on the market and vehicle maintenance and repair would remain similar to existing practices. As such, the operation and maintenance of hybrid electric vehicles are not anticipated to result in hazardous material exposure impacts. Hazardous material exposure impacts may

result at the end-life of the vehicle use due to the hazardous material contents in battery packs. A detailed discussion of battery disposal impacts is provided in [Section 7.3.14.1.2](#).

Additional impacts may occur during the construction and development of gasoline fueling stations. However, it is not anticipated that additional gasoline fueling stations would be required to accommodate the use of hybrid electric vehicles. The increased usage of hybrid electric vehicles in the State would likely utilize existing gasoline fueling stations.

7.3.14.1.2 Waste Management

Potential waste management impacts resulting from the use of hybrid electric vehicles would occur at the end-life of the vehicles or during their disposal. As discussed in Section 2.3.4.3, hybrid electric vehicles have more components than conventional vehicles (e.g., batteries, electric motors, power electronics, and cabling). Most of these materials are of high value so it is anticipated that these components would be reused and recycled to the extent feasible. Recycling practices and protocols for lithium-ion batteries have been in place for decades and are being further developed to handle the various types of lithium-ion batteries used in hybrid electric vehicles and plug-in electric vehicles. Batteries in hybrid electric vehicles are considered to have reached their end-of-life when the battery charge is 80 percent of the new battery capacity. At this point, batteries still have a lot of potential for other “second use” applications, such as providing an energy buffer for solar or wind generation and utility grid support. The likely path for healthy batteries will be to recondition them and redeploy them in service in a non-vehicle application. This approach avoids all of the costs and energy use to produce new batteries and improves batteries’ life cycle emissions and costs because the batteries are kept out of the recycling stream for many years past when they are not fit for use in hybrid electric vehicles. Batteries that cannot be repurposed would likely be recycled and would have the raw materials recaptured to produce new batteries.

As lithium-ion batteries are made out of many materials that can be toxic to humans and animals in chemical reactions (such as water), special treatment is recommended during the disposal of the vehicle battery packs that cannot be recycled. This includes setting aside these battery packs, and proper handling and transport for disposal at the appropriate hazardous material facility. This would ensure that no hazardous materials are disposed of at landfills and that hazardous materials do not enter the waste stream.

Secondary impacts would result from the import and use of hybrid electric vehicles. As discussed in Section 2.3.4.3, the representative project would result in the import of approximately 383,000 hybrid electric vehicles in the State. As existing, conventional, internal combustion engine vehicles would need to be replaced, this would result in an increase in the amount of waste vehicles that would be disposed of in Hawai‘i. It is anticipated that the majority of the vehicles would be disposed of at recycling facilities in the State; however, it is noted that not all car parts or materials may be reused or recycled. Non-recyclable car parts or materials may require disposal at one of the various landfills serving the State or may have to be exported, generating a greater carbon footprint.

7.3.14.1.3 Wastewater

As identified in [Table 7-3](#), there would be no potential impacts to wastewater from the representative HEV project.

7.3.14.2 Best Management Practices and Mitigation Measures

As discussed in Section 3.14, several landfills in the islands of O‘ahu and Hawai‘i are currently at capacity. As such, depending on the proposed project location, the disposal of non-recyclable car

parts/materials may add to existing landfill capacity constraints. The resolution of landfill siting and expansion on several islands are pending or are in the process. Therefore, additional waste produced in the islands of O‘ahu and Hawai‘i may result in potential secondary impacts, pending the resolution of existing landfill capacity constraints.

7.3.15 SOCIOECONOMICS

As identified in [Table 7-3](#), there would be no potential impacts to socioeconomics from the representative HEV project.

7.3.16 ENVIRONMENTAL JUSTICE

As identified in [Table 7-3](#), there would be no environmental justice impacts from the representative HEV project.

7.3.17 HEALTH AND SAFETY

As identified in [Table 7-3](#), there would be no health and safety impacts from the representative HEV project.

7.4 Hydrogen

The representative project involves the production and distribution of hydrogen as an alternative transportation fuel source to replace approximately 20 million gallons per year of gasoline (see Section 2.3.4.5.5). This would require the production of approximately 44 million pounds, or 20 million kilograms, per year of hydrogen. The representative project assumes production of hydrogen from water via a combination of two sources: (1) a 25-megawatt geothermal plant on Hawai‘i Island; and (2) 50 megawatts of solar energy on O‘ahu. This would require the installation and development of distribution infrastructure including pipelines, storage tanks, and fueling stations on Hawai‘i and O‘ahu. The representative project would have the option of using tanker trucks instead of distribution pipelines, or a combination of both. The Summary of Potential Impacts and Best Management Practices/Mitigations in Chapter 6 for both a utility-scale geothermal (Table 6-3) and solar PV facility (Table 6-8) would apply for those facilities.

[Table 7-4](#) presents a summary of the potential environmental impacts for hydrogen, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 7-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Hydrogen

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	General construction and operation impacts (see Section 3.1.3).	Same as those common across construction and operation projects (see Section 3.1.4).
Climate and Air Quality		
Air Quality	General construction impacts (see Section 3.2.4). Potential air emissions associated with distribution of hydrogen.	Same as those common across construction and operation projects (see Section 3.2.5).
Climate Change	Potential beneficial impact; A reduction of 20 million gallons of gasoline would correspond with an annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent.	
Water Resources		
	General construction and operation impacts (see Section 3.3.5). Groundwater likely would be required for the generation of hydrogen.	Same as those common across construction and operation projects (see Section 3.3.6).
Biological Resources		
	None; the generation of hydrogen and use of hydrogen as a vehicle fuel would not result in impacts to biological resources.	N/A
Land and Submerged Land Use		
Land Use	Potential change in land use from the expansion of the existing geothermal facility on Hawai‘i and a future PV complex on O‘ahu. Depending on the actual siting of the facility there could be change in landownership patterns. Potential change in land use in locations where distribution pipeline and storage tanks would be installed and fueling stations constructed. Operation impacts to land use would be limited to facility maintenance activities.	During site selection, consider Hawai‘i land use designations and county overlay zoning. Avoid sensitive features, such as scenic and historic properties, and important designated areas, such as Hawai‘i Volcanoes National Park on Hawai‘i and multiple scenic and historical areas of O‘ahu.
Submerged Land Use	None.	N/A

Table 7-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Hydrogen (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Cultural and Historic Resources		
	<p>General construction and operation impacts (see Section 3.6.6).</p> <p>Additional cultural perspectives and impacts regarding geothermal energy development are described in Section 6.2.6.</p>	<p>Same as those common across construction and operation projects (see Section 3.6.7).</p>
Coastal Zone Management		
	<p>Potential impacts to designated special management areas and affect shorefront access.</p>	<p>Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.</p>
Scenic and Visual Resources		
	<p>General construction impacts (see Section 3.8.3).</p> <p>Long-term visual impacts would occur from the presence of the new production facilities and distribution infrastructure, including pipelines, storage tanks, and fueling stations, and exterior lighting. Visual impacts would be highly dependent on the location and compatibility with the existing viewshed and land uses.</p>	<p>During site selection, avoid:</p> <ul style="list-style-type: none"> • Coastal scenic resources from public viewing points and coastal highways; • Designated scenic byways on Hawai‘i and Kaua‘i; • State, National, and National Historical Parks; • Reserves protected by the Natural Area Reserves System; and • Residential and recreational areas. <p>Consult with the county general land use plans and associated implementation tools such as zoning ordinances and development standards regarding protecting and maintaining open space and scenic resources.</p>
Recreation Resources		
	<p>General construction and operation impacts (see Section 3.9.4).</p>	<p>Same as those common across construction and operation projects (see Section 3.9.5).</p>
Land and Marine Transportation		
Land Transportation	<p>General construction impacts (see Section 3.10.3).</p> <p>Potential long-term land transportation impacts from tanker trucks transporting the produced hydrogen if tankers are used with or in place of pipelines.</p>	<p>None.</p>
Marine Transportation	<p>Potential long-term marine transportation impacts if produced hydrogen is transported to other islands; would require additional handling facilities at harbors as well as ships with the appropriate storage capability.</p>	<p>Consider potential hazards of hydrogen fuel when locating and designing harbor facilities for handling hydrogen; consider compatibility with existing harbor infrastructure and operations.</p>

Table 7-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Hydrogen (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Airspace Management		
	None; the generation of hydrogen or the use of hydrogen as a vehicle fuel would not result in any tall structures or other impacts to regional airspace.	N/A
Noise and Vibration		
	<p>General impacts during construction (see Section 3.12.5).</p> <p>Potential long-term impacts to existing noise and vibration levels, depending on the location of facilities and compatibility with existing noise levels and land uses.</p> <p>Increase in marine vessel transport operations would increase noise levels at the harbors.</p>	Same as those common across construction and operation projects (see Section 3.12.6).
Utilities and Infrastructure		
	<p>Impacts from increased hydrogen production would similar to those in Section 6.2.3 for the geothermal technology and Section 6.7.3 for PV technology.</p> <p>No impacts from hydrogen-operated vehicles because it would not result in a change to electricity demand.</p>	None.
Hazardous Materials and Waste Management		
Hazardous Materials	<p>Minimal hazardous material exposure impacts anticipated from increased hydrogen production at the geothermal facility.</p> <p>No hazardous material exposure impacts anticipated from hydrogen production via a 50-megawatt utility-scale solar PV system.</p> <p>Minimal hazardous waste exposure impacts during distribution of fuel via tankers or pipelines.</p> <p>Minimal impacts from exposure to hazardous materials during construction and development of hydrogen pipelines and fueling stations.</p> <p>Minimal hazardous material exposure impacts during operation of hydrogen fuel-celled vehicles.</p>	If hydrogen were to be distributed via pipelines, proper siting procedures and BMPs would be implemented.

Table 7-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Hydrogen (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Waste Management	<p>No new solid waste to be generated by the geothermal facility for hydrogen production.</p> <p>Minimal waste management impacts would occur during construction of utility-scale PV system for hydrogen production and associated distribution pipelines and fueling stations (see Section 3.14.4).</p> <p>Minimal impacts would occur during the end life of the PV system; discarded solar panels may need to be managed and disposed of as hazardous waste; it is anticipated that primary waste management impacts resulting from the project would be minimal. Other potential impacts may result from displacement of existing internal combustion vehicles, potentially increasing vehicle waste disposal--potential impacts pending resolution of existing landfill capacity constraints.</p>	Displaced vehicle wastes would be disposed of at recycling facilities in the State; non-recyclable car parts or materials may require disposal at one of the landfills serving the State.
Wastewater	<p>Potential wastewater impacts associated with hydrogen production from the representative geothermal project would be similar to those impacts discussed in Section 6.2.</p> <p>Potential beneficial impacts to water resources and wastewater services if the project produced hydrogen using wastewater.</p> <p>Wastewater impacts resulting from solar energy produced hydrogen would likely occur during the manufacturing process. These impacts are discussed in Section 5.4.14.1.2.</p>	None.
Socioeconomics		
	The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income would be small.	None.
Environmental Justice		
	<p>Small environmental justice impacts.</p> <p>Site-specific evaluation of impacted populations required.</p>	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians

Table 7-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Hydrogen (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Health and Safety		
	<p>No significant accident consequences are anticipated as a result of increased use of hydrogen as a vehicle fuel.</p> <p>Storage, handling, and distribution of hydrogen has risks of fire and explosions.</p> <p>Effects on island public safety services would be small; workers needed to construct and operate facilities expected to come from the State’s existing workforce. Police, fire, and medical services would not be adversely affected with this small change.</p>	<p>As production methods are studied, the application of the existing safe infrastructure and associated processes and procedures will be tailored to the specific safety risks of each.</p> <p>First responder training for any unique features of this technology as it is introduced to Hawai‘i may be needed to improve emergency response safety and effectiveness. Training such as the National Alternative Fuels Consortium’s First Responder Safety Training may be used to become trained.</p>

7.4.1 GEOLOGY AND SOILS

7.4.1.1 Potential Impacts

Potential impacts to geology and soils from the construction and operation of the representative project facilities would be the same as those expected for common construction actions as described in Section 3.1.3. Since the amount of land disturbed would be well over one acre, the permitting requirements described in Section 3.1.3 would be fully applicable. Any ground disturbance from installation of pipelines, storage tanks, and fueling stations also would result in the types of potential impacts expected for common construction activities.

Operation of the hydrogen production facilities would not involve activities that would have the potential to affect geology and soils of the area. Likewise, operation of the hydrogen fuel cell vehicles supported by the representative project would not be expected to have any impact on geology or soils.

7.4.1.2 Best Management Practices and Mitigation Measures

BMPs for geology and soils would be the same as those common across construction and operation projects (see Section 3.1.4).

7.4.2 CLIMATE AND AIR QUALITY

7.4.2.1 Potential Impacts

7.4.2.1.1 Air Quality

The representative project would require the construction of facilities to produce hydrogen and the infrastructure to distribute it. Impacts on air quality from the representative project would be the same as those expected for common construction actions described in Section 3.2.4.

The facilities used to produce hydrogen would use either geothermal or solar energy. Using these energy sources would reduce air emissions compared with processes that burn fossil fuels to produce electricity. However, these reduced air emissions may be partially offset during the distribution of hydrogen. Suppliers can transport hydrogen via pipeline or over roadways using tube trailer or cryogenic liquid hydrogen tankers. If hydrogen were transported via pipeline, reduction in air emissions would be realized. However, if hydrogen were transported over roadways, air emissions may be partially offset dependent on the fuel used by the trailer/tanker.

Operation of hydrogen fuel cell vehicles would result in reduced air emissions when compared with vehicles operating using existing internal combustion engines.

7.4.2.1.2 Climate Change

A reduction of 20 million gallons of gasoline would correspond with an annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent.

7.4.2.2 Best Management Practices and Mitigation Measures

BMPs for climate and air quality would be the same as those common across construction and operation projects (see Section 3.2.5).

7.4.3 WATER RESOURCES

7.4.3.1 Potential Impacts

The representative project assumes hydrogen would be generated using electricity from a combination of geothermal technology and solar photovoltaic technology. Potential impacts to water resources from these technologies were described in Sections 6.2.3 and 6.7.3, respectively, and are not repeated here.

7.4.3.1.1 Surface Water

Effects on surface water during construction of hydrogen production plants would be the same as those expected for common construction actions as described in Section 3.3.5.

Runoff from the hydrogen production facilities likely would be different than conditions prior to construction, and if the amount of impermeable surfaces were greater, higher runoff rates would be expected. Management of an increased volume of runoff would depend on the nature of the specific site (for example, whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns.

Operation of hydrogen fuel cell vehicles supported by the representative project would not be expected to have any impact on surface water resources.

7.4.3.1.2 Groundwater

Impacts to groundwater during construction of hydrogen production plants would be the same as those expected for common construction actions as described in Section 3.3.5.

During operations, water from groundwater would likely be the source of the hydrogen produced from the facilities, so both the geothermal and solar energy facilities would have an additional water demand not

considered in either Section 6.2.3 or Section 6.7.3. Based solely on its molecular structure, the minimum amount of water that would be required to produce 44 million pounds of hydrogen on an annual basis would be 396 million pounds, or about 48 million gallons per year. (Ideally, the hydrogen produced would be two-eighths, or one-ninth, of the water processed.) Split between the two facilities, the water demand at each would be about 24 million gallons per year, or 0.066 million gallons per day. These water demands would not be expected to be prohibitive. The groundwater resources on O‘ahu’s and Hawai‘i’s are characterized as having sustainable yields of 407 and 2,410 million gallons per day, respectively, compared to a groundwater usage of only about 190 and 92 million gallons per day (Tables 3-19 and 3-27), so on an island-wide basis, groundwater availability would not appear to be a problem. In addition, other sources of water (e.g., surface water, seawater, or treated wastewater) may be appropriate for hydrogen production.

Operation of hydrogen fuel cell vehicles supported by the representative project would not be expected to have any impact on groundwater resources.

7.4.3.1.3 Floodplains and Wetlands

The proponent of the representative hydrogen project would be expected to avoid floodplains and wetlands areas if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as those described for common construction actions in Section 3.3.5.

7.4.3.2 Best Management Practices and Mitigation Measures

BMPs for water resources would be the same as those common across construction and operation projects (see Section 3.3.6).

7.4.4 BIOLOGICAL RESOURCES

Beyond those identified for geothermal and solar PV projects, as identified in [Table 7-4](#), there would be no potential impacts to biological resources from the representative hydrogen project.

7.4.5 LAND AND SUBMERGED LAND USE

7.4.5.1 Potential Impacts

7.4.5.1.1 Land Use

The representative project involves the production of hydrogen at an existing geothermal facility and/or solar energy facility. Surface land use impacts could occur from the expansion of a geothermal facility on Hawai‘i island and a future solar energy complex on O‘ahu. Both projects could result in removing land from its current uses for the development of hydrogen. Depending upon the actual siting of the solar facility there could be some change in landownership patterns. Operational impacts to land use would be limited to facility maintenance activities.

7.4.5.1.2 Submerged Land Use

As identified in [Table 7-4](#), there would be no potential impacts to submerged land use from the representative hydrogen project.

7.4.5.2 Best Management Practices and Mitigation Measures

- During site selection, consider Hawai‘i land use designations and county overlay zoning.
- Avoid sensitive features, such as scenic and historic properties, and important designated areas, such as Hawai‘i Volcanoes National Park on Hawai‘i and multiple scenic and historical areas of O‘ahu.

7.4.6 CULTURAL AND HISTORIC RESOURCES

7.4.6.1 Potential Impacts

Potential impacts to cultural and historic resources from the construction and operation of the representative project facilities would be the same as those expected for common construction and operation actions as described in Section 3.6.6. Cultural perspectives and impacts regarding geothermal energy development are described in Section 6.2.6.

Operation of the hydrogen fuel cell vehicles supported by the representative project would not be expected to have any impact on cultural and historic resources.

7.4.6.2 Best Management Practices and Mitigation Measures

BMPs for cultural and historic resources would be the same as those common across construction and operational projects (see Section 3.6.7).

7.4.7 COASTAL ZONE MANAGEMENT

7.4.7.1 Potential Impacts

Development of hydrogen fuel production could eventually require development of harbor facilities for handling and distributing produced hydrogen between the islands. The harbor facilities could impact designated special management areas and affect shorefront access. However, these facilities likely would be developed in areas with similar, existing facilities and would most likely be consistent with current uses. Nevertheless, potential impacts could require evaluation through a Federal consistency review under the Coastal Zone Management Program.

7.4.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

7.4.8 SCENIC AND VISUAL RESOURCES

7.4.8.1 Potential Impacts

Potential impacts to scenic and visual resources from the construction of the representative project facilities would be the same as those expected for common construction actions as described in Section 3.8.3.

Long-term visual impacts would occur from the presence of the new production facilities and distribution infrastructure. In addition to the pipelines, storage tanks, and fueling stations on the islands, exterior

lighting would be necessary for safety and security purposes. Visual impacts would be highly dependent on the location and compatibility with the existing viewshed and land uses. If tanker trucks were used along with or instead of distribution pipelines, the visual impacts from the added infrastructure would be reduced or avoided.

7.4.8.2 Best Management Practices and Mitigation Measures

During site selection, avoid sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the three designated scenic byways; State, National, and National Historical Parks; reserves protected by the Natural Area Reserves System; and residential and recreational areas.

Consult with the county general land use plans and associated implementation tools such as zoning ordinances and development standards regarding protecting and maintaining open space and scenic resources.

7.4.9 RECREATION RESOURCES

7.4.9.1 Potential Impacts

Potential impacts to recreation resources from the construction and operation of the representative project would be the same as those expected for common construction and operation actions as described in Section 3.9.4.

7.4.9.2 Best Management Practices and Mitigation Measures

BMPs for recreation resources would be the same as those common across construction and operation projects (see Section 3.9.5).

7.4.10 LAND AND MARINE TRANSPORTATION

7.4.10.1 Potential Impacts

7.4.10.1.1 Land Transportation

Potential impacts to land transportation from the construction of the representative project would be the same as those expected for common construction actions as described in Section 3.10.3.

Long-term impacts would occur if tanker trucks were used to augment or replace the pipeline distribution system for transporting produced hydrogen from the point of production to the point of use (i.e., fueling stations). The use of hydrogen fuel cells in vehicles should not have any adverse impacts to the transportation system.

7.4.10.1.2 Marine Transportation

The representative project could involve marine transport to distribute the produced hydrogen to the other Hawaiian Islands, such as Maui and Kaua'i, which would require additional handling facilities at harbors and ships with the appropriate storage capability.

7.4.10.2 Best Management Practices and Mitigation Measures

Consider the potential hazards of hydrogen fuel when locating and designing harbor facilities for handling hydrogen as well as compatibility with existing harbor infrastructure and operations.

7.4.11 AIRSPACE MANAGEMENT

As identified in [Table 7-4](#), there would be no potential impacts to airspace management from the representative hydrogen project.

7.4.12 NOISE AND VIBRATION

7.4.12.1 Potential Impacts

Short-term noise and vibration impacts would result during construction of facilities required to produce hydrogen and the infrastructure required to distribute it as an alternative transportation fuel source. It is assumed that the hydrogen would be produced via energy from a representative geothermal facility on Hawai'i and also via solar energy on O'ahu. The representative hydrogen project could result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

The representative hydrogen project could potentially result in long-term impacts to existing noise and vibration levels. Noise and vibration would result from operation of production and distribution facilities, including fueling stations. Tanker trucks may be utilized in place of distribution pipelines. Hydrogen would also then be distributed via marine transport to the other islands such as Maui and Kaua'i. The increase in vessel operations could increase noise levels at the harbors, potentially affecting nearby noise and vibration-sensitive receptors identified. Noise and vibration impacts would be dependent on the location and compatibility with the existing noise levels and land uses.

7.4.12.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation (see Section 3.12.6).

7.4.13 UTILITIES AND INFRASTRUCTURE

7.4.13.1 Potential Impacts

Potential impacts to utilities and infrastructure from the construction and operation of the representative project facilities would be very similar to those described in Section 6.2.3 for the geothermal technology and Section 6.7.3 for PV technology.

As identified in [Table 7-4](#), there would be no potential impacts to utilities and infrastructure from the operation of hydrogen-powered vehicles since no electrical demand change is expected for this initiative. However, the construction and operation of new hydrogen fueling stations would be required.

7.4.13.2 Best Management Practices and Mitigation Measures

None noted.

7.4.14 HAZARDOUS MATERIAL AND WASTE MANAGEMENT

7.4.14.1 Potential Impacts

7.4.14.1.1 Hazardous Materials

The Hawai'i Natural Energy Institute prepared a draft environmental assessment to analyze potential impacts of producing hydrogen at the Puna Geothermal Venture Plant ([HNEI 2012](#)). That document reported that there are no known spills or other incidents involving hazardous or toxic substances that would require precautions during placement of equipment at the sites beyond those that would normally occur in an industrial setting, where flammable and hazardous substances are stored and used as part of various operations. As with any fuel, there are hazards involved in hydrogen production, storage, and transportation. However, these can be minimized by adhering to standard industry practices.

It is anticipated that the representative hydrogen production and storage facility would adhere to Federal, State, and local laws and codes and regulations. In the event of an emergency or spill, the project would comply with existing spill and response plans, including compliance with manufacturers' material safety data sheets, OSHA, USDOT, and HDOT requirements. In addition, project personnel would notify first responders and HDOH. As such, hazardous material exposure impacts resulting from increased hydrogen production at a representative geothermal facility would be minimal.

Potential impacts from the production of hydrogen via a PV system would be the same as those expected for common construction actions as described in Section 3.14.4.

Once produced, hydrogen would be distributed to fueling stations either via tankers or via pipelines. The distribution of hydrogen via tankers would occur in accordance with Federal, State, and county laws and regulations for the storage, handling, and transport of fuels. Hydrogen distributed via pipelines would require construction of a pipeline distribution system, and proper siting procedures and BMPs would be implemented.

The representative project also includes use of hydrogen-fueled vehicles, the operation of which would not result in impacts to hazardous material. Hazardous material exposure impacts would be related to the vehicles' end-of-life, in that the vehicles' battery pack to fuel and power the vehicle would require long-term disposal. A detailed discussion of battery disposal impacts follows.

7.4.14.1.2 Waste Management

No new solid waste is anticipated to be generated by producing hydrogen at a representative geothermal facility; therefore, there would be no impacts to waste management.

Minimal impacts would occur during the construction of a utility-scale PV system for hydrogen production. Impacts associated with PV systems are discussed in Section 6.6.14.

The primary waste management impacts resulting from the use of hydrogen as a fuel would occur at the end-of-life of the hydrogen fuel cell vehicles (refer to [Section 7.3.14.1.2](#)). Special treatment is recommended during the disposal of the vehicle battery packs that cannot be recycled, as most batteries are made out of many materials that can be toxic to humans and animals. Special treatment could include setting aside the battery pack, and employing proper handling and transport for disposal at the appropriate hazardous material facility. This would ensure that no hazardous materials were disposed of at landfills and that hazardous materials did not enter the waste stream. Additional discussion regarding batteries and fuel cell disposal can be found in Sections 5.3.14 and 8.5.14.

As discussed in Section 3.14, several landfills on the islands of O‘ahu and Hawai‘i are currently at capacity. As such, depending on the proposed project location, the disposal of non-recyclable car parts/materials may add to existing landfill capacity constraints. The resolution of landfill siting and expansion on several islands are pending. Therefore, additional waste produced on the islands of O‘ahu and Hawai‘i may result in potential impacts.

7.4.14.1.3 Wastewater

Potential impacts to wastewater from the construction and operation of the representative project would be the same as those expected for common construction and operation actions as described in Section 3.14.4.

Wastewater impacts related to using a PV system to produce hydrogen are discussed in Section 5.4.14.1.2.

7.4.14.2 Best Management Practices and Mitigation Measures

7.4.14.2.1 Hazardous Materials

Ensure the hydrogen system meets all appropriate hydrogen codes and standard requirements, is thoroughly tested by the manufacturers, and undergoes third-party acceptance testing.

Site infrastructure designs would also be expected to meet applicable hydrogen safety codes and standards, and installation be conducted by experienced and reputable contractors. These include Federal, State, and county regulations as well as codes of the International Code Council and those developed by the National Fire Protection Association affecting or related to the storage, dispensing, use, and handling of gaseous and liquefied hydrogen.

7.4.14.2.2 Waste Management

- Separate the used battery packs to ensure non-recyclable packs are not batched for recycling.
- Employ proper handling and transport for disposal at the appropriate hazardous material facility.
- During site selection, consider existing landfill capacity constraints.

7.4.14.2.3 Wastewater

BMPs for wastewater would be the same as those common across construction and operation projects (see Section 3.14.5).

7.4.15 SOCIOECONOMICS

7.4.15.1 Potential Impacts

Socioeconomic impacts in Hawai‘i arising from the representative hydrogen project would be very small. The plant apparatus and appliances pipelines, storage tanks, and fuel station apparatus likely would be manufactured outside of the State. Therefore, economic benefits associated with manufacturing would accrue elsewhere. If the pipeline distribution infrastructure was installed, there would be additional, but still very small, socioeconomic impacts. The few jobs directly associated with the production of hydrogen and the temporary jobs associated with the installation of a distribution system would likely be filled by individuals residing within the area of influence (the State of Hawai‘i) and not by in-migrating workers. The impact to population; to employment variables such as the size of the labor force, unemployment

rates, and employment in the State and county government sector; to rental housing; and to personal income would be very small.

7.4.15.2 Best Management Practices and Mitigation Measures

None identified.

7.4.16 ENVIRONMENTAL JUSTICE

7.4.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the representative hydrogen project are expected to be small. Impacts to minority and low-income populations also would be small.

7.4.16.2 Best Management Practices and Mitigation Measures

During site selection of the PV facility on O‘ahu, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

7.4.17 HEALTH AND SAFETY

7.4.17.1 Potential Impacts

Facilities for storing, handling, and distributing hydrogen have potential hazards related to combustion (flammable) and overpressure (explosions) that could extend into the surrounding area. The siting, construction, and operation of these facilities would have to account for these potential hazards through regulatory requirements and guidelines. Effects on public safety services would be small since the workers needed to construct and operate the hydrogen production facilities would be expected to come from the island’s existing work force. Police, fire, and medical services would not be adversely affected with this small change. First responder training for any unique features of this technology as it is introduced to Hawai‘i may be needed to improve emergency response safety and effectiveness. Training such as the National Alternative Fuels Consortium’s First Responder Safety Training may be used to become properly trained.

Potential health and safety impacts associated with the production of hydrogen are addressed in Sections 6.2.17 and 6.6.17. Common construction impacts could occur from standard industrial hazards.

7.4.17.2 Best Management Practices and Mitigation Measures

The BMPs associated with the production of hydrogen are addressed in Sections 6.2.17 and 6.6.17.

7.5 Compressed and Liquefied Natural Gas, and Liquefied Petroleum Gas

The representative natural gas project would offset a total of 20 million gallons per year of gasoline by importing approximately 10 million gallons per year gasoline gallon equivalency of natural gas and increasing local production of liquefied petroleum gas (LPG) to approximately 10 million gallons per year

gasoline gallon equivalency (see Section 2.3.4.5). The imported natural gas would be used to produce approximately 15 million gallons (10 million gallons per year × 1.5362) of liquefied natural gas (LNG).

The representative project assumes LNG would replace synthetic natural gas use. As the distribution system for synthetic natural gas is currently set up in the State, the liquefied natural gas would use the existing infrastructure, with modifications and/or expansions to the existing distribution system occurring to the extent necessary. Likewise, the current liquefied petroleum gas distribution network would be modified and/or expanded as necessary.

The import of natural gas to the State for transportation use would require increased capital for upfront investments to develop a liquefied natural gas import station, the fueling infrastructure on O‘ahu, and for smaller import terminals on the other islands. The representative project assumes natural gas vehicles would not be imported, as car conversions would occur, albeit costly. Passenger vehicles would mostly be converted to compressed natural gas- and propane powered vehicles, while heavy-duty vehicles, including transit buses, waste collection and transfer vehicles, airport shuttles and vehicles, and City and State vehicles would be converted to run on liquefied natural gas.

Table 7-5 presents a summary of the potential environmental impacts for compressed and liquefied natural gas, and liquefied petroleum gas, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of compressed and liquefied natural gas, and liquefied petroleum gas and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 7-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Compressed and Liquefied Natural Gas, and Liquefied Petroleum Gas

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	General construction and operation impacts (see Section 3.1.3).	Same as those common across construction and operation projects (see Section 3.1.4).
Climate and Air Quality		
Air Quality	<p>General construction impacts (see Section 3.2.4).</p> <p>Operational impacts could occur due to marine vehicles importing natural gas generating criteria pollutants, as would trucks used for on-island transport. Leaks and air emissions from the liquid natural gas import station would be possible.</p> <p>While greenhouse gas emissions would be produced, potentially beneficial operational air quality and climate change impacts due to replacement of 20 million gallons of gasoline.</p>	Same as those common across construction and operation projects (see Section 3.2.5).

Table 7-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Compressed and Liquefied Natural Gas, and Liquefied Petroleum Gas (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Climate Change	<p>General construction impacts (see Section 3.2.4).</p> <p>Operational impacts could occur due to marine vehicles importing natural gas generating greenhouse gasses, as would trucks used for on-island transport. Leaks and air emissions from the liquid natural gas import station would be possible.</p> <p>While greenhouse gas emissions would be produced, potential beneficial operational benefits due to replacement of 20 million gallons of gasoline.</p>	Same as those common across construction and operation projects (see Section 3.2.5).
Water Resources		
	General construction and operation impacts (see Section 3.3.5).	Same as those common across construction and operation projects (see Section 3.3.6).
Biological Resources		
	<p>Potential localized impacts from disturbance to marine communities and essential fish habitat during construction and anchoring of offshore facilities (if such facilities are required).</p> <p>No biological resources impacts anticipated during upgrade and expansion of existing onshore infrastructure as these activities are expected to occur in existing developed areas.</p>	Same as those common across construction and operation projects (see Section 3.4.6).
Land and Submerged Land Use		
Land Use	General construction and operation impacts (see Section 3.5.4).	<p>Consider State land use designations, county overlay zones, and other recognized scenic and historic features and areas.</p> <p>Locate new import facilities at existing industrial and harbor locations.</p> <p>Construct natural gas/LPG fueling stations along existing highways.</p>
Submerged Land Use	None; the import of natural gas and subsequent installation of LNG and LPG infrastructure would not impact submerged land use.	N/A
Cultural and Historic Resources		
	General construction and operation impacts (see Section 3.6.6).	Same as those common across construction and operation projects (see Section 3.6.7).

Table 7-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Compressed and Liquefied Natural Gas, and Liquefied Petroleum Gas (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Coastal Zone Management		
	Potential impacts due to development of harbor facilities for handling and distributing natural gas between islands.	Federal consistency review could be required to ensure consistency with the policies and goals of the Coastal Zone Management Program.
Scenic and Visual Resources		
	General construction impacts (see Section 3.8.3). Potential long-term impacts due to new import terminal (onshore or offshore); new industrial facility with one or more aboveground storage tanks; exterior lighting; cargo ship traffic (site-specific).	Same as those common across construction and operation projects (see Section 3.8.4).
Recreation Resources		
	General construction and operation impacts (see Section 3.9.4).	Same as those common across construction and operation projects (see Section 3.9.5).
Land and Marine Transportation		
Land Transportation	Land transportation would be required to distribute gas to local fueling stations. Natural gas would likely replace other petroleum-based products; therefore the amount of truck transportation would not increase but change to a different type of vehicle.	Safety issues would have to be addressed in the development of land-based natural gas infrastructure and operations.
Marine Transportation	The import of natural gas would require development of fueling infrastructure at island harbors, either onshore or offshore. Shipping transportation would require specialized tankers or natural gas carriers to maintain natural gas temperature.	Shipment of natural gas would raise issues of safety and potential accidents that would have to be addressed in the development of infrastructure and operations.
Airspace Management		
	None; the import of natural gas and subsequent installation of LNG and LPG infrastructure would not impact airspace management.	N/A
Noise and Vibration		
	General impacts during construction (see Section 3.12.5). Potential long-term impacts to existing noise and vibration levels, depending on the location of facilities and compatibility with existing noise levels and land uses. Increase in marine vessel transport operations would increase noise levels at the harbors.	Same as those common across construction and operation projects (see Section 3.12.6).

Table 7-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Compressed and Liquefied Natural Gas, and Liquefied Petroleum Gas (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Utilities and Infrastructure		
	<p>Small net change in expected power demand to electric utilities.</p> <p>Infrastructure of LNG/LPG fueling stations would need to be expanded to support demand.</p>	None.
Hazardous Materials and Waste Management		
Hazardous Materials	<p>Potential exposure to hazardous material impacts during import, storage, and distribution of natural gas if accidental spills or releases occur.</p> <p>Potential short-term construction impacts from exposure to hazardous materials during modifications and/or expansions of natural gas distribution system (see Section 3.14).</p> <p>Minimal impacts from exposure to hazardous materials from increased propane production, distribution and use on O‘ahu.</p> <p>The operation of compressed natural gas vehicles and propane-powered vehicles is not anticipated to result in hazardous material exposure impacts.</p>	<p>Safety guidelines should be considered during the design and installation of compressed natural gas refueling facilities including the National Fire Prevention Association’s NFPA 52 Vehicular Gaseous Fuel Systems Code as well as compliance with Federal, State, and local laws and regulations for the storage, handling, and transport of fuels.</p> <p>Safety guidelines would apply similar to those required for natural gas during the handling, transport, and distribution of propane gas, and in the event of accidental releases or spills. Compliance with Federal, State, and local laws and regulations for the storage, handling, and transport of fuels.</p> <p>Vehicle conversions shall occur via licensed technicians associated with vehicle manufacturers and would be certified to meet EPA requirements and to ensure that equipment is properly installed, safe and durable, and meets the associated standards of the vehicle model year.</p>

Table 7-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Compressed and Liquefied Natural Gas, and Liquefied Petroleum Gas (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Waste Management	<p>No potential impacts associated with import and use of natural gas.</p> <p>Potential waste management impacts during construction and development of additional natural gas infrastructure/modification and expansions (see Section 3.14).</p> <p>Minimal impacts associated with modification and expansion of LPG infrastructure.</p> <p>Minimal impacts associated with retrofitting existing vehicle fleet for natural gas/LPG use.</p>	None.
Wastewater	None.	N/A
Socioeconomics		
	The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income would be very small.	None.
Environmental Justice		
	Small environmental justice impacts.	None.
Health and Safety		
	<p>General construction and operation impacts (see Section 3.17.3).</p> <p>Facilities for storing, handling, and distributing compressed or liquefied natural gas or liquefied petroleum gas have potential hazards related to toxic (fumes), combustion (flammable), and overpressure (explosions) that could extend into the surrounding area.</p>	<p>Follow State reporting requirements for releases above regulatory limits.</p> <p>Follow National Fire Prevention Association’s NFPA 52 Vehicular Gaseous Fuel Systems Code.</p>

7.5.1 GEOLOGY AND SOILS

7.5.1.1 Potential Impacts

Impacts on geology and soils during actions to import natural gas and upgrade natural gas and LPG infrastructure and distribution systems would be the same as those expected for common construction actions as described in Section 3.1.3. It is assume the amount of land disturbed the project, or individual

elements of the project would be well over one acre, the permitting requirements described in Section 3.1.3 would be fully applicable.

7.5.1.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures to reduce impacts to geology and soils are discussed in Section 3.1.4.

7.5.2 CLIMATE AND AIR QUALITY

7.5.2.1 Potential Impacts

7.5.2.1.1 Air Quality

Impacts on air quality from the representative project would be the same as those expected for common construction actions described in Section 3.2.4. The representative project would require the construction of facilities to distribute natural gas and liquefied petroleum gas. The construction would include a natural gas import station, regasification facilities, facilities required to increase liquid petroleum gas production on the islands, and the fueling infrastructures for both types of fuel.

The marine vessels required to import natural gas would generate criteria pollutants from their engines as would the trucks required to transport the fuel on the islands. Leaks and air emissions from the natural gas import station would be possible.

7.5.2.1.2 Climate Change

The proposed representative project would replace 20 million gallons of gasoline usage in transportation vehicles in the State. A reduction of 20 million gallons of gasoline would correspond with an annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent. However, although natural gas vehicles generate fewer criteria pollutants and greenhouse gases than gasoline-powered vehicles, they still generate emissions. Consequently, the reduction in greenhouse gas emissions from lowering gasoline usage in passenger vehicles would be partially offset by the emissions from the natural gas vehicles. Typically, the greenhouse gas emissions from natural gas-fueled vehicles are 25 percent lower than conventional gas or diesel powered vehicles ([EPA 2014](#)).

As noted above, the marine vessels required to import natural gas would generate criteria pollutants and subsequently greenhouse gas from their engines as would the trucks required to transport the fuel on the islands. Leaks and air emissions from the natural gas import station would be possible.

7.5.2.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures to reduce air quality and greenhouse gas emission impacts are discussed in Section 3.2.5.

7.5.3 WATER RESOURCES

7.5.3.1 Potential Impacts

Impacts on water resources during actions to upgrade natural gas and LPG infrastructure and distributions systems would be the same as those expected for common construction actions as described in Section 3.3.5.

7.5.3.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures to minimize potential water resource impacts are discussed in Section 3.3.6.

7.5.4 BIOLOGICAL RESOURCES

7.5.4.1 Potential Impacts

Some offshore import infrastructure may be developed to handle natural gas in addition to modification of existing on shore facilities. Some localized disturbance to the marine communities, including potential impacts on essential fish habitat, would occur during the construction and anchoring of offshore facilities. Upgrading and expanding existing onshore natural gas infrastructure is not expected to impact biological resources as they would be expected to occur in existing developed areas. If new land was disturbed, common construction impacts from vegetation clearing could occur as discussed in Section 3.4.5.

7.5.4.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures to minimize construction impacts from vegetation clearing are discussed in Section 3.4.6.

7.5.5 LAND AND SUBMERGED LAND USE

7.5.5.1 Potential Impacts

7.5.5.1.1 Land Use

From a land use perspective, increased use of natural gas would require modifications and/or expansions to existing distribution systems. LPG distribution networks could also require modifications or expansions. A natural gas import station and fueling infrastructure would be required on O‘ahu, and smaller import terminals would be required on the other islands. The location and construction of terminals and associated support facilities would result in land disturbance. There would be no operational impacts on land use.

7.5.5.1.2 Submerged Land Use

As identified in [Table 7-5](#), there would be no potential impacts to submerged land use from the representative project.

7.5.5.2 Best Management Practices and Mitigation Measures

The installation of distribution systems and the siting of import terminals would consider State land use designations, county overlay zones, and other recognized scenic and historic features and areas. The facilities would be located at existing industrial and harbor locations. The natural gas/LPG fueling stations would be constructed along existing highways to be convenient to the driving population.

7.5.6 CULTURAL AND HISTORIC RESOURCES

7.5.6.1 Potential Impacts

Impacts on cultural and historic resources during actions to import natural gas and upgrade natural gas and LPG infrastructure and distributions systems would be the same as those expected for common construction and operation actions as described in Sections 3.6.6.

7.5.6.2 Best Management Practices and Mitigation Measures

The project would be required to apply construction and operations BMPs to minimize impacts to cultural and historic resources, as discussed in Section 3.6.7.

7.5.7 COASTAL ZONE MANAGEMENT

7.5.7.1 Potential Impacts

Importation of natural gas would require development of harbor facilities for handling and distributing LNG between islands. The harbor facilities, either onshore or offshore, could impact designated special management areas and affect shorefront access. However, these facilities would likely be developed in an area with similar existing facilities and would most likely be consistent with current uses. These potential impacts could require evaluation through a Federal consistency review under the Coastal Zone Management Program.

7.5.7.2 Best Management Practices and Mitigation Measures

As part of BMPs, a Federal consistency review could be required to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program.

7.5.8 SCENIC AND VISUAL RESOURCES

7.5.8.1 Potential Impacts

Impacts on scenic and visual resources during actions to import natural gas and upgrade natural gas and LPG infrastructure and distributions systems would be the same as those expected for common construction actions as described in Section 3.8.3.

Long-term visual impacts would occur from importing natural gas on a large-scale via cargo ships from the West Coast of the United States. In addition, an import terminal would be required. The import terminal could be located onshore or offshore. Either location would cause visual impacts from a new industrial facility with one or more aboveground storage tanks. Exterior lighting on the facility would be visible at night. During operations, visual impacts would occur from the arrival, unloading, and departure of cargo ships. Visual impacts would be highly dependent on the location and compatibility with the existing viewshed and land uses. Local and existing suppliers of LPG would increase LPG production and thus visual impacts would not occur from increased use of LPG.

7.5.8.2 Best Management Practices and Mitigation Measures

Sensitive locations such as coastal scenic resources from public viewing points and coastal highways; State, National, and National Historical Parks; and reserves protected by the Natural Area Reserves

System, and residential and recreational areas should be considered when locating a natural gas import facility.

In addition, each of the six islands have general land use plans and associated implementation tools such as zoning ordinances and development standards. Some of the counties' plans include more detail than others, but all include objectives related to protecting and maintaining open space and scenic resources consistent with the State's land use designations. For example, Honolulu County's plan includes policies protecting scenic views, especially those seen from highly developed and heavily traveled areas and locating public facilities and utilities in areas where they will least obstruct important views of the mountains and the sea ([City and County of Honolulu 2002](#)).

Visual impacts should be considered when siting a natural gas import facility. Due to the size of the facility, especially natural gas storage tanks, using measures such as vegetative screening to reduce visual impacts would not be possible. BMPs to minimize impacts to visual resources are described in Section 3.8.4.

7.5.9 RECREATION RESOURCES

7.5.9.1 Potential Impacts

Impacts on recreation resources during actions to import natural gas and upgrade natural gas and LPG infrastructure and distributions systems would be the same as those expected for common construction and operation actions as described in Section 3.9.4.

7.5.9.2 Best Management Practices and Mitigation Measures

Recreation resource impacts should be considered when siting a natural gas import facility. Due to the size of the facility, including natural gas storage tanks, high use recreation areas could be avoided and steps taken through design work to minimize obstructions to recreation activities. Tables 3-47 and 3-48 identify the popular land and sea-based recreation activities.

BMPs and mitigation measures to minimize impacts to recreation resources are described in Section 3.9.5.

7.5.10 LAND AND MARINE TRANSPORTATION

7.5.10.1 Potential Impacts

7.5.10.1.1 Land Transportation

The import of natural gas would require the development of fueling infrastructure at island harbors. These facilities could be either onshore or offshore. The shipping transportation would require specialized tankers or natural gas carriers to keep the LNG at cold temperatures.

Land transportation would be required to distribute the gas to local fueling stations. Because the natural gas would likely replace other petroleum-based products, the amount of truck transportation would not increase but change to a different type of vehicle. Safety issues would have to be addressed in the development of land-based natural gas infrastructure and operations.

7.5.10.1.2 Marine Transportation

Similar to land transportation, the marine shipment of natural gas would raise issues of safety and potential accidents that would have to be addressed in the development of infrastructure and operations.

7.5.10.2 Best Management Practices and Mitigation Measures

None identified.

7.5.11 AIRSPACE MANAGEMENT

As identified in [Table 7-5](#), there would be no potential impacts to airspace management from the representative project.

7.5.12 NOISE AND VIBRATION

7.5.12.1 Potential Impacts

Modifications and/or expansions of the existing CNG, LNG, and LPG distribution systems, as well as construction of an LNG import facility on O‘ahu and smaller import terminals on the other islands, would result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

Importing LNG on a large-scale via cargo ships from the U.S. West Coast and operation of a new import terminal located onshore or offshore, could potentially result in long-term impacts to existing noise and vibration levels. The increase in vessel operations could increase noise levels at the harbors, potentially affecting nearby noise and vibration-sensitive receptors identified. Noise and vibration impacts would be dependent on the location and compatibility with the existing noise levels and land uses.

7.5.12.2 Best Management Practices and Mitigation Measures

BMPs would be the same as those common across projects for construction and operation (see Section 3.12.6).

7.5.13 UTILITIES AND INFRASTRUCTURE

7.5.13.1 Potential Impacts

Potential impacts on island electric utilities would include the addition of the natural gas production and handling facilities including fueling stations for vehicles. The net change in the expected power demand from these facilities to electric utilities is expected to be small. HECO utilities have reported that they could retrofit existing oil fired generators with LNG fuel if sources on the islands are built, although this evolution is not evaluated in this PEIS (refer to [HECO 2013](#)).

7.5.13.2 Best Management Practices and Mitigation Measures

None identified.

7.5.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

7.5.14.1 Potential Impacts

7.5.14.1.1 Hazardous Materials

Natural and synthetic gases, or mixtures of natural and synthetic gases, are not considered hazardous materials (pursuant to CERCLA Section 101(14)); therefore, if a release of one of these substances occurs, CERCLA notification is not required. However, the State of Hawai‘i has mandates in place should such a release occur (see [Section 7.5.17](#)).

Impacts from exposure to hazardous materials during actions to upgrade natural gas and LPG infrastructure and distributions systems would be the same as those expected for common construction and operation actions as described in Section 3.14.4.

7.5.14.1.2 Waste Management

Waste management impacts during actions to upgrade natural gas and LPG infrastructure and distributions systems would be the same as those expected for common construction and operation actions as described in Section 3.14.4.

7.5.14.1.3 Wastewater

No wastewater impacts would occur from the import and use of natural gas. Some amount of wastewater would be produced from the additional propane that would be produced locally. However, as propane is currently being produced in the State, production of additional propane would occur in accordance with existing regulations and would operate similar to existing conditions. As such, minimal effects would occur to existing wastewater services.

7.5.14.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures to reduce hazardous material and waste management impacts are discussed in Section 3.14.5.

7.5.15 SOCIOECONOMICS

7.5.15.1 Potential Impacts

Socioeconomic impacts associated with the transition to a fleet of transit buses, waste collection and transfer vehicles, airport shuttles and vehicles, and municipal- and State-owned to run on natural gas instead of petroleum products vehicles would necessitate the construction and operation of new infrastructure and distribution systems. New net jobs could be created. The number of jobs associated with importation of natural gas and operation of port terminals; the construction of new fueling infrastructure; and related improvements could be moderate. Most of socioeconomic benefit would accrue in the county in which the primary import terminal was located. Jobs directly associated with the effort would likely be filled by individuals residing within the area of influence (the State of Hawai‘i), and most likely residing in the county in which the primary import terminal was located, and not by workers migrating to the State to fill those positions. The representative project would create new net jobs during construction. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income would be very small.

7.5.15.2 Best Management Practices and Mitigation Measures

None identified.

7.5.16 ENVIRONMENTAL JUSTICE

7.5.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the representative project are expected to be small. Impacts to minority and low-income populations also would be small.

7.5.16.2 Best Management Practices and Mitigation Measures

None noted.

7.5.17 HEALTH AND SAFETY

7.5.17.1 Potential Impacts

Facilities for storing, handling, and distributing compressed or liquefied natural gas or liquefied petroleum gas have potential hazards related to toxic (fumes), combustion (flammable), and overpressure (explosions) that could extend into the surrounding area. The siting, construction, and operation of these facilities would have to account for these potential hazards through regulatory requirements and guidelines. Imported natural gas would be stored, handled, and distributed in accordance with Federal, State and county guidelines for combustible materials. This includes compliance with the USDOT's Pipeline and Hazardous Material Safety Administration's (PHMSA) regulatory program to assure safe distribution of natural gas and the HDOH.

As propane is currently processed and distributed in the State, an increase in the amount of LPG available for use would not result in additional health and safety impacts.

7.5.17.2 Best Management Practices and Mitigation Measures

In the event an emergency were to occur during the import of natural gas to the State, owners or operators of facilities or vessels that release the substance into the environment above the reportable limit would be required to notify the State pursuant to the HEER Office legal authorities including the Hawai'i Environmental Response Law ([HRS 128D](#)), the Hawai'i State Contingency Plan ([HAR 11-451](#)), and the Hawai'i Emergency Planning and Community Right-to-Know Act (HEPCRA) ([HRS 128E](#) and [HAR 11-453](#)), as well as USDOT Spill Response Plans and noticing requirements (<http://www.hazmat.dot.gov>).

Additional safety guidelines that need to be considered during the design and installation of natural gas refueling facilities include the National Fire Prevention Association's [NFPA 52 Vehicular Gaseous Fuel Systems Code](#).

7.6 Multi-Modal Transportation

The representative multi-modal transportation project would increase public transit ridership (bus and rail) to avoid personal car travel to eliminate 20 million gallons of gasoline fuel use in 2030 (see Section 2.3.4.6). Increasing public transit use and the sustainability of the operations is important on all islands, but the representative project is assumed to be located on O'ahu. The representative multi-modal

transportation project would increase ridership on the existing conventional diesel bus fixed-route service and rapid rail system.

Table 7-6 presents a summary of the potential environmental impacts for multi-modal transportation, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 7-6. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Multi-Modal Transportation

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	General construction and operation impacts (see Section 3.1.3).	Any new structures would be constructed in accordance with applicable building codes,
Climate and Air Quality		
Air Quality	<p>General construction impacts (see Section 3.2.4).</p> <p>Using electricity to operate the rail transit would result in criteria pollutants from producing electricity from oil products, unless the generation used renewable sources.</p> <p>Although total transportation energy demand would decrease by 14.1 million gallons per year and reduce passenger vehicle emissions, criteria pollutant emissions still would occur from the operation and usage of diesel buses.</p>	Same as those common across construction and operation projects (see Section 3.2.5).
Climate Change	<p>General construction impacts (see Section 3.2.4).</p> <p>Using electricity to operate the rail transit would result in greenhouse gas emissions from producing electricity from oil products, unless the generation used renewable sources.</p> <p>Although total transportation energy demand would decrease by 14.1 million gallons per year and reduce passenger vehicle emissions, greenhouse gas emissions still would occur from the operation and usage of diesel buses.</p>	Same as those common across construction and operation projects (see Section 3.2.5).
Water Resources		
Surface Water	<p>General construction impacts (see Section 3.3.5).</p> <p>Potential improvement to storm water runoff quality from fewer cars on the road (i.e., less contamination).</p>	None.

Table 7-6. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Multi-modal Transportation (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Groundwater	General construction impacts (see Section 3.3.5). Potential improvement to groundwater quality from cleaner runoff.	None.
Floodplains and Wetlands	General construction impacts (see Section 3.3.5).	None.
Biological Resources		
	General construction and operation impacts (see Section 3.4.5).	Locate new rail line or extensions of existing rail lines in areas that are pre-disturbed when possible.
Land and Submerged Land Use		
Land Use	Potential change in land use designation and/or ownership in areas of railway. Reduced demand for gasoline and diesel fuel leading to a decrease in the number of conventional fueling stations, and small parcels of land could be converted to other uses and ownership.	Consider Hawai'i land use designations, county overlay zones, and other recognized scenic and historic features and areas.
Submerged Land Use	None.	N/A
Cultural and Historic Resources		
	General construction and operation impacts (see Section 3.6.6).	None.
Coastal Zone Management		
	None; the representative project does not include locations near the coast.	N/A
Scenic and Visual Resources		
	General construction impacts (see Section 3.8.3). Long-term scenic and visual resource impacts from new infrastructure (site-specific).	Locate new rail infrastructure near existing facilities.
Recreation Resources		
	Potential long-term impacts if new infrastructure intersected an area currently used or with potential for future use for recreational purposes.	Locate new rail infrastructure near existing facilities.

Table 7-6. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Multi-modal Transportation (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Land and Marine Transportation		
Land Transportation	<p>Beneficial impacts to traffic congestion by reducing number of cars on the road.</p> <p>Potential for an expanded and/or new maintenance and heavy maintenance facility for increased fleet of diesel buses.</p> <p>Potential local traffic impacts during construction of infrastructure to support increased fleet of diesel buses and to expand light rail service.</p>	<p>Provide multi-modal options for passengers getting on/off rail/bus at stations, including biking and walking infrastructure and bike share.</p> <p>Use “Transport Oriented Development” as is being done at all future HART stations.</p> <p>Note: The rail and bus efficiencies will be most significant if they are part of a comprehensive, connected multi-modal system.</p>
Marine Transportation	None; while an increase in multi-model transportation could affect inter- and intra-island ferry use, the representative project addresses bus and rail transportation only.	N/A
Airspace Management		
	None; no impacts to airspace management would be expected from the increased use of multi-modal transportation.	N/A
Noise and Vibration		
	<p>General impacts during construction (see Section 3.12.5).</p> <p>Operation of expanded bus and rail systems could potentially result in long-term impacts compared to existing noise and vibration levels, depending on the location of transit corridors and compatibility with the existing noise levels and land uses.</p>	<p>Avoid sensitive receptors for noise and vibration (identified in Section 3.12).</p> <p>Noise avoidance and mitigation measures may be imposed directly as conditions of permit issuance.</p> <p>Take measurements to assess the existing background noise levels at a given site and compare them with the anticipated noise levels associated with the proposed project.</p> <p>Use wheel skirts, sound-absorptive materials under tracks, and automatic track lubrication devices capable of eliminating wheel squeal.</p> <p>Insulate affected buildings.</p> <p>Install sound barriers or other screening mechanisms between the source and the offsite receptors, such as earth berms or vegetation.</p>

Table 7-6. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations – Multi-modal Transportation (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
		<p>Monitor operational noise levels for regulatory compliance, and install further mitigation as needed.</p> <p>Noisy activities during construction should be limited to the least noise-sensitive times of day (see Section 3.12).</p> <p>Use equipment with sound-control devices. Equipment should be adequately muffled and maintained.</p>
Utilities and Infrastructure		
	None; no impacts to utilities and infrastructure would be expected from increased use of multi-modal transportation.	N/A
Hazardous Materials and Waste Management		
Hazardous Materials	Potential impact from exposure. Increased fleet size leads to an increased potential for leaks and spills of lubricating oils, hydraulic fluids, coolants, solvents, and cleaning agents. Ultimately, a well-designed multi-modal transportation system should result in fewer vehicles on the road and a decrease in gas use, leaks, and spills.	Same as those common across construction and operation projects (see Section 3.14.5).
Waste Management	<p>General construction and operation impacts (see Section 3.14.4).</p> <p>Operational impacts include a decline in single vehicle ownership and increased car waste, as well as an increase in the amount of auto shredder residue to landfills.</p>	
Wastewater	General construction and operation impacts (see Section 3.14.4).	Same as those common across construction and operation projects (see Section 3.14.5).
Socioeconomics		
	A well-designed multi-modal transportation system would likely result in a decline of personal vehicles resulting in costs savings and health benefits.	None.
Environmental Justice		
	Small environmental justice impacts.	None.
Health and Safety		
	Potential impacts include improved health as people utilize active transit and have greater access to grocery stores, farmers markets, and healthy food options.	N/A

7.6.1 GEOLOGY AND SOILS

7.6.1.1 Potential Impacts

Construction may include building additional railways, rail stations, or expanding maintenance facilities for multi-modal transportation systems. Potential impacts on geology and soils would be the same as those expected for common construction actions as described in Section 3.1.3. Construction may involve land disturbance, so the permitting requirements described in Section 3.1.3 would be fully applicable.

During operation, the increased use of multi-modal transportation would not involve activities that would have the potential to affect geology and soils of the area. The potential risk of the representative project being adversely impacted from earthquakes would be at an acceptably low level.

7.6.1.2 Best Management Practices and Mitigation Measures

In accordance with applicable building codes, any new facilities constructed as a result of the representative project would require incorporation of seismic provisions appropriate for the project locations.

7.6.2 CLIMATE AND AIR QUALITY

7.6.2.1 Potential Impacts

7.6.2.1.1 Air Quality

Potential impacts on air quality would be the same as those expected for common construction actions as described in Section 3.2.4.

Operation of the rapid rail system would require electricity to power the trains. Although the rail transit system would reduce total transportation energy demand by 5.9 million gallons of fuel resulting in reduced air emissions, criteria pollutants still would be created from producing electricity from oil products. A greater reduction in air emissions would be realized if all electricity were generated from renewable sources rather than from petroleum.

Operation of additional fleets of diesel buses would also generate criteria pollutants. A 55-percent increase in bus ridership would be required to offset this increase with a corresponding decrease in passenger vehicle emissions. The 55-percent increase corresponds to 40.9 million additional transit bus trips per year. Although total transportation energy demand would decrease by 14.1 million gallons per year and reduce passenger vehicle emissions, criteria pollutant emissions still would occur from the operation and usage of diesel buses.

7.6.2.1.2 Climate Change

A reduction of 20 million gallons of petroleum fuel would correspond with an annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent. A rail transit system would reduce transportation energy demand by the equivalent of 5.9 million gallons of fuel in 2030. Both the reduction in fuel usage from personal vehicles and the increase in fuel usage required to generate electricity to operate the trains are included in the 5.9 million gallons calculations. Therefore, 5.9 million gallons is the net fuel savings (Chapter 2). The remaining 14.1 million gallons of avoided fuel use would come from increased transit bus ridership (Chapter 2).

As noted above, the operation of the rapid rail system would still require electricity to power the trains, resulting in greenhouse gas emissions from the electricity generated by oil products. A greater reduction in greenhouse gases could be realized if all electricity would be generated from renewable sources rather than from petroleum.

Similarly, the operation of a fleet of diesel buses would still generate greenhouse gas emissions.

7.6.2.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures to reduce potential air quality and greenhouse gas emission impacts are discussed in Section 3.2.5.

7.6.3 WATER RESOURCES

7.6.3.1 Potential Impacts

This section addresses potential environmental consequences to water resources from use of the Honolulu rapid rail system and increasing the O‘ahu bus system’s number of buses, number of trips, and ridership. Potential impacts are addressed in terms of surface water, groundwater, and floodplains and wetlands.

7.6.3.1.1 Surface Water

Use of the Honolulu rail system and increasing use of the O‘ahu bus system would not be expected to result in adverse impacts to surface water. Construction may include building additional railways, rail stations, and maintenance facilities for the rapid rail system and/or building or expanding maintenance facilities for multi-modal transportation systems. Potential impacts on surface water from construction would be the same as those expected for common construction actions as described in Section 3.3.5. In addition, land disturbance activities would be required to comply with permitting requirements. Therefore, permitting requirements described in Section 3.3.5 would be fully applicable.

During operations, there would be no increases in the potential for stormwater runoff to carry sediments or other contaminants to receiving waters.

The representative project would involve reductions in personal vehicle miles traveled and, therefore, could result in beneficial impacts to surface waters. Runoff from roads and highways typically includes small amounts of anti-freeze/coolant and petroleum products that have been dripped or leaked from vehicles onto the roadway and then washed off with the storm water. It is reasonable to conclude, all other things being equal, that fewer vehicles on the road would be associated with less contamination of this nature on the roadway and less in runoff. Also, it is reasonable to assume that buses in a public fleet would be on a regular inspection and maintenance schedule and, as a result, less apt to experience drips or leaks of contaminants or improperly disposed of engine oil than vehicles not regularly inspected.

7.6.3.1.2 Groundwater

Potential impacts on groundwater from construction of additional railways, rail stations, and maintenance facilities for the rapid rail system and/or building or expanding maintenance facilities for multi-modal transportation systems would be the same as those expected for common construction actions as described in Section 3.3.5.

Similar to the rationale described above, during operation, the representative project would result in no adverse impacts to groundwater. Further, the “cleaner” runoff would eventually make its way into the

groundwater adjacent to roadways, thereby improving the quality of the groundwater in those locations. Rail usage and the increased usage of buses would be not expected to have any effects on water usage or demand.

7.6.3.1.3 Floodplains and Wetlands

The proponent of additional multi-modal transportation systems would be expected to avoid floodplains and wetland areas if only to reduce costs and minimize regulatory requirements. However, if unavoidable, construction considerations would be the same as described for common construction actions in Section 3.3.5.

If additional infrastructure were built, no operational impacts would be expected to floodplains or wetlands from increased use of multi-modal transportation systems.

7.6.3.2 Best Management Practices and Mitigation Measures

None identified.

7.6.4 BIOLOGICAL RESOURCES

7.6.4.1 Potential Impacts

Potential impacts to biological resources may occur from land clearing and disturbance to construct additional infrastructure for the representative multi-modal transportation project. Short-term impacts could occur from human disturbance during construction and the potential spread of invasive species by creating disturbed areas. However, it is anticipated that additional infrastructure associated with the representative project would occur in areas currently built out and developed to service areas with higher populations, reducing the likelihood of impacts to biological resources.

Similarly, there would be no potential impacts to biological resources from the operation or increased use of multi-modal transportation.

7.6.4.2 Best Management Practices and Mitigation Measures

Locate new rail line or extensions of existing rail lines in areas that are pre-disturbed, when possible.

7.6.5 LAND AND SUBMERGED LAND USE

7.6.5.1 Potential Impacts

7.6.5.1.1 Land Use

Construction of additional railways, rail stations, and maintenance facilities associated with the representative project may require additional land for development and/or clearing, grading, and leveling of areas, which could result in a change of land use or ownership.

Areas of railway expansion could require a change in land use designation and/or ownership. As bus and rail service increase in popularity, the number of personally driven vehicles could decrease, reducing the demand for gasoline and diesel fuel. As a result, there could be decreases in the number of conventional fueling stations, and small parcels of land could be converted to other uses and ownership.

7.6.5.1.2 Submerged Land Use

As identified in [Table 7-6](#), there would be no potential impacts to submerged land use from the representative multi-modal transportation project.

7.6.5.2 Best Management Practices and Mitigation Measures

Consider Hawai'i land use designations, county overlay zones, and scenic and historic areas during site selection.

7.6.6 CULTURAL AND HISTORIC RESOURCES

As identified in [Table 7-6](#), there would be no potential impacts to cultural or historical resources from the representative multi-modal transportation project beyond those that could occur during the construction of rail facilities.

7.6.7 COASTAL ZONE MANAGEMENT

As identified in [Table 7-6](#), there would be no potential impacts to coastal zone management from the representative multi-modal transportation project.

7.6.8 SCENIC AND VISUAL RESOURCES

7.6.8.1 Potential Impacts

Potential impacts to scenic and visual resources would be the same as those expected for common construction actions as described in Section 3.8.4.

Long-term visual impacts may occur; however, it is anticipated that additional infrastructure built as part of the multi-modal transportation system would occur in areas currently built out and developed to service areas with higher populations. Therefore impacts to scenic and visual resources would be minimal from increased use of multi-modal transportation.

7.6.8.2 Best Management Practices and Mitigation Measures

Locate new rail infrastructure near existing facilities.

7.6.9 RECREATION RESOURCES

As identified in [Table 7-6](#), there would be no potential impacts to recreation resources from representative multi-modal transportation project.

7.6.10 LAND AND MARINE TRANSPORTATION

7.6.10.1 Potential Impacts

7.6.10.1.1 Land Transportation

The goal of the multi-modal transportation project is to increase public transit use and reduce use of personal cars to save on gasoline use. A beneficial impact of this effort is a reduced amount of traffic congestion by removing cars from the roads. Increased use of transit service diesel buses would require

expanding the fleet of buses and likely create a need for both an expanded or new maintenance and heavy maintenance facility. The overall effect to the land transportation system would be to make it more efficient.

Development of multi-modal transportation projects such as light rail systems, reconfiguring road systems for dedicated bus lanes, or turn out lanes for bus stops could have significant impacts on local traffic during the construction phase. For example, the Honolulu Rail Transit Project will require extensive roadwork during installation of various elements of the project. Additionally, centralized parking facilities may be required in and around major rail and bus stop locations. This not only could have a negative, localized traffic impact during construction, it could also have a lasting, albeit smaller, impact during operations.

7.6.10.1.2 Marine Transportation

As identified in [Table 7-6](#), there would be no potential impacts to marine transportation from the representative multi-modal transportation project.

7.6.10.2 Best Management Practices and Mitigation Measures

The following recommended BMPs would minimize potential land transportation impacts:

- Provide multi-modal options for passengers getting on/off rail/bus at stations, including biking and walking infrastructure and bike and car shares. It is noted that rail and bus efficiencies would provide more benefits if they were part of a comprehensive, connected multi-modal transportation system.
- Initiate “Transport Oriented Development” to the extent feasible, using the Honolulu Authority for Rapid Transportation as a model.

7.6.11 AIRSPACE MANAGEMENT

As identified in [Table 7-6](#), there would be no potential impacts to airspace management from the representative multi-modal transportation project.

7.6.12 NOISE AND VIBRATION

7.6.12.1 Potential Impacts

Development of the representative multi-modal transportation project would result in noise and vibration impacts typical of general construction activities, which are addressed in Section 3.12.5.

Operation of expanded bus and rail systems could potentially result in long-term impacts compared to existing noise and vibration levels. Noise and vibration impacts would be dependent on the location of transit corridors and compatibility with the existing noise levels and land uses.

7.6.12.2 Best Management Practices and Mitigation Measures

Noise and vibration impacts should be considered when siting multi-modal transportation projects. The following recommended BMPs would further reduce noise levels:

- Avoid sensitive receptors for noise and vibration (identified in Section 3.12).

- Comply with Federal, State, and local noise regulations and ordinances. Noise permits would be required if noise levels exceed regulatory limits. Noise avoidance and mitigation measures may be imposed directly as conditions of permit issuance.
- Take measurements to assess the existing background noise levels at a given site and compare them with the anticipated noise levels associated with the proposed project.
- Use wheel skirts, sound-absorptive materials under tracks, and automatic track lubrication devices capable of eliminating wheel squeal.
- Insulate affected buildings.
- Install screening mechanisms or sound barriers between the source and the offsite receptors, such as earth berms or vegetation.
- Monitor operational noise levels for regulatory compliance, and install further mitigation as needed.
- Noisy activities during construction should be limited to the least noise-sensitive times of day (see Section 3.12).
- Use equipment with sound-control devices. Equipment should be adequately muffled and maintained.

7.6.13 UTILITIES AND INFRASTRUCTURE

As identified in [Table 7-6](#), there would be no potential impacts to utilities or infrastructure from the representative project.

7.6.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

7.6.14.1 Potential Impacts

7.6.14.1.1 Hazardous Materials

Operation of an increased fleet size would lead to an increased potential for leaks and spills of lubricating oils, hydraulic fluids, coolants, solvents, and cleaning agents. Ultimately, however, a well-designed multi-modal transportation system should result in fewer vehicles on the road and thus a decrease in gas use as well as a decrease in leaks and spills of oils, hydraulic fluids, coolants, solvents, and cleaning agents.

7.6.14.1.2 Waste Management

Waste management impacts resulting from the representative multi-modal transportation project likely would result during construction and would be similar to those commonly associated with general construction action discussed in Section 3.14.4.

During project operation, hazardous waste may be generated and would be handled, stored, and transported by a licensed hauler to the appropriate permitted disposal facility. A well designed multi-modal transportation system would result in both a decline of personal vehicle ownership and an increase in car waste (from an excess of used vehicle inventory). While most car parts could be recycled, some parts likely would be exported as waste or for recycling off-island, resulting in an increased carbon

footprint. The remaining materials that could not be recycled (e.g., auto shredder residue) would be disposed of in a proper landfill. More information about waste management is available online at <http://www.epa.gov/epawaste/consERVE/materials/auto.htm>.

7.6.14.1.3 Wastewater

Potential impacts on wastewater from construction and operation would be the same as those expected for common construction and operation actions as described in Section 3.14.4.

7.6.14.2 Best Management Practices and Mitigation Measures

- Ensure regulated materials are properly handled to avoid release to the environment.
- Ensure compliance with NPDES wastewater discharge permit requirements.

7.6.15 SOCIOECONOMICS

7.6.15.1 Potential Impacts

Socioeconomic impacts associated with an increase in transit ridership and the resulting avoidance of personal car travel would be very small. Some new jobs (for drivers, mechanics, and support personnel) could be created as additional buses are added to the current fleet. There are no buses manufactured in Hawai'i, so the economic benefit of vehicle manufacturing would accrue elsewhere. The number of jobs associated with the larger fleet of buses, regardless of the fuel options exercised and described Section 2.3.4.6, would be very small. Jobs directly associated with the expanded fleet would be likely filled by individuals residing within the area of influence (the State of Hawai'i), and not by workers migrating to the State to fill those positions. The representative project would not create many new net jobs.

The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income would be very small. There could be positive benefits, however, to the general population and employers. For example, employers who currently offer commuter benefits programs, such as reimbursing for mileage and parking, could instead subsidize bus passes or bike share memberships, thereby providing easier access to the work place as well as saving money and showing environmental stewardship, to which the public (and potential customers) responds favorably

A well designed multi-modal transportation system likely would result in a decline in personal vehicle ownership, resulting in an overall cost savings to individual users and improved health benefits for the population. Active travel involves physical activity. Increased use of bus and rail may result in an increase in walking (i.e., to and from the transit station, to and from errand-running, to and from the workplace) compared with driving a personally owned vehicle. Ultimately, the health benefits of active travel not only result in a healthy lifestyle, they represent cost savings in the form of decreased health problems associated with inactive travel.

7.6.15.2 Best Management Practices and Mitigation Measures

None identified.

7.6.16 ENVIRONMENTAL JUSTICE

7.6.16.1 Potential Impacts

The potential environmental impacts to the general population associated with an increase in public transit ridership are expected to be small.

Public transit initiatives would likely occur in the City and County of Honolulu, where approximately 78 percent of the residents are minority and about 9.3 percent of the residents are low-income. Adverse impacts to environmental resources expected from increased transit ridership would be negligible; in fact, initiating a multi-modal transportation system would be beneficial to low-income and minority communities by making available a means to access healthier activities, healthier food options, education, and jobs that otherwise are not readily available. Therefore, no disproportionately high and adverse impacts to minority populations or to low-income population from an increase in public transit ridership would be expected.

7.6.16.2 Best Management Practices and Mitigation Measures

None identified.

7.6.17 HEALTH AND SAFETY

Potential impacts associated with multi-modal transportation include improved health as more people utilize active transit. For example, walking and biking are considered good forms of exercise. A well designed multi-modal transportation system also would provide access to grocery stores, farmers markets, and other healthy food options.

8 ENVIRONMENTAL IMPACTS FROM ELECTRICAL TRANSMISSION AND DISTRIBUTION

This chapter presents the potential environmental impacts that could be expected from electrical transmission and distribution systems (see Section 2.3.5). The electrical transmission and distribution technologies would be required to fully implement the distributed and utility-scale renewables presented in earlier chapters. For each technology evaluated in this chapter, there is a representative project that aids the PEIS in presenting and characterizing the potential environmental impacts. These representative projects are described in detail in Section 2.3.5 and are summarized again here for each technology. The potential impacts are presented for each environmental resource area. As was described in Chapter 3, many of the activities and technologies could result in environmental impacts that would be common of typical construction projects and may not be unique to the specific activity or technology. In these cases, the presentation of potential impacts in this chapter refers the reader to the appropriate section in Chapter 3 that presents these common impacts for that resource area. Therefore, the details in this chapter deal primarily with those impacts that would be unique to the specific activity or technology being evaluated.

Each of the sections below includes a summary table of the potential environmental impacts and best management practices (BMPs) for that technology. Not all technologies have the potential to impact all environmental resource areas analyzed in this document. Therefore, the summary tables also identify and screen those resource areas that are not expected to be impacted by the technology. This approach is consistent with DOE's sliding scale approach to the preparation of NEPA analyses.

8.1 On-Island Transmission

The representative project for on-island transmission of electricity is a new electrical connection to a large, renewable energy generation plant. The project assumes that the generation source is 20 miles from the nearest transmission line and the transmission line operates at 69 kilovolts. The transmission line would be assumed to have a 100-foot-wide, 20-mile-long, 0.38-square-mile disturbed area for right-of-way easement, and a 70-foot pole or structure height. The representative project allows for use of an underground transmission line when feasible.

[Table 8-1](#) presents a summary of the potential environmental impacts for on-island transmission, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology; and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 8-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – On-Island Transmission

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	General impacts during construction (see Section 3.1.3).	Same as those common across construction projects (see Section 3.1.4).
Climate and Air Quality		
	General impacts during construction (see Section 3.2.4).	Same as those common across construction projects (see Section 3.2.5).
Water Resources		
Surface Water	<p>General impacts during construction (see Section 3.3.5).</p> <p>Operational impacts include possible alteration of stormwater runoff along transmission corridor as vegetation is reestablished. Any single drainage path expected to experience minimal alteration.</p> <p>Potential application of herbicides to maintain transmission corridor could produce negative environmental impacts if they reach surface waters.</p>	<p>Same as those common across construction projects (see Section 3.3.6).</p> <p>If herbicides are applied, use appropriate handling, storage, and application guidelines according to manufacturer guidance and chemical-specific material safety data sheets.</p>
Groundwater	<p>General impacts during construction (see Section 3.3.5).</p> <p>No adverse operational impacts unless herbicides applied to maintain transmission corridor.</p>	
Floodplains and Wetlands	Potential impacts during construction (see Section 3.3.5).	

Table 8-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – On-Island Transmission (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Biological Resources		
	<p>General impacts to terrestrial ecosystems during construction, including potential access roads (see Section 3.4.5).</p> <p>Operational maintenance of cleared areas around towers and vegetation height along transmission corridor.</p> <p>Potential bird and bat collisions with towers and lines, especially nocturnal flying species.</p>	<p>Same as those common for construction projects (see Section 3.4.6).</p> <p>Use helicopters in remote and rugged terrain without vehicular access.</p> <p>Apply landscape and habitat perspectives to transmission line route planning to avoid high-risk areas and configurations.</p> <p>Use shorter towers to place lines below bird flight paths.</p> <p>Apply horizontal line arrays rather than vertical arrays, when possible.</p> <p>Orient lines parallel to typical flight paths where possible.</p> <p>Install bird flight diverters appropriate to species of concern and landscape characteristics.</p> <p>Use underground transmission lines in extremely high-risk areas.</p>
Land and Submerged Land Use		
Land Use	Transmission line corridors and location of substations and switching yards could result in changes of land ownership patterns and land use.	<p>If feasible and cost effective, install transmission lines underground to minimize visual effects to adjacent land uses.</p> <p>Early coordination with landowners to identify potential issues associated with easements and rights of way.</p>
Submerged Land Use	None; the on-island transmission project would not extend offshore.	N/A
Cultural and Historic Resources		
	<p>Common impacts to cultural resources during construction and operation. See Section 3.6.6.</p> <p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p>	Same as those common across construction and operation projects. See Section 3.6.7.

Table 8-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – On-Island Transmission (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
	<p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	
Coastal Zone Management		
	<p>General impacts during construction and operation (see Section 3.7.8).</p> <p>Potential impacts to coastal zone resources (site-specific).</p>	<p>During site selection, avoid the beach and near offshore areas.</p> <p>Evaluate through a Federal consistency review under the Coastal Zone Management Program.</p>
Scenic and Visual Resources		
	<p>General impacts during construction (see Section 3.8.3).</p> <p>Long-term visual impacts associated with towers, transmission lines, cleared transmission corridors, substations, and switching yards.</p>	<p>Same as those common across construction projects (see Section 3.8.4).</p> <p>Consider sensitive locations and route adjustments when locating transmission lines.</p> <p>Apply right-of-way management to reduce adverse impacts.</p> <p>Use structure design and materials with the least adverse impacts to scenic and visual resources.</p>
Recreation Resources		
	<p>General impacts during construction (see Section 3.9.4).</p> <p>Long-term obstruction to some recreational activities; conversely, some activities could be enhanced by improved access (e.g., from access roads for installed transmission infrastructure).</p>	<p>Same as those common across construction projects (see See Section 3.9.5).</p>

Table 8-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – On-Island Transmission (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Land and Marine Transportation		
Land Transportation	<p>Potential traffic congestion during construction from wide-load hauling of transmission line components (e.g., towers and tower foundations).</p> <p>Short-term impacts during line stringing.</p> <p>Impacts during construction and operation if transmission line installation required road crossings.</p>	Same as those common across construction and operation projects (see Section 3.10.4).
Marine Transportation	None; the on-island transmission project would not extend offshore.	N/A
Airspace Management		
	<p>Potential air traffic impacts during construction if helicopters are used to transport supplies or for line stringing.</p> <p>Potential construction and operation impacts and hazards to civilian and military aviation due to topography and high presence of low-altitude aviation.</p> <p>Potential long-term impacts from radio frequency interference.</p>	<p>Same as those common across construction and operation projects (see Section 3.11.4).</p> <p>Coordinate with FAA and other entities if transmission line installation is near an airport.</p> <p>Redefine airspace if necessary and practicable.</p> <p>Depending on the location of the transmission lines relative to airports or agricultural land that could use aircraft for crop dusting, line marker balls may be required or recommended to ensure visibility of the transmission line from nearby aircraft.</p>
Noise and Vibration		
	<p>Short-term noise and vibration impacts during construction.</p> <p>Potential vibration and humming noise during operation from loose hardware.</p> <p>Sizzles, crackles, hissing noises possible, especially during periods of higher humidity.</p>	<p>Same as those common across construction projects (see Section 3.12.6).</p> <p>Apply routine maintenance to mounting hardware and insulators.</p> <p>Use polymer insulators instead of ceramic or glass.</p>

Table 8-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – On-Island Transmission (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Utilities and Infrastructure		
	Potential impacts related to adding electricity capacity to the grid.	<p>Same as those common across construction and operation projects (see Section 3.13.4).</p> <p>The utility may need to consider grid-balancing measures, as follows:</p> <ul style="list-style-type: none"> • Projects requiring 5 to 50 megawatt grid connections are discussed in Chapter 6. • Projects requiring 51 to 99 megawatts scale in a manner similar to the 5- to 50-megawatt projects discussed in Chapter 6. • Projects requiring 100-megawatt or larger grid connections are required to comply with the Public Utilities Commission requirements for Transmission Line Approval and Power Purchase Agreements.
Hazardous Materials and Waste Management		
Hazardous Materials	<p>General impacts from exposure to hazardous materials during construction (see Section 3.14.4).</p> <p>Potential impacts from exposure to hazardous materials during operation and maintenance from use of herbicides to maintain transmission corridor.</p>	Same as those common across construction and operation projects (see Section 3.14.5).
Waste Management	None; any vegetation cleared likely would be composted or reused.	N/A None
Wastewater	General impacts during construction (see Section 3.14.4).	Same as those common across construction projects (see Section 3.14.5).
Socioeconomics		
	Minimal beneficial impacts during construction and operation.	None
Environmental Justice		
	<p>Small environmental justice impacts.</p> <p>Site-specific evaluation of impacted populations required.</p>	During site selection, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

Table 8-1. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – On-Island Transmission (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Health and Safety		
	<p>Potential health and safety impacts to workers during installation, maintenance, and repairs of the transmission lines. Typical industrial hazards.</p> <p>Additional health and safety risks specific to electrical generation, transmission, and distribution industry.</p> <p>Potential health and safety impacts to the public during operation of the transmission lines as a result of electromagnetic fields generated. Limited to areas immediately adjacent to transmission lines.</p> <p>Police, fire, and medical services would not be adversely affected.</p>	<p>During the installation, maintenance, and repair of transmission lines, ensure activities are conducted and personnel trained in accordance with OSHA guidance related to power generation: https://www.osha.gov/SLTC/powergeneration/</p> <p>Read available literature about electromagnetic fields and radio frequency health.</p>

8.1.1 GEOLOGY AND SOILS

8.1.1.1 Potential Impacts

Potential impacts on geology and soils would be the same as those expected for common construction actions as described in Section 3.1.3. Since the amount of land disturbed would be well over one acre, the permitting requirements described in Section 3.1.3 would be fully applicable.

The construction of a 20-mile-long transmission line could cross multiple types of terrain as well as encounter many differing land uses and owners. General means of protecting against soil erosion or contamination would be expected to be similar all along the route, but specific approaches may have to be employed to accommodate different land use needs and expectations of landowners. For example, actions going across roads or along road rights of way, particularly State roads, would have to incorporate control measures consistent with roadway operations.

Operation of the installed transmission line would not involve activities that would have the potential to affect geology and soils of the area.

8.1.1.2 Best Management Practices and Mitigation Measures

BMPs for geology and soils would be the same as those common across construction projects (see Section 3.1.4).

8.1.2 CLIMATE AND AIR QUALITY

8.1.2.1 Potential Impacts

8.1.2.1.1 Air Quality

The representative on-island transmission project could result in air quality impacts typical of general construction activities as described in Section 3.2.4.

Operation of an electrical transmission system would not produce criteria pollutants. Minimal emissions from vehicles may result during required maintenance of the transmission line.

8.1.2.1.2 Climate Change

The representative on-island transmission project could produce greenhouse gases typical of general construction activities as described in Section 3.2.4.

Operation of an electrical transmission system would not produce greenhouse gases. Emissions from vehicles required to maintain the transmission line would be minimal.

8.1.2.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction projects (see Section 3.2.5).

8.1.3 WATER RESOURCES

8.1.3.1 Potential Impacts

8.1.3.1.1 Surface Water

Potential impacts on surface water would be dependent on the location of the transmission line structures and potential crossings of surface waters; but in general, would be the same as those expected for common construction actions as described in Section 3.3.5.

During operation there would be no activities that would have the potential to affect surface waters other than possible changes in storm water runoff from along the transmission line while vegetation was re-established. Because the disturbed ground would be spread out over such a large area (i.e., along the 20-mile-long transmission line), any single drainage path would be expected to experience very minor changes, if any.

Operation and maintenance of the transmission line could involve occasional applications of herbicides to keep vegetation at reasonable levels and access roads open. Depending on their characteristics and concentrations, herbicide chemicals can produce adverse environmental impacts if they reach surface waters.

8.1.3.1.2 Groundwater

Construction of the representative project would not be expected to impact groundwater. However, during construction actions, loosened soil conditions result in decreased storm water runoff and would result in more water soaking into the ground and potentially reaching the groundwater. Any impacts would be

temporary, as once construction was complete, the ground surface would be returned to preconstruction condition.

Water needs during construction would be expected to come from groundwater resources, either via municipal water systems or private wells, but they would be minor, involving such uses as for dust suppression and soil compaction.

During long-term operation of the transmission line, there would be no impacts to groundwater. However, herbicide use to maintain vertical clearance for rights-of-way could cause adverse impacts to groundwater if not used appropriately.

8.1.3.1.3 Floodplains and Wetlands

The proponent for the electrical transmission line project would be expected to avoid floodplain and wetland areas if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

8.1.3.2 Best Management Practices and Mitigation Measures

If used, ensure herbicides are licensed for intended use and they are handled, stored, and applied in accordance with the manufacturer guidelines and material safety data sheets.

8.1.4 BIOLOGICAL RESOURCES

8.1.4.1 Potential Impacts

Potential impacts to biological resources from construction and operation of electrical transmission lines would include vegetation clearing for the installation of transmission line structures, maintenance of vegetation underneath transmission lines, and bird collisions with transmission lines and towers.

Installation of the representative project would require clearing of vegetation to install foundations and subsequent maintenance of a cleared area around the tower. Vegetation underneath the transmission lines would need to be trimmed and maintained to a height that would not interfere with the lines and create a fire hazard. Construction may also require access roads. In more remote and rugged terrain, use of helicopters could reduce the amount of surface disturbance; any related disturbance to biological resources would be limited to helicopter landings and take-offs.

Long-term impacts on vegetation, wildlife, and protected species would largely depend on the routing of the transmission lines. Because transmission lines can be constructed through areas without existing access and across steeper topography, they have the potential to encroach on more remote landscapes that may have high conservation value. Although the individual land disturbances for the towers are relatively small, they could provide opportunity for establishment of invasive or nonnative plant species.

The towers and transmission lines are potential collision hazards to birds, especially nocturnal flying seabirds and bats. Also of concern would be water birds and colonial nesting species that concentrate in smaller areas (i.e., wetlands and nesting colonies) and create areas with high numbers of bird flights as well as wider ranging species such as the Hawaiian hawk and Hawaiian goose.

8.1.4.2 Best Management Practices and Mitigation Measures

In addition to the standard BMPs for typical construction activities (see Section 3.4.6), a variety of approaches could be taken to minimize potential bird and bat collisions. These include the following:

- Use shorter tower heights so that the transmission lines would hang below the typical flight height.
- Use vegetation and topography as a means to shield power lines from flight paths.
- Use power line configuration with fewer layers of lines (i.e., horizontal versus vertical arrays).
- Consider underground installations in high-risk areas ([KIUC 2010](#)).
- Locate transmission lines away from lighted sources. Although transmission towers are not lighted, transmission lines located in proximity to light sources that attract and disorient night flying seabirds could increase the probability of collisions.
- Locate transmission lines away from wetlands, ridgelines, and protected refuge areas that attract concentrations of birds and bat roost trees and thus could increase the potential impacts to avian species and the Hawaiian hoary bat.
- Use landscape perspective in route planning. Bird flight patterns follow landscape features. Consider these flight patterns during transmission line route planning.
- Install one of the numerous bird flight diverters on the transmission lines to reduce avian impacts. The different designs can be reviewed and selected based on the particular species being protected and the characteristics of the surrounding landscape.

8.1.5 LAND AND SUBMERGED LAND USE

8.1.5.1 Potential Impacts

8.1.5.1.1 Land Use

The representative on-island transmission line project would require a 20-mile-long corridor in addition to substations and switching yards, all of which could result in changes to land ownership patterns and land uses.

Long, linear projects could affect numerous landowners. The proponent or utility would coordinate with each individual landowner to obtain a right-of-way easement to allow the use of the property for the transmission line.

8.1.5.1.2 Submerged Land Use

As identified in [Table 8-1](#), there would be no potential impacts to submerged land use from the representative project.

8.1.5.2 Best Management Practices and Mitigation Measures

A BMP to reduce potential impacts to land use includes installing new transmission lines underground to minimize potential visual or other impacts to adjacent properties.

Early coordination with landowners to identify potential issues associated with easements and rights of way.

8.1.6 CULTURAL AND HISTORIC RESOURCES

8.1.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operational phases of an on-island transmission project if effective conservation and BMPs are not implemented. During construction, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6.

8.1.6.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction and operation projects (see Section 3.6.7).

8.1.7 COASTAL ZONE MANAGEMENT

8.1.7.1 Potential Impacts

Impacts to coastal zones were evaluated based on the extent to which a project would conflict with the policies of the Hawai'i Coastal Zone Management Program and potentially affect special management areas, shorefront access, and shoreline erosion. The representative on-island transmission project could affect coastal zone resources but would largely depend on the specific project location. Projects near the shoreline would have the most potential to impact shore setbacks areas, shorefront access, and special management areas.

8.1.7.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures to reduce the above impacts include the following:

- Avoid the beach and near offshore areas, and

- Evaluate the project through a Federal consistency review under the Coastal Zone Management Program.

8.1.8 SCENIC AND VISUAL RESOURCES

8.1.8.1 Potential Impacts

The representative on-island transmission project would result in scenic and visual resource impacts typical of general construction activities described in Section 3.8.3.

Long-term visual impacts would result from placement of the 70-foot-tall structures that support the transmission line, the transmission line itself, the permanent right-of-way where vegetation would be controlled (as opposed to natural growth) to avoid interference with the transmission line, and from a substation or switching yard. The visual impacts of the new transmission line would depend on the topography, land cover, and existing land uses. For example, tall-growing trees must be permanently removed from the right-of-way to allow line maintenance; whereas, in agricultural areas, the right-of-way could still be used for agriculture and pasture land after construction ends and the fields are restored. The magnitude of potential visual impacts would be related to the transmission line's potential to change the visual character of the area.

8.1.8.2 Best Management Practices and Mitigation Measures

In addition to the standard BMPs for typical construction activities (see Section 3.8.4), projects should also avoid sensitive locations such as coastal scenic resources from public viewing points and coastal highways; the three designated scenic byways; State, National, and National Historical Parks; reserves protected by the Natural Area Reserves System; and residential and recreational areas.

Consult with the county general land use plans and associated implementation tools such as zoning ordinances and development standards regarding protecting and maintaining open space and scenic resources.

Choose the structure design and material that would best avoid conflicts with scenic and visual resources. For examples, structures constructed of wood or of rust-brown oxidized steel may blend better with wooded landscapes.

8.1.9 RECREATION RESOURCES

8.1.9.1 Potential Impacts

The representative on-island transmission project could result in recreation resource impacts typical of general construction and operational activities described in Sections 3.8.3.

Long-term recreation resource impacts could result in obstructions to some recreational activities. Conversely, some recreation activities could be compatible with new transmission lines and increased access from the right-of-ways created for transmission line maintenance. Such activities include hiking, hunting, backcountry camping, and birding.

8.1.9.2 Best Management Practices and Mitigation Measures

Recreation resource impacts should be considered when siting the on-island transmission line. Tables 3-47 and 3-48 identify the popular land- and sea-based recreation activities in Hawai'i. The *State*

Comprehensive Outdoor Recreation Plan (SCORP) provides detailed matrixes of all recreation areas on each island and the recreational activities that take place at each area ([DLNR 2009](#)).

8.1.10 LAND AND MARINE TRANSPORTATION

8.1.10.1 Potential Impacts

8.1.10.1.1 Land Transportation

Some local impacts could occur to land transportation in the vicinity of the transmission line construction. These impacts could include increased truck traffic for delivering construction materials (e.g., towers, cabling, and tower foundations). These impacts are expected to be short-term in specific locations as construction proceeds along the 20-mile route.

In areas where transmission lines are installed along existing road rights-of way, impacts may be greater because the construction would occur near existing traffic. Some short-term road closures (e.g., less than one day) may occur during cable stringing across roads.

8.1.10.1.2 Marine Transportation

As identified in [Table 8-1](#), there would be no potential impacts to marine transportation from the representative project.

8.1.10.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction and operation projects (see Section 3.10.4).

8.1.11 AIRSPACE MANAGEMENT

8.1.11.1 Potential Impacts

Construction of the representative on-island transmission project could cause short-term impacts to airports if any part of the 20-mile-long line occurred nearby. During construction, some project locations could require use of helicopters to install towers and string power cabling. Construction air traffic could temporarily impact other aviation operations in the vicinity and would have to be coordinated with the FAA and other potentially affected organizations.

Although the representative on-island transmission project would be only about 70 feet tall, well below the criteria (200 feet) for evaluation as an obstruction to airspace, long-term use of the transmission line could impact airspace and present a hazard to civilian and non-civilian aviation. The transmission line could cross mountainous terrain and, depending on routing, towers could be located on or along ridges and across valleys. Hawai'i has an abundance of low-elevation aviation including military helicopter training, U.S. Coast Guard operations, and civilian tour operators, and transmission towers and lines could pose a hazard to these activities.

As outlined in Section 3.11, there is a variety of airspaces defined within the Hawaiian Islands. Some airspace designations may require redefinition if a transmission line is located through or near a specific area. Also, construction sites in the vicinity of airports would require evaluation to ensure that the transmission line would not be an obstruction to air traffic and pose a safety hazard.

Depending on the location of the transmission line, marker balls may be required on the catenary lines (transmission lines between support structures). These guidelines regarding installation and lighting of these catenary markers are found in FAA Advisory Circular AC 70/7460-1K, *Obstruction Marking and Lighting* ([FAA 2007](#)).

8.1.11.2 Best Management Practices and Mitigation Measures

Coordinate with the appropriate authorities as appropriate regarding airspace designations.

If the transmission line goes near or through an airport, coordinate with the FAA and potentially affected organizations to ensure the transmission line would not be an obstruction to air traffic and pose a safety hazard. This could include the installation of catenary markers on the transmission lines.

8.1.12 NOISE AND VIBRATION

8.1.12.1 Potential Impacts

The representative on-island transmission project could result in noise and vibration impacts typical of general construction activities described in Section 3.12.5.

Corona noise is the most common type of sound association with on-island transmission line operation. Often described as hissing, sizzles, or crackles, corona noise is caused by ionization of electricity in moist air near the wires; noise levels increase with humidity. Though corona noise is audible near the transmission line, it quickly dissipates with distance and is masked by typical background noises. Long-term noise and vibration impacts from operation of a 69-kilovolt transmission line would be negligible.

8.1.12.2 Best Management Practices and Mitigation Measures

Perform routine maintenance and repair dirty or cracked insulators on mounting equipment to minimize vibration and humming noise. When possible, use longer-lasting polymer insulators instead of ceramic or glass insulators.

8.1.13 UTILITIES AND INFRASTRUCTURE

8.1.13.1 Potential Impacts

The representative on-island transmission project would add electricity to the power grid and, as such, would be required to comply with the Public Utilities Commission (PUC) requirements for Transmission Line Approval and Power Purchase Agreements. Those requirements include interfacing with the appropriate island utility (see Section 3.13.1).

The addition of a large generation source or many small generations sources (e.g. residential solar or wind) either individually or in combination would require the affected utility, the PUC, DBEDT, and the reliability administrator (if this position, under consideration by the PUC, is created) to consider grid-balancing measures such as smart grid (see Section 2.3.5.3) and energy storage (see Section 2.3.5.4).

8.1.13.2 Best Management Practices and Mitigation Measures

The utility may need to consider grid-balancing measures, as follows:

- Projects requiring 5 to 50 megawatt grid connections are discussed in Chapter 6.

- Projects requiring 51 to 99 megawatts scale in a manner similar to the 5- to 50-megawatt projects discussed in Chapter 6.
- Projects requiring 100-megawatt or larger grid connections are required to comply with the Public Utilities Commission requirements for Transmission Line Approval and Power Purchase Agreements.

8.1.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

8.1.14.1 Potential Impacts

8.1.14.1.1 Hazardous Materials

The representative on-island transmission project could result in impacts from exposure to hazardous materials typical of general construction activities described in Section 3.14.4.

Potential impacts from exposure to hazardous materials would be related to occasional applications of herbicides to maintain vegetation and to keep access paths clear. The use of large quantities of herbicides or chemicals can produce adverse environmental impacts in the event of an emergency, spill, or accident.

8.1.14.1.2 Waste Management

As identified in [Table 8-1](#), there would be no waste management impacts from the representative on-island transmission project.

8.1.14.1.3 Wastewater

The representative on-island transmission project would result in wastewater impacts typical of general construction and operation activities described in Section 3.14.4.

8.1.14.2 Best Management Practices and Mitigation Measures

Ensure herbicides are appropriately approved or licensed for the intended use and handled, stored, and applied in accordance with the manufacturer guidelines and the chemical-specific material safety data sheets.

8.1.15 SOCIOECONOMICS

8.1.15.1 Potential Impacts

Socioeconomic impacts from the representative on-island transmission project would involve a temporary construction and installation workforce of about 20 workers for about 6 months ([MacDonald and Martinez 2013](#)). The number of jobs associated with the operations and maintenance of the transmission lines would be very small, about three full-time positions. Jobs directly associated with the installation of the lines and maintenance of those lines likely would be filled by individuals residing within the State of Hawai‘i and not by in-migrating workers.

8.1.15.2 Best Management Practices and Mitigation Measures

None identified.

8.1.16 ENVIRONMENTAL JUSTICE

8.1.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the representative on-island transmission project are expected to be small; however, on-island transmission projects proposed in sensitive or protected areas potentially could have significant impacts that must be assessed. The potential and magnitude of any environmental justice impacts would be dependent on the specific locations for the project and its proximity to low-income and minority populations.

8.1.16.2 Best Management Practices and Mitigation Measures

During site selection of the transmission line, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

8.1.17 HEALTH AND SAFETY

8.1.17.1 Potential Impacts

The representative on-island transmission project would cause potential health and safety impacts to workers during all phases of the project; i.e., installation, maintenance, and repair. These impacts would be typical of standard industrial hazards.

There would be potential health and safety impacts to the public during operations of the transmission lines as a result of electromagnetic field (EMF) and/or radio frequency concerns. Since the mid-twentieth century, electricity has been an essential part of our lives. Electricity powers our appliances, office equipment, and countless other devices that we use to make life safer, easier, and more interesting. Use of electric power is something we take for granted. However, some have wondered whether the EMFs produced through the generation, transmission, and use of electric power might adversely affect our health. Numerous research studies and scientific reviews have been conducted to address this question.

One of the largest evaluations to date was led by two U.S. government institutions – the National Institute of Environmental Health Sciences (NIEHS) of the National Institutes of Health and DOE – with input from a wide range of public and private agencies. This evaluation, known as the Electric and Magnetic Fields Research and Public Information Dissemination (EMF RAPID) Program, was a six-year project with the goal of providing scientific evidence to determine whether exposure to power-frequency EMF involves a potential risk to human health.

In 1999, at the conclusion of the EMF RAPID Program, the NIEHS reported to Congress that the overall scientific evidence for human health risk from EMF exposure is weak. No consistent pattern of biological effects from exposure to EMF had emerged from laboratory studies with animals or with cells. However, epidemiological studies (studies of disease incidence in human populations) had shown a fairly consistent pattern that associated potential EMF exposure with a small increased risk for leukemia in children and chronic lymphocytic leukemia in adults. Since 1999, several other assessments have been completed that support an association between childhood leukemia and exposure to power-frequency EMF. These more recent reviews, however, do not support a link between EMF exposures and adult leukemias. For both childhood and adult leukemias, interpretation of the epidemiological findings has been difficult due to the absence of supporting laboratory evidence or a scientific explanation linking EMF exposures with leukemia. Additional information and commonly asked questions and answers regarding EMF and potential health effects can be found online in the NIEHS report ([NIEHS 2002](#)).

Specifically for transmission lines, the report provides the following ([NIEHS 2002](#)):

- At a distance of 300 feet and at times of average electricity demand, the magnetic fields from many transmission lines can be similar to typical background levels found in most homes. The distance at which the magnetic field from the line becomes indistinguishable from typical background levels differs for different types of lines.
- In the United States, there are no Federal standards limiting occupational or residential exposure to 60-Hz EMF. At least six states have set standards for transmission line electric fields; two of these also have standards for magnetic fields. In most cases, the maximum fields permitted by each state are the maximum fields that existing lines produce at maximum load-carrying conditions. Some states further limit electric field strength at road crossings to ensure that electric current induced into large metal objects such as trucks and buses does not represent an electric shock hazard. Hawai‘i does not have specific standards for transmission line electric or magnetic fields.

Effects on each island’s public safety services would be small since the workers to construct and to operate the transmission line and associated substation and switching yard are expected to come from the island’s existing workforce (see above). Police, fire, and medical services would not be adversely affected with this small change in employment.

8.1.17.2 Best Management Practices and Mitigation Measures

Ensure all activities are conducted and personnel trained in accordance with OSHA guidance related to power generation ([OSHA 2014a](#)).

Read literature by the following organizations to learn about EMFs and radiofrequency health: The World Health Organization, Institute of Electrical and Electronics Engineers, The National Institutes of Health, OSHA, the Federal Communications Commission, and the Centers for Disease Control and Prevention (CDC).

8.2 Undersea Cables

The representative undersea cable project would transfer power between two islands via a 10-inch high-voltage direct current (HVDC) undersea cable. The undersea cable would be bounded by two land-sea cable transition sites with a converter station at each end. The stations each would have a total footprint of 6 acres (3 acres plus an additional 3 acres for laydown and future expansion). They would each be located within 0.5 mile from the shoreline and within 10,000 feet of the endpoints of the cable. The undersea cable would have two-way transmission capability and could transmit 200 megawatts of renewable energy without grid instability (i.e., transmitted at a constant rate). The cable package would operate at 150 kilovolts. The undersea cable would connect to the land-sea transition sites within 10,000 feet from the shoreline. The land-sea transition sites would serve as substations for the cable; connecting one island’s grid to the other. The PEIS does not specify a length of the representative undersea cable project as the distance between the main Hawaiian Islands varies significantly and this analysis is not intended to represent any specific project or route. Undersea cables of different lengths would have the same types of impacts; however, longer cables would have the potential for a higher magnitude of impacts due to the slightly larger footprint.

[Table 8-2](#) presents a summary of the potential environmental impacts for undersea cables, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the

technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

8.2.1 GEOLOGY AND SOILS

8.2.1.1 Potential Impacts

Onshore Activities

Potential impacts on soils from the representative undersea cable project would be associated with construction or other soil-disturbing actions associated with the land-sea transition, and would be the same as those expected for common construction actions as described in Section 3.1.3. It is estimated that a minimum of 1 acre of land at each end of the undersea cable would be disturbed with the HDD setup and the subsequent converter station construction, so the permitting requirements described in Section 3.1.3 would be fully applicable.

No impacts to surface geology or soils would be expected from the operation of an undersea cable and land/sea transition sites.

Offshore Activities

At the locations where the HDD would break out on the ocean floor, ocean sediments would be disturbed and dispersed to some degree. The drilling mud or slurries used in the HDD would also be released at the breakout point. These dispersed sediments would increase turbidity for at least some period of time and, depending on the currents or wave actions at the site, would settle out in different locations, possibly in areas of coral or other bottom communities of concern. Potential impacts to such communities would not only depend on whether they are present near the site, but also whether they are periodically subjected to naturally occurring high turbidity.

HVDC cable installation may occur in two primary ways: laying on the surface of the ocean floor or burial through shallow trenches on the ocean floor. Multilayer sheathing is a common feature in extruded cable for submarine power transmission and provides environmental benefits, such as neutral EMFs (DC cable magnetic field is lower than the earth’s natural magnetic field), oil-free cables, and low electricity losses. HVDC submarine cables are not limited by distance nor grid constraints and deliver electricity with minimal electrical losses ([ABB 2013](#)).

In those instances where the cable may be buried, it typically would be done in areas with muddy sediments by using a plow-like device at the time the cable was deployed or by using a remotely controlled installing device after the cable was laying on the sea floor. In both cases, sea floor sediments would be disturbed and suspended in the water for some time. In shallow areas, this could even cause turbidity that was visible to people at the surface, but in the majority of areas, these suspended solids would not be expected to move far or present any visible evidence. Over time, the trenches would be filled in completely as a result of natural currents and associated movements of sediments. Although dependent on site-specific ocean currents, experience with the trenching devices is that much of the disturbed sediments settle back down in the same location to provide at least some backfill for the cable. Impacts to soils or sediments of the disturbed areas would be minor. Installation of the undersea cables would be expected to have no effects on geology, but the sea floor geology could have adverse impacts on the cable. In rocky areas, particularly in sloped areas where it may be difficult to secure the cables to the floor, over time even minor movement could abrade the cable exterior and eventually cause damage.

Activities involving discharges of dredged or fill materials into the waters of the U.S. are regulated by the U.S. Army Corps of Engineers under Section 404 of the *Clean Water Act*. Accordingly, a USACE Section 404 permit likely would be required for the HDD action because the breakout point for the cables could require fill material to stabilize the location. Any action that requires a USACE Section 404 permit must also obtain certification from the State pursuant to Section 401 of the *Clean Water Act*. The certification dictates BMPs and monitoring and assessment plans to ensure project actions comply with State water quality standards. A Section 404 permit and Section 401 certification may also be required for the placement of the undersea cable; that is, to the extent such actions are done within the territorial seas (the area within about 3 nautical miles of the shore). Depending on how it was to be performed, the action of burying cables along the ocean floor might be considered excavation and filling all in a single action rather than a discharge of dredged or fill materials, so USACE may not consider it applicable to 404 permitting ([Sharples 2011](#)). If there was any question about the applicability of a Section 404 permit, discussion with USACE would be the appropriate course of action.

Operation and maintenance of the undersea power cable could have localized impacts on undersea sediment if cable repairs are required. Sea floor sediments would be disturbed and suspended if the cable must be moved to make necessary repairs. However, maintenance repairs are expected to occur infrequently and be confined to short segments of the undersea cable.

8.2.1.2 Best Management Practices and Mitigation Measures

Onshore Activities

Avoid areas with highly erodible soils and high slopes for converter station sites. The HDD operation would also require an area of good stability. Standard construction BMPs are identified in Section 3.1.4.

Offshore Activities

Deploy devices such as silt curtains in specific locations, such as the HDD breakout point, to help reduce potential impacts. However, devices such as silt curtains often have limited effects, particularly if wave or current action is high at the site.

Schedule such project activities during seasonal periods when wave, current, and wind would be expected to be at lows.

Route cables to avoid steep slopes, sharp changes in slopes, and suspended spans. Coral reefs fringe all the islands and living coral reefs, along with extremely rugged seafloors, dominate between east Lānaʻi and west Maui. The submarine canyons and landslides west of Molokai would prove challenging due to steep slopes. Cable installation technologies include various means of dealing with problematic sea floor

conditions that include rock cutting, burying the cable under ballast or cement, or placing support devices across areas where the cable would be installed. It is expected that any of these potential technologies would become more difficult with increased depths.

8.2.2 CLIMATE AND AIR QUALITY

8.2.2.1 Potential Impacts

The representative undersea cable project would result in impacts to air quality typical of general construction activities described in Section 3.2.4.

[Section 8.2.13.1](#) addresses the positive benefits of an interconnection of island electrical grids via an undersea cable. One of those benefits would be the increased ability of each respective grid to accommodate additional renewable energy. That benefit would have a direct and applicable benefit to air quality since the air emissions of criteria pollutants and greenhouse gas emissions would be reduced with an increased deployment of renewable energy electricity generation.

8.2.2.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction projects (see Section 3.2.5).

8.2.3 WATER RESOURCES

8.2.3.1 Potential Impacts

8.2.3.1.1 Surface Water

Onshore Activities

Onshore activities associated with the representative undersea cable project at both islands would use HDD to bring the power cable through the land-sea transition site and construction of a converter station at or near the HDD setup site to condition the power for relay to the electrical grid. Impacts on surface water from construction of onshore activities would be the same as those expected for common construction actions as described in Section 3.3.5.

Operation of the converter station and power cable would not affect surface waters other than possibly changing the quantities of storm water runoff from the site as a result of changes in the characteristics of the surface areas (e.g., cement foundations). Whether the constructed site would include more or less impermeable surfaces would depend on the nature of the preconstruction site. If the runoff volume were increased, its management would depend on the nature of the specific site (for example, whether there were collection ditches or detention ponds already available), but the amount of land and impermeable surfaces involved would not be expected to present unusual or difficult runoff management concerns.

Offshore Activities

At the locations where the HDD would break out on the ocean floor, ocean sediments would be disturbed and dispersed to some degree. The drilling mud or slurries used in the HDD could also be released at the breakout point. Drilling mud, which is primary bentonite clay, and drill cuttings would be circulated back to the shore work site during drilling operations, and actions would be taken to minimize any loss of drilling mud when the breakout point is reached. However, it is difficult to control all of the drilling mud when one end of the hole is underwater, and it is assumed some would be released. Depending on the currents at breakout point, these disturbed sediments could cause increased turbidity at the site for some

period of time and could settle out in different locations. As indicated in [Section 8.2.4](#), the HDD of the representative project would avoid disturbing the more productive marine environment, such as coral reefs, by extending to about 10,000 feet from the shoreline; therefore, it is unlikely that coral communities would be impacted by the dispersed sediments. The presence of other habitats of concern would be a site-specific issue. With regard to the installation of the other portions of the undersea cable, sea floor sediments would be disturbed and dispersed to some degree at the locations where the cable was buried or anchored. These dispersed sediments would increase turbidity for at least some period of time and would settle out in different locations.

There would be no expected impacts to land-based surface water. Marine water quality could be affected during operation if maintenance repairs of the undersea cable are required. Disturbance of sediments surrounding the repair site could temporarily increase water turbidity. However, those impacts would be restricted to the short segments of the cable where repairs are needed.

8.2.3.1.2 Groundwater

Onshore Activities

Effects on groundwater from construction and operation of the representative undersea cable project would be the same as those expected for common construction actions as described in Section 3.3.5.

If there was an increase in runoff (as described above) there could be an associated change in groundwater recharge. However, the area involved is relatively small and, depending on where runoff from the facility would go or how it would be managed, the action may simply represent a change in where water soaks into the ground.

Offshore Activities

No groundwater impacts would be expected from the offshore activities associated with deployment or operation of the power cable.

8.2.3.1.3 Floodplains and Wetlands

Onshore Activities

It is reasonable to assume that the proponent of an undersea power cable project would avoid onshore construction in a floodplain or wetland if at all possible, if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

Offshore Activities

As noted above, a USACE Section 404 permit likely would be required for the placement of the cables on the ocean side of the system. The HDD breakout points would be expected to require placement of fill material to stabilize the location, and potential burial of the undersea cable at other locations, depending on the method used, may also require fill. Any action that requires a USACE Section 404 permit must also obtain certification from the State pursuant to Section 401 of the *Clean Water Act*, which would ensure the actions, including any cable maintenance and repairs, complied with State water quality standards. If there was any question about the applicability of a Section 404 permit, discussion with USACE would be the appropriate course of action.

8.2.3.2 Best Management Practices and Mitigation Measures

Devices such as silt curtains could be deployed at the HDD breakout point to help reduce potential impacts. However, devices such as silt curtains often have limited effects, particularly if wave or current

action is high at the site. Correspondingly, another mitigation measure normally considered would be to schedule such project activities during seasonal periods when wave, current, and wind would be expected to be at lows.

Schedule sea floor disturbing activities during seasonal periods when wave, current, and wind would be expected to be at lows.

Develop land-sea transition sites in a manner that would not add to runoff volumes, speeds, and sediment loads.

8.2.4 BIOLOGICAL RESOURCES

8.2.4.1 Potential Impacts

Impacts to the marine environment from the representative undersea cable project would be mostly confined to construction disturbances during installation. The extent of impacts to marine habitats would depend on whether the cable was buried or placed on the ocean floor and on the type of marine habitats along the selected route. Although the physical disturbance (i.e., displacement or mortality of marine organisms) during installation of the cable would be relatively short term for many marine communities, the duration of the effect would likely vary for particular habitats and organisms. For example, a disturbance in an area of mud sediment would be relatively short-term, although suspension of sediments could cause longer-term impacts to corals if reefs are located nearby; a disturbance in a coral reef would require much longer time to recover, particularly deepwater corals, which are slower growing, and could potentially impact a larger number of marine species. Impacts to the seafloor could also impact essential fish habitat where the cable would be shallower than a quarter mile or traversing precious coral beds. Impacts to biological resources similar to those that could occur during construction, also could occur during operations if cable maintenance or repairs are needed. However, maintenance repairs would be expected to occur infrequently and typically be confined to a short segment of the undersea cable.

The Humpback Whale National Marine Sanctuary covers a large area surrounding the Hawaiian Islands, particularly between O‘ahu and the islands that comprise Maui County. Potential impacts during construction in that area could involve collisions with the marine mammals because of additional boat activity.

During operation, an undersea power cable could introduce an EMF into the marine environment along the cable. Although potential impacts to and responses of marine organisms to EMFs are not fully understood, many marine species such as sharks, marine mammals, sea turtles, and some bony fishes have well developed electrosensory systems that may be involved in orientation, homing, and navigation or in life functions such as detection of prey and predators ([Normandeau et al. 2011](#)). The potential strength of the EMF surrounding the cable is a function of the voltage, cable shielding, and whether the cable is buried or laid along the ocean floor. However, the EMF attenuates relatively quickly with distance from the cable (15 and 30 feet for AC and DC cables, respectively) along and above the seafloor, and the potential impacts to those species most sensitive to EMFs is likely to be relatively small ([Normandeau et al. 2011](#)).

In the near shore environment, there could be potential impacts (i.e., disturbance) to productive shallow marine habitat such as fringing and barrier reefs, fishponds, sea grass habitats, sandy and rocky beaches, and marine pools during cable laying. HDD under the shoreline would minimize potential impacts to marine habitats along the shoreline. However, marine habitats could be disturbed at the HDD breakout point. Furthermore, suspension and then deposition of sediments during HDD could extend the construction impact beyond the immediate vicinity of cable. Of particular concern would be corals and

other photosynthetic organisms that could be covered in sediment. The potential impacts would depend on the specific location and the marine habitats in the area. Shallower, near-shore marine areas contain some of the more productive marine environments because the photosynthetic zone reaches to the ocean floor. However, there also are prolific deepwater corals that are slow growing, highly valued (e.g., black corals), and support a precious coral fishery.

Potential impacts of the converter stations would be typical of general construction and operation activities described in Section 3.4.5.

8.2.4.2 Best Management Practices and Mitigation Measures

In addition to the standard BMPs for typical construction activities (see Section 3.4.6), the following BMPs and mitigation measures could reduce or help avoid the above-identified impacts:

- Project sites within or near existing developed areas should minimize disturbance of sea turtle habitats (e.g., nesting beaches), resting areas for monk seals (i.e., beaches), seabird nesting sites, and remnants of native coastal vegetation that likely would occur in less developed coastal areas.
- Minimize nighttime light management to avoid attraction and disorientation in seabirds and nesting sea turtles if present in the project area.
- Avoid sensitive or high value marine habitats by collocating undersea cables of the representative project with existing cables.
- Mitigate potential impacts to humpback whales and other marine mammals by using dedicated observers to detect their presence in the impact area.
- Coordinate with the National Marine Sanctuary and the NMFS to develop an undersea cable route and laying (during construction) plan to help protect threatened and endangered species and identify high-value marine habitats and resources
- Additional best management practices would likely be recommended on a project specific basis for the installation of undersea cables to protect EFH including: schedule construction outside of coral spawning periods, relocate corals found in the cable path and monitor over time, locate HDD breakout points at locations that would minimize the impact on coral resources, and develop a maintenance and replacement plan that considers impacts to EFH.
- Site HDD breakout point and undersea cable away from sensitive biological resources.
- Consider EMF shielding through cable burial or encasement in areas of sensitive species.

8.2.5 LAND AND SUBMERGED LAND USE

8.2.5.1 Potential Impacts

8.2.5.1.1 Land Use

The representative undersea cable project would result in impacts typical of general construction and operation activities described in Section 3.5.4.

8.2.5.1.2 Submerged Land Use

Installation of a cable on the ocean floor would introduce a new submerged land use and consequent obstruction along the undersea corridor that could require coordination with owners/operators of existing undersea cables.

The waters around the islands have dumps of subsurface munitions and chemical weapons, especially around O‘ahu, which could impact the route along which the representative undersea cable project would travel.

8.2.5.2 Best Management Practices and Mitigation Measures

The following BMPs and mitigation measures could reduce or help avoid the above identified impacts:

- Avoid or minimize the crossing of areas of high use, including existing or planned telecommunications cables.
- Conduct bathymetry studies to help define and locate existing pipe and cable corridors and munitions dumps.
- If there is a need for undersea cables to cross seabed obstructions, especially in areas that are congested with subsea pipelines and/or telecommunication cables, use mattresses to support the cable above obstructions or use protective sleeves over the obstructions.

8.2.6 CULTURAL AND HISTORIC RESOURCES

8.2.6.1 Potential Impacts

Potential adverse impacts could occur to cultural, historic, and related natural resources during construction and operational phases of an inter-island undersea electrical cable project and associated onshore ancillary facilities if effective conservation and BMPs are not implemented. During construction in onshore, nearshore, and offshore locations, direct impacts to archaeological and historic properties, including burial sites and protected traditional and customary activities, could result from the clearing, grading, and excavation of a project area and from construction of facility components and associated infrastructure if archaeological sites, historic structures, or traditional cultural properties are located within the footprint of the project. Worker and public presence during operational activities of a project increases the likelihood of unauthorized access to culturally sensitive areas and the possibility of vandalism and collection of artifacts. Operations can have a visual, noise, or restricted access effect on sensitive cultural and historic resources, landscapes, vistas, hunting and fishing locations, subsistence gathering activities, and ceremonial aspects in the vicinity of a project. Operating facilities may also have an adverse impact on a historical building, structure, or district by being incompatible with the historic context of a structure or area.

Additional and more detailed descriptions of cultural and historic resource impacts commonly associated with general construction and operational activities of renewable energy technologies and facilities are presented in Section 3.6.6.

8.2.6.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction and operation projects. See Section 3.6.7.

8.2.7 COASTAL ZONE MANAGEMENT

8.2.7.1 Potential Impacts

Construction of the representative undersea cable project would require a Federal consistency review to ensure the project is consistent with the policies and goals of the Coastal Zone Management Program. The project would require a power cable connection between the onshore converter station and the undersea cable offshore. Depending on the location of where the cable would cross under the shoreline, the project could impact designated special management areas, restrict shorefront access, and/or affect shoreline erosion. The converter station, which would be built 0.5 mile from the shoreline, also could potentially affect designated special management areas. Similar types of impacts could occur during operation of the cable if maintenance repairs are needed in cable segments near the shoreline.

8.2.7.2 Best Management Practices and Mitigation Measures

Evaluate the project through a Federal consistency review under the Coastal Zone Management Program.

8.2.8 SCENIC AND VISUAL RESOURCES

8.2.8.1 Potential Impacts

The representative undersea cable project would result in impacts typical of general construction and operation activities described in Section 3.8.3 and [Section 8.2.7.1](#).

8.2.8.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction and operation projects (see Section 3.8.4).

8.2.9 RECREATION RESOURCES

8.2.9.1 Potential Impacts

The representative undersea cable project would result in impacts typical of general construction activities described in Section 3.9.4.

Generally speaking, short-term impacts would be related to construction activities (e.g., HDD, cable lay, converter station construction); long-term impacts would be those associated with the operations of a project (e.g., energy transmission via cables and converter station operation).

The representative project would have a significant impact on recreation resources if it impedes access to or displaces recreation resources or users.

Almost all recreation resources discussed in Section 3.9 are under the stewardship of a government (county, State, or Federal) for the public; access to these resources is already provided and would likely be on public property. During construction, it is possible that related equipment could be staged in an area that could cause users to take detours to a recreation resource. It is possible that construction activities could block access to the resource.

Neither construction nor operation associated with laying undersea cables and the converter stations would have an adverse impact on land-based nature recreation, sports activities, or interpretive recreation

(nature parks, botanical gardens, scenic lookout, historic/cultural sites, and educational/interpretive displays). Non-stationary activities, such as walking/jogging, may need to be rerouted (displacement) if construction activities affect public rights-of-way. Impacts would cease once construction was completed.

Impacts to water-based recreation from HDD activities may occur during undersea cable installation. For instance, an area set up to accommodate HDD activities may be on or near a popular surfing spot. At least during the duration of the construction activities, recreation users would be displaced. Depending on the location of the drilling activity, one or more activities may be affected. Activities along the cable route would also be impacted during the temporary presence of the cable laying ships. Impacts would cease once construction was completed.

During the operational period, impacts to recreation resources are unlikely but could occur if maintenance repairs of the undersea cable are needed. Maintenance repairs are expected to occur infrequently and be confined to short segments of the cable where repairs are needed. Potential impacts to recreation resources would be similar to those that could occur during construction.

8.2.9.2 Best Management Practices and Mitigation Measures

Install cable in locations that already accommodate undersea cables (e.g., communications cables).

Recreation resource impacts should be considered when siting the land-sea transition site. Tables 3-47 and 3-48 identify the popular land- and sea-based recreation activities in Hawai‘i. Review the SCORP prior to siting the land-sea transition sit (refer to [DLNR 2009](#)).

8.2.10 LAND AND MARINE TRANSPORTATION

8.2.10.1 Potential Impacts

8.2.10.1.1 Land Transportation

The representative undersea cable project could potentially increase truck traffic during delivery of construction materials (e.g., cables and installation equipment). Any impacts would be short-term, during construction activities.

8.2.10.1.2 Marine Transportation

Construction of the representative undersea cable project would have minimal short-term impacts (i.e., less than a month) on civilian and military marine and submarine transportation. A buffer area around and below the cable laying ship would have to remain clear of all surface and submarine transportation. The buffer area would be a moving area as the cable laying ship travels the installation pathway. The length of the construction would vary depending upon the submarine topography, the length of the cable route, and whether the cable is being buried or laid on the surface of the ocean floor but is expected to be less than a month.

Construction of an undersea power cable and land-sea transition facilities may have short-term impacts on local marine traffic. Assuming the cable from the onshore converter station to the offshore main undersea cable is installed via a horizontal direction drill under the shoreline, offshore construction ships during construction of the HDD and the installation of the power cable in the HDD would have to remain free of marine transportation traffic. A buffer zone around the connection site with the undersea cable also would have to remain free of surface and submarine marine transportation while the power cable connection is

completed. Construction activity would be coordinated with the U.S. Coast Guard to ensure that civilian and military mariners are aware of the activity.

During operation of the undersea cable, impacts similar to those during construction, could affect civilian and military marine and submarine transportation in the vicinity of sites where maintenance repairs are needed. However, maintenance repairs are expected to occur infrequently and be confined to short segments of the cable route.

8.2.10.2 Best Management Practices and Mitigation Measures

Construction and maintenance activity would be coordinated with the U.S. Coast Guard to ensure that civilian and military mariners are aware of the activity.

Location of the undersea cable would need to be marked under water and digitally recorded to avoid future disturbance to the cable and for the safety of future work that could be conducted in the vicinity. Coordination with the HDOT Harbors Division should be done during project planning to avoid underwater locations that could be impacted by future harbor expansion (e.g., dredging).

8.2.11 AIRSPACE MANAGEMENT

As described in [Table 8-2](#), there would be no potential impacts to airspace management from the representative undersea cable project.

8.2.12 NOISE AND VIBRATION

8.2.12.1 Potential Impacts

During construction of the representative undersea cable project local noise ordinances described in Section 3.12 could be temporarily exceeded, and the project would require a permit variance. In addition, construction noise outside of permitted hours could occur. Offshore construction noise from equipment and vessels, and vibration caused by potential pile-driving, could exceed regulatory levels. Sources of noise or vibration from survey activity may include single-beam echosounders, multi-beam echosounders, side-scan sonars, and shallow-penetration sub-bottom profilers.

Construction noise in general can impact biological resources, scenic and visual resources, recreation resources, cultural resources, worker health and safety, and possibly public health. According to the “Incidental Harassment Authorization” ([77 FR 43259; July 24, 2012](#)), exposure to elevated sound levels from vibratory and impact pile driving may result in temporary impacts to marine mammal hearing and behavior. However, the NMFS stated in its Biological Opinion of the Authorization that it does not expect any takes of marine mammals by injury, serious injury, or mortality ([NMFS 2012](#)). Marine mammal prey species, such as fish, and sea turtles may also be temporarily impacted. Noise and vibration impacts would be dependent on the location and compatibility with the existing noise levels and land uses. Another study ([Nedwell et al. 2003](#)) evaluates the subsea acoustic noise and vibration impacts associated with construction of an offshore wind project. It evaluates the noise propagation from activities such as pile driving and cable trenching. Using a modified decibel scale to account for inter-species differences in hearing ability [i.e., $dB_{ht}(Species)$],¹ the study uses 90 dB_{ht} as the threshold level when significant avoidance behavior would occur. The estimated noise levels measured for a cable trenching operation for an offshore wind farm would be below this avoidance threshold. The impacts would be negligible because of the temporary nature (short duration) during construction; however, the intensity level (sound level)

¹ See <http://www.subacoustech.com/underwater-noise/audiograms-and-the-dbht/>.

may cause some temporary behavioral avoidance (combined noise of surface ships and any underwater trenching) but would never rise to the level at which physical injury or death would occur. By comparison, the report describes the effects of pile driving support structures for wind turbines, where approximately 75 percent of the sound levels exceeded the avoidance threshold.

Long-term noise and vibration impacts from operation of the representative undersea cable project would be negligible. Noise and vibration impacts from land-based converter stations would be the typical of general construction activities described in Section 3.12.5.

Potential noise and vibration impacts similar to those that could occur during construction, could occur during operations of the undersea cable if maintenance repairs of the cable are needed. However, maintenance repairs are expected to occur infrequently.

8.2.12.2 Best Management Practices and Mitigation Measures

When required, requests for Incidental Harassment Authorization must include monitoring and reporting plans.

The following BMPs and mitigation measures could reduce or help avoid the above-identified impacts ([NMFS 2012](#)):

- Temporal restrictions (such as not conducting vibratory pile driving during peak humpback whale season in Hawai‘i)
- Establishment of an exclusion zone (a buffer to prevent harassment [injury] of any marine mammal species).
- Pile-driving shutdown and delay procedures (if a marine mammal or sea turtle approaches or enters an exclusion zone);
- Soft-start procedures (a technique that allows marine mammals and sea turtles to leave the immediate area before sound sources reach maximum noise levels);
- In-situ underwater sound monitoring (sound monitoring during sheet pile and test pile driving); and
- Visual monitoring (an onsite, biologically trained individual approved in advance to monitor sound during pile driving).

Additional BMPs include the following:

- Avoid sensitive receptors for noise and vibration (identified in Section 3.12).
- Restrict noisy land-based or near-shore construction activities to daytime hours.
- Use maintained construction equipment with sound control devices.

8.2.13 UTILITIES AND INFRASTRUCTURE

8.2.13.1 Potential Impacts

The representative undersea cable project would add electricity to the local power grid and, as such, would be required to comply with the Public Utilities Commission (PUC) requirements for Transmission

Line Approval and Power Purchase Agreements. Those requirements include interfacing with the appropriate island utility (see Section 3.13.1).

In association with an undersea cable, the addition of a large generation source or many small generations sources (e.g. residential solar or wind) either individually or in combination would require the affected utility, the PUC, DBEDT, and the reliability administrator (if this position, under consideration by the PUC, is created) to consider grid-balancing measures such as smart grid (see Section 2.3.5.3) and energy storage (see Section 2.3.5.4).

Also, when connecting electrical grids, an undersea cable may impact the following items as it pertains to utilities and infrastructure:

- Enabling the transmission of power and ancillary services in both directions and allowing the networks to operate in a coordinated fashion;
- System flexibility in resource planning, operations, and reliability;
- Flexibility in siting and interconnection of renewable energy generation;
- Flexibility in preventing curtailment of renewable energy resources; and,
- Reducing oil usage for electricity generation.
- Creating a large system contingency. 200 megawatts is larger than any single generation resource in the State, and a failure of the cable or either converter station could negatively impact the stability of the grids that the undersea cable connects.

For additional discussion on whether an O'ahu-Maui interisland transmission system may be in the public interest, see open Docket 2013-0169 at the Hawai'i PUC's Document Management System:

<http://dms.puc.hawaii.gov/dms/DocketSearch>.

8.2.13.2 Best Management Practices and Mitigation Measures

- The local utility may need to consider grid-balancing measures.
- Projects requiring 100-megawatt or larger grid connections are required to comply with the Public Utilities Commission requirements for Transmission Line Approval and Power Purchase Agreements (as it pertains for the purchase of the power/energy purchase).
- Pursuant to Hawai'i Revised Statutes 269-131 to 135, a Certified Cable Company (any person or persons, company, corporation, or entity who owns or controls a high-voltage electric transmission cable system and who receives a certificate of public convenience and necessity from the public utilities commission) would be selected through a competitive process.

8.2.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

8.2.14.1 Potential Impacts

8.2.14.1.1 Hazardous Materials

Impacts from hazardous material exposure from the representative undersea cable project would be typical of those for construction projects described in Section 3.14.4.

8.2.14.1.2 Waste Management

General construction and operational waste management impacts are discussed in Section 3.14 and would be applicable to the project construction. In addition, waste specific to the representative project likely would be generated onboard the construction vessels and barges. Such waste would be returned to shore for disposal at the appropriate landfill.

8.2.14.1.3 Wastewater

Minimal to no wastewater is anticipated from construction and operation of the cable and the converter stations.

8.2.14.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction and operation projects (see Section 3.14.5).

8.2.15 SOCIOECONOMICS

8.2.15.1 Potential Impacts

Direct socioeconomic impacts (related to changes in project-driven employment) in Hawai‘i from the representative undersea cable project would be very small.

Jobs directly associated with the laying of an undersea cable or maintenance repairs during operation likely would be filled by individuals currently residing outside the State of Hawai‘i. The undersea cable project would not create many new net jobs, and hence, the impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income would be very small.

Socioeconomic impacts associated with the land-sea transition site would be small. Construction of the converter stations would take approximately 24 months. The grading and foundation work would require 20 construction workers, and building erection would require 10 to 15 construction workers. Electrical installation would require 20 additional construction workers. The positions would not overlap. These jobs likely would be filled by individuals residing in the State of Hawai‘i and not by in-migrating workers. The construction of a land-sea transition site would not create many new net jobs. The impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and personal income would be very small.

8.2.15.2 Best Management Practices and Mitigation Measures

None identified.

8.2.16 ENVIRONMENTAL JUSTICE

8.2.16.1 Potential Impacts

The potential environmental impacts to the general population associated with the representative undersea cable project are expected to be small. Since an environmental justice impact is one that would be disproportionately high and adverse to low-income or minority populations, the potential for

environmental justice impacts also would be small. The likelihood of disproportionate impacts to these populations would be highly dependent on the specific location of the project.

8.2.16.2 Best Management Practices and Mitigation Measures

During site selection for the land-sea transition site and converter stations, conduct a detailed environmental impact study to determine the specific location of low-income populations and minority populations, specifically Native Hawaiians.

8.2.17 HEALTH AND SAFETY

8.2.17.1 Potential Impacts

The representative undersea cable project would cause potential health and safety impacts to workers during all phases of the project; i.e., installation, maintenance, and repair. The workers would be subject to standard industrial hazards. Health and safety impacts also include risk from electricity generation, transmission, and distribution, as outlined by OSHA at <https://www.osha.gov/SLTC/powergeneration/index.html>.

Potential health and safety impacts to the public during operation of the undersea cable and converter stations could involve EMFs. The potential for health and safety impacts from EMF is described briefly in [Section 8.1.17](#).

Impacts on public safety from construction and operation of the representative undersea cable project would be the same as those as described in Section 3.17.3.

8.2.17.2 Best Management Practices and Mitigation Measures

Ensure all activities are conducted and personnel trained in accordance with OSHA guidance for construction, including marine construction: (https://www.osha.gov/pls/oshaweb/owadisp.show_document?p_table=STANDARDS&p_id=10772; see also [OSHA 2014b](#)).

Effects from EMF dissipate rapidly as a function of distance. Typically, facilities such as converter stations would be constructed with the converter equipment inside a fenced area to protect both the equipment and the nearby public.

8.3 Smart Grid

The representative smart grid project would consist of a comprehensive, robust, secure communications infrastructure capable of near real-time communication to more than 100,000 remote devices (see Section 2.3.5.3.4).

[Table 8-3](#) presents a summary of the potential environmental impacts for smart grid, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and BMPs and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 8-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Smart Grid

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	None; installing electronic equipment and upgrading software for the representative smart grid project would not involve land disturbance and therefore would not impact geology and soils.	N/A
Climate and Air Quality		
	None; installing electronic equipment and upgrading software for the representative smart grid project would not involve land disturbance and therefore would not impact climate or air quality.	N/A
Water Resources		
	None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and therefore would not impact water resources.	N/A
Biological Resources		
	None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and therefore would not impact biological resources.	N/A
Land and Submerged Land Use		
	None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and would not impact land and submerged land use.	N/A
Cultural and Historic Resources		
	None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and therefore would not impact cultural or historical resources.	N/A
Coastal Zone Management		
	None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and therefore would not impact coastal zone management.	N/A
Scenic and Visual Resources		
	None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and therefore would not impact scenic or visual resources.	N/A

Table 8-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Smart Grid (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Recreation Resources		
	None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and therefore would not impact recreation resources.	N/A
Land and Marine Transportation		
	None; installing electronic equipment and upgrading software for the representative project would not involve land or marine transportation.	N/A
Airspace Management		
	None; installing electronic equipment and upgrading software for the representative project would not involve installation of towers and therefore would not impact airspace management.	N/A
Noise and Vibration		
	None; installing electronic equipment and upgrading software for the representative project would not construction activities or result in any operational noise.	N/A
Utilities and Infrastructure		
	Power transmission using smart grid technologies assumes that other measures such as energy storage and renewables are also implemented. Potential benefits and concerns are discussed in Section 2.3.5.3.	None.
Hazardous Materials and Waste Management		
Hazardous Materials	Potential impact from exposure to hazardous materials that may be present in old utility meters that are replaced by smart meters.	Handle any hazardous materials according to applicable county, State, and Federal regulations, including OSHA requirements.
Waste Management	Potential impacts from exposure related to disposal of old utility meters.	Implement recycling program to process old meters to the extent practicable.
Wastewater	None; installing electronic equipment and upgrading software for the representative project would not involve wastewater services.	N/A
Socioeconomics		
	As technologies advance, the requirements of existing jobs will change.	Utility companies and other smart grid stakeholders will need to retrain current employees and recruit new ones as the growing industry creates more jobs.

Table 8-3. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Smart Grid (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Environmental Justice		
	None; installing electronic equipment and upgrading software for the representative project would not result in environmental justice impacts.	N/A
Health and Safety		
	Standard industrial hazards to workers installing electrical equipment. Minimal potential for health and safety impacts to the public associated with electromagnetic fields and radiofrequency.	During the installation, maintenance, and repair of transmission lines, ensure activities are conducted and personnel trained in accordance with OSHA guidance related to power generation: https://www.osha.gov/SLTC/powergeneration/ Read available literature about electromagnetic fields and radiofrequency health.

8.3.1 GEOLOGY AND SOILS

As identified in [Table 8-3](#), there would be no impacts to geology and soils from the representative smart grid project.

8.3.2 CLIMATE AND AIR QUALITY

As identified in [Table 8-3](#), there would be no impacts to climate and air quality from the representative smart grid project.

8.3.3 WATER RESOURCES

As identified in [Table 8-3](#), there would be no impacts to water resources, including surface water, groundwater, floodplains, and wetlands from the representative smart grid project.

8.3.4 BIOLOGICAL RESOURCES

As identified in [Table 8-3](#), there would be no impacts to biological resources from the representative smart grid project.

8.3.5 LAND AND SUBMERGED LAND USE

As identified in [Table 8-3](#), there would be no impacts to land and submerged land use from the representative smart grid project.

8.3.6 CULTURAL AND HISTORIC RESOURCES

As identified in [Table 8-3](#), there would be no impacts to cultural or historical resources from the representative smart grid project.

8.3.7 COASTAL ZONE MANAGEMENT

As identified in [Table 8-3](#), there would be no impacts to coastal zone management from the representative smart grid project.

8.3.8 SCENIC AND VISUAL RESOURCES

As identified in [Table 8-3](#), there would be no impacts to scenic or visual resources from the representative smart grid project.

8.3.9 RECREATION RESOURCES

As identified in [Table 8-3](#), there would be no impacts to recreation resources from the representative smart grid project.

8.3.10 LAND AND MARINE TRANSPORTATION

As identified in [Table 8-3](#), there would be no impacts to land or marine transportation from the representative smart grid project.

8.3.11 AIRSPACE MANAGEMENT

As identified in [Table 8-3](#), there would be no impacts to airspace management from the representative smart grid project. The representative project assumes the use of existing radio towers.

8.3.12 NOISE AND VIBRATION

As identified in [Table 8-3](#), there would be no impacts to noise and vibration from the representative smart grid project.

8.3.13 UTILITIES AND INFRASTRUCTURE

8.3.13.1 Potential Impacts

Adding smart grid capability is one tool that each island utility could implement (some in Hawai'i are currently doing so; see Section 2.3.5.4) to manage transmission of power from diverse sources. The effects to the utilities and the islands' power customers would be more reliable and less fossil-dependent power. Power transmission using smart grid techniques assumes that other measures such as energy storage and renewable sources are also implemented. See Section 2.3.5.4 for more details regarding implementation benefits and concerns.

8.3.13.2 Best Management Practices and Mitigation Measures

None identified.

8.3.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

8.3.14.1 Potential Impacts

8.3.14.1.1 Hazardous Materials

Implementation of the representative smart grid project would be largely software- and telecommunications-based. Project installation would occur in existing homes where old analog meters are currently in operation. There could be some hazardous materials within the older utility meters.

8.3.14.1.2 Waste Management

Impacts related to waste management could occur, as removed analog meters would need to be disposed of. Similarly, impacts may result when the smart meters reach their end-of-life and need to be disposed of. To the extent feasible, these wastes could be minimized through electronic recycling efforts and repurposing of these materials. As such, consideration should be given to development and implementation of an electronic recycling plan or potential repurposing of these meters which could also effectively recover materials that could contain potentially hazardous substances.

8.3.14.1.3 Wastewater

As identified in [Table 8-3](#), there would be no impacts to wastewater from the representative smart grid project.

8.3.14.2 Best Management Practices and Mitigation Measures

Handle any hazardous materials according to applicable county, State, and Federal regulations, including OSHA requirements.

Employ proper handling and transport for disposal of old analog meters as well as smart meters at their end-of-life at the appropriate hazardous material facilities to ensure no hazardous materials are disposed of at landfills and that no hazardous materials enter the waste stream.

8.3.15 SOCIOECONOMICS

8.3.15.1 Potential Impacts

The representative smart grid project would introduce a requirement for utility workers to develop new skillsets. The number of employees necessary to support a smart grid project would not be significantly different than that currently in place. Therefore, any socioeconomic impacts from the representative project would be very minor.

8.3.15.2 Best Management Practices and Mitigation Measures

Utility companies and other smart grid stakeholders will need to retrain current employees and recruit new ones as the growing industry creates more jobs.

8.3.16 ENVIRONMENTAL JUSTICE

As identified in [Table 8-3](#), there would be no environmental justice impacts from the representative smart grid project.

8.3.17 HEALTH AND SAFETY

8.3.17.1 Potential Impacts

Concerns have been raised about the safety of smart meters, mainly because they give off the same kinds of radiofrequency (RF) waves as cell phones and Wi-Fi devices. The following information on the potential safety of smart meters was obtained from the American Cancer Society (<http://www.cancer.org/cancer/cancercauses/othercarcinogens/athome/smart-meters>; see also [American Cancer Society 2012](#)).

Smart meters are typically installed outside the home, either in place of or as part of existing analog meters. The level of exposure to RF energy depends on the distance from the smart meter antenna and the communications protocol used in the smart meter. The frequency and power of the RF waves given off by a smart meter are similar to that of a typical cell phone, cordless phone, or residential Wi-Fi router. However, smart meters are typically only in operation a small portion of the time because they only send and receive short messages at set intervals throughout the day (often several times an hour).

Because smart meter antennas typically are located outside the home, people are much farther away from the source of RF waves than with personal cell phones, cordless phones, or Wi-Fi routers. In addition, walls between the person and the smart meter's antenna further reduce the amount of RF energy exposure. For these reasons, the exposure to RF energy from smart meters is estimated to be much less than the typical exposure people receive through cell phones, cordless phones, and/or home Wi-Fi routers. Smart meters emit RF waves, which are a type of electromagnetic radiation, so there is the "potential" for them to cause harm. The "actual" risk of harm, if it exists, is likely to be extremely low, for a number of reasons.

The RF waves that smart meters give off are a form of electromagnetic energy that falls between frequency modulation (FM) radio waves and microwaves. Like FM radio waves, microwaves, visible light, and heat, RF waves are a form of non-ionizing radiation. They do not have enough energy to cause cancer by directly damaging the DNA inside cells. RF waves are different from stronger (ionizing) types of radiation such as x-rays, gamma rays, and ultraviolet (UV) light, which can break the chemical bonds in DNA. Long-term exposure to ionizing radiation is a known cause of cancer.

At very high levels, RF waves can heat up body tissues. But the levels of energy given off by smart meters are much lower, and are not enough to raise temperatures in the body. The low levels of energy that smart meters give off at their source are further diluted by the distance they typically need to travel to reach people (unlike cell phones, for instance) and by any walls they have to pass through.

Smart meters are still fairly new, so there has been very little direct research on the possible health effects of exposure to RF from smart meters. Research has been done, however, on the possible health effects of RF waves in general and from other sources. For example, a good deal of research has focused on the possible link between cell phone use and cancer in recent years. Some research has suggested that the RF waves from cell phones might produce biological effects in human cells (in lab dishes), but it's not clear if these effects could possibly cause tumors or help them grow in people.

Several dozen studies have looked at the possible link between cell phone use and cancer (mainly brain tumors) in people. Most of these studies have not found a link, but a few studies have found a possible link. All of these studies have suffered from limitations that prevent researchers from being able to draw firm conclusions, so this continues to be an area of active research. Several agencies (national and international) study different environmental exposures to determine if they can cause cancer. The

American Cancer Society looks to these organizations to evaluate the risks based on evidence from laboratory, animal, and human research studies.

For example, the major goal of the International Agency for Research on Cancer (IARC), which is part of the World Health Organization, is to identify causes of cancer. IARC has not assessed smart meters specifically, but it has recently classified RF radiation as “possibly carcinogenic to humans.” This is based on the finding of a possible link in at least one study between cell phone use and a specific type of brain tumor. IARC considers the evidence overall to be “limited” because of the conflicting findings and generally low quality of the studies that have been done. In general, most experts agree at this time that the evidence of a possible link between RF waves and cancer is limited. This is based on the generally poor quality of studies done so far and the fact that it’s not clear how the low levels of energy in RF waves might cause cancer. But experts also agree that more research is needed to assess this risk.

Many researchers continue to examine the possibility of other health effects from exposure to extremely low levels of RF energy. For example, researchers are studying the possible link between cell phone use and problems such as headaches, dizziness, vision problems, disturbed sleep, loss of memory, and the development of benign tumors of the nerve connecting the ear and the brain. So far, there is no conclusive evidence of such links.

One concern with cell phones has been whether the RF waves they give off might interfere with electronic medical devices such as heart pacemakers. According to the U.S. Food and Drug Administration (FDA), cell phones should not pose a major risk for most pacemaker wearers, especially if the phone is kept more than 6 inches from the device as normally occurs in typical cell phone use. Because smart meters would generally be much farther away, they are not expected to pose such problems.

Other organizations have concerns and opposing views on the potential safety risks associated with smart meters. While they acknowledge that there is no scientific literature that specifically evaluates the health risks of smart meters because they are a relatively new technology, they have extrapolated the results from studies on effects of EMF and cell phones. Some of the opposing views on the health risks of smart meters have been published in 2012 by the Santa Cruz County, California Health Services Agency (<http://emfsafetynetwork.org/wp-content/uploads/2009/11/Health-Risks-Associated-With-SmartMeters.pdf>); see also [CSC-HSA 2012](#)) and the American Academy of Environmental Medicine (<http://emfsafetynetwork.org/wp-content/uploads/2009/11/AAEM-Resolution.pdf>; see also [AAEM 2012](#)).

8.3.17.2 Best Management Practices and Mitigation Measures

According to the American Cancer Society, there is no clear evidence at this time that RF waves from smart meters (or other devices) can cause harmful health effects. The low levels of energy from RF waves have not been clearly shown to cause problems even at close range, and the energy decreases the farther a person is from the transmission source.

If there is any increased risk, it is likely to be extremely small – even smaller than any possible increased risk from cell phones. Although it’s not clear if cell phones cause any health problems, some experts recommend that people concerned about possible health effects keep the device at least 3 to 4 inches from the head to lower exposure to RF waves, just to be safe. In the case of smart meters, people are already much farther from these devices, and an added degree of safety is provided by the one or more walls between the person and the smart meter antenna.

Some people may still have health or other concerns (such as privacy) related to the use of smart meters on their homes. In some places where smart meters are being installed, people have the choice to opt in or opt out of having them.

8.4 Energy Storage

There are many forms of energy storage; therefore this PEIS identifies two representative projects to provide a better perspective of potential impacts (see Section 2.3.5.4.4). Both projects consider separate facilities and different capacity energy systems. The first project is an energy storage system for a 400-room hotel or resort facility intended to maintain critical systems. This distributed utility system uses flywheel energy storage because of its small footprint, fast response time, and life cycle. The second energy storage project is for a renewable energy generation plant where the energy storage system serves as a bridging power function. The project assumes that one-third of the generation capacity is needed in storage and that the energy storage is co-located with the generation source that is already connected to the power grid. This utility-scale system uses sodium-sulfur battery storage because of response time, discharge duration, and modularity to allow for more or less power depending on the generation capability.

[Table 8-4](#) and [Table 8-5](#) present a summary of the potential environmental impacts for energy storage technologies for a distributed flywheel system and a utility-scale battery system, respectively, whether such impacts are resource-specific, regardless of the technology employed, or occur solely because of the technology and B and/or measures to mitigate such impacts. Those resource areas with no impacts are shaded and were not carried forward for analysis.

Table 8-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Energy Storage: Flywheel

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	N/A
Climate and Air Quality		
Air Quality	General construction impacts (see Section 3.2.4). No long-term impacts from operation; the flywheel energy storage system would not produce criteria pollutants from fossil fuels. No fossil fuel would be burned and no fugitive dust would be generated.	Same as those common across construction and operation projects (see Section 3.2.5).
Climate Change	General construction impacts (see Section 3.2.4). Negligible increase in greenhouse gas emissions during operation of the flywheel energy storage system.	Same as those common across construction and operation projects (see Section 3.2.5).

Table 8-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Energy Storage: Flywheel (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Water Resources		
Surface Water	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	N/A
Groundwater	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	N/A
Floodplains and Wetlands	General construction and operation impacts (see Section 3.2.5).	Same as those common across construction projects (see Section 3.3.5).
Biological Resources		
	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	N/A
Land and Submerged Land Use		
	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	N/A
Cultural and Historic Resources		
	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	N/A
Coastal Zone Management		
	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	N/A
Scenic and Visual Resources		
	None; the flywheel energy storage system would not cause adverse visual impacts as it would be installed in the utility room and would be compatible with the existing setting.	N/A
Recreation Resources		
	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	N/A
Land and Marine Transportation		
	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	N/A

Table 8-4. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Energy Storage: Flywheel (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Airspace Management		
	None; installation of energy storage technologies would not involve any tall facilities; therefore, no impacts to airspace management would be expected.	N/A
Noise and Vibration		
	General construction impacts (see Section 3.12.5). Operational noise levels for the representative flywheel energy storage system would be less than 70 dBA at a distance of 3 feet.	Same as those common across construction and operation projects (see Section 3.12.6). The flywheel equipment could be installed inside a sound-insulated room to further dampen any noise from being noticed by hotel guests.
Utilities and Infrastructure		
	Beneficial impacts to the utilities and the distributed generator by helping to manage power demand.	None.
Hazardous Materials and Waste Management		
Hazardous Materials	None; no hazardous materials would be required for the construction or installation of a flywheel energy storage system.	N/A
Waste Management	General construction and operation impacts (see Section 3.14.4).	Reuse or recycle flywheel system components to the extent feasible.
Wastewater	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	N/A
Socioeconomics		
	Very small impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income.	None.
Environmental Justice		
	None; installation of a flywheel for energy storage would not result in environmental justice impacts.	N/A
Health and Safety		
	General construction and operation impacts (see Section 3.17.3). No added impacts to each island's public safety services since the workers to construct and to operate the facility are expected to already reside on the island.	None.

Table 8-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Energy Storage: Sodium-Sulfur Battery

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Geology and Soils		
	General construction and operations impacts (see Section 3.1.3).	Same as those common across construction and operations of projects (see Section 3.1.3).
Climate and Air Quality		
Air Quality	General construction impacts (see Section 3.2.4). Negligible increase in criteria pollutants during operations. No fugitive dust generated during operation.	Same as those common across construction projects (see Section 3.2.5).
Climate Change	Negligible increase in greenhouse gas emissions during operation, since fossil fuels would not be burned.	None.
Water Resources		
Surface Water	General construction and operations impacts (see Section 3.3.5).	None.
Groundwater	Minimal groundwater impacts during construction of the sodium-sulfur battery facility. Potential for increased runoff in the long-term and decrease in groundwater recharge.	None.
Floodplains and Wetlands	General construction and operation impacts (see Section 3.2.5).	Same as those across construction and operation projects (see Section 3.3.5).
Biological Resources		
	None; the battery energy storage system would involve minor land disturbance in previously developed locations.	N/A
Land and Submerged Land Use		
	None; the battery energy storage system would involve minor land disturbance in previously developed locations.	N/A
Cultural and Historic Resources		
	General impacts during construction and operation (see Section 3.6.6).	Same as those common across construction and operation projects (see Section 3.6.7).
Coastal Zone Management		
	General impacts during construction and operation (see Section 3.7.8).	Evaluate through a Federal consistency review under the Coastal Zone Management Program.

Table 8-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Energy Storage: Sodium-Sulfur Battery (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Scenic and Visual Resources		
	General impacts during construction and operation activities (see Section 3.8.3).	Same as those common across construction projects (see Section 3.8.4).
Recreation Resources		
	None; the battery energy storage system would involve minor land disturbance in previously developed locations.	N/A
Land and Marine Transportation		
	None; the battery energy storage system would involve minor land disturbance in previously developed locations	N/A
Airspace Management		
	None; the battery energy storage system would not involve tall facilities and not impact airspace.	N/A
Noise and Vibration		
	General impacts during construction (see Section 3.12.5). Negligible long-term noise and vibration impacts during operation.	Same as those common across construction and operation projects (see Section 3.12.6).
Utilities and Infrastructure		
	Potentially beneficial impacts to utilities by helping to manage power generation.	None.
Hazardous Materials and Waste Management		
Hazardous Materials	Potential hazardous material exposure impacts during construction and operation due to presence of hazardous chemicals inside the battery.	Handle, package, store, and transport battery according to all applicable county, State, Federal regulations, including USDOT and ICAO regulation, both during setup and decommissioning. Dispose of batteries and/or battery components in a manner that minimizes hazardous material exposure impacts. Fire suppression material appropriate for the type of battery should be stored nearby.
Waste Management	General construction and operation impacts (see Section 3.14.4). Potential impacts may occur during disposal of battery at its end of life.	Dispose of battery and battery components in a manner that minimizes hazardous waste impacts.
Wastewater	None; the battery energy storage system would involve minor land disturbance in previously developed locations.	N/A

Table 8-5. Summary of the Potential Environmental Impacts and Best Management Practices/Mitigations, including Resource Areas with No Potential for Impacts – Energy Storage: Sodium-Sulfur Battery (continued)

Resource Area	Potential Impacts	Best Management Practices/ Mitigation Measures
Socioeconomics		
	Very small impacts to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income.	None.
Environmental Justice		
	None; installation of a sodium-sulfur battery for energy storage would not result in environmental justice impacts.	N/A
Health and Safety		
	General impacts during construction and operation (see Section 3.17.4). Small potential for impacts to public safety services.	Install and implement safety measures and procedures to isolate batteries from fire threats and to enable fire suppression and emergency response.

8.4.1 GEOLOGY AND SOILS

8.4.1.1 Potential Impacts

8.4.1.1.1 Flywheel – Distributed Energy Source

As identified in [Table 8-4](#), there would be no impacts to geology and soils from the representative flywheel energy storage project.

8.4.1.1.2 Sodium-Sulfur Batteries – Utility-Scale Energy Source

Effects on geology and soils from installation of the battery system would be the same as those expected for common construction actions as described in Section 3.1.3. The group of batteries that would be installed under the representative project represents a large grouping of equipment with a footprint of 26,000 square feet, or 0.6 acre. With footing excavations, equipment laydown areas, electrical connections to the adjacent renewable energy facility, and the need for a heavy load access road, it is reasonable to assume that the total amount of soil disturbed by the project could be over 1 acre, so the permitting requirements described in Section 3.1.3 could be fully applicable.

Operation of the battery energy storage facility would not involve activities that would have the potential to affect geology or soils of the area.

8.4.1.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction projects (see Section 3.1.4).

8.4.2 CLIMATE AND AIR QUALITY

8.4.2.1 Potential Impacts

8.4.2.1.1 Air Quality

Flywheel – Distributed Energy Source

The representative flywheel energy storage project would result in air quality impacts typical of general construction activities described in Section 3.2.4. Most units of the system would be manufactured offsite and moved into position at the site.

Operation of the representative flywheel energy storage system would not produce criteria pollutants from fossil fuels. No fossil fuels would be burned and no fugitive dust would be generated during operation. Beneficial impacts to air quality would result from the use of energy storage devices since the technology would increase the usefulness of variable renewable energy electrical generation sources, which could offset generation using diesel fuel.

Sodium-Sulfur Batteries – Utility-Scale Energy Source

The representative battery energy storage project would result in air quality impacts typical of general construction activities described in Section 3.2.4. As with the flywheel project, most units of the battery system would be manufactured offsite and moved into position at the site.

Operation of the representative battery energy storage system would not produce criteria pollutants from fossil fuels. No fossil fuels would be burned and no fugitive dust would be generated during operation.

8.4.2.1.2 Climate Change

Flywheel - Distributed Energy Source

This technology could result in impacts typical of general onsite construction activities, which are addressed in Section 3.2.4. Most units of the system would be manufactured off-site and moved into position at the site.

Operation of an energy storage system would not produce measureable amounts of greenhouse gases. No fossil fuels would be burned during operation.

Sodium-Sulfur Batteries – Utility-Scale Energy Source

This technology could result in impacts typical of general on-site construction activities, which are addressed in Section 3.2.4. Most units of the system would be manufactured off-site and moved into position at the site.

Operation of an energy storage system would not produce measureable amounts of greenhouse gases. No fossil fuels would be burned during operation.

8.4.2.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction projects (see Section 3.2.5).

8.4.3 WATER RESOURCES

8.4.3.1 Potential Impacts

8.4.3.1.1 Surface Water

Flywheel – Distributed Energy Source

As identified in [Table 8-4](#), there would be no impacts to surface water from the representative flywheel energy storage project.

Sodium-Sulfur Batteries – Utility-Scale Energy Source

Impacts on surface water from installation of the representative battery energy storage system would be the same as those expected for common construction actions as described in Section 3.3.5.

During operation there would be no activities that would have the potential to affect surface waters other than possibly increased storm water runoff from the site. If the pre-construction project site had natural vegetation, the completed project site would have a higher percentage of impermeable surfaces and, accordingly, would generate more storm water runoff. The amount of land involved is minor and would not be expected to present unusual or difficult runoff management concerns.

8.4.3.1.2 Groundwater

Flywheel – Distributed Energy Source

As identified in [Table 8-4](#), there would be no impacts to groundwater from the representative flywheel energy storage project.

Sodium-Sulfur Batteries – Utility-Scale Energy Source

Construction of the representative battery energy storage facility would not be expected to impact groundwater nor would they be expected to involve any unusual sources of contamination.

Periods during construction when large amounts of loosened soil might result in decreased storm water runoff, as described above, would also represent periods when there would be more storm water soaking into the ground and potentially providing recharge to groundwater. As noted previously, these would be temporary conditions with little potential to have any notable effect on groundwater.

Water needs during construction would be expected to come from groundwater resources, either via municipal water systems or private wells, but they would be minor, involving such uses as for dust suppression and in soil compaction.

The long-term presence and operation of the energy storage facility would be associated with increased runoff (as described previously) and potentially an associated decrease in groundwater recharge. However, the area involved would be small and, depending on where runoff from the facility would go or how it would be managed, the action may simply represent a change in where water soaks into the ground.

8.4.3.1.3 Floodplains and Wetlands

The proponents of either energy storage project would be expected to avoid floodplain and wetland areas if only to reduce costs and minimize regulatory requirements. However, if they could not be avoided, construction considerations would be the same as described for common construction actions in Section 3.3.5.

8.4.3.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction and operation projects. See Section 3.3.6.

8.4.4 BIOLOGICAL RESOURCES

As identified in [Table 8-4](#) and [Table 8-5](#), there would be no impacts to biological resources from either representative energy storage project.

8.4.5 LAND AND SUBMERGED LAND USE

As identified in [Table 8-4](#) and [Table 8-5](#), there would be no impacts to land and submerged land use from either representative energy storage project.

8.4.6 CULTURAL AND HISTORIC RESOURCES

8.4.6.1 Potential Impacts

8.4.6.1.1 Flywheel – Distributed Energy Source

As identified in [Table 8-4](#), there would be no impacts to cultural or historical resources from the representative flywheel energy storage project.

8.4.6.1.2 Sodium Sulfur Batteries – Utility-Scale Energy Source

Impacts on cultural and historic resources from the representative battery energy storage system would be the same as those expected for common construction and operation actions as described in Section 3.6.6.

8.4.6.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction and operation projects (see Section 3.6.7).

8.4.7 COASTAL ZONE MANAGEMENT

8.4.7.1 Potential Impacts

8.4.7.1.1 Flywheel – Distributed Energy Source

As identified in [Table 8-4](#), there would be no impacts to coastal zone management from the representative flywheel energy storage project.

8.4.7.1.2 Sodium-Sulfur Batteries – Utility-Scale Energy Source

Impacts on coastal zone management from the representative battery energy storage system would be the same as those expected for common construction and operation actions as described in Section 3.7.8.

8.4.7.2 Best Management Practices and Mitigation Measures

Evaluate the project through a Federal consistency review under the Coastal Zone Management Program.

8.4.8 SCENIC AND VISUAL RESOURCES

8.4.8.1 Potential Impacts

8.4.8.1.1 Flywheel – Distributed Energy Source

As identified in [Table 8-4](#), there would be no impacts to scenic or visual resources from the representative flywheel energy storage project.

8.4.8.1.2 Sodium-Sulfur Batteries – Utility-Scale Energy Source

Impacts on scenic and visual resources from the representative battery energy storage system would be the same as those expected for common construction and operation actions as described in Section 3.8.3.

Long-term visual impacts are not expected since the storage system would be co-located with an existing renewable energy generation source that is already connected to the transmission line.

8.4.8.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction and operation projects. See Section 3.8.4.

8.4.9 RECREATION RESOURCES

As identified in [Table 8-4](#) and [Table 8-5](#), there would be no impacts to recreation resources from either representative energy storage project.

8.4.10 LAND AND MARINE TRANSPORTATION

As identified in [Table 8-4](#) and [Table 8-5](#), there would be no impacts to land or marine transportation from either representative energy storage project.

8.4.11 AIRSPACE MANAGEMENT

As identified in [Table 8-4](#) and [Table 8-5](#), there would be no impacts to airspace management from either representative energy storage project.

8.4.12 NOISE AND VIBRATION

8.4.12.1 Potential Impacts

8.4.12.1.1 Flywheel – Distributed Energy Source

The representative flywheel energy storage project could result in noise and vibration impacts typical of general construction activities described in Section 3.12.5.

Operational noise levels would be less than 70 dBA at 3 feet from the source of the flywheel energy storage facility. The sound would dissipate to around 58 dBA at 50 feet with no other sound absorption or mitigation measures. If inside an insulated room, the sound would be much less.

8.4.12.1.2 Sodium-Sulfur Batteries – Utility-Scale Energy Source

As with the flywheel project, the representative battery energy storage project could result in noise and vibration impacts typical of general construction activities described in Section 3.12.5.

Operational noise levels for the battery technology are low as well. Operational noise and vibration levels would be similar to existing noise levels. Long-term noise and vibration impacts from operation of the representative energy storage project would be negligible.

8.4.12.2 Best Management Practices and Mitigation Measures

BMPs and mitigation measures would be the same as those common across construction and operation projects (see Section 3.12.6).

For operational noise associated with the flywheel equipment, the equipment could be installed inside a sound-insulated room to further dampen any noise from being noticed by hotel guests.

8.4.13 UTILITIES AND INFRASTRUCTURE

8.4.13.1 Potential Impacts

Both representative energy storage projects would result in beneficial impacts by helping to manage power demand and generation. In addition, energy storage, in general, provides more reliable and less fossil-fuel-dependent power to the islands' power customers. Most successful energy storage projects connected to a power grid assume that other measures such as smart grid technology and renewable sources are also implemented.

8.4.13.2 Best Management Practices and Mitigation Measures

None identified.

8.4.14 HAZARDOUS MATERIALS AND WASTE MANAGEMENT

8.4.14.1 Potential Impacts

8.4.14.1.1 Hazardous Materials

Flywheel – Distributed Energy Source

As identified in [Table 8-4](#), there would be no impacts from exposure to hazardous materials from the representative flywheel energy storage project.

Sodium-Sulfur Batteries – Utility-Scale Energy Source

Sodium-sulfur batteries contain sodium, sulfur, beta-alumina ceramic electrolyte, and sulfur polysulfide components, which are considered hazardous materials and would be subject to USDOT and International Civil Aviation Organization regulations.

8.4.14.1.2 Waste Management

Flywheel – Distributed Energy Source

The representative flywheel energy storage project could result in waste management impacts typical of general construction activities, which are addressed in Section 3.14.4.

Sodium-Sulfur Batteries – Utility-Scale Energy Source

Sodium-sulfur batteries contain sodium, sulfur, alumina, and sodium polysulfide components that could be recycled or disposed of at the end of their life by routine industrial processes. As most of these materials are of high value, it is anticipated that most battery materials would be captured through reuse and recycling processes. Recycling practices and protocols for batteries are being further developed to handle various types. Batteries are considered to have reached their end-of-life when the battery charge is 80 percent of the new battery capacity. At this point, batteries still have a lot of potential for other “second use” applications, such as providing an energy buffer for solar or wind generation and utility grid support. The likely path for healthy batteries would be reconditioning and redeploying in other applications. This approach would avoid all of the costs and energy used to produce new batteries and would improve battery lifecycle emissions and costs by keeping them out of the recycling stream for many years past their use.

8.4.14.1.3 Wastewater

As identified in [Table 8-4](#) and [Table 8-5](#), there would be no impacts to wastewater from the either representative energy storage project.

8.4.14.2 Best Management Practices and Mitigation Measures

Sodium-sulfur batteries contain components that may be toxic to humans and animals such as chromium compounds, particularly hexavalent chromium, if not disposed of properly. Therefore, special treatment is recommended during the disposal of the battery parts that cannot be repurposed or recycled. This includes testing for chromium using EPA’s Toxic Characteristic Leachate Procedure test methods. Those battery wastes exceeding maximum concentration levels of 5.0 milligrams per liter would be required to be set aside as hazardous waste, and proper handling and transport for disposal at the appropriate hazardous material facility would be required.

The following BMPs could reduce the above-identified impacts for both representative projects:

- Reuse or recycle batteries at their end of life to the extent practicable.
- Handle, package, store, and transport battery according to all applicable county, State, and Federal regulations, including USDOT and ICAO regulation, both during setup and decommissioning.
- Dispose of batteries and/or battery components in a manner that minimizes hazardous material exposure impacts.
- Fire suppression material appropriate for the type of battery should be stored nearby.

8.4.15 SOCIOECONOMICS

8.4.15.1 Potential Impacts

Direct socioeconomic impacts in Hawai‘i from the representative energy storage projects would be very small. Construction jobs directly associated with the project likely would be filled by individuals residing within the State of Hawai‘i. Operation jobs likely would be filled by current workers. The overall impact to population; to employment variables such as the size of the labor force, unemployment rates, and employment in the State and local government sector; to rental housing; and to personal income would be very small.

8.4.15.2 Best Management Practices and Mitigation Measures

None identified.

8.4.16 ENVIRONMENTAL JUSTICE

As identified in [Table 8-4](#) and [Table 8-5](#), there would be no environmental justice impacts from either representative energy storage project.

8.4.17 HEALTH AND SAFETY

8.4.17.1 Potential Impacts

8.4.17.1.1 Flywheel Technology

Potential health and safety impacts from construction and operation would be the same at the typical impacts describes in Section 3.17.3

Effects on each island public safety services would be small since the workers to construct and to operate the facility are expected to come from the island's existing work force (see [Section 8.4.15](#)). Police, fire, and medical services would not be adversely affected with this small change.

8.4.17.1.2 Sodium-Sulfur Batteries – Utility-Scale Energy Source

Sodium-sulfur batteries contain sodium, sulfur, beta-alumina ceramic electrolyte, and sulfur polysulfide components. Batteries have the potential to short-circuit, which can lead to fires. Some batteries contain corrosive liquid, which can injure people or damage property. Sodium-sulfur batteries contain sodium, which presents a safety hazard, as pure sodium can spontaneously burn when in contact with air and moisture.

Effects on each island public safety services would be small since the workers to construct and to operate the facility are expected to come from the island's existing workforce (see [Section 8.4.15](#)). Police, fire, and medical services would not be adversely affected with this small change.

8.4.17.2 Best Management Practices and Mitigation Measures

Review and update first responder training, as necessary, for any unique features of these technologies as they are introduced to Hawai'i.

The battery system must be protected, including employing safety enhancement measures to prevent the potential for fires and the spread of fires from occurring. This includes the use of insulation boards between blocks in the battery module to prevent leaking molten materials from causing a short circuit, the use of anti-fire boards between battery modules to prevent fires from spreading, the implementation of a monitoring system, the installation of fire-prevention equipment, and a fire-fighting structure for fire preparedness and safety, as well as a fire evacuation and guidance plan.

9 COMMENT-RESPONSE DOCUMENT

9.1 Introduction

9.1.1 BACKGROUND

This chapter of the *Hawai‘i Clean Energy Programmatic Environmental Impact Statement* (Hawai‘i Clean Energy PEIS; DOE/EIS–0459) contains responses to comments the U.S. Department of Energy (DOE) received on the Hawai‘i Clean Energy Draft PEIS. It is commonly referred to as a Comment-Response Document and is abbreviated CRD herein. DOE prepared this PEIS consistent with the Council on Environmental Quality (CEQ) regulations that implement the National Environmental Policy Act (NEPA) (40 CFR Parts 1500 to 1508), the DOE’s procedures for implementation of NEPA (10 CFR Part 1021), and DOE’s guidance issued October 2004, *The EIS Comment-Response Process*, as applicable.

The following paragraphs describe the public comment and related processes.

9.1.2 HAWAI‘I CLEAN ENERGY DRAFT PEIS

DOE issued the Hawai‘i Clean Energy Draft PEIS in April 2014 for public comment. The U.S. Environmental Protection Agency announced the availability of the Draft PEIS for public review and comment in the *Federal Register* on April 18, 2014 (79 FR 21917); this announcement began a 90-day comment period, which ended on July 17, 2014. The Department also issued a Notice of Availability on April 18, 2014 (79 FR 21909). The Draft PEIS evaluated the potential environmental impacts, and the potential best management practices to mitigate these impacts, associated with 31 energy efficiency activities and renewable energy technologies that could assist the State of Hawai‘i in meeting the goals established under the Hawai‘i Clean Energy Initiative (HCEI).

The April DOE Notice of Availability invited commenters to submit their comments on the Draft PEIS by U.S. mail, email, through the Hawai‘i Clean Energy PEIS website, and at public hearings held at the following eight locations:

- Lihue, Kauai Island – May 12, 2014
- Kailua-Kona, Hawai‘i Island – May 13, 2014
- Hilo, Hawai‘i Island – May 14, 2014
- Kahului, Maui Island – May 15, 2014
- Kaunakakai, Molokai Island – May 19, 2014
- Lāna‘i City, Lāna‘i Island – May 20, 2014
- Honolulu, O‘ahu Island – May 21, 2014
- Kāne‘ohe, O‘ahu Island – May 22, 2014

DOE received 151 comment documents (e.g., emails, letters, and hearing transcripts) consisting of 582 specific comments on the Draft PEIS from Federal, State, and local government agencies, Native Hawaiian and other organizations, and members of the public. These comments were in statements transcribed by a court reporter at the public hearings (the statement of each speaker is a separate comment document), or in written documents submitted at those hearings or sent to DOE via email, the Hawai‘i Clean Energy PEIS Website, or the U.S. postal service.

The electronic images of the comment documents (including transcripts for each commenter at the public hearings) that DOE received on the Draft PEIS have been posted on the PEIS Website (<http://www.hawaiiicleanenergyPEIS.com>); these images include brackets that identify the specific

comments addressed in this CRD. Table 9-1 (at the end of this Introduction) lists all comments received and the unique comment identifier assigned to each comment. The table points to the locations in this CRD where the reader can find particular comments and the DOE responses. Table 9-2 contains the same information but sorted by commenter.

9.1.3 HOW DOE CONSIDERED PUBLIC COMMENTS

Using guidance provided in *The EIS Comment-Response Process* (http://energy.gov/sites/prod/files/nepapub/nepa_documents/RedDont/G-DOE-EIS_cmnt_response.pdf), DOE assessed and considered public comments on the Hawai‘i Clean Energy Draft PEIS, both individually and collectively. Some comments resulted in updates to the PEIS; others resulted in a response to explain DOE policy, to refer readers to existing information in the PEIS, answer technical questions, explain technical issues, correct reader misinterpretations, or provide clarification.

A number of comments provided valuable suggestions on improving the Draft PEIS. As applicable, the responses in this appendix identify changes that DOE made to the PEIS as a result of comments.

9.1.4 METHODOLOGY

DOE reviewed all comment documents (e.g., letters and emails) received, identified discrete comments within each document, categorized the discrete comments, and, as appropriate, grouped the same or similar comments and prepared a summary comment. This approach enabled DOE to consider, individually and collectively, all comments received on the Draft PEIS in an efficient manner, and to respond to those comments. The following list highlights key aspects of DOE’s approach to capturing, tracking, and responding to public comments on the Draft PEIS:

- DOE read all comment documents and their attachments to identify and categorize comments. As a part of this process, DOE reviewed technical attachments (e.g., reports or technical articles) for potential applicability to the PEIS. After comment identification, DOE grouped individual comments by categories or subcategories and assigned each comment to an expert in the appropriate discipline to prepare a response. Senior-level experts reviewed each response to ensure technical and scientific accuracy, clarity, and consistency, and to ensure that the response addressed the comment.
- Frequently, more than one commenter submitted identical or similar comments. In such cases, DOE grouped the comments (referred to herein as a summary comment) and prepared a single summary response for each group.
- To the extent practicable, DOE organized and presented the comments in this document by topic. Each comment-response pair, individual or summary, consists of three parts: (1) information on the source of the comment, including the number (unique identifier) of the submitted comment document and the comment number, or for summary comments, the number of comments summarized, (2) the individual or summary comment, and (3) the response.
- To the extent practicable, this CRD presents the comments as provided by the commenters (see next bullet). In some cases, however, DOE paraphrased individual comments to capture their meaning if they were general in nature (for example, for or against a technology), if they indicated something was incomplete or insufficient but did not provide specific examples (for example, “cumulative impacts are inadequate”), or if they indicated something was not safe (for example, undersea cables) but provided no specific information. Comments grouped and

summarized for response are, of necessity, paraphrased; however, DOE made every effort to capture the essence of every comment included in a comment summary.

- DOE did not modify certified transcripts of public hearings. However, some transcripts (and letters, emails, and web comment) contained obvious errors (for example, misspelled names or words). DOE corrected such errors in the extracted comments. Similarly, DOE deleted extraneous material (such as repeated words) from extracted comments whenever such a deletion would not alter the meaning of the comment. The original images of all comments received, including the text of each hearing transcript as certified by the court reporter, are posted on the PEIS Website (<http://www.hawaiiicleanenergyPEIS.com>).
- If the meaning of a comment was not clear, DOE made a reasonable attempt to interpret the comment and respond based on that interpretation.

9.2 Organization of the Comment-Response Document

This CRD contains the comments received on the Draft PEIS and the DOE responses to them. DOE identified discrete comments from comment documents and categorized them according to the topical outline prepared for this CRD, as follows:

- Policy – [Section 9.3.1](#)
 - Energy Planning
 - Hawai‘i Clean Energy Initiative
 - Island Energy Independence
 - PEIS Scope
 - Utility
- Regulatory – [Section 9.3.2](#)
 - Bureau of Ocean Energy Management
 - Permitting
- Technology/Activity – [Section 9.3.3](#)
- Environmental Resource Area – [Section 9.3.4](#)
- PEIS Process and Structure – [Section 9.3.5](#)
 - Cooperating Agencies
 - Information Request
 - Public Involvement
 - General
- Out of Scope Comments – [Section 9.3.6](#)
- Duplicate Comments – [Section 9.3.7](#)

Because a number of comments were similar, DOE combined and summarized them and prepared a single summary response for the summary comment. These summary comments and responses also are grouped by the above categories.

This CRD contains every comment DOE received directly or forwarded via the State of Hawai‘i on the Draft PEIS (either in summaries or individually) and the DOE responses. Table 9-1 lists comments received, grouped by comment subject matter, the names of the commenters, and the location in this CRD of the comment-response pairs. Table 9-2 contains the same information but sorted by commenter.

9.3 Comments and Responses

9.3.1 POLICY

9.3.1.1 Energy Planning

Comment 114-3: When we talk about \$4.5 million going for oil, part of needing an environmental study has to be, you know, it's done well. If we're not spending our own oil, somebody wants a piece of that for a billion dollars, and who's going to decide if we're not spending it on oil, we're going to spend it on something else. So we better do it right if it's the state that's spending money, if it's the citizens that are spending the money, we have to work very hard with Molauna [*transcriber*: phonetic spelling], Mr. Ellison and all of us here to decide what is the best way to provide energy for Lānaʻi.

Response: The PEIS was developed to present the potential environmental impacts for a broad range of energy efficiency activities and renewable energy technologies, not for specific projects. Decisions on which activities and technologies will be implemented on each island and Statewide, and the associated costs of these proposed activities and technologies, will be determined by private market participants, the State of Hawaiʻi, and the Public Utilities Commission (PUC) with input from other organizations and the public. The information in the PEIS can be used in concert with engineering and economic feasibility studies to determine the overall feasibility and potential environmental impacts of specific future projects.

9.3.1.2 Hawaiʻi Clean Energy Initiative

Summary Comment SC001 (57-1, 106-6, 3-2, 58-40): Commenters expressed concern that Hawaiʻi's renewable energy plans are to push for wind farm development and that the State should be working on a master plan for different types of renewable energy development. Commenters also stated that the means and schedule for achieving Hawaiʻi's renewable energy goals should be described in the PEIS. One commenter stated that identifying renewable energy generation for the state would not necessarily increase the requirement for renewable energy penetration to help meet [HCEI] goals.

Response: The PEIS does not identify a preference for any specific renewable energy technology or activity but rather presents a wide variety of technologies and actions that could be used by the State to help achieve the year 2030 goals established in the Renewable Portfolio Standard (RPS) and Energy Efficiency Portfolio Standard (EEPS) of 40 percent and 30 percent, respectively. The PEIS presents an independent assessment of the potential environmental impacts of such technologies by analyzing "representative projects," which generically characterize a project that could be implemented in the state of Hawaiʻi. Analyzing the

means, schedule, or technology penetration rate are beyond the scope of this PEIS. Policy, funding, schedules, and other parameters are part of the Federal, State, and local ongoing legislative and regulatory processes as they relate to the State's renewable energy goals.

The Hawai'i Electric Companies (HECO) have developed plans (for example, reference Docket No. 2014-0183 and Docket No. 2014-0192) outlining potential paths forward to meet the State's clean energy goals, which rely on contributions from all types of renewable energy technologies. These plans are currently under review by numerous stakeholders with the Hawai'i Public Utilities Commission (PUC) before they can be approved. In addition, rather than focusing on any one technology to meet the State's energy goals, two of Hawai'i's energy policy directives are to (1) develop a diversified energy portfolio that maximizes renewable generation, and (2) support market-led investments and pricing structures that align with the State's energy policy and economic goals (see <http://energy.hawaii.gov/energypolicy>).

Summary Comment
SC002 (123-4, 37-
4, 58-3, 58-54, 61-
1, 98-9):

Several commenters stated that local Hawaiian communities may be affected by renewable energy development and that sacrificing those communities just because the State needs to meet its renewable energy goals in a certain time period might be irresponsible. Commenters wanted to know how DOE's future guidance that is developed out of the PEIS will address energy prioritization concerns and influences on decision-making and resultant policies.

Response:

Preparation of the PEIS is an important step in evaluating the potential environmental, cultural, and socioeconomic impacts of the outlined renewable energy technologies and activities in Hawai'i. Public involvement is a cornerstone of the NEPA process, and DOE encourages interested parties to remain involved in all phases of project planning and permitting as individual projects are proposed throughout the State. The PEIS does not provide specific environmental impact analyses that would result in any prioritization of renewable energy technologies or activities or decisions on which efforts would receive Federal funding. The PEIS provides information on potential environmental impacts for the development of guidance should DOE or the State decide to prepare it. Prioritization would depend on current geopolitical and economic conditions, among other things, and could require further analyses of that nature. The PEIS would be used as a reference document for any such analysis.

From the State of Hawai'i's [DBEDT's] perspective, the PEIS can support the environmental review of future clean energy initiatives in Hawai'i by identifying common impacts from a variety of clean energy technologies, local resources that could be potentially impacted, local entities that should be consulted, regulatory processes in place, and

available best management practices to minimize foreseen environmental impacts. The PEIS does not serve to recommend or prioritize any specific clean energy technology or policy.

Summary Comment SC003 (105-1, 117-10): Two commenters stated that the government has ignored the affected communities in making “progress” on renewable energy development and should stop chasing unenforceable HCEI goals with taxpayer money.

Response The growing interest and sophistication of Hawai‘i’s communities in the field of energy reinforces the importance of community engagement on all energy-related activities with the potential for environmental impacts. For this reason, the PEIS was prepared under the mandates of NEPA, which include provisions for public involvement throughout the entire analysis. Specifically, DOE and the State held eight scoping meetings on O‘ahu, Maui, Kaua‘i, Lāna‘i, Molokai, and Hawai‘i to gather input on the scope of the PEIS. Further, upon release of the Draft PEIS, DOE and the State held an additional eight meetings on O‘ahu, Maui, Kaua‘i, Lāna‘i, Molokai, and Hawai‘i to gather input on the Draft PEIS. An additional purpose of these meetings was to engage the community on energy-related matters and to consider public perspectives on the issues evaluated in the PEIS. It should be noted that the Hawai‘i Clean Energy PEIS was prepared, in part, in response to public scoping comments received on the HIREP:Wind PEIS.

The Hawai‘i Clean Energy Initiative (HCEI) is a vital step in transforming the way in which energy efficiency and renewable energy resources are planned and used in the State. One of the primary drivers behind HCEI is to reduce and stabilize ratepayer costs for energy. Hawai‘i’s energy policy is rooted in the principle of maximizing the deployment of cost-effective clean energy investments to save taxpayer money.

Hawai‘i’s clean energy goals are enforceable in that non-compliance by Hawai‘i’s electrical utilities could lead to penalties levied by the PUC. HRS 269-92(c) states, “If the public utilities commission determines that an electric utility company failed to meet the renewable portfolio standard, after a hearing in accordance with chapter 91, the utility shall be subject to penalties to be established by the public utilities commission; provided that if the commission determines that the electric utility company is unable to meet the renewable portfolio standards due to reasons beyond the reasonable control of an electric utility, as set forth in subsection (d), the commission, in its discretion, may waive in whole or in part any otherwise applicable penalties.”

Comment 58-2: There is ambiguity in saying the energy efficiency goal represents 30% of projected growth in electricity by 2030, and then say energy consumption decreased by 14.5% since 2008. What is the source of this

projected growth and how do these statements relate to one another? (P. 1-2)

Response:

The source of the projected 30 percent growth in electricity is based on projections that were forecast by the State as a result of various studies, including data gathered for the utilities' Integrated Resource Plans, a Maximum Achievable Potential Efficiency Case study prepared for HECO, a Completed HCEI Analysis of the HCEI Road Map, and studies by the National Renewable Energy Laboratory and the End-Use Efficiency Working Group. Energy efficiency in the State comes from two major sources: (1) the electric energy savings using renewable displacement technologies or off-set technologies such as solar water heating systems and sea water air conditioning (which, as of January 1, 2015, apply toward Hawai'i's newly established EEPS); and (2) the electricity savings by the energy efficiency programs. Based on the data gathered and different modeling scenarios, a high-efficiency case (maximum achievable) could yield a 30 percent decrease in electricity use reductions Statewide by 2030 (4,300 gigawatt-hours) when compared with a business-as-usual scenario. The 14.5 percent discussed represents the reductions from energy efficiency savings that have occurred since 2008 as a percentage of total electricity demand—the savings being represented by the sum of electricity sale and electricity reductions from the efficiency programs. By statutory requirement, the PUC evaluates the EEPS every five years, as of 2013, and may revise the standard. The goal may be adjusted to maximize cost-effective, energy-efficiency programs and technologies.

Comment 101-1:

And this subject of the environmental impact as a planning process is -- is very much in the -- in the mind of our community. So it just so happened that tonight is one of those areas that we have an opportunity to provide some input. And thank you very much for coming, we appreciate all the effort that you have made towards providing the community with information.

So I realize that this programmatic environmental impact statement is at a higher level or at a macro level and it's not project specific. So in the process you are able to accumulate a lot of information that will be helpful to the community, to the government, to the public, and to the private sector, who ultimately will be involved in the actual drafting of an environmental impact document that will be very specific to the actual project when it's proposed.

Our concern -- and thank you very much for that summary. And our concern kind of is that in the current state where environmental impact - - project impact statement is prepared in the state, it is the developer who picks the person or the company or the group that will provide or prepare the environmental impact statement. It is our sentiment, it is our concern

that it should be the local government who should select an independent third party who will do the actual preparation of the document.

And we all know that this is paid for by the project developer. So under the current process, the project developer selects the firm that will do the actual preparation of the document, so what we are saying is it -- since this is a process, this is a planning document, this is actually a groundbreaking planning document since it will impact the whole state and every community because it refers to energy, we would like to recommend and have a key element in your finding to address the process by which EIS is done in the state of Hawai'i.

I had an opportunity to have a conversation with one of your members and we are aware that in California, for example, the process is the local government selects the firm that will do the environmental impact document or prepare the environmental impact document paid for by the developer. So in the real sense of the true meaning of an independent and something that the community can have faith on, it should be chosen by the local government or in the case of Hawai'i, the local government is in charge of the planning -- I mean, the approval process.

So we feel that it's about time, since we are in a groundbreaking phase, it's about time we change by which the environmental impact documents are prepared in the state of Hawai'i. I don't see this in the planning process that you address and that you mentioned or made mention tonight and so we'd like to take this opportunity to please incorporate this in your -- in one of the elements that -- I think it's very, very important.

All the information that you have gathered, the technology, the mitigation measures, those are all important, those are all being addressed, but who prepares that? That is our -- what we're trying to say should be prepared by an independent body chosen by the government, by the local government, that is involved in the approval process.

Response:

While a change to the environmental impact statement process may occur in the future, under the current State environment assessment/environmental impact statement law (HRS 343), the role of the State or local government does not include selecting the entity that will prepare the environmental documents for projects/actions proposed by private developers. The Department of Health's Office of Environmental Quality Control (OEQC) implements HRS 343 and Environmental Impact Statement Rules (Chapter 11-200, HAR). For more on OEQC, see <http://health.Hawaii.gov/oeqc/>. The Hawai'i State Legislature has the authority to statutorily amend HRS 343 and, thereby, influence how future State environmental assessments and environmental impact statements (EA/EISs) would be conducted.

Comment 125-2: It will be important to balance the Hawai‘i Clean Energy Initiative against more than just reducing our reliance on fossil fuel. Hawai‘i is a very fragile environment, and its biggest industry relies on the inherent beauty of that environment. When weighing renewable energy strategies, issues of aesthetics, cultural resources and environmental protections must be front and-foremost. They cannot be second-tier considerations, or after-the-fact considerations.

Response: One of the Hawai‘i State Energy Office’s energy policy directives is to effectively balance technical, economic, environmental, and cultural considerations when assessing the viability of a particular clean energy project or policy. Not all clean energy projects are created equal, and in order to find the most beneficial long-term solutions, focus should be on projects that make the best use of land and resources. This requires collaboration with partners in the public and private sectors to focus on the most beneficial projects, ensuring that challenges are met with a spirit of collaborative problem solving.

DOE’s primary purpose in preparing this PEIS is to provide information to the public, Federal, State, and local agencies, Native Hawaiian and other organizations, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support the HCEI. The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

Comment: 142-1: The state has a goal of 70 percent clean energy by 2030. One path is the Hawai‘i Clean Energy Initiative, and there are other paths, and I discussed the three other paths. I wanted to elaborate a little bit on them. One is the microgrid, community power microgrid as Parker Ranch and the Lana`i experiment. You may know that the University of California San Diego, La Jolla campus, stayed lit during California's largest blackout that knocked out parts of Arizona and Mexico. Stayed lit because it was able to island, to separate itself from the grid. Microgrids are very important. The military is looking into microgrids. So it's a Hawaii-based system. It's here. It's commercial. The second is a standalone. It's using the gas grid with solar. NRG is the largest privately owned utility in the United States. They operate coal generation. They recognize that's the past and gas is the future combined with solar. There are a number of companies on the web which offer solar and gas. There are gas companies on the mainland that give credit for customers who put in solar water heaters. So the two are compatible together. The third that I mentioned yesterday was

interacting cars with buildings, and I referenced the fact of Japan doing it after the Fukushima incident. But I was looking today on the MECO rate case, docket 2011-0092, and the MECO curtailment plan lists vehicle to building interactions. Not only that, but the Maui JUMP/Smart experiment, smart grid experiment on Maui is currently testing vehicle to grid. It's important to point out that the PEIS has no discussion whatsoever on reliability and no discussion whatsoever on cost. Therefore, there is no reasonable explanation on why any of the four should be eliminated from discussion.

Response:

While microgrids are one potential system component of smart grids, they are not presented for analysis as such in this PEIS; they are instead presented as examples of current projects underway in Hawai'i that are advancing the development of smart grid capabilities. Section 2.3.5.3 discusses microgrids as an element of smart grids and a potential means of improving reliability and preventing power outages. Section 2.3.5.4 discusses energy storage. The PEIS anticipates that multiple technologies, including solar power (Sections 2.3.2.4, 2.3.3.7, and 2.3.3.8) and solar water heating (Section 2.3.1.6), could be integrated to achieve the year 2030 goals established in the RPS and EEPS of 40 percent and 30 percent, respectively. The purpose of the PEIS is to identify and evaluate the potential environmental impacts from clean energy technologies and activities; therefore, it does not discuss the environmental impacts of conventional (fossil fuel) facilities.

DOE has structured the PEIS analysis of impacts by activity and technology. If a project is considered in the future that uses multiple technologies, the impacts of all the technologies and activities would need to be assessed. In many instances, these could be evaluated as "connected actions" under NEPA.

9.3.1.3 Island Energy Independence

Summary Comment SC004 (82-3, 100-4, 107-1, 110-1, 113-3, 116-4, 117-11, 125-1, 27-3, 84-4, 91-5, 98-10, 86-1, 98-8, 140-1):

Several commenters expressed concern over energy independence for each Hawaiian island and that no single island should have to support another island's energy needs, particularly since some islands are more energy aware while others consume larger quantities of power. Some commenters expressed the belief that renewable energy development on less-populated, beautiful islands like Molokai and Lāna'i to provide service to more developed islands like O'ahu would ruin those islands and that connecting the islands with undersea cables would only serve the more energy consuming and unsustainable communities.

Response:

The Hawai'i Clean Energy PEIS was prepared, in part, in reaction to public scoping comments received on the HIREP:Wind PEIS, which had planned to analyze the environmental impacts from large wind farms on the islands of Maui, Lāna'i, and Molokai, with a cable to O'ahu. HIREP

is no longer being pursued, and has been replaced by this PEIS, which is Statewide and not focused on any particular technology.

The PEIS is an important component in evaluating the potential impacts from a wide variety of renewable energy technologies and activities that could be implemented in Hawai'i to support the HCEI. The PEIS will also help the State decide on the appropriate mix of technologies and activities that could be implemented on each island including the potential for sharing that power between islands or whether certain islands would benefit from being energy independent. Each of the islands has a different level of access to renewable energy resources where development of these resources may be more advantageous on one island compared to the development of a comparable resource on another island; these characteristics should be taken into consideration for an appropriate evaluation of the energy needs and potential resultant impacts.

While the PEIS is intended to help evaluate these scenarios, it is not intended, nor does it provide, specific and detailed decisions on how to meet the clean energy objectives of the State and island of Hawai'i.

Comment 37-2: The DOE should focus and consider their initiatives on the county level and not at a State level. Each Mayor of each county should have "subject matter jurisdiction" of how energy is managed: It is in their respective counties, it is their fiduciary responsibility, and it is in their communities.

Response: The intent of the comment is understood; however, as a federal agency, DOE works with both the State and county governments. How initiatives are managed at the State level is between the State of Hawai'i and the individual counties.

Comment 80-3: So the other thing that I did ask for in the hearing that you and Cory mentioned in 2012 was an analysis by island. We noticed that we are not inter-connected in the utilities in the state of Hawai'i. Each island is a sole and independent body. And about the only energy connectivity we have is the barge that comes in when the weather is good. Sometimes it doesn't come in.

Response: An analysis of renewable energy resources and energy demand by island is beyond the scope of this PEIS. Such an analysis in combination with an economic analysis of cost per unit energy for various technologies, an analysis of current infrastructure capacity, mapping of development constraints, among other things, and this PEIS could provide excellent tools for planning and prioritizing future energy projects and informing policy. A statement to this effect was added to Section 1.4.

A Power Supply Improvement Plan (PSIP), filed in Docket 2014-0183, has been developed for each of the three HECO company electric utilities:

Hawaiian Electric Company (O‘ahu), Maui Electric Company (Maui, Lāna‘i, and Molokai), and Hawaii Electric Light Company (Hawai‘i island). So, there are three power supply improvement plans total, covering five islands. Kaua‘i Island Utility Cooperative (KIUC) servicing Kaua‘i is not a party to Docket 2014-0183 and was not required by the PUC to develop a plan.

The Distributed Energy Resource proceeding, Docket 2014-0192 covers all six “main” Hawaiian islands serviced by Hawai‘i’s public electric utilities: Kaua‘i, O‘ahu, Molokai, Lāna‘i, Maui, and Hawai‘i.

Comment 104-3: Now, Moloka‘i’s peak load is never above a meager seven megawatts. So it would be financially beneficial to the rate payer to establish a renewable portfolio here, which would only require an amalgam of, say, a two to three megawatt solar park (which other islands have), some pumped hydrostorage (which other islands have), and a waste-to-energy landfill (which other islands have.) Maybe we should ask ourselves the question, do we want to wean ourselves off of fossil fuels by constantly paying for the undersea cable folly, or do we want to wean ourselves off of HECO by creating our own renewal strategy that will generate and distribute energy on Moloka‘i for Moloka‘i.

Response: The Hawai‘i State Energy Office (HSEO) recognizes that the citizens of Molokai—as well as the other Hawaiian islands—are taking a vested interest in their energy future and supports solutions that can be implemented to lower and stabilize electricity rates for Molokai ratepayers.

The purpose of the PEIS is to evaluate the environmental impacts of the many potential renewable energy technologies including energy efficiency and distributed or utility-scale technologies that the State of Hawai‘i could implement. The PEIS is not intended to prioritize energy solutions or promote one technology over another. DOE has structured the PEIS analysis of impacts by activity and technology. The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits.

Comment 109-2: I represent an organization, Ikehu Moloka‘i. We have over 800 members. And we continue to meet every month, continue to look for alternatives. We have our meetings maybe every two months; and hopefully we can get a little bit more on that, called the Moloka‘i Clean Energy Initiative. And we will be more than glad to share some of that information with you folks that we’ve gathered from some of the people here on the island. With that, I just wanted to share a statement from Moloka‘i Ranch, which comes from their web site. I would like this to go on the record because

this is what they say, and this is on there about the project, the cable project. "Ikehu Moloka'i has the potential to convert the island to 100 percent renewable and to accomplish the following goals." And I will just read a few. "Stabilize and reduce the cost of the energy to make it more affordable for Moloka'i residents and businesses, enable the grid to absorb more distributed renewable energy. For example, residential and commercial rooftop solar systems. Allow Moloka'i to be self-sufficient in energy, putting island residents more in control of their energy future and help make the island a global model of sustainability.

Produce electricity for Moloka'i only. No connection to a cable or export to other islands." I want to repeat that. "Produce electricity for Moloka'i only, no connection to a cable or export to other islands." This is a statement that Moloka'i Ranch made. So, I just wanted that to go on record. We continue to work hard and look for alternatives.

Response:

HSEO recognizes the citizens of Molokai—as well as the other Hawaiian islands—are taking a vested interest in their energy future and supports solutions that can be implemented to lower and stabilize electrical rates for Molokai ratepayers.

The PEIS is not intended to prioritize energy solutions (e.g., independent vs. connected island grids). Rather, the PEIS provides information on potential environmental impacts that could be used by the State and other stakeholders for guidance in developing plans that would consider and prioritize the various energy solutions.

9.3.1.4 PEIS Scope

Summary Comment
SC005 (2-2, 84-5,
84-9):

Commenters suggested that analysis of alternatives should include more criteria, such as robustness, reliability, schedule-ability, economic analysis, lifecycle analysis, potential for intentional harmful acts, potential for and scale of emergency/disaster impacts, firm power versus intermittent power, and relative ease of integration onto each island's grid.

Response:

The analyses in the PEIS focus primarily on issues associated with a NEPA review; specifically, the potential environmental impacts of undertaking a representative technology or activity in one of 31 categories described in Chapter 2 and potential best management practices to mitigate these impacts. However, it is not unreasonable to expect that future project assessments, planning, and policy-making could benefit from the analyses noted by the comment. A statement to this effect has been added to Section 1.4.

Summary Comment
SC006 (111-5, 114-
5, 38-9):

Commenters stated that the PEIS should address indirect and longer-term impacts that are broader in scope than just site-specific scenarios as

identified in the PEIS. One commenter asked whether facilities that are no longer viable would be removed or repurposed.

Response:

The PEIS is not a site-specific evaluation and does not address impacts associated with project- or location-specific renewable energy development or actions in Hawai‘i. It is a programmatic evaluation of the many potential technologies and activities that could help Hawai‘i achieve the HCEI goals. The State of Hawai‘i’s intent regarding the Clean Energy PEIS is for the Federal, State, and county governments, the general public, and private developers to use the PEIS as a reference document when project- and location-specific EISs for renewable energy projects are prepared.

Long-term energy planning is an important goal for Hawai‘i in reducing its dependence on imported oil for its energy needs. The PEIS presents an independent assessment of the potential environmental impacts of such technologies by analyzing “representative projects,” which generically characterize a project that could be implemented in the State of Hawai‘i. The potential impacts are generally discussed as they relate to construction, operation, maintenance, and decommissioning phases of the projects. The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. Such reviews would include potential impacts associated with repurposing and/or decommissioning of facilities at the end of useful operational phases. Decommissioning is a key consideration during project planning, and is now typically required by the landowner along with up-front funding mechanisms. Both public and private landowners in Hawai‘i can require tenants to demonstrate and provide financial ability to decommission the project and restore the site after the lifetime of the project. Decommissioning may also be a condition of county and State land use permits in Hawai‘i.

Regarding indirect and long-term impacts, when it comes to environmental review required for individual projects, both the Federal (NEPA) and Hawai‘i (HEPA) EA/EIS laws require the project proponent or proposed agency to discuss the cumulative and secondary impacts a project may have on the environment. As defined under NEPA (10 CFR 1508.7) and HEPA (HAR §11-200-2), a cumulative impact is “the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.”

Summary Comment SC007 (98-1, 98-2, 98-7, 98-11): Commenters were concerned about economic drivers that affect energy use such as changes to tourism and military activities, food supplies to support populations, and cargo shipments. The comments expressed concern that if renewable energy was developed in Hawai‘i, there would be less need for fuel and fuel storage facilities, fewer harbor facilities, and less need for trucking. Two comments also expressed concern that hazards and economic impacts associated with decommissioning of existing facilities would not be addressed.

Response: The PEIS evaluates potential impacts to the socioeconomic climate in Hawai‘i, as well as the indirect impacts listed above, in its impacts analysis of the representative projects. Impacts to utilities and infrastructure are also discussed in the PEIS and would be analyzed in any environmental review documents required for individual projects. The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. If renewable energy technologies or activities identified for implementation in Hawai‘i have the potential to cause socioeconomic impacts, those factors would be taken into consideration as part of project-specific environmental reviews, including those related to decommissioning. (See the response to Summary Comment SC006.)

Summary Comment SC008 (38-5, 38-6, 38-7): Some comments suggested the PEIS should consider lifecycle impacts of each technology, including potential accidents and disasters; impacts to areas outside of Hawai‘i involved in the inputs to each system; and the embedded resources involved in the creation, operation, and maintenance of each system.

Response: For each of the renewable energy technologies evaluated in the Draft PEIS, DOE provided a characterization of the types of impacts that could occur, including those resulting from accidents. Where applicable, the PEIS includes lifecycle evaluation of the development of a technology, e.g., the discussion on bioenergy technologies includes the lifecycle evaluation of the development of the biomass feedstock in Hawai‘i. The PEIS does not evaluate the specific potential impacts of continuing to extract and transport oil to Hawai‘i. This is essentially the No-Action Alternative. Additionally, the PEIS does not assume the import of palm oil or any other biomass feedstock from outside the state.

Summary Comment SC009 (78-1, 78-2): Some comments suggested that the PEIS should present a more robust economic analysis of alternatives, including cost per unit energy produced, Hawaiian comparative economic advantage for certain energy technologies, triple bottom line accounting, and analysis of potential systemic impacts to low-income households.

Response: Although broader and deeper economic analysis will be necessary for the people and governments of Hawai‘i to choose the best paths forward when assessing the impacts of actual projects being proposed, it is beyond the scope and resources of this PEIS to develop such analyses. The only alternative to DOE’s proposed action is to continue to support, through funding and other actions, the State of Hawai‘i in meeting its HCEI goals on a case-by-case basis, but without guidance to integrate and prioritize funding decisions and other actions. Each individual clean energy project proposed in the future that is required to undergo NEPA and/or HEPA environmental review will be required to discuss the socioeconomic impacts of the project, as well as project alternatives.

Summary Comment SC010 (111-1, 111-2, 118-1, 118-8): Commenters indicated that there were not enough details in the Draft PEIS and more work is required.

Response: The scope of the PEIS is to provide an overview of the potential impacts of energy efficiency activities and renewable energy technologies that could be deployed in Hawai‘i to achieve the HCEI goals. The nature of a programmatic EIS is to analyze impacts on a regional scale, which does not allow for a detailed analysis or presentation. This programmatic analysis of impacts will assist the various decision-makers in future planning. The Final PEIS has been updated in several instances to provide more information in response to public comments. Some examples include, but are not limited to, including secondary impacts from growing biomass crops, providing more details related to potential impacts to cultural resources, and including potential impacts that could be associated with maintenance of an undersea cable.

The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations. Projects would also need to comply with HRS 343 for State environmental review.

Comment 2-3: I would like to see an emphasis on sources like Biomass, OTEC, Marine Hydrokinetic, Geothermal, Municipal Waste and Electrical Energy Storage.

Response: The PEIS includes discussions on the stated technologies in the following sections:

- Biomass – 2.3.2.1, 2.3.3.1
- Ocean Thermal Energy Conversion – 2.3.3.6

- Marine Hydrokinetic – 2.3.3.5
- Geothermal – 2.3.3.2
- Municipal Solid Waste – 2.3.3.4
- Energy Storage – 2.3.5.4

The intent of the PEIS is to identify and discuss the most prominent examples of current renewable energy technologies that might be used to meet HCEI goals, not to establish a preference or hierarchy of technologies in comparison to others.

Comment 2-4: Conservation and demand management should always be part of the mix.

Response: Information on conservation and demand management can be found in Sections 2.3.1.2 and 2.3.1.4.

Comment 2-6: Wind, Photovoltaic, Solar Hot Water and LNG I think have immediate commercial viability and can fend for themselves.

Response: The PEIS includes discussions on the stated technologies in the following sections:

- Wind – 2.3.2.5, 2.3.3.9, 2.3.3.10
- Photovoltaic – 2.3.2.4, 2.3.3.7
- Solar Water Heating – 2.3.1.6
- Liquefied Natural Gas – 2.3.4.5

The intent of the PEIS is to identify and discuss the most prominent examples of current renewable energy technologies that might be used to meet HCEI goals and the environmental impacts of these technologies, not to establish a preference or hierarchy of technologies in comparison to others.

Comment 4-1: Some well informed people believe that this EIS below will be used by the IPP-HECO group to get around an EIS for all the damage that will be done in Kalaheo. Though as far as the state is concerned, private developers will use the PEIS “when project-specific EISs are prepared” or “tiered off” of this one. This suggests we better be paying attention, since this PEIS could provide a short cut for future, more specific developers’ projects:

Response: The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations. The PEIS is meant to be used as a

reference document when project- and location-specific EISs for renewable energy projects are prepared. The PEIS will support the drafting of any “tiered” environmental review documents by highlighting the impacts that must be considered, at minimum, in the individual project environmental review documents. The PEIS can also help guide the relevant permitting agencies when assessing the impacts of a given project within their area of jurisdiction.

Comment 38-1: The U.S. Department of Energy is to be commended for broadening the range of issues to be analyzed beyond the Big Wind project. However, I hope officials will provide a thorough response to those who say goal of the Hawai'i Clean Energy Initiative is not really to explore energy alternatives, but to preserve Hawai'i Electric Company.

Response: DOE's primary purpose in preparing this PEIS is to provide information to the public, Federal and State agencies, Native Hawaiian and other organizations, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support HCEI. The PEIS does discuss impacts to utilities and infrastructure; however, it does not conduct analysis on the preservation of HECO or any other utilities. An appropriate forum for this type of discussion is the PUC.

HCEI is a partnership between the State of Hawai'i and the U.S. Department of Energy, launched in 2008 to bring together business leaders (including Hawai'i's utilities), policy makers, and concerned citizens committed to leading Hawai'i to energy independence.

Comment 45-3: The one item included for each County (erroneously stated as “country”) within the State, is the “cost per Kilowatt Hour” rate, a different rate for each County.

a. All 8 Islands are separated by the Ocean and every Island produces the Electrical Power for the needs of the Island.

b. The cost to produce Alternate Energy is not found anywhere. Why?

c. What is the real cost to produce Alternate Energy, be it Solar, Wind, Bio Mass, etc.? Why is this information missing?

d. What is the purchase price that HEI, HELCO & MEC, pay Alternate Energy Companies to produce 1 Kilowatt of Electrical Power? Why is the purchase price to buy Alternate Energy based on the same amount as the cost to produce I Kilowatt of energy using Oil? Why is the PUC allowing this practice to continue? One of the responsibilities assigned to the PUC is to over-see the Power Generation companies and prevent

irregularities from occurring? Is the PUC complying with this responsibility?

e. When will the consumer receive a reduction in Electricity Rates?

f. When will a complete review and change in purchasing Electrical Power from the Alternate Energy companies take effect to include changes to the Hourly Rate for the consumers?

Response:

The specific prices at which Hawai'i's utilities buy power from third-party clean energy producers can be found with the PUC. The price varies by facility, as each facility has independent variables that impact the overall cost of the project, and hence the rate at which it can sell power to the utilities. The prices that Hawai'i utilities pay to generate electricity from oil can also be found with the PUC. On a case-by-case basis, the PUC, along with the Consumer Advocate, and other stakeholders determines whether or not the prices submitted and charged by Hawai'i's utilities are in the best interest of Hawai'i ratepayers.

The cost of electricity in Hawai'i fluctuates with the global demand for fossil fuels, the source of energy, when it is purchased, how much is purchased, and other factors. A detailed discussion of the possible effects on electricity rates is beyond the scope of this PEIS.

DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. This information, coupled with the engineering and economic feasibility studies for specific projects, among other information, should improve the overall energy planning in Hawai'i. Technology cost assessments are outside of the scope of the PEIS.

Comment 57-2:

To help assess how the State will be able to accommodate the various technologies, it is important to know and the DPEIS should attempt to describe the maximum amount of intermittent power that can be safely absorbed by the grid on each island. The DPEIS should describe the existing amount and percentage of intermittent renewable power on each island relative to that island's grid. This is particularly important in light of numerous utility scale solar and wind projects announced or in the planning stages.

Response:

The maximum amount of intermittent power that can be safely absorbed by the grid on each island is dependent on the existing utilities and the existing or planned transmission connections available to serve the power source. For example, customers are allowed to generate renewable energy for themselves and/or sell energy that they generate back to the utility for

distribution in the grid. However, utility companies are ultimately in control of how much renewable energy they will accept and transmit. Any further analysis or speculation regarding maximum amount of intermittent power currently or potentially available in the future on each island is beyond the scope of the PEIS.

The HECO companies have developed plans (for example, reference Docket No. 2014-0183 and Docket No. 2014-0192) outlining potential paths forward to meet the State's clean energy goals, which are intended, in part, to reduce curtailment. (Information about the particular dockets can be found at <http://dms.puc.hawaii.gov/dms/DocketSearch>.) These plans are currently under review by numerous stakeholders before they can be approved by the PUC. In addition, as individual projects are proposed across the state, including on Hawai'i island, they each will be reviewed by the PUC, the affected permitting agencies, other local decision-makers, and the general public to assess whether or not they should be developed. The amount of curtailed energy from new and existing facilities is part of this assessment process.

Comment 58-7: Please explain why DOE refuses to evaluate impacts/benefits of small, safe nuclear, which is not listed as a "clean" technology in HRS 269-91, but then devotes a section to LNG, which is not listed as "clean" technology either.

Response: Hawaii's Renewable Portfolio Standards (RPS) law specifies certain types of renewable electric energy that can be used to offset fossil fuel sources. Renewable electric energy is defined in HRS 269-91 as "electrical energy generated using renewable energy as the source." Qualified renewable energy is that generated or produced using the following sources:

- Wind;
- The sun;
- Falling water;
- Biogas, including landfill and sewage-based digester gas;
- Geothermal;
- Ocean water, currents, and waves, including ocean thermal energy conversion;
- Biomass, including biomass crops, agricultural and animal residues and wastes, and municipal solid waste and other solid waste;
- Biofuels; and
- Hydrogen produced from renewable energy sources.

Since nuclear power is not defined as renewable, it does not meet the definition of an energy source that would qualify under Hawai'i's RPS. Likewise, the PEIS does not evaluate the use of LNG as a renewable

energy for electricity generation, rather, LNG is evaluated as a potential alternative transportation fuel. Since the HCEI includes a goal to reduce oil used for ground transportation by 70 percent, LNG was evaluated as an alternative for that purpose.

Comment 58-8: If "buildings consume more energy than any other sector, including transportation," why not prioritize DOE funds to support SWAC [sea water air conditioning] for Honolulu, (P. S-3) since O'ahu is the state's energy hog? Same with solar water heating: if it could "reduce household energy consumption by 40%," please explain why you would not prioritize this in your guidance. (P. S-4)

Response: The PEIS is not intended to prioritize energy solutions (e.g., independent vs. connected island grids) or identify where to put DOE funds. Instead, the PEIS provides information on potential environmental impacts that could be used by State and other stakeholders for guidance in developing plans that would consider and prioritize the various energy solutions.

Comment 58-9: Same with solar water heating: if it could "reduce household energy consumption by 40%," please explain why you would not prioritize this in your guidance. (P. S-4)

Response: The PEIS does not make judgment on which energy technology is best. The best could vary by island, location within an island, maturity of the technology, potential environment impacts, and the economics of development. DOE agrees that energy efficiency should be a significant part of the equation.

Comment 58-25: Why was "existing and projected energy demand" of the military excluded from discussion/analysis when the military is such a huge presence and energy consumer here? (P. 2-31) The absence of this data skews any and all analysis and results. Please revise to include projected military energy consumption, or explain how your "guidance" can be credible without it.

Response: The military energy demand is included in the total projected demand presented in Section 2.1.1. It is not necessary to segregate all contributors to this demand to determine potential environmental impacts. Any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

Note that NEPA requires the Federal Government, including the U.S. Department of Defense, to make environmentally informed decisions when implementing major Federal actions and to integrate environmental values into its decision-making processes by considering the

environmental impacts of its proposed actions and reasonable alternatives to those actions.4.2

Comment 58-29: SWAC [sea water air conditioning] is a neglected technology, especially since it is "cheaper" and can provide cooling for "10 million cubic feet," enough for multiple high rise, office buildings, etc. in Honolulu. (P. 2-51) Will the DOE prioritize this in its guidance? O'ahu could solve its own consumption and demand problems instead of looking to Lana'i and Maui for an expensive and destructive energy solution.

Response: This PEIS is a programmatic evaluation of the many potential technologies and activities that could help Hawai'i achieve the HCEI goals. The PEIS does not provide recommendations on the best ways to meet Hawai'i's clean energy goals, nor does it prioritize one technology over another. Any decision by DOE or other Federal agency to provide funding to a specific project, regardless of which technology is employed, would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

Sea water air conditioning is analyzed in the PEIS in Sections 2.3.1.5 and 4.2 and is one of the energy efficiency technologies currently being pursued on O'ahu (see http://oeqc.doh.Hawaii.gov/Shared%20Documents/EA_and_EIS_Online_Library/Oahu/2000s/2009-09-23-OA-FEIS-Honolulu-Seawater-AirConditioning.pdf).

Comment 62-3: Is an undersea cable needed or can O'ahu generate its own renewable power? The original reason for the expansion of the PEIS was to allow for other options to be considered that would obviate the need for an undersea cable. Early on the consensus was that O'ahu would not be able to generate enough renewable power on its own. That original assessment may not have been valid in light of HECO receiving positive responses to its 200 MW renewable energy RFP (with many of those projects now in the interconnection review process). Taking these projects into account, HECO is now projecting somewhere near 500 MW of utility scale and distributed generation renewables coming online in the next several years.

Response: The scope of the PEIS was broadened beyond the original scope of the HIREP:Wind EIS (75 FR 77859, December 14, 2010) in order to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. Evaluating the need for an undersea cable to connect the Hawaiian Islands is beyond the scope of this PEIS. Furthermore, DOE is not proposing any specific project,

activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described.

Comment 87-7: This is the 21st century. And I'm sorry, I know you did a lot of work on this project and I really appreciate it. My honest opinion is that it's never going to work. We're not going to buy your power because it's going to cost too much money.

Response: DOE's proposed action is not related to developing clean energy projects in Hawai'i in order to sell power to Hawai'i ratepayers. The PEIS is intended to provide information to the public, Federal and State agencies, Native Hawaiian and other organizations, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support HCEI.

Comment 100-2: When you look at the energy consumption on this island or in the islands, you have two major players; it's the military and the telescopes. You know, so when you talk about generating all this electricity, especially at our expense, I want to know for whom, and what do we get out of it. Because we're not getting anything out of it except the short end of the stick. We get the sickness, we've got the sleepless nights.

Response: DOE cannot speak to the electricity needs of the telescopes or the U.S. Department of Defense, nor the sources of their electricity. The utilities must account for all utility customers when purchasing clean energy or fossil fuels for its generating units, including larger entities who consume significant amounts of electricity. The PUC regulates the rate at which power is sold to both public and private entities.

According to information on DBEDT's website (energy.Hawai'i.gov/wp-content/uploads/2014/11/HSEO_FF_Nov2014.pdf), the military accounts for approximately 8 percent of the petroleum used in Hawai'i. Electricity production, ground transportation, and commercial aviation each account for approximately 28 percent of petroleum use. The U.S. military is also undergoing an effort to reduce its reliance on fossil fuels and increasing implementation of renewable energy technologies.

Comment 102-8: Well, what about the people? I mean, if you -- that's what I can see if those alternative energies are used, if you have ocean -- ocean technology and -- besides wind and whatever other -- if you have 31 technologies, I'd have to go over there and see what the other 20 that I don't know about yet, you know, that we don't -- Maui doesn't need that. We don't have like O'ahu 900,000, a million people to deal with. So that's my concern, is that the people are being left out because more windmills could be built or maybe liquid natural gas -- some company, private company -- like I guess the mayor is -- there's a -- that burn the waste thing I think is

planned or somebody is going to do that, so that -- I mean, when they burn all that garbage, right, instead of putting it in the landfill, well, that -- where is that energy going to go? So is it -- is it going to lower the people's price of the kilowatts? And that's -- that's the bottom line, is can regular people, regular locals, live here on this island and sustain, you know, and live and work and play here. And I don't -- I mean, I -- I don't -- I don't really see -- I mean, it's really a struggle for a lot of people, as you may already -- well, some of you that are -- live here already know. It's a tough life and I -- I'm just in a different situation, I don't -- I don't have to worry about basically anything other than a couple little bills, but I really feel for those people on the island here.

Response: The PEIS evaluates the potential environmental impacts of several different renewable energy technologies. The PEIS does not identify a preference between technologies since the selection would be based on many site-specific conditions. Similarly, the PEIS does not specifically identify the effects of each technology on the overall cost of electricity to the consumer. The Hawai'i Consumer Advocate serves to represent Hawai'i ratepayers when specific policies and projects are under consideration by the PUC. The cost of energy passed on to the ratepayer is a high priority for the State of Hawai'i and local energy stakeholders.

Comment 113-5: We're back to companies wanting to do things for the best of the people. I have to point out to John -- you're saying you are from Tampa? I lived south of Tampa. And the hard part with that, it reminds me, just like what Lāna'i is going through now. Water was our biggest problem in Florida. So, they wanted to build the big diesel plant, but they didn't want to put it on the beach where it should have been. Because of the ebb and flow of the tides, it should have been on the beach. But they put it on the bare land side of Tampa Bay. It just took a long time to get back to almost natural what it was. But now this big company decided, well, you know, they had enough people to lobby that -- oh, no, you can't put it on the beach because that's where all our tourists go. Gee, that sounds just like Honolulu and Lāna'i compared to Tampa and the little part of Florida where I lived. So their diesel plant that got built there on the very inside of Tampa Bay. So now, the flow of the low and high tide cannot pull all of the -- the left over salt, you know, out of the bay. So eventually the bay is going to die again because it is going to have too much desalination. So, I just wanted to make sure that people don't, you know, get snookered, if that's the word, into saying yes, this is good, this is better than you know, and it's better for the people. But like we said, you have to look at all the islands to see that there's a difference on each island. But I definitely want to see that Lāna'i stays the way it is. I have more comments here.

Response: The PEIS does not propose any specific projects, assess the impacts from any such project, nor eliminate the need for project-specific

environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations. Any projects proposed on Lānaʻi that require DOE action or funding will require review of the potential environmental impacts.

Comment 110-4: I mean, a couple of other questions is, also is if the state has any policies that help out the individual homeowners? I mean, there's a lot of different tax breaks that are going around. But I've never seen any tax break for homeowners who are off the grid on their own. You've got to either have solar, because there's paperwork for that, or you've got to have, you know, a solar water heater or some other sources. But there is people that are using their own technology or creating their own fuel. But they're, you know, they're creating their own fuel on site. But there's -- I haven't seen any breaks for them.

Response: The State of Hawaiʻi Renewable Energy Technologies Income Tax Credit is available to homeowners who file an income tax return in the State of Hawaiʻi. This tax credit is available for homeowners not connected to the grid who produce power independently for personal use via solar thermal, solar electric, and wind power. For more information, see the Hawaiʻi RPS statute, HRS 269-91, and the Hawaiʻi Renewable Energy Technologies Income Tax Credit statute, HRS 235-12.5.

Comment 111-10: Will the government still be funding the state for the projects that they know are the worst projects when it comes to environmental impact? How much support are they going to receive Federally?

Response: The level of Federal funding the State receives in the future for energy uses is yet to be determined. The State and local governments, along with the people of Hawaiʻi, will develop the future energy portfolio for the State, including assessing individual projects as they are proposed. The PEIS provides an informational resource for assessing one menu of options, not specific guidance on which path to follow. Further, the PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

Comment 112-5: We have diesels coming up, first of all, with help with our water situation. And I just don't understand, and nobody is going to tell us, I'm sure, how

did Murdoch get permission to have the wind mills on Lānaʻi when he ain't even here anymore. That really for most of us. And I don't know what else to say three and a half minutes -- I cannot say what I really want to say. Hope the other people will get up and talk, have a chance to talk about it. Thank you for the opportunity for the impact.

Response:

Actions already undertaken cannot be changed by this PEIS, and DOE was not a party to the agreement reached between the previous and current owners of Lānaʻi. There is an open docket with the Hawaiʻi PUC that seeks to determine whether or not a wind farm on Lānaʻi and cable to Oʻahu is in the public's interest (reference Docket No. 2013-0168).

DOE's primary purpose in preparing this PEIS is to provide information to the public, Federal and State agencies, Native Hawaiian and other organizations, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support the HCEI. This environmental information could be used by decision-makers, developers, and regulators in determining the best activities and technologies to meet future energy needs. The public could use this PEIS to better understand the types of potential impacts associated with the various technologies.

Comment 114-6:

I assume that the Federal Department of Energy has some interest in receiving grants or maybe placing grants to Hawaiʻi. I read this as a guide. I think that's the word you used, this is for guidance. I understand that whatever projects that the state decides will still need to go through an Environmental Impact Study. So I think we all need to hopefully be stay attuned to this.

Response:

DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawaiʻi. Any future site-specific renewable energy projects would have to comply with applicable Federal, State, and local (County approvals and permits, which could include an environmental review under NEPA or HEPA).

Comment 116-1:

The PEIS is an important document that will be used to guide us in making decisions to support the State Energy in achieving goals established in the HCEI. These decisions will have tremendous impacts on Hawaiʻi's future; for better or worse. Therefore, it is of utmost importance that the PEIS be accurate and presented to the stakeholders in a way that is unbiased, so that the people of Hawaiʻi will be able to exercise good judgment in helping the DOE make the right decisions when it comes to the future HCEI projects.

Response: Agreed. DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described.

Comment 116-3: From what I've gathered, a primary initiative of the PEIS is to guide "project planning and development to substantially streamline the project - specific environmental review and permitting process, to include community input as well as lessen the potential for controversy over specific projects." From that, I hope that a truly comprehensive statement can be created which will fairly present options so that all of our priorities can be in sync.

Response: Agreed. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described. Any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations that could tier from the analysis in the Hawai'i Clean Energy PEIS.

Comment 119-3: Okay, now, is there any kind of agreement with this issue that we are against it? We don't want it on this island. As you can see, Kahuku now operates with burns. One of the wind mills did catch fire. Now, who takes care of these materials? Who takes care of it? Who is in charge of this big -- and they bring it to the islands and they will generate money for their own usage. We didn't even get anything, we never get nothing. And I can tell you another thing, the gasoline on this island is almost \$6 per gallon. Okay? And talk about the issue that the gasoline truck from Singapore goes to Honolulu through the three refineries. They have to put the ethanol inside the gasoline to distribute it to the other islands on the oil barge. Now, how much are we going to pay the 170 now and the one that's coming to beside the same thing? Is it going to be the same price or is it going to be a different price? Remember now, we have only one gas station on this island and that gas is almost \$6 per gallon. So, how can we give any corporation or anything else to go to the energy? Therefore, is up like everything else.

Response: DOE's primary purpose in preparing this PEIS is to provide information to the public, Federal and State agencies, Native Hawaiian and other organizations, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support the HCEI. This environmental information could be used by decision-makers,

developers, and regulators in determining the best activities and technologies to meet future energy needs. The public could use this PEIS to better understand the types of potential impacts associated with the various technologies.

The maintenance and operation of existing facilities is the responsibility of the entities who own the facilities, which may or may not include the local utilities. Local, Federal, State, and county regulatory and emergency action agencies oversee the maintenance and operation of existing facilities to ensure accidents, including fires, are handled according to law and best management practices.

Comment 119-4: Reading about it. First Chapter, Genesis, what does it say? I created Heaven and Earth. I bring the wind, the sun, the moon. I bring everything for your benefit. But then people nowadays, I don't know who they are, they want to make money from small little towns like Hana, Moloka'i, Lāna'i. I don't think it's right. But who is saying -- who am I to say what is right or what is wrong -- but in your eyes, you can see what goes on in the island, in the town. And people been very, very upset about this kind of stuff because we are too accustomed to the lifestyle that we really like now. Thank you very much.

Response: One of the primary drivers behind the HCEI is to reduce and stabilize ratepayer costs for energy. Hawai'i's energy policy is rooted in the principle of maximizing the deployment of cost-effective clean energy investments to save taxpayer money. DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i.

Comment 131-2: Did the PEIS plan take into consideration Larry Ellison's plans for Lana'i and Parker Ranch's new Paniolo Power Co. plans to create a new micro-grid and compete directly with HELCO to lower rates?

Response: The PEIS evaluates a broad range of activities and technologies and does not evaluate any specific project application. To this end, the PEIS does not consider any specific projects proposed on Lāna'i or any other island.

Comment 138-7: In summary, this PEIS is disappointing. It appears to be designed to pave the way for further reckless development at the expense of local residents and our environment. In spite of all the verbiage it fails to properly address core issues associated with "clean energy development", failing to recognize the fact that energy development is seldom "clean." Subversion of the NEPA process in this fashion is a gross disservice to the residents of Hawai'i and our nation.

Response: A programmatic EIS can take any one of several approaches to addressing potential alternatives and impacts over a broad geographic area. The Hawai'i PEIS analyzes potential impacts of renewable energy development via "representative projects," which provide a hypothetical basis for analysis so that the reader can understand the typical, potential environmental impacts that could occur and what to be aware of when designing or reviewing future projects. The potential impacts are generally discussed as they relate to construction, operation, maintenance, and decommissioning phases of the projects.

The comment on the term "clean" is well taken. All large-scale projects, including renewable energy projects, will have some degree of environmental impact. In the context of this PEIS, "clean" implies the sources of energy are from renewable resources (not fossil fuels).

Comment 139-1: I was speaker 84 in Hilo. My comments are on page 84, 85, 86. My comments were very specific. I also provided as part of the record a spread sheet listing the generation methods and the rating criteria for each generation method.

I requested that you identify, using the criteria on the spread sheet I submitted or your criteria, the best generation method for use on Hawai'i Island, taking into consideration the install cost, the operation cost and the environmental footprint.

The preferred alternative you offered does not do this. In fact all the DEIS offers is data with no compilation of that data to conclude the preferred generation method for Hawai'i Island. If this is what we get for 21/2 million dollars, THIS WAS ANOTHER SQUANDERING OF OUR TAX DOLLARS.

Please provide me a copy of these comments since your commenting format does not provide me a means to print my comments.

A GREAT DISAPPOINTMENT. No guidance for how we should proceed providing power and transportation fuel on Hawai'i Island.

Response: The PEIS is not intended to recommend any specific technologies for deployment in Hawai'i. DOE's primary purpose in preparing this PEIS is to provide information to the public, Federal and State agencies, Native Hawaiian and other organizations, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support the HCEI. This environmental information could be used by decision-makers, developers, and regulators in determining the best activities and technologies to meet future energy needs. The public could

use this PEIS to better understand the types of potential impacts associated with the various technologies.

The HECO companies have developed plans (for example, reference Docket No. 2014-0183 and Docket No. 2014-0192) outlining potential paths forward to meet the State's clean energy goals, which rely on contributions from all types of renewable energy technologies. These plans are currently under review by numerous stakeholders with the Hawai'i PUC before they can be approved. In addition, as individual projects are proposed across the state, including on Hawai'i island, they will require review by the PUC, affected permitting agencies, other local decision-makers, and the general public to assess whether or not they should be developed.

The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

Comments received during the PEIS scoping process in 2012 were all considered when DOE developed the overall scope of analysis for the Draft PEIS. Any comments received on the Draft PEIS, whether written or presented at a public hearing, have been specifically addressed in the Final EIS as part of this Comment-Response Document.

Comment 140-2: Other islands should not take the pollution involved in generating geothermal power, only to have power sent to O'ahu in some half-baked wildly expensive method like an under sea power cable. ""Best management practices" that are supposed to make the ill conceived cable work are untried and, at best, expensive delusions. Environmental justice demands that the power users also bear the burden of power generation. ... Let O'ahu take the risk if O'ahu takes the power.

Response: It is recognized that any decision to develop energy technologies on other islands with a primary purpose of supplying energy to O'ahu would involve many factors in addition to those associated with potential environmental impacts, and which are beyond the scope of the PEIS. Potential environmental justice impacts associated with the undersea cable are presented in Section 8.2.16.1.

Comment 146-2: The NEPA rules say explicitly that you must consider reasonable alternatives, alternatives that are beyond the scope of your agency, that are beyond your desire, that are beyond your funding, and even reasonable alternatives that you have to change the laws for. That is

explicit in the NEPA rules and regulations. If an alternative is reasonable, it must be considered.

Now, let's separate for a moment a goal and a roadmap. If your goal is to get to Haleiwa, you can take the H-1 to the H-2 or you can go up the Windward side. There are different roads to achieve the same goal. The goal is 70 percent renewable by 2030. Throughout this document, it says that a roadmap, the path taken is the HCEI initiative. That is one of several reasonable alternatives to achieve the goal.

There are several other reasonable alternatives that have nothing to do with the Hawai'i Clean Energy Initiative.

Response: The alternatives considered by DOE are addressed in Section S.9 of the PEIS Summary. Implementation of the HCEI in Hawai'i is not one of DOE's alternatives. As stated in Section S.9, implementation of the HCEI will occur whether or not DOE develops the guidance and information presented in the PEIS.

Comment 146-3: For example, NRG, the largest independent power producer in the country, largely dependent on coal, has said they see the change coming and the answer is a gas grid with solar on the roof and to disconnect from the electric grid.

The gas company in Hawai'i has existed for over a century. The EIS explains that there's over a thousand miles of underground pipes throughout our state. The gas company delivers gas to places that do not have pipes. It is possible to redesign the system so we have not an electric grid, but a gas grid with solar and the possibility of batteries. That is entirely feasible, it's being considered, but it's not given weight in this document.

The second alternative is community power. Dan mentioned in the beginning Parker Ranch. Microgrids are a reality. This 1370-page document listed on part of one page microgrids, and only discussed military microgrids, even though Parker Ranch is proposing a microgrid for Waimea and has proposed that the long-range answer might be for them to take power away from HELCO on the west side of the island.

Microgrids are islandable systems. UCSD, University of California at San Diego, La Jolla, was lit up during the great southwest blackout that knocked out power to tens of millions of people. The person who was in charge of that is designing the Lana'i system.

A third alternative is vehicles and buildings interacting together. The Japanese are experimenting with this where the vehicle is the battery. During the height of the day, the power goes from the solar panel into the battery of the car. When the house needs energy, it can suck it back out

of the vehicle. This is reality, it's being tested, and it's simply missing because the HCEI agreement is all about how you keep HECO whole. And it is not a goal to keep HECO whole, the goal is 70 percent renewable by 2030.

Response: It is not the DOE's action to implement the HCEI in Hawai'i or any of the specific renewable energy technologies that might be used to achieve its goals. Rather, DOE developed and considered a broad range of renewable energy technologies, sufficiently mature enough to be described and evaluated. Some of the alternative technologies described in the comment, or at least elements of those technologies, are addressed in the PEIS. It is important to note that renewable energy technologies ultimately implemented in Hawai'i are not limited to those addressed in the PEIS. While microgrids are one potential system component of smart grids, they are not presented for analysis as such in this PEIS; they are instead presented as examples of current projects underway in Hawai'i that are advancing the development of smart grid capabilities.

The PEIS does not consider any specific proposed project in the State or on Lāna'i. The PEIS discusses the environmental impacts from the clean energy technologies that could be deployed on any island, including the potential impacts from smart grid and energy storage technologies.

Comment 146-4: I want to conclude with one other statement that's absolutely key. NEPA requires a table that lists the alternatives and systematically looks at each of the alternatives for each of the impacts. NEPA calls for a table. Even if you assume that I'm wrong on these three other alternative roadmaps, the no analysis alternative is simply listed and then there is no comparison whatsoever in the document for the preferred alternative and the no analysis by the different possible impacts. That is simply missing from the document.

Response: As described in Section S.9 of the PEIS, the DOE proposed action is to develop guidance on renewable energy technologies and other measures that might be used to implement the HCEI in Hawai'i. The other alternative considered is to not develop the guidance, which in NEPA terminology is the no-action alternative. The comparison of potential environmental impacts between the proposed action and the no-action alternative is sufficiently simple that a table would provide no benefit over what is described in Section S.9. However, comparison of the potential environmental impacts associated with the various technologies does benefit from a tabular presentation and is included in the PEIS.

Comment 147-1: I'm a justice advocate, and I'm going to direct my comments to that. I am also the assistant executive director of Life of the Land, and in that capacity I have reviewed numerous documents, EIS's over the years, including several programmatic EIS's. So I was kind of curious why this

was a programmatic EIS, and I went on the web to do kind of a search of programmatic EIS's, and what was really weird to me is most of them seem to have required a supplemental document, and I was wondering why that was, because not many EIS's that I've reviewed have actually required a supplemental.

Response:

As described in PEIS Section 1.2.2, DOE considers this document a programmatic EIS because it considers technologies and activities at a programmatic level rather than at a project- or location-specific level. With regard to EIS supplements, they are to be prepared whenever there are substantial changes to the proposal or in information available relevant to environmental concerns (40 CFR 1502.9(c)(1)). One type of programmatic EIS that DOE prepares is a site-wide EIS, which evaluates environmental impacts associated with certain large, multiple-facility DOE sites. By its own regulations (specifically 10 CFR Part 1021), site-wide EISs are to be evaluated at least every 5 years by means of a supplemental analysis; if the analysis determines a supplemental EIS is appropriate, then one is prepared. These two types of supplements likely account for the supplemental EISs noted by the commenter.

Comment 147-2:

So I do have some familiarity with these documents, and I'm kind of perplexed on a number of levels about this. It's clear that in the last decade at least, the community has expressed strong, strong support for roof top solar. That has been the number one thing that communities all around Hawai'i have said. And in 1984 the president of Hawaiian Electric actually said by 2000 Hawai'i is going to be a hundred percent renewable. So it's kind of confusing to me that in 2014 we're reviewing a document that said should the federal government provide guidance or not. So that I found very interesting.

Response:

As described in Sections S.2 and 1.2.1, the primary purpose of the PEIS is to provide information to all interested or involved parties on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support the HCEI. It is not DOE's role to select the specific technologies or projects that should be implemented; rather, it is DOE's objective to provide information and guidance that can be used to support the State of Hawai'i in achieving the HCEI goals.

Comment 147-4:

So this document does a really good job of laying out different technologies, and we really appreciate that. But it seemed to me that a lot of this information is available in other places. So wouldn't it have been better, and probably cheaper, just to do a website with links to all the different technologies and that kind of stuff, where people could then go into the public library and pull up the link that they're most interested in.

To get a community person to look at a 1300-page document and go through it to find what they're really interested in, that ain't gonna happen.

Response:

DOE and the cooperating and participating agencies (PEIS Section 1.3.2) made a concerted effort to make the Draft and Final PEIS available to the public and all interested parties. DOE disagrees that people would generally find it easier or more convenient to search through a list of links on a website than to search through the indexed PEIS. The PEIS contains relatively brief descriptions of technologies relevant to Hawai'i and limited to those that likely would be used in the State. The material was prepared by individuals with technical and communication training to summarize the information in a format and technical level to be absorbed by the general public. This effort generally involved the review of a great number of technical information sources, including websites. The material was also vetted by these trained personnel to validate the sources. The analysis and presentation of potential impacts also incorporates a focus on Hawai'i as opposed to a more generic approach. So the PEIS preparers have done much of the work that would be required of individuals searching a website of links. For those individuals wanting more information, the PEIS provides references (often in the form of links to websites) where additional detail can be found. Finally, DOE does not believe a website of links would satisfy the intent of NEPA to provide information.

Comment 147-5:

So my next point is the timing of the release of this document, which I find really concerning during a very heated election season, and this is one of the most heated election seasons we've had in Hawai'i for a while. So the money that the taxpayers have spent and will be spending on this document, I think the community wants to say, why don't we instead actually start doing something that will move us down the road to energy self-reliance. I know that final EIS's generally have an ROD, a record of decision in the final. So I'm wondering what this one is going to be. You're either going to provide guidance or you're not going to. It seems like a lot of money is being spent on that question.

So with Hawai'i families struggling to stay afloat, to me it's kind of unconscionable that the government would spend money on a process like this. It's actually kind of insulting. We have a lot of people struggling here.

Response:

Most people agree that NEPA and the Hawai'i Environmental Policy Act (HEPA) provide benefit to the general public and help in promoting actions that are protective of the environment. Even if one disagrees with this premise, these acts and their associated regulations must be followed and represent costs to those required to implement them. It is an objective of the PEIS that the effort and costs associated with its preparation will

facilitate and ultimately reduce the cost of implementing NEPA/HEPA requirements for future, project-specific actions.

9.3.1.5 Utility Structure

Summary Comment SC011 (102-6, 110-2, 110-3, 110-6, 27-2, 45-1, 81-1, 81-4, 85-2, 85-3, 87-1, 93-4, 131-1, 134-4): Several commenters expressed concern that dealing with the various private utility companies in Hawai‘i is very difficult and that they have only their corporate interests in mind and do not care about the people of Hawai‘i. Commenters stated that the PEIS process should only pay attention to what the ratepayers are demanding and not what the corporate powers want. Some commenters felt that community-owned utilities should be evaluated as an option.

Response: The State of Hawai‘i has a Public Utilities Commission (PUC) that plays an integral role in establishing energy rates, tariffs, charges, and fees, as well as issuing guidelines concerning the interconnection to the electrical grid and general management of utility businesses in the State. In addition, the Hawai‘i Consumer Advocate serves to represent Hawai‘i ratepayers when specific policies and projects are under consideration by the PUC. Issues such as access to the electrical grid and cost of energy passed on to the ratepayer are high priorities for the State of Hawai‘i and local energy stakeholders. The utility companies and organizations; however, are important components of the energy structure and economic outlook for the State, which includes renewable technologies and activities. The utility companies and organizations; Federal, State, and local government; academia, commissions, and many other organizations will have to work together in attaining Hawai‘i’s renewable energy goals. Economic factors such as continued viability of the utility companies must also be taken into consideration in evaluating renewable technologies and potential site-specific impacts to any of the Hawaiian islands.

Expanding the analysis in the PEIS to include potential impacts associated with community-owned utilities would not be appropriate. Inclusion of community-owned utilities is not a DOE action, would not affect any potential guidance, and would not be associated with any of the specific technologies or activities evaluated in the PEIS. The PEIS process is independent from the utilities, though the utilities, community-owned or otherwise, may find the environmental analysis helpful.

Comment 75-9: Finally I encourage you to read a recent document that was released by the PUC under some Decision and Orders that were released on April 29th, and it's called the "Commission's Inclination on the Future of Hawai‘i’s Electric Industry.

Response: Per your recommendation, DOE read *Commission's Inclination on the Future of Hawai'i's Electric Industry*. DOE is neutral with respect to the positions of the Hawai'i PUC.

9.3.2 REGULATORY

9.3.2.1 Bureau of Ocean Energy Management

Summary Comment SC012 (122-1, 122-6): One commenter stated that the PEIS was unclear on what the authority was for the Bureau of Ocean Energy Management (BOEM) and that the PEIS does not provide information describing where the outer continental shelf is located in Hawai'i. Another commenter suggested that the State of Hawai'i should be the primary regulatory authority for permitting requirements for marine-based projects in waters around Hawai'i.

Response: Pursuant to the *Outer Continental Shelf Lands Act* (43 U.S.C. 1331–1356, P.L. 212), the Bureau of Ocean Energy Management has been vested with jurisdictional authority for submerged lands greater than 3 miles seaward of the Hawaiian coastline; that is, the area referred to as the Outer Continental Shelf. BOEM has no jurisdictional authority in Hawaiian waters from the coastline to the 3-mile state/federal boundary. This authority does not apply to any area on the OCS within the boundaries of any unit of the National Park System, National Wildlife Refuge system, National Marine Sanctuary system, or any National Monument. Section 1.3.2.2 has been updated to clarify BOEM's mandated authority.

Regarding the comments about Hawai'i being the primary regulatory authority for marine-based projects, the PEIS does not change the jurisdictional authority between the Federal and State governments.

Comment 122-2: Describe how, what types of activities BOEM will provide that will help Hawai'i move forward with its renewable energy development program/plan.

Response: The BOEM Pacific Region Office of the Environment is involved with cooperative ocean studies in Hawai'i and in conducting NEPA analyses and evaluations required of BOEM actions. The Pacific Region employs environmental scientists representing multiple ocean biological and physical science disciplines and renewable leasing specialists tasked to carry out the Bureau's mission of promoting energy independence, environmental protection, and economic development through responsible, science-based management of offshore conventional and renewable energy and marine mineral resources. The Pacific Region also has access to subject matter experts nationwide on ocean renewable energy projects. Information about BOEM's activities in Hawai'i is online: <http://www.boem.gov/State-Activities-Hawaii/>.

Comment 122-3: Information provided in the PEIS states that BOEM’s primary environmental resource areas of interest are water resources (ocean), submerged land use (how deep is it to the ocean bottom in Federal jurisdiction?), and marine transportation. Technologies of interest include utility-scale renewables and transmission associated with offshore wind, undersea cables and marine hydrokinetic (wave?) energy.

Response: That is correct. BOEM regulations (30 CFR Part 585) provide a process for the Bureau to grant leases for proposed offshore renewable energy projects (wind, wave, and tidal) on the outer continental shelf and to grant rights-of-way and rights-of-use and easements for the transmission of renewable energy sources. BOEM authority does not extend into National Parks, National Refuges, National Marine Sanctuaries, or National Monuments.

9.3.2.2 Permitting

Comment 38-17: The PEIS should also analyze how to ensure that regulations and enforcement agencies are prepared to ensure the safety of new technologies.

Response: Section 3.17 presents information on occupational and public health and safety regulations, both Federal and State, and how they relate to the development of renewable energy. Section 3.17.3 includes a discussion on common safety and health impacts. Chapters 4 through 8 include discussions on those safety and health impacts that are unique to a particular renewable energy technology or activity.

Comment 56-1: As energy developers begin drafting then publishing their project EIS documents, OHA urges their agents or representatives to proactively engage OHA beneficiaries early and often.

Response: All potential renewable energy projects would have a site-specific environmental review, whether a State or Federal process. DOE agrees that OHA beneficiaries should be involved. OHA can also connect DOE and other individual clean energy project proponents with groups representing Native Hawaiian interests in order to conduct early consultation with these entities. However, DOE can only ensure OHA involvement when DOE is actively engaged in the project (e.g., DOE funding). DOE encourages OHA to continue to actively work with State and private corporations at every phase of relevant projects.

Comment 57-6: Page 2-13, Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and their Roles.

a. We recommend that this table include a list of the relevant permits and approvals that each listed agency administers. That would be a useful

addition to the type of information that would assist developers in obtaining information from the respective agency.

b. State Land Use Commission (LUC) Role. The information for the LUC does not reflect its primary role and responsibilities. We recommend replacement with the description from the LUC's website: <http://luc.Hawaii.gov/about/>

Response: DOE agrees that a comprehensive list of relevant permits and approvals would be useful for review of specific project proposals; however, DOE has prepared the PEIS in a way that would prolong its accuracy and usefulness. Rather than providing a static list of permits and regulation in effect today, the PEIS provides contact information for the regulating agencies and typical permitting scenarios to help narrow down the process for future developers.

Table 2-2 was updated to reflect the description from the provided website.

Comment 58-1: You observe that "Engaging impacted communities early in the process and addressing concerns raised prior to submitting permit applications can significantly shorten permitting timelines as agencies are typically more comfortable with permit approvals of specific projects that have community support," (P. 2-5) and that "Developers may need to adjust their projects" (P. 6-149). Please specifically address how DOE will insure this occurs in future "guidance."

Response: Any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations. The NEPA public involvement process is prescriptive with specific actions that must occur during the project pre-decisional and planning phases. By including these referenced statements in the PEIS, DOE can stress the importance of early community engagement in any DOE environmental review documents drafted for future clean energy projects.

Private endeavors would be required to meet applicable local permitting requirements. The terms for public involvement would be subject to those local mandates.

Comment 59-1: Maui County's "Countywide Policy Plan" adopted in 2010 includes a number of goals, objectives, policies, and implementing actions in support of renewable energy. Some of the more significant ones are listed below.

F. Strengthen the Local Economy

Goal: Maui County's economy will be diverse, sustainable, and supportive of community values.

Objective:

4. Expand economic sectors that increase living-wage job choices and are compatible with community values.

Policies:

- a. Support emerging industries, including the following:
- b. Renewable-energy industry;

I. Improve Physical Infrastructure

Goal: Maui County's physical infrastructure will be maintained in optimum condition and will provide for and effectively serve the needs of the County through clean and sustainable technologies.

Objective:

3. Significantly increase the use of renewable and green technologies to promote energy efficiency and energy self-sufficiency.

Policies:

- a. Promote the use of locally renewable energy sources, and reward energy efficiency;
- b. Consider tax incentives and credits for the development of sustainable- and renewable-energy sources;
- c. Expand education about energy conservation and self-sufficiency;
- d. Encourage small-scale energy generation that utilizes wind, sun, water, biowaste, and other renewable sources of energy;
- e. Expand renewable-energy production;
- f. Develop public-private partnerships to ensure the use of renewable energy and increase energy efficiency;
- g. Require the incorporation of locally appropriate energy-saving and green building design concepts in all new developments by providing energy-efficient urban design guidelines and amendments to the Building Code;

- h. Encourage the use of sustainable energy to power vehicles;
- i. Promote the retrofitting of existing buildings and new development to incorporate energy-saving design concepts and devices.;
- j. Encourage green footprint practice;
- k. Reduce Maui County's dependence on fossil fuels and energy imports;
- I. Support green building practices such as the construction of buildings that aim to minimize carbon dioxide production, produce renewable energy, and recycle water; and
- m. Promote and support environmentally friendly practices in all energy sectors. Implementing Actions:
 - a. Adopt an energy-efficiency policy for Maui County government as a model for other jurisdictions; and
 - b. Adopt a Green Building Code, and support green building practices.

Various renewable energy activities proposed in Maui County will be subject to normal permit review procedures and sometimes environmental review under the Hawai'i Environmental Policy Act (HEPA). The Department anticipates that in its role as a reference document the Final PEIS will assist with the preparation of such project proposals and their required permit and/or HEPA review.

Response:

Maui County's *Countywide Policy Plan* is an extension of the State's Hawai'i Clean Energy Initiative and is consistent with the goal of reducing the State's dependence on imported oil. The PEIS can serve as an important component of the HCEI and Maui County's plans and policies through programmatic evaluations of potential impacts from renewable energy development and actions throughout the State.

Comment 65-6:

Describe the Hawai'i State Department of Health's permitting responsibilities with respect to National Pollution Discharge Elimination System permits as noted below in the Permitting and Consultation Requirements sections of the Final PEIS for both Sea Water Air Conditioning and Ocean Thermal Energy Conversion (pgs. 2-52 and 2-130).• Clean energy projects within state waters would have to apply to the Hawai'i State Department of Health at least 180 days prior to commencement of operations to receive an NPDES permit. The project would then have to meet all conditions set forth in their NPDES permit, including numeric effluent limitations established to protect water quality in the receiving water. Applicants for clean energy projects within federal waters would have to apply to the EPA for this permit. • Clean energy projects would be required to demonstrate to the satisfaction of the

Hawai'i State Department of Health and EPA that the intakes for their facilities would meet 316(b) requirements prior to receiving their NPDES permit. In order to meet the state's water quality standards, a zone of mixing (per HAR 11-54-9) may need to be approved through the permitting process. The zone of mixing is a limited area around the discharge outfall where dilution would be allowed. The permittee would be required to conduct a dilution study to determine the dilution factor representative of the zone of mixing. The permit would then include conditions or limitations with consideration of the dilution factor. If an acceptable zone of mixing could not be established, alternatives such as treating the water (for example, nutrient removal or temperature adjustment) before discharge should be considered.

Response: Sections 2.3.1.5.3 and 2.3.3.6.3 have been updated to include the suggested text regarding Hawai'i DOH's NPDES permitting responsibilities.

Comment 65-7: Discuss CWA Section 404 permitting responsibilities in the Permitting and Consultation Requirements sections within Chapter 2 of the Final PEIS for Sea Water Air Conditioning, Ocean Thermal Energy Conversion, Marine Hydrokinetics, Off-Shore Wind, and Undersea Cable. Note that CWA Section 404 compensatory mitigation may be required for unavoidable impacts to species and their habitat such as coral reefs. Describe best management practices that can be incorporated into future project-level analysis to minimize damage from moorings, anchors, anchor lines, and pipelines during construction, particularly in areas near coral reefs. Areas should be designated for moorings and anchors that specifically avoid impacts to corals. Areas of high coral value should be marked with buoys to ensure avoidance of those areas during construction.

Response: Sections 2.3.1.5.3, 2.3.3.5.3, 2.3.3.6.3, 2.3.3.10.3, and 2.3.5.2.3 have been updated with additional information regarding the potential for compensatory mitigation under Section 404 of the CWA if projects involve unavoidable impacts to species and their habitat

Comment 82-2: If you want to have new energy here, then you've got to get regulators that are really going to regulate it.

Response: Section 2.2 provides a description of the general permitting processes and regulations associated with renewable energy technologies. As the role suggests, regulators must comply with these regulations during all phases of a project.

Comment 98-6: One big concern I have was typically when new stuff comes along, the corporations get out ahead of the regulatory agencies. That happens over and over. There's new stuff developed. For example, with that Huhanoa

Biofuel Plant just down the coast, they were all set to get their clean air permit. There happened to be some concerned citizens living around there who happened to have enough money to hire a lawyer, and lo and behold they did not deserve that permit. But it would have gone ahead if there wouldn't have been some people that had the money to hire a lawyer there. This is the kind of stuff that happens because even the supposedly renewable energy, there's a lot of brain washing out there, a lot of people jumping in thinking they're going to make a quick buck. And they typically get out way ahead of the regulations. So that needs to be looked at.

Response: Those future projects or activities that might be funded or supported by DOE or other Federal agencies or subject to Federal or State permits would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations. Private endeavors would be required to meet applicable local permitting requirement. Section 2.2 provides guidance on the types of permits and regulatory requirements that are required for such work.

Comment 111-8: Also, I'd like to know, these are guidelines for the state -- what about people that are doing their own personal energy projects at home?

Response: Several of the technologies discussed in Sections 2.3.1 and 2.3.2 are suitable for at-home implementation. These projects would have to comply with local regulations and permits, as applicable. Section 2.2.1 provides reference information regarding local and State permitting guidelines.

Comment 111-9: And what are the repercussions if the state chooses to just totally ignore all this research and suggestions that you've done, what are the repercussions from that?

Response: For those projects with DOE involvement (i.e., funding support) DOE would have input and would use the analysis in the PEIS. However, many projects could occur without DOE or Federal involvement. In those cases, there are checks and balances in the regulatory and permitting system that would ensure that projects are properly reviewed, including those involved with the HEPA (HRS 343). By identifying potential impacts from various clean energy technologies, the PEIS serves as another resource for regulatory agencies in Hawai'i to reference when identifying and assessing the potential environmental impacts from individual clean energy permits submitted for their review. It also serves to inform that public, which could improve its capability to provide accurate comments and oversight during public involvement opportunities.

Comment 122-4: Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles

State of Hawai'i Pg 2-12

There is no mention of the Coastal Zone Management (CZM) Program within the Office of Planning. One of the things that the CZM Program does is to review and to alert other State agencies of federal projects/activities being proposed in the state and to have them reviewed for consistency with approved state coastal programs.

Response: Thank you for your comment. The subject text has been revised to reflect the CZM Program.

Comment 122-5: State of Hawai'i Pg 2-14

DLNR and ALL of the Divisions within DLNR listed in Table 2-2 need to be consulted during the permitting review process for any/all developers proposing renewable and any other energy project.

DLNR is the department charged for responsibility for Hawai'i's on land, in the air and in the water (both fresh and marine); terrestrial resources, "human use" water resources, oversees development being proposed for state-owned lands, as well as on private and public lands that lie within the State Land Use Conservation District. DLNR works to preserve, sustain and lessen effects of change to Hawai'i's historic and cultural assets. DLNR's Division of Aquatic Resources manages Hawai'i's aquatic resources and ecosystems through its commercial fisheries, resource enhancement, resource protection, habitat enhancement, education, and recreational fisheries programs.

Response: DOE appreciates DLNR's input and clarification on these processes. The permitting discussion in Section 2.2 is intended to be used as a guide for all future renewable energy projects in Hawai'i and Table 2-2 has been modified to include the information provided in the comment. Those future projects or activities that might be funded or supported by DOE or other Federal agencies or subject to Federal or State permits would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations. Private endeavors would be required to meet applicable local permitting requirement, including those of the DLNR.

Comment 122-14: DAR agrees that following Best Management Practices (BMPs) and mitigative measures that will minimize potential impacts to the aquatic environment as well as aquatic resources is a requirement that all applicants/developers proposing future projects and programs to promote clean energy must be followed. Additionally, when the applications with the detailed proposals for specific projects, programs, technologies,

developments, etc. for clean energy are finally submitted; these proposals must be sent to the agencies responsible for the resources and environment that could be impacted by the proposed activity. The responsible agency must be given time to review and comment on the proposed activity and the comments should be taken seriously. It is only at this stage of any proposed project/program that the agency/office responsible for the resource or environment that may be impacted is able to provide comments and recommendations that any potential impact of the proposed project/activity on the environment and Hawai'i's natural resources may have. It is also at this stage, that DAR will be able to review and comment of the proposed activities and their potential impacts to Hawai'i's aquatic environment; the shoreline, near-shore and offshore environments and the aquatic resources.

Response: DOE appreciates DLNR Division of Aquatic Resources' input and clarification on these processes. Section 2.2.4 has been updated to include this additional information.

9.3.3 TECHNOLOGY/ACTIVITY

9.3.3.1 Alternative Transportation Fuels and Modes

Comment 2-5: Electric Vehicles are making steady progress, but I think nominal range needs to be closer to 200Mi for it to be competitive with conventional vehicles. LNG vehicles make sense, but the new distribution infrastructure limits its appeal.

Response: While these conclusions sound reasonable, DOE's primary purpose in preparing the PEIS is to provide information that can be used by decision-makers, developers, and regulators in determining the best renewable energy activities and technologies to meet future energy needs in Hawai'i. Additionally, the information in the PEIS regarding alternative vehicle fuels and modes should aid consumers in their selection of fuel types for their vehicles, should they wish to make a change.

Comment 54-5: The main impact would be in clean energies effects on the collection of gas tax revenues which provide the user funding of the State's roadways. This impact is recognized within the Programmatic Environmental Impact Statement however it is treated as a problem that will have to be solved separately. Since the alternative fuel for transportation include electric vehicles, hybrids, multi-modal, hydrogen, and liquefied/compressed natural gas/liquefied petroleum gas, as displacement of gasoline, a new funding mechanism to provide for roadway maintenance and construction would need to be eventually put into place to address revenue shortfalls from the gas tax.

Response: The PEIS cannot identify the new funding mechanism for roadway maintenance and construction. This would need to be determined by the State as specific actions are considered that would actually reduce the collection of gasoline tax revenues.

Comment 58-5: You say because, unlike electricity, "transportation does not have statute-mandated goals," so strategies to reduce the use of petroleum fuel for ground transportation in Hawai'i "currently rely heavily on influencing personal behavior." (P. 2-159). Please specifically detail how you see this happening and how "influencing personal behavior" will be incorporated into your guidance.

Response: The PEIS provides information on potential environmental impacts for the development of guidance should either DOE or the State decide to prepare it. Prioritization would depend on current geopolitical and economic conditions and could require further analyses of that nature. The PEIS would be used as a reference document for any such analysis. It is outside the scope of the PEIS to discuss specific methods of influencing personal behavior to reduce fossil fuel consumption for transportation; however, some examples could include encouraging use of public transportation, biking, carpooling, and other alternative commuting options.

Section 2.3.4.6 considers that the applicability of each transportation option varies by person and circumstance, but all have the potential for Hawai'i residents to reduce fuel usage while reducing their commute and increasing personal mobility. All of the multi-modal transportation options reduce the number of vehicles on the road and thus the total vehicle miles traveled, the required fuel usage, and roadway congestion.

Comment 102-5: There's going to be a serious exodus of people leaving Hawai'i because -- well, when you drive down the street, you can see the price of gasoline here, so -- and the diesel, if you have a diesel car, that's, of course, higher. We don't have any liquid natural gas like Sacramento. I see -- where I'm -- was born and raised, they have -- you see the buses that says natural gas on the top. We here on Maui, we drive diesel buses. We bought -- we buy them from O'ahu, the used buses -- or there may be some new ones, but I know in the past, in the beginning of our bus transportation, we've had -- we bought the old diesel buses.

Response: While natural gas is not currently being used for buses in the State, the Hawai'i Center for Advanced Transportation (HCATT), the Hawai'i Natural Energy Institute, and the National Park Service are currently in the process of developing and demonstrating hydrogen fuel cell-powered shuttle buses in Hawai'i Volcanoes National Park (see Section 2.3.4.4.1). Further, HCATT is currently working on demonstrating other projects using fuel cell technology. While future commercial transportation

systems are not yet readily available, continued progress in alternative fuels and alternative fueled vehicles is a part of the HCEI goal.

As stated in Section 2.3.4.1.4, “Some volume of the biodiesel is produced in the State by Pacific Biodiesel, a company that has built several production facilities in other states and countries. However, the company’s local production of biodiesel comes primarily from waste oil feedstock on O’ahu, Maui, and Hawai‘i island (Pacific Biodiesel 2013; RMI 2006). Some of this biofuel has been contracted to HECO and the HDOT for a biofuel-powered emergency generating power plant at Honolulu International Airport (DBEDT 2012c). Some fuel is also used in local transportation (bus) fleets, including by the City and County of Honolulu.”

Comment 110-5: I mean, even for transportation to meet that goal of 70 percent is a really interesting goal to cut the fuel cost by 70 percent. I mean, the only way to do that is to, you know, switch out people's cars. But there is technologies and people that are doing it individually, saving fuel, becoming more fuel efficient with their vehicles which means they use - - get better mileage -- which means they're consuming less fuel. I mean, it's not -- to reach those reductions is not necessarily you have to stop all of it.

Response: To clarify, the State’s HCEI goal is not to reduce the fuel cost by 70 percent, but rather to reduce energy consumption (by reducing petroleum use or increasing the fuel economy of cars and light trucks). USDOT regulations, known as Corporate Average Fuel Economy (CAFÉ), were enacted 1975 and established separate standards for passenger cars and light trucks to attain the maximum feasible levels in each model. In 2011, fuel economy was raised to 54.5 miles per gallon for cars and light-duty trucks by model year 2025. The revision in the CAFÉ standards aligns with the State of Hawai‘i’s goal to reduce petroleum usage for transportation. The State of Hawai‘i also encourages the use of electric vehicles, as they are energy efficient, environmentally friendly, and use electricity that can be domestically produced. Further discussion of electric vehicles can be found in Chapter 2, Section 2.3.4.

9.3.3.2 Biofuels

Comment 1-2: Solution number two biofuels for our trucks busses, tractors and airplanes.

Response: Section 2.3.4.1 discusses biofuels as a potential renewable fuel for ground and air transportation vehicles.

Comment 38-14: Evaluate pros and cons of growing algae for fuel.

Response: The use of algae as a biofuel is addressed in numerous places in Chapter 2: it can be used for hydrogen production for fuel cells (Section 2.3.2.3.1), in applications for municipal solid waste (Section 2.3.3.4.2), as a biodiesel feedstock (Section 2.3.4.1.1), and as advanced biofuel (Section 2.3.4.1.2). Information relevant to the various technologies is provided; however, the use of algae is not analyzed in detail as a representative project because other sources of biomass were selected to represent this broad technology. As a result, the potential environmental impacts of algae use are not presented in the PEIS. There are references cited in the PEIS of other environmental review documents where additional information can be found:

http://www.HawaiiCleanEnergyInitiative.org/storage/pdfs/6_SpecificEconomicModeling_ScottTurn.pdf

Comment 58-38: The Aina Koa Pono Big Island project was rejected by the PUC months ago. (P. 2-166). It should be removed.

Response: Thank you for your comment. The contract was indeed rejected by the Public Utilities Commission (PUC) on December 23, 2013 (Decision and Order # 31759) Docket # 2012-0185. The information was removed from the PEIS.

Comment 64-12: Try to highlight that large areas of cleared then cultivated land can have secondary impacts downstream to the marine environment potentially triggering consultations regarding marine resources. [6.1.4]

Response: Sentences were added to Sections 6.1.4.1.1 and 6.1.4.1.2 noting the potential secondary impacts to marine environments from sediment and chemical runoff from crop cultivation.

Comment 64-19: Strict adherence to BMPs would be required for growing crops for biofuel to prevent the runoff of fertilizers, pesticides, etc to the groundwater and to the marine environment. [7.1.3.1.1]

Response: Agreed. This potential impact is discussed in Section 7.1.3.1.1, and the related BMPs are listed in Section 3.3.6.

Comment 98-4: I didn't see anything about growing algae for fuel. I hope that's evaluated someplace.

Response: The use of algae as a biofuel is addressed in numerous places in Chapter 2: it can be used for hydrogen production for fuel cells (Section 2.3.2.3.1), in applications for municipal solid waste (Section 2.3.3.4.2), as a biodiesel feedstock (Section 2.3.4.1.1), and as advanced biofuel (Section 2.3.4.1.2).

9.3.3.3 Biomass

Comment 38-16: S-32 "Table S-9a. Summary of Impacts for Utility-Scale Renewable Technologies and Activities ... Air Quality ... Biomass ... "

The PEIS should include information about the proposed Hu Honua biofuel plant, where emissions would have been above acceptable levels, but this was only discovered by action from a citizen group.

Response: The potential air quality impacts of biomass and biofuel are discussed in Section 6.1.2.1.1. As a programmatic EIS, the PEIS does not identify impacts associated with specific projects, whether current or projected. However, any future projects must comply with permitting requirements to ensure that emissions are below applicable standards.

Comment 64-11: Biomass plant would require up to 5,000 acres of dedicated crop land, biodiesel up to 30,000 acres. If these lands are converted from other land use types the potential for soil erosion would be significant. Suggest including appropriate BMPs to reduce soil erosion be included in this section or referenced from other sections. [6.1.1.1]

Irrigation of biomass crops would result in increased soil erosion, especially if the high end of the land required is used. Suggest environmentally BMPs be considered to prevent erosion and water usage. [6.1.3.1.1]

Response: Section 6.1.1.1 of the PEIS identifies soil erosion as a potential concern for the biomass technology, and Section 6.1.1.2 refers the reader to common construction-related BMPs that were described in Section 3.1.4. Section 3.1.4 contains numerous BMPs to prevent, minimize, or mitigate soil erosion associated with typical land disturbing activities. Similarly, Section 6.1.3.1.1 describes potential stormwater runoff and water use as concerns for the technology and Section 6.1.3.2 refers to applicable BMPs described in Section 3.5.6. The amount of acreage required and the

magnitude of the impacts resulting from water usage and runoff would be dependent on the type of biomass crop being grown and harvested.

Comment 75-1: For this island, there is, I think, a very high importance of biomass power and geothermal as our two sources of firm, dispatchable, renewable energy.

Response: The PEIS discusses the potential for biomass power and various biomass sources in Sections 2.3.2.1 and 2.3.3.1. The PEIS discusses the potential for geothermal sources and technologies in Sections 2.3.1.3 and 2.3.3.2.

Comment 75-2: There's an additional multiplier economic benefit that I wanted to make sure you understood as you look at the potential environmental impact of biomass power on the island, and that is by having a commodity of wood chips being sold to a power plant, it provides a substantial enough business that the forestry industry would be able to support the investment into the roads, the equipment necessary to operate a forestry operation here, a forestry industry on the island, which I think is an important part of our future economy.

These are trees that were planted on former sugar land. The environmental impact of these trees is far less than sugar was, and it can be replanted, and the wood can supply the power plant for years to come. And by having a forestry industry, you can then actually afford to harvest the very large, beautiful logs and sell them to local value-added sawmills and other forestry industries that can get established. They wouldn't be able to establish themselves on their own, but with the commodity of wood chips, you can support a forestry industry that I think will have multiplier benefits.

Response: The PEIS discusses the potential for biomass power and various biomass sources in Sections 2.3.2.1 and 2.3.3.1. The PEIS recognizes that Hawai'i island has the largest inventory of timber resources in the State. The PEIS discusses a variety of biomass technologies in Section 2.3 and evaluates the potential environmental impacts in Chapters 5 and 6 for representative projects. The specific socioeconomic impacts of using forest residues as a biomass source are not detailed due to the programmatic nature of the PEIS.

Comment 75-3: Woody biomass is also important on O'ahu for co-firing with coal in the AES power plant. I think it's something I know they're exploring, and I think it's something that they should further explore because it's a way to use existing equipment at the AES power plant and use a locally produced fuel to supplement that.

Response: AES is exploring this and has tested eucalyptus trees at its coal-fired facility on O'ahu.

The PEIS addresses the use of biomass in a combustion power plant (either directly or co-fired) in Section 2.3.3.1.2, and the discussion in Section 2.3.3.1.4 recognizes it as a proven technology.

Comment 76-1: It just upsets me, if we're calling this a green energy program, that biomass, especially eucalyptus chips, are even considered because how much carbon is put back into the air by just burning wood is ridiculous and backward. And if we're going to have a forest industry, we should have our high-value, wonderful wood, not chipping and burning pulp.

Response: The PEIS recognizes that a forest industry that supports the biomass energy industry could include production of high-value wood in addition to wood chips from harvest residues (Section 2.3.2.1.1). The PEIS does not prioritize one project or technology over another.

Section 6.1.2 discusses potential air pollutants produced from direct combustion of wood biomass.

Comment 83-1: You mentioned bio-matter. And not mentioned was oil seeds that I can remember. Oil seeds are a crop that has big potential, I think, for this island. Some years ago when I was named for the College of Ag. they imported 8,000 oil palm trees and planted them out to different farmers, cooperative farmers. Those trees are now starting to produce oil palm nuts, and we're looking to form a cooperative to actually make biodiesel. So, we will grow our own biodiesel, we won't be importing it from Indonesia or any place else. There is a lot of land here in the islands that do that kind of thing, so I think there's a potential for making biodiesel here in the state as a transportation fuel, possibly as an electric fuel too, although I think there's better ways like solar to go there.

Response: The PEIS discusses oil crops in the Energy Crops section of Section 2.3.2.1.1. Within Section 2.3.3.1.4, the representative projects are a biodiesel plant and an electric power plant that produce biodiesel from oil crops. Biodiesel is also discussed as a transportation fuel in Section 2.3.4.1.

Comment 122-9: 2.3.2.1.1 Description of Technology Pg 2-56

(The final PEIS provides information about various biomass crops, but details about any proposed programs are not provided. Additionally, there is no discussion provided about any future plans for moving Hawai'i towards a position to become independent in the area of food production. There is no discussion about provisions for space/land for agricultural purposes)

Has Hawai'i's biomass crops been determined? Are they crops that currently exist in Hawai'i or are they crops that will be introduced? If

introduced ... there should be criteria to be sure that they do NOT become invasive.

The decrease in production of sugar cane and pineapples will leave more land available for the "production of biomass crops." What is the percentage of the available land that would be dedicated to production of biomass crops in relation to land available for agricultural/consumptive crops? How can the State be more "independent" and not have to rely heavily on imports if no one is looking into making more land available for agricultural/consumptive crops?

Response:

DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i, including biomass as an energy source.

The Feedstock Production section within Section 2.3.2.1 discusses the variety of biomass crops being researched for use in energy production. Of the many species being introduced, some have been established on the islands for years, while other species are being considered specifically as energy crops. Invasive species are a major concern for any species introduction and are discussed in the Section 2.3.2.1.1. The State of Hawai'i has a weed assessment and quarantine system to screen and evaluate potential risks of particular species.

Food independence is another top priority of the State of Hawai'i; however, assessing how Hawai'i can be more food independent is outside the scope of the PEIS. The potential concern about land, space, and water for biomass energy and food production is discussed in Section 2.3.2.1.1. It is not possible to estimate the amount of land or water that ultimately would be dedicated to biomass production, as it is a developing industry and the amount of land needed is dependent on the types of crops selected and the land area selected for cultivation. However, according to the November 2013 edition of "Hawai'i Energy Facts & Figures" (http://energy.hawaii.gov/wp-content/uploads/2011/10/EnergyFactFigures_Nov2013.pdf), the State estimates that about 136,000 acres are available for biomass production without affecting any current food production land.

9.3.3.4 Compressed Natural Gas/Liquefied Natural Gas

Comment 58-42: DOE says that it will not evaluate LNG for electrical generation, only transportation, because it does not meet the definition of "renewable" or "clean." (P. 2-195). In the next page you say that "DBEDT believes that LNG could play a limited, transitional role in the power generation market." (P. 2-197). Clearly this sentence was inserted belatedly, even

the font size is different from the rest of the text; this indicates that DBEDT insisted on its insertion. Please explain the inconsistency, please identify the time frame contemplated by "transitional" and please explain whether DBEDT is driving your "guidance" process or DOE is.

Response:

The DOE has prepared the Hawai'i Clean Energy PEIS in conjunction with several cooperating and participating agencies ranging from the U.S. Department of Interior, the U.S. Department of Agriculture, the U.S. Environmental Protection Agency, the U.S. Department of Defense, the U.S. Department of Transportation, and the State of Hawai'i including DBEDT. DOE's guidance process is discussed under DOE's Purpose and Need for Agency Action (Section 1.2.1). As discussed, DOE's purpose and need for action is based on a 2008 memorandum of understanding with the State of Hawai'i that established the long term HCEI partnership. Consistent with the MOU, DOE's Proposed Action is to help support the State in achieving the year 2030 goals established in the RPS and EEPS of 40 percent and 30 percent, respectively. An evaluation of LNG as a transitional fuel for power generation is outside the scope of the PEIS due to the complexities surrounding LNG import and use in the State including various uncertainties and risks associated with long-term infrastructure investments, global commodity prices and energy markets—which must first be addressed and the final decision of which would be left up to the State. As such, there is no timeframe associated with the use of LNG as a transitional fuel.

Comment 65-5:

Discuss, qualitatively, the potential for LNG as a transitional, cleaner replacement of oil for electricity within Hawai'i, including:

- How utilizing LNG could support greater renewable energy integration.
- Infrastructure investments necessary to utilize LNG as an energy source.
- Feasibility of importing LNG from U.S. (West Coast), U.S. (Gulf Coast), Alaska, Canada, Australia, Mexico, Indonesia, or Asia.
- Pricing trends of natural gas and corresponding effects on importing/exporting LNG.

Response:

As discussed in the previous comment response (58-42), the evaluation of LNG for power generation is not provided in the Hawai'i PEIS as it is not considered "renewable" or "clean" and would not contribute to HCEI goals for electricity generation. Therefore, this request is outside the scope of the PEIS; however, in response to EPA's comment, Hawai'i's DBEDT offers the following:

EPA's comments correctly reflect the complexities surrounding the decision to develop LNG import capacity for Hawai'i as an electricity generation option, particularly given the islands' isolated geographical location and the various uncertainties and risks associated with long-term infrastructure investments, global commodity prices and energy markets. DBEDT's strategy regarding LNG as an electricity generation option has therefore been designed with these uncertainties and mitigation options

specifically in mind. DBEDT's comments relative to the potential use of LNG as a transitional fuel are filed in association with Docket 2014-0183.

9.3.3.5 Distributed Generation

Summary Comment SC013 (38-8, 145-1, 145-6, 151-2): Commenters expressed their belief that microgrids would be the best direction for the State, or asked that the PEIS address the pros and cons of microgrids and the resulting decreased reliance on the electrical utility companies.

Response: While microgrids are one potential system component of smart grids, they are not presented for analysis as such in this PEIS; they are instead presented as examples of current projects underway in Hawai'i that are advancing the development of smart grid capabilities. Section 2.3.5.3 discusses smart grid technology (including smaller-scale systems) and impacts from the representative project are discussed in Section 8.3. Microgrids typically are built using distributed electricity generation, but some models look at using many smaller centralized generating facilities. Section 2.3.2 discusses distributed renewable energy technologies; Chapter 5 addresses potential environmental impacts of those technologies.

Comment 58-28: To state that "The HECO companies are taking a proactive approach to implementing interconnection of customer-sited electricity generation" (P. 2-46) is absurd. HECO's September, 2013 "rule" virtually halted solar installation, and there's not been a single verified circuit or system overload event to support it. See: <http://www.forbes.com/sites/jeffmcmahon/2014/03/21/steven-chu-solves-utility-companiesdeath-spiral/>. Please provide data to support this statement.

Response: HECO follows a PUC-approved process for reviewing and approving rooftop PV applications. As of December 31, 2014, more than 12 percent of O'ahu customers have rooftop photovoltaic systems (reference PUC Docket No: 2014-0192 filing by Hawaiian Electric Industries on 1/21/15, Page 1, first bullet point under "Summary of This Filing"). With that said, changes in utility interconnection requirements in recent years have caused solar generation growth to slow down. For example, total PV generation doubled between 2012 and 2013, from 201 GWh to 404 GWh. However, the pace of growth was not maintained in 2014, which had a total PV generation of 559 GWh. Section 2.3.1.4.2 has been revised to clarify the interconnection process.

Comment 75-7: The PUC is going to have to make decisions about wheeling. Wheeling is an important policy framework that has not been established in this state, and it needs to be.

Response: Wheeling is defined as the process of transmitting electric power from a seller's point of generation across a third-party transmission and distribution system to the seller's retail customer. It is not considered a renewable energy technology and, therefore, is not analyzed in the PEIS. The concept of wheeling is familiar to the PUC and other policy makers. A docket (No. 2007-0176) on wheeling is before the PUC. The final outcome of the PUC decisions on wheeling does not affect the potential environmental impacts as presented in the PEIS.

Comment 87-2: There is a worldwide energy revolution. And if you look around the world, you'll see the people going to distributed power, they're going to decentralized power. They're not building large centralized power plants because the distribution costs are not going to be able to be competitive.

Response: Hawai'i is a recognized leader in distributed energy generation, and distributed energy generation is considered a significant part of clean energy generation plans moving forward. Section 2.3.2 discusses distributed renewable power generation technologies. Chapter 5 addresses potential environmental impacts of those technologies.

Comment 87-4: Last year in Hawai'i, we installed 179 megawatts of solar power, and it's going to double this year and it's going to double next year. And my community is not on the grid. We are not going to connect to the grid because it would cost us too much money.

Response: This comment reflects a community successfully analyzing alternatives and selecting the technological, and likely behavioral, solutions to meet their energy needs. It is recognized that in the case of the comment, a grid tie-in was not economically accessible to the community; in other situations, installation of household-level renewables may not be economically accessible.

9.3.3.6 Distributed Photovoltaics

Comment 20-3: We need more personal PV systems which are less evasive to our country view planes and more economical to our wallets.

Response: Personal (distributed generation) PV systems are discussed in Section 2.3.2. DOE's primary purpose in preparing this PEIS is to provide information to the public, Federal and State agencies, Native Hawaiian and other organizations, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support the HCEI. The PEIS does not make recommendations for the best technologies to be implemented in Hawai'i.

Comment 102-3: [sic] photovoltaics going slowly, the state maybe not giving the kind of rebates back -- I think they were cutting them back. I don't own a home, I

basically -- I'm in a -- I'm in an ohana, but I don't really worry about those kind of costs because -- but, anyway, that's a whole 'nother private issue, but I can see how the people of Hawaii when 37 -- well, when I arrived here, a person from the Sierra Club wrote in The Maui News I guess the price of energy was -- a kilowatt was around 33 cents, 33.5, and now it's my understanding it's around 37 and a half. We still have A & B burning coal and bio gas and when you look at the amount of photovoltaics as far as on homes, it's just slow to me.

Response:

Section 2.3.1.4 discusses incentives and programs including rebates and loans for energy projects such as photovoltaics. The DOE and North Carolina State University maintain the Database of State Incentives for Renewables and Efficiency (<http://www.dsireusa.org>), a comprehensive source of information on incentives and policies that support renewables and energy efficiency in the United States. In response to the comment, there is a personal tax credit for solar water heating and photovoltaics. There is also a rebate program for personal solar water heaters and solar attic fans. Solar loan incentive programs are also provided in the City and County of Honolulu and Maui County.

Comment 102-7:

I'm definitely disappointed that when we have all these windmills and we -- even though we have some of these photovoltaic systems, I still think the opportunity for businesses and homes, that should be the priority, 'cause that's the people, the people that are going to create businesses, jobs, the people that are going to live here. But because that's not a priority, that's where you'll get the exodus of -- it's just going to be too expensive to live here. You can't -- I mean, five years down the road, gas isn't going to be \$4.50, the kilowatt -- I mean, if you have all these windmills and it's still 37 and a half cents, where has the price come down? Only for those people that have been able to afford photovoltaics up to now. Everybody knows that -- I was telling Mark that take a -- taking a neighborhood, let's say there's 500, 500 homes here, you're not going to have 500 homes with 500 photovoltaics on there. It's all -- because MECO can't transition, take those 500 homes and say, Oh, okay, smooth everything out. It's almost like maybe 25, 50 homes might have it, but -- but the goal would be is if there's 500 homes right here in this Maui Lani neighborhood, they should have the opportunity to have photovoltaic. Over in Central Maui or any area, Kihei, any home should be able to, my feeling is, get a loan and put up some photovoltaics and work themselves into the system. But I don't think that's a reality. I think what's going to happen is there's going to be a -- you know, that only so many -- there's going to be only so many people be able to have those photovoltaics and then there would be more alternative energy uses, whether it -- well, I don't know, we may not even need that much power, because we only have 150,000 people, folks, you know. I mean, we don't need -- I mean, if MECO were to put up double the -- more windmills, if the -- that -- the -- Ulupalakua, the ranch over there, increase their wind

farm. If A & B decides to take 10,000 acres and put up their own solar -- that mirror, the mirror like they do on the Big Island and create some power.

Response: The PEIS evaluates the potential environmental impacts of several different renewable energy technologies, including distributed photovoltaic systems. The PEIS does not identify a preference for a technology since the selection would be based on many site-specific conditions. Similarly, the PEIS does not specifically identify the effects of each technology on the overall cost of electricity to the consumer.

Comment 106-4: The only way we can move forward intelligently on Hawai‘i is rooftop solar. HECO has tried to stop slow down rooftop solar everywhere they can -- the 15 percent limit, all the other balderdash associated with that one. Kauai itself, by next year, is going to be over 50 percent rooftop solar in terms of total generation because it's not part of HECO and they can do what's right.

Response: The PEIS recognizes distributed solar photovoltaic as one of several options to meet Hawai‘i's clean energy goals. However, DOE does not determine the balance of energy technologies used in the State. The PEIS process is independent from the utilities, though they may find the environmental analysis helpful.

Comment 106-7: We need distributed generation, which you did talk about briefly. I would just like to say that rooftop solar has very few impacts. We're coming to the point where batteries can be utilized, we don't need to even be on the grid anymore. We certainly don't need to build a catastrophic cable through the humpback whale's sanctuary and saddle all Hawai‘i rate payers with the cost.

Response: The potential impacts from distributed generation (including rooftop solar) are discussed in the PEIS. DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai‘i. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described.

Comment 108-2: I believe the favorable course for Moloka‘i and for all of the islands will be to focus on projects that work specifically for them. For us, I believe that solar power is the best thing. Raising that arbitrary 15 percent level on solar would be very good; that would be a good start; and then having some battery storage would of course be helpful

Response: DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described.

The discussion of Interconnection Standards in Section 2.3.1.4.2 has been revised to address the 15 percent level mentioned in the comment.

Comment 113-2: As you know, everybody has to help with the energy. And, like I spoke here before, I've put the photovoltaics on my house. I put the minimum amount, which they wanted eight. Actually, they wanted ten, but I only had six on my house. My lowest electric bill was \$23. Right now I'm running around \$80, but I find people are paying anywhere from \$220 to \$250 for your electric bill. And I have the minimum amount. So I'm glad to hear that they're looking at lowering the cost of those things or getting more rebates.

Response: Thank you for your comment. Photovoltaics and solar energy installations can be an effective method of lowering electrical costs.

Comment 138-1; (1) residential PV may "exceed the capacity of a local power grid or utility." It is possible to install residential PV systems in "hybrid" mode where the PV system is the primary power source for a residence, with the utility as a backup. In this configuration the utility is not required to absorb unwanted PV-generated power. This would have no adverse impact on the utility. The PEIS fails to recognize that distributed, rather than centralized, power generation is the future;

Response: The purpose of the PEIS is to evaluate the environmental impacts of the many potential renewable energy technologies including energy efficiency and distributed or utility-scale technologies that the State of Hawai'i could implement. The PEIS is not intended to prioritize energy solutions or promote one technology over another. The Hawai'i PEIS provides analysis of both centralized and distributed generation. Distributed renewables are analyzed in the Section 2.3.2. Centralized (or utility-scale) renewable technologies are addressed in Section 2.3.3.

Comment 149-3 But tonight I heard something which is really good: gas and solar. So that's exciting to me. So a little bit of positive there.

Response: The concept of a "gas grid with solar and the possibility of batteries" was described by a commenter earlier in the public meeting as a means of eliminating the need for an electric grid. The technology of distributed photovoltaics is described in Section 2.3.2.4 of the PEIS. The use of

natural gas or liquefied natural gas (LNG) for power generation is not evaluated in the PEIS because it does not meet the requirements under the RPS. As a result, natural gas use in generating electricity is beyond the scope of the PEIS. However, additional information on this topic was compiled in response to another comment, specifically Comment 65-5. The response to Comment 65-5 in Section 9.3.3.4 is referenced here rather than being repeated.

9.3.3.7 Electric Vehicles

Comment 58-4: You note that electricity consumption has decreased since 2004, and that increased conservation measures will continue the decline. Then you suggest that increased renewable generation "will only improve the power availability for electric vehicles." (P. 2-176). What you really mean is that if we keep building more wind than the grid can take, the curtailed amount will be left over for EVs. This fails to address the lack of incentive to "change behavior" to move people from fossil -fueled vehicles to EVs. Please elaborate how DOE's guidance will address this.

Response: The Hawai‘i Clean Energy PEIS includes a discussion of renewable energy but also of various ways to reduce energy usage including energy conservation strategies, incentives and programs to encourage the use of alternative energy, and the use of multi-modal transportation such as mass transportation, ridesharing/carsharing, active transit options, telecommuting, and alternative work schedules. Incentives and programs are discussed in Section 2.3.1.4. Additional discussion regarding multi-modal transportation is provided in Section 2.3.4.6. Where information was available, incentives for using alternative transportation are discussed, including programs from HDOT to encourage ridesharing (see Section 2.3.4.6.2).

Comment 58-39: The estimated 87,848 electric vehicles you envision, needing 5.2% of the State's firm power is a useless number; the highest need for EVs is on O'ahu, so please provide the number for that island, since you managed to provide the capacity available island by island. (P. 2-179 to 180).

Response: To clarify, the estimated 87,848 electric vehicles noted in the PEIS is a part of a hypothetical representative project assumed to avoid 20 million gallons of gasoline fuel by 2030. This figure is not meant to be the projected amount of electric vehicles anticipated for use in the State by 2030. The purpose of the representative project is not to describe an actual or proposed project but to provide a hypothetical basis for analysis so that the reader can understand the typical, potential environmental impacts that could occur and what to be aware of when designing or reviewing future projects. According to the Hawai‘i State Energy Office (HSEO), as of April 2015, there are 2,498 registered electric vehicles on O‘ahu (3,396 Statewide). For more information, see HSEO website, “Electric

Vehicles in Hawai‘i” (<http://energy.hawaii.gov/testbeds-initiatives/ev-ready-program>).

Comment 112-3: I drive an electric car, as everybody knows, everywhere, and it only costs me about 50 cents a day to drive an electric car. And we have gas, for the record, at \$5 and 70-some cents a gallon on Lāna‘i. This is insane, folks.

Response: Thank you for your comment. Electric vehicles can be an effective method of lowering transportation costs.

Comment 145-3: I want to shift gears a little bit and talk about the future. One of the things in terms of energy is transportation. We had to close the doors here this evening because there was so much noise from this vehicular traffic outside. And you know what it is? It's not the engine so much, it's those big fat tires people have to have because they look good, they're fancy and they like the big mag wheels. A lot of the vehicle noise you're hearing out here is big fat tires going down the road because they look cool and because people have been driving these gigantic vehicles with the seat they're in, the seat next to them, couch in the back, maybe another couch back there, play area for the kids, stereo system, TVs, all that stuff, and they're rolling down the road in these gigantic contraptions. Huge.

What we really ought to have is something similar to a bicycle, but a vehicle. A capsule made of composite materials, thinner tires, smaller brakes, quiet, electric, thin. You don't get stuck in traffic jams. You can go around. You don't have to build the infrastructure, all the streets. And these gigantic vehicles with all these seats and these giant wheels and these mag wheels, and the third, fourth, fifth road, kid play areas, they're killing machines. They add up in safety and everyone has to armor themselves with all these gigantic vehicles, and I don't see any mention of really a shift in thinking in a plan like this, but that's the type of shift we need to make in terms of looking to the future, having a healthier, quieter, cheaper, more practical lives for all of us, and we're just not there yet. This is kind of old school, just like this old microphone.

Response: Section 2.3.4.2 discusses electric vehicle technology, and Sections 7.2 and 7.3 provide discussions of the general environmental impacts of plug-in and hybrid electric vehicles, respectively. The types of electric vehicles described in Section 2.3.4.2 are those DOE considers most likely to replace traditional vehicles based on current technology. While the PEIS does not include a discussion of the type of vehicle the commenter describes, the lack of mention does not preclude its use. As the electric vehicle technology grows and evolves, new vehicle configurations will undoubtedly be developed and public acceptance will likely expand accordingly.

9.3.3.8 Electrical Transmission and Distribution

Comment 58-20: Then you say that even though electrical transmission is not specifically addressed in the HCEI, that "these actions would be a direct result of implementing new renewable energy technologies or improving the existing electrical network" and therefore are an "integral element of this PEIS." (P. 2-22) This indicates a preordained preference for centralized transmission (i.e. cable) over other options like a micro-grid potential or firming the grid to accept more DG. Please explain if this is the case.

Response: DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i, such as undersea transmission cables and smart grids. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described.

Electrical transmission and distribution is integral to many of the technology options, whether for distributed or utility-scale generation of electricity. Section 2.3.5.4 includes technologies that could be used to improve the reliability of the grid. Including transmission and distribution as integral elements of the PEIS does not indicate a preference for utility-scale, centralized transmission, or an undersea cable; it is simply an attendant set of technologies that could improve the use of either distributed or utility-scale generation. Section 2.3.5.3 includes a discussion of ongoing microgrid projects. While microgrids are one potential system component of smart grids, they are not presented for analysis as such in this PEIS; they are instead presented as examples of current projects underway in Hawai'i that are advancing the development of smart grid capabilities.

Comment 58-26: In the absence of any analysis of military demand, and in light of the fact that a "microgrid" is referenced as an alternative to be considered exactly once in 1,300 pages, you then give considerable attention to three military choices to pursue microgridding. (P. 2-231) Please revise to reflect DOE's intent with respect to its anticipated "guidance" on the value of microgrids.

Response: While microgrids are one potential system component of smart grids, they are not presented for analysis as such in this PEIS; they are instead presented as examples of current projects underway in Hawai'i that are advancing the development of smart grid capabilities. The potential environmental impacts associated with microgrids (smart grids) are discussed in Section 8.3.

Comment 84-7: You know, depending on a distant power source that's transmitted from a great distance is not the future of energy development and it does not lead to reliability. The solar panel on the roof and battery and energy storage and inverters, that's reliability.

Response: Losses due to transmission and distribution of electrical generation are typically well known and understood and factored into reliability assessments. Reliability can be approached in a number of ways, and diversification is one option; giving households the option of using grid power, onsite renewable power, or back-up stored power. The PEIS provides the potential environmental impacts for the variety of renewable energy generation technologies available.

9.3.3.9 Energy Conservation

Comment 52-1: [Section 2.3.1.1] should highlight the sustainability benefits of preserving historic buildings. Existing buildings represent embodied energy, thus demolition and new construction are detrimental to energy efficiency.

Response: Section 2.3.1.1.1 (under Retrofits) has been updated to include additional discussion regarding inherent energy conserving features in older buildings.

Comment 116-5: The section on conservation actions was very limited and should be developed further. Our home has a photovoltaic system, which has been very effective. Potential future investments into expensive, alarming projects like an undersea cable through a marine sanctuary could perhaps be better spent elsewhere. I'm sure that it would also help this PEIS accomplish its mission to "lessen the potential for controversy."

Response: Energy conservation practices are numerous, well-established, and well-documented in the public domain. The PEIS provides references to several bodies and programs in Hawai'i that can provide additional energy conservation information. As indicated in Chapter 4, there are few, if any, environmental impacts associated with energy conservation.

9.3.3.10 Energy Efficiency

Summary Comment SC014 (2-7, 39-1, 38-15, 58-11, 58-12, 58-14, 58-48, 62-1, 98-5, 134-7): Analysis should include technologies in groups; for instance, the impacts of a cable should include all of the impacts for any power generation projects feeding into the cable.

Response: For the purposes of the PEIS, analysis of impacts is performed and organized by activity and technology. If a project is considered in the future that uses multiple technologies, the impacts of all would need to

be assessed. In many instances, these could be evaluated as “connected actions” under NEPA.

Comment 144-1: I'm a licensed professional engineer, and in the submittal that I got a copy of, I was very pleased to see heat pumps mentioned, but mentioned in a very wrong context. It says there I'm not recommending ground source heat pumps. Well, good because ground source heat pumps are primarily used for space heating in residential properties on the mainland. To my knowledge, we don't have any ground source heat pumps in Hawai'i. We probably do, but I never heard of them.

Response: The commenter's knowledge is consistent with discussions in the PEIS. As described in Section 2.3.1.3, the ground source heat pump technology is not currently employed in the state and is not expected to be employed in any notable amount by 2030. Section 2.3.1.1.1 and 2.3.1.1.2 have been updated to include a discussion on heat pump water heaters. Additional references have been included to point the reader toward more resources of information.

9.3.3.11 Energy Efficient Buildings

Comment 58-21: Why is Kauai the only county to adopt the IECC (international energy Conservation Code)? (P . 2-28). Why has Honolulu not done this? Please explain whether this is from building industry pressure or something else.

Response: It is the prerogative of the various county administrations or councils to adopt the latest energy building code. The State Building Code Council (SBCC), which includes building code officials from all counties, is presently working to update the energy code to IECC 2015. Once this is done, or even before, it is the prerogative of each county to determine when to move to adopt this updated energy building code. Under HRS 107-28, “each county shall amend and adopt the energy building code no later than two years after the adoption of the Hawai'i State building code by the SBCC.” The SBCC adopts State codes applicable to buildings built by the State government. The goal is to have the SBCC develop the code and then have the counties adopt a similar or identical code.

Comment 58-22: DOE says the State "plans on strengthening new construction policies and building codes." (P. 2-32) Given that energy use in buildings is so high and potential energy savings is so huge, when exactly will these policies and codes be strengthened? Please specifically provide data on the State's plans along with an explanation of why it has not been done before.

Response: The State of Hawai'i continues to strengthen new-construction policies and building codes in accordance with Federal and International Code regulations. As discussed in Section 2.3.1.1.2, the State Building Code Council is in the process of proposing amendments to the 2012

International Energy Conservation Code. Further, the State is in the process of developing a Tropical Energy Code to address conditions unique to the State's tropical climate. In addition, the State continues to amend HRS 196-9 to facilitate the development of more energy efficient buildings through LEED standards and the increased use of alternative fuels. Future updates to the codes are imminent and will continue to be adopted as they are modified and refined to suit energy and building policies appropriate for the State of Hawai'i. Regardless, the status of the State's progress on strengthening the construction policies and building codes has no bearing on the potential environmental impacts of actions related to energy efficient buildings.

Comment 58-24: At P. 2-45 you suggest that Honolulu has removed the incentive to promote green building by waiving permit fees because of high PV use/insufficient staffing. If this is a correct assessment of the current situation, please indicate whether DOE would provide funding to [reinstate]. It's ridiculous to stifle green building in the place where it is most needed.

Response: The mayor of Honolulu signed a bill that eliminated the waiver for PV permit fees, which was implemented in 2007 as an incentive to the PV industry to install the energy-saving systems. With the number of PV systems growing at a very high rate, the industry is doing well and the incentive was no longer deemed necessary. The fees collected are being used to hire additional inspectors to improve service and streamline the permitting process. The 'reinstate permit fees for solar' ordinance passed in 2013, City and County of Honolulu City Council Ordinance 13-1 (2013), which can be found at the City Council's website: <http://www.honolulu.gov/status-and-text.html>.

Comment 58-27: If energy retrofits to 402,321 residential units in Honolulu alone by 2030 would result in energy savings of 14% (P. 2-34), this is almost half of the 30% energy efficiency and conservation goal by 2030 (P. 1-1). Please indicate if DOE will prioritize this in your "guidance" and if not, why not.

Response: The energy savings of 14 percent refers to just the City and County of Honolulu. Thus, it is not 14 percent of the 30 percent energy efficiency and conservation goal. The 14 percent is a small percentage of a larger whole that includes the 30 percent energy efficiency goal for all of the Counties and islands combined.

The PEIS provides information on potential environmental impacts for the development of guidance should DOE or the State decide to prepare it. Any prioritization would depend on current geopolitical and economic conditions and could require further analyses of that nature. The PEIS would be used as a reference document for any such analysis.

Comment 98-12: We need to look at building codes, building design, subdivision covenants. Some people say you can't have clothes lines. Zoning so people don't have to drive really far to work and shopping. Street designs so you don't need cars.

Response: The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

Comment 144-2: However, heat pump water heating is a major item in the state of Hawai'i. The Hawaiian Electric Company introduced this in the late 1970s when they put in the six million BTU centrifugal type heat pump water heater at the Ala Moana Americana Hotel. I was told that it was the largest one in the world. When this heat pump went in, it completely eliminated the gas bill for this 1200-room hotel and it did not raise the electric bill.

The reason why is it captured the waste heat from the existing cooling tower, which was undersized, and so for the first time the air-conditioning system worked as properly designed.

And so the heat pump did not increase the electric bill, it eliminated gas consumption for water heating purposes. By the next decade there were 600 large commercial heat pumps chugging away in Hawai'i. All the major hotels have them.

Back in the beginning, the Senate gave some very nice Senate certificates encouraging customers to consider heat pump water heating. It was done extensively throughout Hawai'i. Typical big heat pump, like the one at the Ala Moana Americana, had a COP of 6. That means for every unit of waste, every unit of electric energy that it consumed, it reached into the cooling tower, grabbed five units of energy and delivered all six to the existing hot water system. It eliminated the gas bill for water heating and it did not increase the electric bill at all, because the air -- the cooling tower had been undersized, and for the first time in its life it ran as designed and the improvement and efficiency of the air-conditioning system more than made up for the addition of the electrical load of this at the time, the largest heat water system in the world.

Eventually by -- before I retired, we had over 600 large commercial heat pumps chugging away on O'ahu. And not only that, every year the Edison Electric Institute offered some great competition in the U.S., and that is of the -- for the Edison Award. So Hawaiian Electric applied and I have submitted copies of our application, and yes, this little utility way out in

the big ocean won the 1994 U.S. Edison Award because of our tremendous work in introducing heat pump water heating to Hawai'i.

Response: Sections 2.3.1.1.1 and 2.3.1.1.2 of the PEIS have been updated to include discussion on heat pump water heaters. Additional references have been included to point the reader toward more resources of information.

Comment 144-3 So to sign off, I'm glad you mentioned it. You don't want to forget those ground source. We don't use them out here, but for the water source and air source heat pumps, and better yet, the high-lift lead chillers where the heat pump becomes part of the air-conditioning system and it takes the waste heat from the building and recycles it for water heating purposes, those systems have a COP of 8. In other words, for every unit of energy that it increases to make it run, it delivers eight units to the water heating system. So thank you for putting in heat pumps, but do change the description.

Response: Thank you for your comment. The ground source heat pump technology is still described in the Final PEIS, and it continues to be described as a technology expected to have no notable use by 2030. The discussion in Section 2.3.1.1 has been expanded to include the heat-pump-type of energy recycling described by the commenter.

9.3.3.12 Energy Storage

Comment 27-1: There is a sense of frustration with the electrical Companies inability to handle the output of the solar generation that is overflowing. Many feel that each island could generate enough solar and wind to run each island, we just need to develop adequate storage. And perhaps look at new or updated utility companies that are willing to handle this idea.

Response: The PEIS (Section 2.3.5.4) discusses energy storage technologies and systems for use with various forms of energy generation, including solar and wind.

Comment 38-11: Evaluate the pros and cons of various storage methods for intermittent energy sources (solar, wind, etc.)

Response: The PEIS was developed to present the potential environmental impacts for a broad range of energy efficiency activities and renewable energy technologies. The potential environmental impacts for a variety of energy storage methods are presented in Section 8.4.

Comment 42-1: Thank you for allowing us to comment on this PEIS in support of Hawai'i's Clean Energy Initiative. We would like to share our thoughts on why pumped-storage hydro (PSH) is an appropriate energy storage technology for Hawai'i.

Our company, Innovative Power Projects LLC, is seeking to develop closed-loop PSH projects in Hawai'i with 8-hours of energy storage, to allow the project to serve as dispatchable firm capacity, and to use recycled fresh water in our reservoirs. With siting at appropriate locations, these projects would be designed to create a new source of irrigation water in the area using this recycled treated R-1 wastewater. It makes sense to leverage the PSH investment, ultimately funded by Hawai'i's community, by satisfying multiple community needs, not only energy storage, therefore allowing this concept to be more economical and cost effective when considering these multiple benefits, along with a design life of more than 50 years.

The PSH technology would complement the increased use of renewable energy, reduce fuel imports, and provide dispatchable capacity, spinning reserve, frequency regulation and voltage support capability for the electric utility.

Response: The PEIS was developed to present the potential environmental impacts for a broad range of renewable energy technologies, including pumped-storage hydroelectric, which can be found in Section 2.3.5.4.1. The PEIS does not identify a preference among these technologies.

Comment 57-5: There is little discussion on power storage alternatives and associated impacts. This need is evident from the recent fire at the Kahuku wind farm battery site. The potential for pumped storage hydropower should also be described, as this is being considered by at least a couple of wind projects and could significantly improve the reliability of solar and wind power sources.

Response: Energy storage technologies are discussed in Section 2.3.5.4. This includes batteries and pumped-storage hydroelectric. The potential environmental impacts of representative energy storage projects (flywheel and batteries) are discussed in Section 8.4.

Comment 75-6: And finally it's further off, but pumped-storage hydro is certainly one that you should include. I know that there's interest on this island as well as on Maui for that.

Response: The PEIS discusses pumped storage hydroelectric as an energy storage technology in Section 2.3.5.4.1

Comment 87-6: And the same thing is about to happen with batteries. And it's already happening with fuel cells and other types of water storage. You are basically using 18th century technology where we nail the wire to a tree when the Pony Express had the telegraph.

Response: The PEIS was developed to present the potential environmental impacts for a broad range of energy efficiency activities and renewable energy

technologies. The potential environmental impacts for a variety of energy storage methods are presented in Section 8.4.

9.3.3.13 Geothermal

Summary Comment SC015 (31-2, 31-3, 32-2, 33-3, 60-1, 60-3, 61-2, 61-6, 67-1, 67-3, 67-4, 67-5, 68-1, 68-2, 68-3, 68-4, 69-1, 69-2, 82-4, 84-8, 85-1, 92-1, 93-1, 135-1, 135-4, 136-2, 137-1, 138-4, 138-5, 140-3): Numerous commenters expressed opposition to geothermal technology based on perceived health and safety risks to surrounding communities from accidents, emergency releases, and leaks, as well as from normal operations including noise from drilling and air emissions. Many considered the PEIS to be biased in favor of geothermal technology because they feel it does not adequately describe the well-documented public opposition to the technology and the reasons for that opposition. Many of the commenters framed their opposition with experiences with the Puna Geothermal Venture power plant on the island of Hawai‘i and in dealings with the operators of that power plant and with State agencies regulating those operations. Comments described people living near the Puna plant as getting none of the benefits from the plant while experiencing associated adverse impacts. One comment even faulted the PEIS for identifying geothermal as a possible (hypothetical) energy source, among others, for use in generating hydrogen, which could then be used as an alternative fuel source.

Response: DOE recognizes there is opposition to the geothermal technology in Hawai‘i and acknowledges this opposition in the PEIS (Section 2.3.3.2.2) along with a summary of the adverse impacts cited by opponents. These adverse impacts are also discussed in Section 6.2 in terms of a representative geothermal power plant project. As noted in Section 1.2.1 of the PEIS, DOE’s primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai‘i. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described. The generation of hydrogen from geothermal is one of many clean energy technologies discussed in the PEIS (Section 7.4).

With regard to the comments about the Puna Geothermal Venture power plant on Hawai‘i island, it is beyond the scope of this PEIS to determine and evaluate the specific environmental impacts from this facility, or any other individual facility.

Summary Comment SC016 (61-3, 67-1, 68-5, 69-4, 90-3, 91-2): Several commenters described geothermal development as being offensive to Pele and to traditional Hawaiian religious practices. One commenter noted that whether or not this was the case, the ads asserting that geothermal development is “Pele’s gift” are offensive and baseless.

Response: The Native Hawaiian culture, and impacts to cultural practices from the many clean energy technologies presented, is an important consideration of the PEIS (e.g., Sections 3.6.2 and 3.6.3). With regard to potential impacts associated with geothermal technology, Section 6.2.6.1 notes that active volcanoes and their rift zones are considered sacred by Native Hawaiians. Additional information discussing the cultural importance of Pele was added to the section.

The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations. Furthermore, as part of that review, all future geothermal projects would be required to identify and present the cultural impacts of the project in the State EIS/EA.

Summary Comment SC017 (61-4, 61-7, 67-1, 135-3): Several commenters expressed their positions that the geothermal technology does not represent clean energy nor is it renewable energy because geothermal power plants have to regularly drill new wells. Several of the commenters also noted the noise issue associated with the latter concern of drilling new wells.

Response: There may be no universally accepted definition of “clean energy,” but the concept is generally associated with, or includes, energy produced through the use of renewable energy resources. DOE considers geothermal energy to be a renewable resource because proper management of the geothermal reservoir results in the rate of energy extraction about equal to a reservoir’s natural heat recharge rate (see <http://energy.gov/eere/geothermal/geothermal-basics>). While this is the ideal situation, the subsurface process of circulating water for heat recovery can be very complicated, and it is not unusual for thermal drawdown to occur within the specific portion of the geothermal reservoir being affected by the production and injection wells. That is, the water from the production well often carries a decreasing amount of heat over time and the efficiency of power production decreases accordingly. When decreases in power production become excessive, a typical recovery action is to drill new wells into portions of the geothermal reservoir that have not been tapped by the existing circulation system. Over time, when the quantity of circulating water is decreased or stopped, the heat will rebuild in the affected area. However, when there is a power generating plant with specific feed rates to maintain, new wells are a typical response rather than decreasing production from the existing wells. As noted in Section 6.2.12.1, noise produced during drilling activities is a recognized

environmental impact for the geothermal technology. Associated best management practices are listed in Section 6.2.12.2.

Geothermal is also defined as “renewable energy” under current Hawaii state law (HRS 269-91).

Summary Comment SC018 (38-13, 91-3, 91-4, 93-2, 97-1, 100-1, 138-6): Several commenters expressed their concerns over the use of fracking in geothermal development, indicating it was dangerous practice and associated with unintended consequences.

Response: The PEIS does not consider hydro-fracturing as a renewable energy technology or activity. Rather, the PEIS includes a discussion of hydro-shearing as an example of enhanced geothermal systems (Section 2.3.3.2.1). Hydro-fracturing refers to breaking up subsurface rock formations in order to collect trapped fossil fuels, primarily natural gas. Hydro-shearing refers to opening up existing fractures and fissures in subsurface areas where there is heat but insufficient permeability to support a conventional hydrothermal power plant. Although the two processes might be considered similar, hydro-fracturing is implemented at higher pressures and generally with larger volumes of water in order to generate new fractures rather than just opening existing ones. Section 6.2.1.1 describes the potential impacts from the inducement of small seismic events that should be addressed for any planned enhanced geothermal project.

Summary Comment SC019 (38-19, 77-1, 95-1): Several commenters expressed concern over the impact of a geothermal power plant on groundwater and the amounts of freshwater that would be required for its operation.

Response: Section 6.2.3.1.2 discusses the potential impacts of a geothermal power plant on groundwater and the amount of freshwater that could be required to support a power plant. Very briefly, a modern, conventional hydrothermal power plant would extract water from the subsurface geothermal reservoir, extract heat from the water at the surface, then inject the water back into the same reservoir. Requirements applicable to the completion of geothermal wells (e.g., requirements in HAR 13-183-71) specify that overlying aquifers of fresh water, if present, be sealed off in the well (e.g., by solid well casing running through the fresh water aquifer) so that the geothermal fluid could not impact the higher-quality water either during the geothermal fluid extraction or its injection. Design and operating plans for a power plant would be required to include means and procedures to monitor for losses of geothermal fluids either above ground or below ground and, if the plant utilized a binary cycle, for losses of the organic working fluid. Depending on the nature of the power plant’s cooling system, there could be evaporative losses of cooling water that would have to be replenished. However, if the availability of

freshwater were limited or otherwise of concern, alternative cooling system designs would likely be pursued.

Summary Comment SC020 (61-5, 67-1, 76-2, 89-1, 89-2, 134-6): Several commenters expressed concern that construction and operation of geothermal power plants in areas such as those assigned to volcanic hazardous Zone 1 is unsafe for the operations and facilities themselves and the actions could increase hazards to surrounding inhabitants. A related comment was critical of the same actions because they would result in reliance on a power source that was at too high a risk of catastrophic loss and as a result should be considered a dangerous and reckless alternative for power production.

Response: The PEIS recognizes that the areas identified with the highest potential for geothermal energy development are volcanic rift zones (see Section 2.3.3.2.2). The PEIS evaluation of geological hazards (Section 3.12) shows that these rift zones basically coincide with areas categorized as having the highest potential for eruptions and lava flows; that is, the areas of high geothermal potential are in or near the Level 1 zones. Section 6.2.1.1 addresses the potential impacts associated with geothermal technology and concludes that there is no analytical evidence indicating the construction and operation of a geothermal power plant would increase the natural geologic risks associated with the site and, accordingly, would not increase the natural risk posed to inhabitants of the area. Any potential impacts would need to be further evaluated on a site-specific basis for any future geothermal power plant project.

With respect to the comment about the risk of relying heavily on geothermal power, one of the core elements of the State's energy policy is to diversify its energy portfolio (Section 1.1.1), thereby, in terms used in the comment, avoiding too many of its eggs in any one basket.

Summary Comment SC021 (60-4, 93-6): Several comments were an expression of opposition to geothermal energy. In some instances the comment included identification of a renewable energy technology the commenter felt was more acceptable or preferred.

Response: Thank you for your comment. The intent of the PEIS is to identify and discuss the most prominent examples of current renewable energy technologies that might be used to meet HCEI goals, not to establish a preference or hierarchy of technologies in comparison to others.

Summary Comment SC022 (60-2, 67-1, 82-1, 134-2): Several commenters expressed their opinions that geothermal energy was neither clean nor renewable and characterized their opposition to geothermal energy with experiences with the Puna Geothermal Venture power plant on the island of Hawai'i. The commenters expressed concern with the operators of that power plant and with State agencies regulating

those operations and described the operations as presenting undo risks to the health and safety of area residents.

Response:

There may be no universally accepted definition of “clean energy,” but the concept is generally associated with, or includes, energy produced through use of renewable energy resources. DOE considers geothermal energy to be a renewable resource because of the balance between the rate of energy extraction and the reservoir’s natural heat recharge rate (<http://energy.gov/eere/geothermal/geothermal-basics>). This is the ideal situation; in practice, the subsurface process of circulating water for heat recovery can be very complicated and it is not unusual for thermal drawdown to occur within the affected portion of the geothermal reservoir. That is, the water from the production well often carries a decreasing amount of heat over time and the efficiency of power production decreases accordingly. At this point, new wells are drilled into untapped portions of the geothermal reservoir, allowing the heat to rebuild in the affected area. Alternatively, a power plant could decrease production rates; however, when there is a power generating plant with specific feed rates to maintain, new wells are a typical response rather than decreasing production from the existing wells.

Geothermal is also defined as “renewable energy” under current Hawaii state law (HRS 269-91).

DOE recognizes there is opposition to the geothermal technology and acknowledges this opposition in the PEIS (Section 2.3.3.2.2) along with a summary of the adverse impacts cited by opponents. These adverse impacts are also noted in Section 6.2 of the PEIS where the general, potential impacts of a hypothetical geothermal power plant project are addressed for multiple resource areas. DOE’s primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai‘i. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described. With regard to the geothermal technology, some opponents have suggested the PEIS shows a bias for the technology because not enough is said about adverse impacts, whereas proponents of the technology may feel a bias against the technology because of how much is said. DOE has provided a fair and reasonable amount of information with the realization that the PEIS covers such a broad scope that discussions on any individual topic must be limited.

With regard to the comments about the Puna Geothermal Venture power plant on Hawaii Island, it is beyond the scope of this PEIS to determine and evaluate the specific environmental impacts from this facility, or any

particular facility, and causes for the issues identified, or to develop specific mitigation measures.

Comment 1-1: [sic] solution number one is geothermal, for our island and for our State.

Response: DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described.

Comment 3-1: Geothermal is done safely in other countries. H2S is not a real problem, some local residents have blown a little rotten egg smell (very common and well known in refinery and oil and gas business) into a pollution scare that's out of reality. They provoke over reaction by similarly ignorant local politicians and money is spent!

Response: DOE appreciates the commenter's willingness to provide a comment and express his opinions. However, DOE also appreciates the comments of those who oppose the geothermal technology and certainly does not question their sincerity.

All geothermal facilities in Hawai'i must, are, or would be, required to comply with the EPA clean air standards, in addition to other laws and regulations.

Comment 67-1: As a purpose of the PEIS is to decide what projects will receive federal funds, and DOE acknowledges that the Hawai'i Clean Energy Initiative (HCEI) may involve transmission of geothermal electricity from Hawai'i Island by undersea cable, my comments are intended to urge DOE to decide that geothermal development should not be funded or considered in the Clean Energy Initiative (and any undersea cable component should be abandoned.) The first reasons why DOE should not fund geothermal development are that it offends Pele, it is not clean energy, it is unsafe and as a resource it depletes. Another way of saying it offends Pele is to say it is folly to build industrial scale developments that drill into the volcano in lava zone one. The risks are well illustrated by the history of the Puna Geothermal Venture (PGV) facility, and the instances where emergency community evacuations were required. The PEIS does not examine those instances and the readily available and extensive documentation surrounding them. That material shows geothermal development is not safe. The PEIS does not review the constant need of PGV to drill new wells, making serious noise problems for residents in

the area and also illustrating the non-renewable aspect of geothermal energy.

Response: This PEIS is not intended to determine what projects will receive federal funds, but rather to inform such decisions. DOE's primary purpose in preparing the document is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. This environmental information could be used by decision-makers, developers, and regulators in determining the best activities and technologies to meet future energy needs. Furthermore, the PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

To address specific issues raised in the comment, see Section 6.2.6.1 for a discussion of potential cultural impacts and Section 6.2.17 for a discussion of potential health and safety impacts and associated best management practices to mitigate those impacts.

Comment 67-6: It is also evident that much of the Draft PEIS is intended to promote the production of hydrogen as a politically favored energy resource. While the hydrogen idea itself is not adverse to the public interest, the connection of hydrogen to geothermal energy contradicts the public's interest for the reasons described above – that is: geothermal energy is unsafe, unclean and renewable. Perhaps the prior political momentum in support of geothermal development is now being transferred to support hydrogen production. If so, that is a bad mistake.

Response: DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described. The fact that the PEIS uses geothermal or solar energy as a potential source of electricity for hydrogen development is not a bias. As stated in Section 2.3.2.3.2, the best way to generate hydrogen on the islands is through electrolysis, which would require large amounts of electricity (the PEIS uses a representative geothermal facility and a representative solar facility to create hydrogen). This electricity could be generated through a variety of renewable sources; regardless of how the

energy is generated, the potential impacts would need to be accounted for based on the generation technology used.

Comment 38-12: Evaluate when geothermal resources will run out.

Response: Evaluating when geothermal resources will run out is outside the scope of the PEIS. DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i.

Comment 38-18: S-32 "Table S-9a. Summary of Impacts for Utility-Scale Renewable Technologies and Activities ... Air Quality ... Geothermal" The analysis seems to minimize impacts.

Response: The table format necessitates very short statements of potential impacts for all resource areas. The full PEIS evaluation of impacts to air quality from the geothermal technology, in terms of the representative project, can be found in Section 6.2.2.

Comment 38-20: S-39 "Table S-9a. Summary of Impacts for Utility-Scale Renewable Technologies and Activities ... Hazardous Materials ... Geothermal" The PEIS should evaluate risks from a pentane fire and/or explosion.

Response: The description of the representative project for the geothermal technology (Section 2.3.3.2.4) describes use of a binary system, which uses a working fluid with a low boiling point, such as n-pentane (as described in Section 2.3.3.2.1). While the potential impacts associated with hazardous materials management (PEIS Section 6.2.14.1) do not specifically call out pentane, the discussion notes that hazardous materials would be present, including materials such as petroleum products and solvents, and associated impacts could result if they were not managed properly and released to the environment. Section 6.2.17 addresses potential health and safety impacts (including accidents) and recommended best management practices to mitigate those impacts.

Comment 63-2: As a resident of Hawai'i Island and owner of agricultural land within less than one mile of a potential geothermal drill site, I implore you to review the historical documentation thoroughly and consider the consequences of geothermal development to the land, natural environment, and people who reside on Hawai'i Island. Photovoltaic or solar power is definitely a clean energy source and is readily available throughout Hawai'i with its year round 12-hour days. Technology is sufficiently advanced that power production occurs even during overcast and rainy days.

Thank you for taking the time to consider my comments. In my opinion, the draft PEIS needs significant work before final approval. Please give serious consideration to the experiences of the people who have lived

through the historical mishaps of the Puna Geothermal Venture (PGV) facility on Hawai‘i Island.

Response: DOE recognizes there is opposition to the geothermal technology and acknowledges this opposition in the PEIS (Section 2.3.3.2.2) along with a summary of the adverse impacts cited by opponents. These adverse impacts are also identified in Section 6.2 of the PEIS where the general, potential impacts of a hypothetical geothermal power plant project are addressed for multiple resource areas. DOE’s primary purpose in preparing the document is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai‘i. DOE is not proposing any specific project, activity, or technology, nor is DOE attempting to establish a preference or hierarchy of technologies in comparison to others. The alternative technologies noted in the comment, as well as others, are also addressed in the PEIS.

Comment 69-5 We have better and safer options in solar, biomass, biofuels, and other alternatives. Please oppose this corrupt, dangerous, economically wasteful, and callously biased push to ignore all evidence and proceed forward with geothermal drilling and hydraulic fracturing in Hawai‘i’s Lava Zone 1.

Response: DOE recognizes there is opposition to the geothermal technology and acknowledges this opposition in the PEIS (Section 2.3.3.2.2) along with a summary of the adverse impacts cited by opponents. These adverse impacts are also identified in Section 6.2 of the PEIS where the general, potential impacts of a hypothetical geothermal power plant project are addressed for multiple resource areas. DOE’s primary purpose in preparing the document is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai‘i. DOE is not proposing any specific project, activity, or technology, nor is DOE attempting to establish a preference or hierarchy of technologies in comparison to others. The alternative technologies noted in the comment, as well as others, are also addressed in the PEIS.

Comment 80-4: I would point out that the current version of geothermal relies heavily on Pentane as a binary for their binary systems. Add to which point there is no binary, there is no energy from the geothermal plant. So it is no more or less secure than any other fossil fuel group derived process for this island.

Response: As briefly described in Section 2.3.3.2.1, the working fluid in a binary system, which can be any organic compound with a low boiling point,

remains within a closed loop during plant operation; it is not consumed or otherwise destroyed for its inherent energy content. The working fluid is transformed to vapor by absorbing heat from the geothermal fluid; the working fluid vapor runs through a turbine to produce electricity and then condenses back to a liquid and restarts the process.

Comment 81-3: As far as geothermal -- this is not my opinion because I am not a geologist -- but my friend in San Diego, Nora Robbins, Ph.D. in geology for over 30 years, has traveled the world, she knows our geology here. She's visited our island and many other Polynesian 16 islands. She says "no way" to geothermal. She says it's too poisonous, it will induce earthquakes, it will induce seismology is the term, yeah. These are things I didn't know until I asked her about it. I said, "Nora, what is the deal?" Her opinion is after all the experience she has, no way on thermal, no way on this island. So that's my considered opinion too for just now.

Response: The PEIS discussion of potential geology and soil impacts and air quality impacts for the geothermal technology, which can be found in Sections 6.2.1 and 6.2.2, respectively, describe induced seismicity and gas production as aspects of the geothermal technology; both impacts would need to be addressed during the design, construction, and operation phases of any future facility.

As explained in Section 6.2.1.1, induced seismicity is primarily a concern for operations that include injection of water under high pressure or low-temperature water into the geothermal reservoir. These are not conditions that would be expected for a power plant in Hawai'i, but even under such conditions the seismicity is of relative low magnitudes, not felt by most people.

Comment 84-2: We don't like more geothermal because we've had experience with it.

You've heard a lot about geothermal, and I know I am going to run out of time, so I won't say a lot about it except that the experience of geothermal, the reality of geothermal in Hawai'i, is so different than the reality of geothermal worldwide; and that's why we're against it. We don't not like geothermal, we've just seen what happens in Hawai'i.

We all love and respect Mike and all the individuals involved, but we don't like the actual reality of it. It's more toxic than elsewhere because of our volcanic geology, it's more unstable than elsewhere. And let's say there was -- let's say the state was depending on geothermal in Puna and there was a cable -- right now as we speak, there's a lava flow heading -- that if it continues for another 10 months -- will cut off the geothermal plant from the rest of the world right now. So it's unpredicted, unexpected. And that's when I come to reliability.

Response: DOE recognizes there is opposition to the geothermal technology and acknowledges this opposition in the PEIS (Section 2.3.3.2.2) along with a summary of the adverse impacts cited by opponents. These adverse impacts are also identified in Section 6.2 of the PEIS where the general, potential impacts of a hypothetical geothermal power plant project are addressed for multiple resource areas. DOE's primary purpose in preparing the document is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described.

The PEIS recognizes that the areas identified with the highest potential for geothermal energy development are volcanic rift zones (see Section 2.3.3.2.2). The PEIS evaluation of geological hazards (Section 3.12) shows that these rift zones basically coincide with areas categorized as having the highest potential for eruptions and lava flows; that is, the areas of high geothermal potential are in or near the Level 1 zones. Section 6.2.1.1 addresses the potential impacts associated with the geothermal technology and concludes that there is no analytical evidence indicating that the construction and operation of a geothermal power plant would increase the natural geologic risks associated with the site and, accordingly, would not increase the natural risk posed to inhabitants of the area. Any potential impacts would need to be further evaluated on a site-specific basis for any future geothermal power plant project.

Comment 92-2: Right now PGV is producing -- last year it was 22 percent of the Island's electricity. Puna uses about six percent. So when you talk about geothermal making energy less expensive, it hasn't happened on this island. We are more expensive than the other islands that don't have geothermal.

Response: Although the electricity rates on the island of Hawai'i are above the State average, they are not the highest of all the islands. According to data published by the State, average rates are slightly higher on Kauai, Molokai, and Lāna'i (<http://energy.Hawaii.gov>), but otherwise the comment is well taken. A comparison of energy costs for operating facilities on each island can be found on the PUC's Annual Reports to the Legislature (<http://puc.hawaii.gov/reports/annual-reports/>). However, it is beyond the scope of the PEIS to determine and present the detail of what contributes to the different electricity rates on the different islands.

Comment 92-3: Also, that energy is being exported from a mile from my house to Kona. And there's no reason it should be exported to O'ahu so that we can have

the impacts in our neighborhood, so that other people can leave their hotel rooms open and still air condition their room.

So, Mahalo, I appreciate what you're doing. And know that, you know, it's our hearts that are on the line because this is our families and this is our farms.

Response: The types of environmental impacts that would be expected to be of concern for a utility-scale geothermal power plant are addressed in the PEIS, but the PEIS is not intended to prioritize any specific technology or address any specific project. Although the PEIS can be used to support the evaluation of site-specific projects, either as a reference source or to be tiered from, specific projects would require additional environmental impact analyses that address potential impacts, as applicable, to site-specific facilities or communities. These additional analyses would be required under NEPA, if the proposed action is to be implemented, permitted, or financially supported by an agency of the Federal government, or under HEPA if there is no connection to Federal actions. It is recognized that any decision to develop energy technologies on other islands with a primary purpose of supplying energy to O'ahu would involve many factors in addition to those associated with potential environmental impacts, and which are beyond the scope of the PEIS.

9.3.3.14 Hydroelectric

Comment 58-10: There is a question whether the statement that utility-scale hydroelectric "according to the utilities" is not feasible for Hawai'i is accurate. (P. S-6) Please provide data supporting this statement.

Response: The reference text in the Draft PEIS attributed the statement to the incorrect entity. The PEIS was corrected to cite the U.S. Army Corps of Engineers rather than "utilities." Similar text in Sections 2.3.3.3.2 and 2.3.3.3.4 has been modified to cite the appropriate Corps of Engineers reference and to clarify the information cited from that reference.

Comment 58-31: To say a "site is considered potentially economically feasible if it can produce energy comparable with the O'ahu HECO rate of \$.25 per kWh" is outdated (P. 2-69). Energy costs on the mainland run around \$.11 per kWh, and HECO just accepted undisclosed bids for \$.16 per kWh. Please revise.

Response: The statement in question (in Section 2.3.2.2.2) was extracted from a U.S. Army Corps of Engineers document that evaluated the feasibility of large-scale hydroelectric projects. Its purpose in the PEIS is to provide a sense of why no large-scale hydroelectric projects currently exist or would likely be built. Section 2.3.2.2.2 has been revised to correct reference errors.

9.3.3.15 Hydrogen

Comment 88-1: I would like to broaden this discussion a little bit. Solar and wind, they're both free, clean energy sources. But they have -- they both have a problem. Now, the sun doesn't shine at night, the wind isn't always blowing. But I am not here to talk about problems, I am here to talk about solutions.

There's a third energy source that nobody seems to be paying any attention to, and we're surrounded by it. There's this Pacific Ocean out here. Think H₂O, not OTEC, hydrogen. But, the problem is the hydrogen isn't free. You've got to extract it from the water. Now, that's where our solar and wind comes in. When it's producing plenty, free energy, it takes energy to extract the hydrogen from the water. Once you extract it, you've got a product that you can transport, you can store, it's perfectly mobile, perfectly usable. And essentially with solar and wind, the energy is free so the product is free. You can produce it on any of the islands. We're surrounded by this beautiful ocean. So I would just like to share this idea with you and, you know, I think this should be part of the discussion.

Response: Section 2.3.5.4.1 has been expanded to provide additional information relevant to the potential for hydrogen generation from seawater using intermittent sources of electricity.

Comment 99-1: One, to get liquid hydrogen, there's a couple of byproducts -- and pretty non-polluting oxygen and maybe a little sea salt. Not too bad. But then also, well, if you start thinking about, well, okay, using up the water in the ocean, you're going to have the level go down. I don't think we've got too much to worry about there. But, hey, they say sea levels are rising. There is islands out there in the Pacific going under. So, if we -- you know -- if we did reduce a little bit it wouldn't be a bad thing I don't think.

Response: Thank you for your comment and acknowledgement that hydrogen production through electrolysis of sea water is a potential clean, renewable energy technology. The PEIS does not discuss the potential of the hydrogen-producing technologies to lower sea levels, as this impact has not been scientifically confirmed.

Comment 134-3: 2. (Unsubstantiated assertion) On page 2-77 in section 2.3.2.3.2, the Draft PEIS states:

Centralized hydrogen production using electricity generated by geothermal, wind, or solar would need to be located near those geothermal, wind, and solar sources for hydrogen production to be economical. This assertion is silly on its face. The cost of electricity as the H₂ generation plant is moved away from the generating facility is an incremental one of line loss. The reason significant economic cost might

be felt with a more distant plant is if the utility charge to use the existing grid to transport the electricity. This is a billing, administrative, Public Utilities Commission, and legislative issue—not a cost issue. In fact, there are advantages to building a hydrogen facility where it has access to many sources of electricity, not just one, particularly if in doing so the generation is closer to the user.

Response: The discussion of centralized hydrogen production was taken from the Draft environmental assessment entitled, *Hawai‘i Natural Energy Institute Electrolyzer-based Hydrogen Production System to Support Additional Variable Wind and Solar Renewable Energy Sources on the Grid and Provide the Hydrogen to Fuel Public Transportation* (HNEI 2012c). The fact that a hydrogen production facility could be further from electricity production facilities (such as geothermal, wind, or solar generators) would not have an impact on the potential environmental impacts presented in Section 5.3.

9.3.3.16 Marine Hydrokinetics

Comment 64-14: There will be many BMP's relevant here that are project and site-specific. It may be worth highlighting this fact, currently it could come across to the reader that BMP's are basic. The mitigation measures that will need to be implemented will be manageable, but very likely not be basic. [6.4.4.2, 6.5.5.2, 6.9.4.1]

Response: Chapter 3 of the PEIS presents the common BMPs associated with each environmental resource area and Chapters 4 through 8 cover the basic BMPs specific to the analyzed technology (in terms of the representative project). All potential renewable energy projects would have a site-specific environmental review, whether a State or Federal process. Any BMPs would be specific to such review and could be more (or less) stringent than those listed in the PEIS.

Comment 96-1: I was doing some homework, and I noticed that the Department of Energy has done some extensive research on the wave energy. And if there's a need for whatever reason that I don't know of to have a grid system, that seems to be the best way to go. The 2009 study that is on line is well worth the read. And just recently, they compiled a 2012 Environmental Impact Study. And it's pretty extensive, 143 pages. And I think that, as I said, if for some reason we need to keep a grid, that would make the most sense. If we study what's happening in Kāne‘ohe at the military, they've had some pretty good results. Quite a few companies out there have devices that ride on the waves.

Response: Section 2.3.3.5.2 includes a discussion about the Wave Energy Test Site at Kāne‘ohe. Data gathered from this demonstration facility could help to inform interconnection requirements for any commercial-scale marine

hydrokinetic projects, should they be developed in Hawai'i. The NEPA documents issued to date on the Wave Energy Test Site are addressed in Section 2.3.3.5.2.

Comment 122-10: 2.3.3.5.4 Representative Project Pg 2-126

No description of what a representative oscillating wave surge converter (hydrokinetic projects) would look like was provided because of the difficulty in trying to describe with accuracy what that project would look like. The document states that the type of wave as well as the technology for harnessing the energy from the wave needs to be looked at and determined.

Response: The potential environmental impacts of marine hydrokinetic technologies were presented in Section 6.4 in terms of the range of potential applications identified in Section 2.3.3.5.2. This is because of the uncertainty of marine hydrokinetic technology readiness. However, regardless of which specific technology was deployed, there would potentially be impacts to the shoreline, near-shore, and offshore environments.

The PEIS does not eliminate the need for project-specific environmental review of individual projects that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits, regardless of which technology or activity was pursued. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

9.3.3.17 Multi-Modal Transportation

Comment 2-1: Municipal Waste and Geothermal in particular are the ideal energy source to replace oil fired generation capacity, as it is a reliable, schedulable energy source. Solar and Wind are less desirable sources of energy, as the utility cannot simply "turn the lights off" with the setting sun or if the wind quits blowing. Thus the investment in infrastructure must be maintained, and sufficient reserve capacity must always be on standby to offset lost output from the unreliable sources.

Response: DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described.

Comment 65-14: Expand the discussion on multi-modal transportation to include overall system efficiency, the ease of making connections between different modes of transportation, and optimal configuration of multi-modal transit options. Discuss system efficiency in terms of reductions in: (1) single occupancy vehicle usage, and (2) vehicle miles traveled.

Response: Section 2.3.4.6 has been updated to include a discussion on multi-modal transportation system efficiency including reductions in single occupancy vehicle usage and vehicle miles traveled. As discussed therein, transportation energy efficiency is largely dependent on the integration of multi-modal transportation systems with effective land use planning (i.e. the incorporation of transit-oriented development principles or increased mix-use development in the urban environment would support mobility and accessibility to multi-modal transportation systems). By combining these two principles, maximum system efficiency can be achieved. The benefits of providing increased travel options in densely populated areas or near residential homes, and within proximity of multiple land uses, provides a convenient, optimal configuration to travelers; thus greatly reducing dependence on single occupancy vehicles and vehicle miles travelled.

Comment 65-15: Include bike sharing as an example of multi-modal transportation and elaborate accordingly. The Draft PEIS discusses active transit options, such as biking or walking, as well as ride sharing/car sharing, but it does not mention bike sharing (pg. 2-200; pgs. 2-208-210). Bike sharing is a low-cost, flexible public transportation service that provides on-demand access to a network of publicly rentable bicycles. Typically, public bicycles are distributed across a service area at fixed destination-based station locations. With the ability to make point-to-point trips, like sharing systems generally accommodate shorter trips that replace less efficient auto and transit trips.

Response: Section 2.3.4.6.3 has been updated to include a discussion regarding bike sharing.

9.3.3.18 Municipal Solid Waste

Comment 38-21: S-40 "Table S-9a. Summary of Impacts for Utility-Scale Renewable Technologies and Activities ... Waste-to-Energy ... Waste Management..."

The PEIS should analyze impacts to zero waste initiatives such as reducing, re-using, and recycling. These reduce the need to produce and ship replacement items to Hawai'i, meaning less need for fuel, ships, harbor facilities, and trucks.

Response: Section 2.3.3.4 discusses the four components of the municipal solid waste industry: recycling, composting, landfilling, and waste-to-energy via incineration.

Comment 58-33: Please explain why only 25% of municipal solid waste in Hawai‘i is recycled. (P. 2-113)

Response: The sentence in Section 2.3.3.4.1 was deleted from the Final PEIS because the basis for the amount of recycling accounted for in Hawai‘i is beyond the scope of the PEIS and does not affect impacts. The PEIS does not provide guidance on solid waste recycling programs in Hawai‘i, other than using solid waste as a feedstock for waste-to-energy production. The important factor is that the State could increase the amount of waste-to-energy applications that would divert a higher percentage of wastes from landfills.

Comment 58-34: You say H-Power has been providing 90 MW of power on O‘ahu since 1990, processing 3,000 tons of waste per day, (P. 2-118) but not what percentage of O‘ahu's waste this represents, nor how much more power would be produced if 100% of O‘ahu's waste was recycled. Please provide.

Response: The percentage of the waste stream that is processed by H-Power in O‘ahu is dynamic and varies from year to year; therefore, it would be inappropriate to document a specific quantity in the PEIS.

Information on the percentage of waste diverted from landfills to H-Power is provided by the City and County of Honolulu's Department of Environmental Services at: http://www.opala.org/solid_waste/archive/facts2.html. As shown therein, in 2013, approximately 262,358 tons of O‘ahu's total waste stream was processed at H-Power, with 81,989 tons converted to ash and residue that was then disposed of in landfills. Notwithstanding the amount of ash and residue generated, H-Power processed approximately 30.1 percent of O‘ahu's total waste stream.

9.3.3.19 On-Island Transmission

Comment 47-1: Some maps help further explain the advantage of the Coral Sea Rd. underground power line route over the HCDA overhead power line route. Note on the second image that the green circle shows where the HCDA overhead route and the Coral Sea Road underground route CONVERGE. This is because the rest of the route must be UNDERGROUND because it is in a high traffic airport area. High power lines near any airport can be struck by low flying helicopters and small planes. Power lines near ANY airport landing area should be UNDERGROUND.

[This comment document contains material specific to a site on O‘ahu. The document provides support for placing electrical lines underground rather than overhead. It does not appear that this document is intended as a comment on the PEIS; rather, the comment is an email to distribution, of which the PEIS comment email address is included. Because the document supports a type of on-island transmission for a renewable energy project, it has been included and classified as an "On-Island Transmission" comment for the record.]

Response: The PEIS evaluates a broad range of activities and technologies and does not evaluate any specific project application. Any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

Any proposed projects near airports would require coordination with the Federal Aviation Administration and the Hawai‘i Department of Transportation-Airports Division, and an evaluation of potential impacts to navigable airspace.

9.3.3.20 Photovoltaics

Summary Comment SC023 (124-1, 141-1, 87-5, 112-2, 84-3, 31-1): Several comments provide a statement that solar photovoltaics are the best choice for Hawai‘i.

Response: Solar power matched with storage and other measures to improve stability and reliability is certainly a very strong option. The continuing technical developments, falling prices, and growth of worldwide experience in this field indicate that solar will continue to be a compelling route to meeting energy needs. DOE’s primary purpose in preparing the PEIS, however, is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai‘i. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described. The potential environmental impacts from the installation and/or construction of solar photovoltaic systems are discussed in Section 6.6.

Comment 57-3: The relationship between distributive and utility scale photovoltaic (PV) systems relative to this maximum amount should also be discussed. How much of this maximum amount will be taken up by the announced utility scale projects? The number of building permits for residential and commercial PV projects on O‘ahu has declined precipitously following the utility's requirement for pre-approval for connection. Areas that are

already saturated by intermittent renewable power should be disclosed and shown graphically on maps. Will the development of utility scale solar farms be at the expense of residential and commercial PV systems?

Response: The PEIS does not analyze the relative saturation of electrical grids or circuits on the grids. Specific safe and reliable levels of intermittent power supplies connected to the grid are difficult to determine, but are generally dependent on the technology and design of the grid and are generally being increased over time; both through upgrades and new understanding in this evolving field. If utility-scale intermittent power sources are designed with matched backup, storage, and reliability measures, they would not necessarily preclude grid tie-in of intermittent distributed generation sources. If the grid and grid-scale back-up and reliability measures are improved; then there could be more availability for both distributed generation and utility-scale tie-ins.

As to the speed of increasing grid capacity for intermittent renewable power supplies, the PEIS only analyzes potential technical upgrades (such as Smart Grid and energy storage). The pace at which those upgrades are made is determined by technical business and policy decisions, among others; individuals wishing to pursue faster uptake of intermittent distributed energy generation can install non-grid-tied systems and/or advocate for policy change and/or work through business to create new forms of utility provision.

Comment 58-35: "For purposes of analysis, the representative utility-scale solar PV transmits electricity to grid and does not have energy storage capabilities." (P. 2-133) Please explain why storage was eliminated from your analysis.

Response: Energy storage is analyzed in other sections of the PEIS specifically in Sections 2.3.5.4 and 8.4. The representative utility-scale PV system analyzes the impacts of only the generation side. A matched storage system may be quite beneficial for grid stability and energy reliability, and would provide the added benefit of allowing more intermittent supply tie-ins, both utility scale and distributed.

Comment: 80-1: I didn't see anything that gave a cost for solar per watt. Was there a fixed cost per watt for solar in your analysis anywhere?

[Dr. Summerson reply: We did not look at the cost per watt.]

I see. Okay, well, thank you. I don't know what to say. If there's no cost per watt, all electricity is free or it all costs a million dollars a watt. I'm sorry, I'm stunned.

Response: Project or technology cost analysis is outside the scope of the PEIS. With that said, the cost per watt for solar power production depends on

many factors beyond the price of the panels, panel capacity, and solar gain. Economic evaluation should be carried out at the project level when determining the best options for meeting specific energy needs of the individuals, communities, businesses, or governments being served by the project.

A comparison of energy costs for operating facilities on each island can be found in the PUC's Annual Reports to the Legislature: <http://puc.hawaii.gov/reports/annual-reports/>.

Comment 80-2: This process with -- you make note of the fact that the Hawai'i process starts in 2008. We're 2014. I can tell you in 2008 the cost of solar was about \$6 a watt, and it was hard to get. Today, the solar is -- it's about \$1.30 a watt, and I can buy it at my local farmers market or I can go into Home Depot.

And so, what I'm suggesting to you is that what you've done is you've analyzed the death of the dinosaur. The utility -- the mega utility is broad to versus done. And this is not just my opinion. Morgan Stanley came out with a recent analysis that said basically the same thing, that if you were holding stock in any major utility that is not in the northeastern part of the United States, you're going to lose your ass. Okay?

Response: DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in support of the HCEI. DOE is not proposing any specific project, activity, or technology and, accordingly, DOE is neutral with respect to the general projects, activities, and technologies that are described. Therefore, the PEIS does not specifically describe or predict the economic viability of specific energy delivery strategies.

Comment 80-5: The one thing I can pretty much guarantee is the sun is going to come up tomorrow.

Response: Thank you for your comment.

Comment 81-2: And, you know, we know Germany has installed solar, and they're shocked and surprised. They're creating much, much more electricity than they anticipated. Germans are slow, Siemens and all that crowd, they're very sharp guys. Yeah? So if they can do it, we can do it.

Response: The PEIS evaluates distributed (Section 2.3.2.4) and utility-scale (2.3.3.7) solar technologies and the associated potential impacts of both (Chapters 5 and 6, respectively). Both are considered important renewable energy components of Hawai'i's policy to achieve HCEI goals.

Comment 102-4: And, of course, affordable homes is really very slow. That's kind of like the worst thing here on Maui. I think the direction of the mayor and the county council -- even though I support their affordable housing, the key issue is affordable rentals. So that if they can put on, you know, on affordable rentals affordable photovoltaics, then people can live here.

Response: Section 2.3.1.4 discusses rebates, loans, and other programs to make energy efficiency projects like photovoltaic installations more affordable.

Comment 113-4: A lot of the tourists come here, you know, and I ask them, because they still see some signs around about no wind mill or support the wind mill. I ask them, I said, "Have you ever seen our solar farm? They pass it every day. They go, "What solar farm?" You know, so I'm for solar because it's low impact, it's low to the ground, you won't see these things sticking up there; and it's free energy. It's like the wind. But I don't want to see the wind mills on Lānaʻi.

Response: Section 5.5.8 discusses the potential scenic and visual impacts of wind turbines and associated mitigation.

9.3.3.21 Sea Water Air Conditioning

Comment 75-5: A third technology I want to make sure that you include is sea water air conditioning. That's going to happen much sooner than OTEC, and it's an important way to use our resources just offshore here or right below us for air conditioning. And by doing that, we displace the power that you would get from other sources for air conditioning, so I think that's an important technology to include.

Response: The PEIS discusses sea water air conditioning in Section 2.3.1.5 and associated potential environmental impacts in Section 4.2.

Comment 122-8: 2.3.1.5.4 Representative Project Pg 2-52

DLNR has already received requests for review for project proposals involving sea water air conditioning that would cool buildings for Honolulu businesses.

Response: The purpose of the representative project is not to describe an actual or proposed project but to provide a hypothetical basis for analysis so that the reader can understand the typical, potential environmental impacts that could occur and what to be aware of when designing or reviewing future projects. The information in question was included in the technology deployment discussion in Section 2.4.1.5.2.

9.3.3.22 Smart Grid

Comment 74-1: I am hoping that you do a safety check [of the health and safety impacts of smart meters].

Response: The PEIS addresses the general health and safety impacts of the smart grid technology, including smart meters, in Section 8.3.17.1 Any future site-specific renewable energy projects, including those involving smart meters, must adhere to Federal, State and local regulatory processes and requirements. Another comment response (44-1) addresses the health and safety of smart meters (see Section 9.3.4.8).

9.3.3.23 Solar Water Heating

Comment 58-30: Why, if solar water heating can reduce consumption by 40%, do you say it is "a feasible, if not ideal, energy-efficiency solution"? (P. 54) Please specifically explain why it's not "ideal."

Response: The sentence in Section 2.3.1.6.2 has been clarified.

9.3.3.24 Undersea Cable

Summary Comment SC024 (119-2, 106-3, 107-2): Several comments provided a statement that the undersea cable project is real, not hypothetical.

Response: Although hypothetical projects analyzed in the PEIS may in some instances largely reflect actual projects (implemented or proposed), the purpose of the PEIS is to highlight potential types and magnitudes of impacts associated with such projects. The PEIS does not provide site-specific analysis that would need to be considered should actual projects be pursued. At the point in which actual projects are planned or ongoing, the PEIS would be an informational resource presenting general impacts, and a more robust analysis of specific impacts and alternatives would need to be developed.

Summary Comment SC025 (138-2, 96-2, 85-4, 104-1, 103-2, 106-5, 87-3, 84-1, 84-6, 93-7, 136-3): Many commenters felt that undersea cables should not be included in the PEIS due to their potential impacts to wildlife, unproven benefits, high transmission losses, and high opportunity costs relative to other options. Many commenters also felt that the PEIS is biased in favor of undersea cables and presents neither a full analysis of impacts nor an economic analysis.

Response: Undersea cables are only one potential option among many renewable technologies and activities that could be implemented to achieve the HCEI goals. Undersea cables have been successfully deployed without detrimental transmission losses. In particular, the NORNED cable has successfully connected Norwegian and Dutch utility grids over a longer

distance than any potential cable routes in Hawai'i. Because of the success of this and similar projects, any new undersea cable project in Hawai'i could implement proven best management practices to reduce the risk to the environment, inefficiencies related to downtime, and costs of operations and maintenance. The PEIS uses the same categories and standards to analyze the impacts of all proposed transmission strategies, including the undersea cable. Potential environmental impacts to biological resources, including whales, from an undersea cable are addressed in Section 8.2.4.

The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations. Such review would include economic analysis of the specific project, including those addressing the concerns of the comments.

Summary Comment SC026 (108-1, 108-3): Two commenters expressed concerns about specific locations of converter stations associated with an undersea cable.

Response: Maps in the PEIS indicate direct line distance between islands, not identified cable routes. Any future cable project would require one land-sea transition site at either end of the cable, and would require detailed analysis for siting both the cable and the transition sites. In addition, any future site-specific renewable energy projects must adhere to Federal, State and local regulatory processes and requirements.

Summary Comment SC027 (109-1, 145-2): Two commenters expressed their opposition to undersea cables and one commenter, speaking for Molokai, extended the opposition to the Big Wind Project.

Response: The PEIS does not advocate for or against any particular project or activity in any particular location. The PEIS presents a non-exclusive menu of potential technologies and activities and evaluates their potential environmental impacts. It is up to the people, governments, and businesses of Hawai'i to build a path (or paths) forward. As identified in the Amended Notice of Intent and the Draft PEIS (Section 1.1.2), the original scope of the HIREP:Wind EIS was modified as a result of public comment to evaluate a broader range of activities and technologies and to not evaluate any specific proposals.

Comment 38-2: I also hope to hear why, in "Table S-8. Summary of Impacts for Selected Technologies and Activities," page S-29, beneficial impacts are

identified, complete with a Web address for more information, for only one alternative--the undersea cable.

Response: Table S-8 has been revised to provide a more consistent presentation of potential impacts to various technologies.

Comment 58-13: DOE utterly fail to mention any impact of repair and maintenance of an undersea cable laid in the Humpback Whale Sanctuary. (P. S-25, middle block, top) Please revise.

Response: Section 8.2 has been modified to include a discussion about the maintenance and repair of an undersea cable, independent of location.

Comment 58-15: Please provide data to support the claim that "long-term noise and vibration impacts from operation of undersea cable is negligible." (P. S-28)

Response: Section 8.2.12.1 elaborates on the conclusion presented in the PEIS Summary. In brief, there could be short-term impacts from construction noise and vibration. Such impacts would require analysis prior to any decision by DOE or other Federal agency to provide funding for the analyzed project. Such analysis would include an assessment of longer-term impacts. From a programmatic standpoint, longer-term noise and vibration would be the same as typical construction projects and would be negligible when mitigation measures are employed, as presented in Sections 3.12.5 and 3.12.6, respectively.

Comment 58-16 Please provide data and source of data to support the claim that an undersea cable would "improve power system economics and reliability of each island." (P. S-29) An earthquake in 2006 left O'ahu without power for three days; Lana'i was untouched, not a light bulb dimmed.

Response: The PEIS references DBEDT's Initial Public Comments in Response to Hawai'i Public Utilities Commission Order No. 31356. As provided in Section 8.2.13.1, the reference can be obtained online at: <http://dms.puc.Hawaii.gov/dms/DocumentKeySearch.jsp> [Enter "2013-0169" (without quotes) into "Docket No." field and click on "Search" button. DBEDT response is dated 09/09/2013.]

Comment 58-17: You state that one benefit of an undersea cable is "reduced renewable energy curtailments." (P.S-29). This raises the question of why we have allowed resource overbuild to the point that we need a cable to ameliorate the situation? This demonstrates poor planning on the part of the State that should not be perpetuated and should be pointed out in your guidance.

Response: It is outside the scope of the PEIS to address past planning and development decisions. The PEIS only looks to discuss the

environmental impacts of renewable energy technologies that may be proposed to address Hawai‘i’s electricity needs, which will support more informed decision-making when evaluating projects that would impact an island's overall energy demand. DBEDT notes energy use reduction through efficiency and conservation is one of the top strategies of HCEI targeting existing developments. On April 28, 2014, the Hawai‘i PUC ordered the Hawaiian Electric Companies to develop and implement major improvement action plans to aggressively pursue energy cost reductions, proactively respond to emerging renewable energy integration challenges (including curtailment), improve the interconnection process for customer-sited solar photovoltaic systems, and embrace customer demand response programs, including a Power Supply Improvement Plan, a Distributed Generation Interconnection Plan, and the integrated interconnection queue proposal for the HECO Companies. These plans are currently under review and discussion prior to approval (reference Docket Numbers 2014-0183 and 2014-0192).

Comment 58-19: DBEDT /HSEO's "5-point" energy strategy includes a pre-ordained "connecting the islands through integrated, modernized grids." (P. 2-13) This can't be done without an undersea cable, so please explain whether DOE favors an undersea cable, contrary to your claim that this PEIS is only to provide "guidance" for future actions. (P. 1-5)

Response: While the State’s Energy Office does advocate for investment in undersea cable infrastructure (see <http://energy.Hawaii.gov/energypolicy>), the State Energy Office is still awaiting a determination by the PUC on whether a grid tie between O‘ahu and Maui is in the public interest. The Memorandum of Understanding between the State of Hawai‘i and DOE does not require the Federal Government, DOE in this case, to support each technology the State proposes. Therefore, at this time, DOE does not advocate for or against the stated roles, policies, and aims of any of the agencies listed in Table 2-2; nor does it advocate for or against any one technology.

The State’s energy policy has been clarified in Section 1.1.1.

Comment 58-44: Electrical fields are retained within the cabling through industry-standard shielding; however, magnetic fields are not completely retained within an undersea cable. (P. 2-219). This is quite the understatement: Please quantify the impact.

Response: The strength and extent of EMFs around undersea cables is variable with system design. Cable design can reduce EMF strength and extent. There is public concern over potential for EMF impacts, and the PEIS describes the existing body of research. If an undersea cable project is pursued,

analysis of EMF will need to be done at a project level when specific designs and siting are known.

Comment 58-45: Please strike the entire section that follows: "in its current configuration, each island in Hawai'i maintains its own isolated power grid. An undersea cable could be used to interconnect these island grids. Power generated on an island where renewable energy potential is high but demand is low (i.e., Moloka'i, Lana'i, Maui, and Hawai'i) could be transmitted to O'ahu, where the demand for energy is high, but viable amounts of renewable energy resources to meet the demand are limited. Additionally, connecting island grids could help prices rise less abruptly than they are expected to without the cable and could also reduce the uncertainty of rates rising with oil price shocks (DBEDT 2013l). This would be achieved by being able to move lower cost power (populated areas with a larger base to recoup costs) to an area of high costs (remote areas with lower populations). Renewable generation facility costs would be spread over a much larger population base. Using undersea cables could allow for more use of renewable resources at predictable energy prices not tied to the price of foreign oil imports. At today's oil prices, an interisland transmission cable would be cost effective, based on reasonable cost assumptions and renewable resource availability (DBEDT 2013l). An interisland cable also could provide emergency backup electricity between islands because electricity could flow through the cables in either direction."

THIS IS HIREP:WIND (NOW "DEFUNCT") ALL OVER AGAIN; NOT A SINGLE CLAIM IS SUBSTANTIATED; THE FACT THAT DBEDT WANTS IT DOES NOT MEAN WE WILL ACCEPT IT; THESE CLAIMS RUN COUNTER TO THE OBVIOUS ADVERSE IMPACTS YOU NOTE ON P.2-286, 2-287, 2-291 AND 2-292. YOU DON'T NEED A CABLE IF THERE IS NO RESOURCE TO SEND OVER IT.

Response: Section 2.3.5.2.2 has been revised to remove much of this information, as it is unnecessary for the environmental impact analyses in this PEIS.

Comment 58-46: DOE claims that a beneficial impact of an undersea cable is "higher penetration of renewable generation on each connected island grid." (P. 2-314/hard copy, P. 2-312 disk). This claim has never been substantiated, please provide support for this statement.

Response: Section 2.3.5.2.2 has been revised to provide a more general discussion of the feasibility and potential deployment of an undersea cable in Hawai'i.

Comment 106-1: My name is Mike Bond, B-O-N-D, I live on the west end. My family has been in Hawai'i for nearly 200 years and we're extensive on all the

islands. I wanted to briefly touch on my own personal background in the energy business. I was project manager of a Department of the Interior Electric Power Research Institute Study, a national study of the impacts of underground and high tension wires for the Navy. I was project manager of several sanguine Studies of hundreds of thousands of square miles for potential cable laying, as well as many other energy-related projects. I was the chair of the 28-Nation group that integrated or spoke the working documents for integrating the Soviet Union's grid with the west, etc. I was the CEO of an energy company and worked very long and hard for Al Gore in the energy part of the 2000 presidential campaign. I'm very pro -- totally pro renewable energy -- which is why I'm very concerned and upset by this document. There isn't time to go into it -- I have read a good part of it there isn't time to go into it, I am going to give an extensive response written. But I would just like to say the one thing that concerns me the most is the tacit acceptance of the underground cable and the tacit acceptance of DBEDT's arguments in favor of the cable. And in fact, Mr. Glick being here tonight, Mr. Glick has long been a very strong proponent of the cable. And I personally, with more than 30 years of experience in the energy business, I have to say I think the cable is a disaster. It's hyper-costly and it's basically in my view a political corporate scam.

Response: The PEIS seeks to objectively assess the potential environmental impacts of a broad spectrum of energy efficiency activities and renewable energy technologies, including undersea cables. The PEIS includes readily available information for each activity or technology and has been revised based on comments. These revisions include some of the discussions related to the undersea cable as well as the potential adverse impacts and associated mitigation strategies.

Comment 107-3: The Draft goes so far as to agree that the grid tie is "in the public interest". How can a project whose cost will certainly raise all ratepayers' electricity bills and have massive environmental impacts be in the public interest?

Response: Section 2.3.5.1.2 was modified to remove the quote that claims an undersea cable is in the public interest.

Comment 107-5: At the same time, the Draft acknowledges that the impacts of electromagnetic fields from the operation of undersea cables on marine species are unknown and that researchers are working to determine the extent and the magnitude of the impacts. Shouldn't the Draft recommend that no cables be laid until these impacts are known and validated? Or, in the very least, the Draft should recommend that the Uncertainty Principle as outlined by the Rio Convention be applied.

Response: The majority of peer-reviewed, scientific literature does not indicate that EMF negatively impacts the health and safety of humans, plants, and

animals. The PEIS discusses impacts to aquatic species utilizing electro- and magneto- reception, but the full impacts are not yet known. Cable design can reduce EMF strength and extent. There is public concern over potential for EMF impacts, and the PEIS describes the existing body of research. The inclusion of the undersea cable as a technology in this PEIS provides no basis for recommending or not recommending any future project and does not indicate that DOE endorses any specific type of technology discussed.

Comment 107-6: We have come a long way worldwide towards protecting our marine resources since I worked with Dr. Ken Norris at Oceanic Institute in the early 1970's. Dr. Norris was doing groundbreaking research on humpback whales that led to the creation of the Hawaiian Islands Humpback Whale sanctuary. The sanctuary needs to be respected, and particularly its annual six-month moratorium on activities such as cable construction. I may have missed the mention of this in the Draft. And if it's not there, it should be.

Response: Sections 3.4.3.1.2 and 3.4.4.1.2 discuss the endangered humpback whale and the Hawaiian Islands Humpback Whale National Marine Sanctuary, respectively. The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

Comment 107-8: I also challenge the Draft's assumption that undersea cables have no environmental justice impacts. Isn't the degradation of the fisheries in areas where population who rely on fishing for subsistence a potential environmental justice impact? Similarly, wouldn't industrial projects on less-populated islands connected via an inter-island cable have the environmental justice impact of subjecting residents to "disproportionally high and adverse impacts" by substantially changing the nature of their island? Thank you.

Response: The potential for disproportionately high and adverse impacts to low-income and minority populations during cable construction and operation would need to be evaluated on a site-specific basis for any future project and avoided or mitigated accordingly. This is true of any project receiving Federal funding, regardless of which technology was used. Environmental justice is presented in the PEIS in Section 3.16 and specifically is discussed relative to an undersea cable in Section 8.2.16.

Comment 111-7: When we're talking about our area, when we're talking about our animals, I would like to see the Draft -- the PEIS -- I would like to see it include

more information from NOAA. I would like to know how they plan on protecting the whales when it comes down to the guidelines for submarine cables saying that the Hawai'i humpback sanctuary is exempt from the guidelines that they have in place. Why are they exempt, and how much damage will really take place. On the PEIS I see during construction -- well -- I'm sorry, there is going to be more than that. It's going to be a lot more than that.

Response:

The Office of National Marine Sanctuaries (ONMS) within the National Oceanic and Atmospheric Administration (NOAA) established guidelines on how to consider proposals to install and maintain submarine cables within National Marine Sanctuaries (NMS) (i.e., a review and permitting process). Because of varying jurisdictions and activities in some NMS, other review and approval processes would apply in specific NMS (including the HIHWNMS). As stated in the guidelines, in all NMS if another Federal permit or license is required (e.g., BOEM right-of-way or COE Section 404 permit) to install an undersea cable, the Federal agency issuing the permit would require consultation with ONMS in accordance with section 304(d) of the NMSA. An undersea cable would not be exempt from NOAA review.

To address the public comment, Section 2.3.5.2.3 was modified to clarify this statement. NOAA and the National Marine Fisheries Service were involved with defining the scope of the PEIS and provided comments to DOE on preliminary drafts of the Draft PEIS. More specific impacts, including those to the endangered humpback whales, can only be analyzed at the project planning phase when specific system details and siting are known. NOAA recently issued its Draft Management Plan and Draft EIS for the Hawaiian Islands Humpback Whale National Marine Sanctuary (http://hawaiihumpbackwhale.noaa.gov/management/management_plan_review.html).

Comment 116-2:

After reading through the PEIS Summary and then looking through the pages of the Draft PEIS, several things caught my attention. The first was that although it stated that it "does not propose any specific project, activity or technology at this time" that the presentation of the 31 different clean energy technologies and activities within the statement could lead people to have a biased perspective. For example, in Table S-8 (which is the Summary of Impacts for Selected Technologies and Activities), the box pertaining to undersea cables and their impact on Utilities and Infrastructure, contained bulleted points describing beneficial impacts, as well as a hyperlink to a "full list of benefits" whereas none of the other technologies and activities contained beneficial information in this format. It could be very misleading to the average reader. Moreover, the potential negative impacts, though listed, seem to be downplayed and vague. Although the PEIS included potential negative impacts and made

references to sections relevant to those impacts, they were not fairly represented in the tables. These inconsistencies may result in minimizing potential problems with the undersea cable as well as forming misconceptions about potential benefits.

Response: The PEIS seeks to objectively assess the potential benefits and impacts of a broad spectrum of energy efficiency activities and renewable energy technologies. The PEIS includes readily available information for each activity or technology and has been revised to provide a more balanced presentation of each technology. These revisions include some of the discussions related to the undersea cable.

Comment 148-1: I'm actually a resident of southeast Maui, and I appreciate that I could come here tonight on O'ahu because I was at another meeting on Thursday. But I'm appreciative that the process is moving along. I'm a little concerned that this programmatic EIS may be a little bit of a step backward in one way, in that I really feel a sense of urgency to move forward with actual specifics and projects and ways of creating more renewable energy in different forms and making it useable on a large scale.

I'm a bit unique in that I've been living in southeast Maui off the grid since the mid-1970s with wind power, PV power as it's become affordable, and small scale hydro, most of which we built ourselves over the years. In fact, in the '70s we were manufacturing windmills for a number of people in east Maui. And it is possible to do it in a very isolated place, cut off from the grid, but it's not efficient. It takes a lot of expertise and a lot of work, where my experience with renewable systems is they work better the more interconnected they are.

And for that reason I believe that even a unit such as one of our counties or islands is too small to really be able to sustain the percentages of renewables that we would need, and also a lot of us like to see to be able to move away from fossil fuels. And certainly if we're talking about getting up into the 70 percent range, even with efficiency we're going to have a very large amount of wind, solar, maybe pump to hydro storage, maybe wave energy, geothermal. And if it's mixed together and if the wind and PV is staged in different places so that one cloud does not take out all of the PV at once when windy or less windy conditions don't affect all of the wind energy, then I think that it will function a lot better.

So being a proponent of interconnectivity of the islands and more renewables, I would like to see us move forward with more specific and large-scale projects as soon as we can so that we can move away from our current practices, and I'm glad that the 343 process will remain intact. I served as chair of the Maui Planning Commission for many years and

we were the accepting agency for many documents, and that process works when it's done well.

Response: The commenter expresses his support for interconnectivity of the islands (undersea cables) based on his own experience. Section 2.3.5.2.2 of the PEIS identifies the potential benefits, concerns, and challenges that would be associated with such a project.

9.3.3.25 Wind

Summary Comment SC028 (6-1, 9-1, 10-1, 11-1, 14-1, 15-1, 15-2, 16-1, 17-1, 18-1, 19-1, 20-1, 20-2, 21-1, 25-1, 26-1, 29-1, 70-1, 123-1, 123-3): Multiple commenters expressed concern that new wind turbines might be located near specific types of facilities, such as schools or homes, or in specific communities, such as Kahuku.

Response: Section 6.8 addresses the various potential environmental impacts of a utility-scale wind project on nearby communities. The PEIS does not propose or analyze any specific project and, as a result, does not address potential impacts to the specific facilities or locations identified in these comments. The PEIS uses representative projects to help focus the discussions on the types of impacts that might be expected from specific technologies, whether wind turbines or any of the 31 technologies and activities analyzed in the PEIS. The representative projects are intended to be reasonable examples based on conditions in Hawai‘i, but are hypothetical and not intended to represent any real or proposed project. Although the PEIS can be used to support the evaluation of site-specific projects, either as a reference source or as a baseline of certain conditions, specific projects would require additional environmental impact analyses that address potential impacts to site-specific facilities or communities. Any future site-specific renewable energy projects must adhere to Federal, State and local regulatory processes and requirements.

Summary Comment SC029 (17-2, 23-1, 25-2, 26-2, 29-5, 58-18, 119-5): Several commenters expressed concern over avian and bat mortalities associated with wind turbine technology, with some comments noting that impacts could include the State bird, the Nene goose. A few comments also expressed the opinion that the PEIS’ use of “potential” in this regard was an understatement because avian and bat mortalities would be a certainty.

Response: The PEIS has identified mortality of avian and bat species from collisions with turbine blades as a primary concern for the operation of wind turbines (see Section 5.5.4 for wind turbines implemented as distributed technologies; Section 6.8.4 for utility-scale, land-based wind turbines;

and Section 6.9.4 for offshore wind turbines). The PEIS describes that risks are based on site-specific habitat characteristics as well as the individual behaviors of the species within that habitat. Accordingly, a more detailed evaluation of specific impacts is beyond the scope of this programmatic effort, but general measures that can be implemented to minimize risks are described in Section 3.4.6.

In addition to the measures discussed in Section 3.4.6, under State law (HRS 195D), all new wind farms in Hawai‘i that “take” or harm protected (avian) species are required to develop and implement a Habitat Conservation Plan for the lifetime of the project to mitigate impacts to protected (avian) species and their habitats. Any action could also be subject to the Endangered Species Act.

Use of the word “potential” to describe impacts to avian and bat species is not an attempt to understate the concern; rather, the terminology is commonly used in environmental evaluations such as the PEIS when additional detail is needed to make more specific impact projections. Further, documents prepared under NEPA analyze a proposal for a Federal action. Therefore, any effects would be potential because the decision to proceed with the Federal action is determined only after completion of the analysis.

Summary Comment SC030 (38-22, 117-7, 121-1, 121-2): A few commenters suggested that the wind turbine technology described in the PEIS is outdated or that the PEIS should consider other wind harnessing technologies that are less harmful to wildlife.

Response: The technologies evaluated in this PEIS are not exclusive; they represent the most prominent examples of renewable energy technologies currently employed. In describing the land-based wind power technology, the PEIS (Section 2.3.3.9.1) recognizes that alternative approaches to harness wind energy are being pursued by various entrepreneurs and some of those technologies, if proven effective, could possibly present decreased impacts to wildlife as suggested in some of the applicable comments. However, for purposes of the analysis in this PEIS, such alternative technologies are considered too early in development to address in any detail.

Summary Comment SC031 (5-1, 9-4, 12-1, 14-2, 17-3, 24-1, 26-5, 28-1, 30-1): Several commenters simply expressed their preference of solar energy over wind energy.

Response: DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. DOE is not proposing any specific project, activity, or technology, nor is DOE attempting to establish a preference or hierarchy of technologies in comparison to others.

Summary Comment SC032 (8-1, 105-2, 116-6): Commenters expressed concern that wind turbines and associated power cables, if transmitting power to other islands, are contrary to preserving the islands' beauty and natural qualities and, in general, wrong for Hawai'i.

Response: Several of the resource areas evaluated in the PEIS were selected and defined to address the types of concerns expressed in these comments. With respect to utility-scale land-based wind turbines, DOE addressed these types of concerns in resources areas such as land use, cultural and historic resources, scenic and visual resources, recreation resources, and others. However, these are difficult questions to evaluate because they are generally heart-felt, personal concerns pertaining to the individual's quality of life and expectations with regard to that quality. A goal of the environmental review process, however, is to at least identify such concerns so they can be considered in the decision-making process. The PEIS does not eliminate the need for a project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other federal agencies in the future or subject to Federal or State permits.

Summary Comment SC033 (22-1, 25-3, 25-4, 26-3, 26-4): Several commenters stated opposition to utility-scale wind turbines because they take away from opportunities for the installation of private solar systems and keep people dependent on utility companies. As an example, one comment described a scenario of utility-scale wind turbines "consuming space on the HECO grid" so that private homes could no longer qualify for solar panel installation permits.

Response: With regard to interconnection of private solar systems into the grid, Section 2.3.2.4.2 describes the manner in which HECO establishes interconnection requirements for distributed energy resources (from all sources, not just solar). Discussion of the prioritization of interconnecting utility-scale versus distributed energy resources is outside the scope of the PEIS.

Summary Comment SC034 (112-1, 112-4): Several commenters express their concern and opposition to any action that would dedicate large areas of Lāna'i to power generation technologies such as wind farms for the primary purpose of supplying power to O'ahu.

Response: The position voiced in these comments is noted and Chapter 6 addresses the types of environmental impacts that would be of concern for large wind farm projects. DOE is not proposing any specific project, activity, or technology; nor is DOE attempting to establish a preference or hierarchy of technologies in comparison to others. Therefore, the PEIS does not address potential impacts to a specific location, such as Lāna‘i, from a specific project as identified in these comments.

Although the PEIS can be used to support the evaluation of site-specific projects, either as a reference source or as a baseline for certain conditions, the PEIS does not eliminate the need for a project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations. DOE and the State recognize that any decision to develop energy technologies on other islands with a primary purpose of supplying energy to O‘ahu would require analysis of many factors in addition to potential environmental impacts; such analysis is beyond the scope of the PEIS.

Summary Comment SC035 (29-4, 123-2, 9-2): Commenters noted there would be depreciation of home values as a result of being close to wind turbines.

Section 6.8.8 notes that some individuals object to the appearance of wind turbines, feeling they are an unnatural intrusion to the natural scenery and viewshed. Conversely, some people consider wind turbines to be graceful and modernistic and are not opposed to their presence. The National Renewable Energy Laboratory’s *Renewable Electricity Futures Report* (see http://www.nrel.gov/analysis/re_futures/) states that, as with conventional power plants and transmission lines, a potential consequence of wind turbines is a reduced property value near the facility. However, published research with regard to wind turbines has found little evidence to substantiate widespread concerns of property value reductions. This might be attributed to siting and setback practices commonly used for locating wind turbines. The Futures Report indicates that continued research needs to focus on changes in property values over time.

Summary Comment SC036 (58-37, 117-7): Two commenters expressed their concerns regarding the endangered ‘Ua‘u and bat populations on Kaua‘i and not excluding that island from consideration for wind turbines.

Response: The PEIS does not indicate that Kaua‘i would necessarily be excluded from development of utility-scale wind technology, rather it states (PEIS Section 2.3.3.9.4) that such development on Kaua‘i would be extremely

difficult because of the high population of endangered sea birds. Any location proposed for development of wind technology would have to be evaluated on a site-specific basis for potential impacts to wildlife. With regard to the endangered Hawaiian petrel (or 'Ua'u), Section 3.4.3.1.1 recognizes the presence of this species on Lāna'i. In addition, the presence of the Hawaiian hoary bat **has been documented on Hawai'i, Maui, O'ahu, and Kaua'i**, but **its presence** on Lāna'i is not as clear cut, or at least not as well documented. The PEIS (Section 3.4.3.1.1) describes additional efforts being taken by the USFWS to better understand the distribution, population status, and ecology of the Hawaiian hoary bat **throughout the main Hawaiian islands**, but the USFWS *1998 Recovery Plan for the Hawaiian Hoary Bat* specifically states there were no verified records of this species' presence on Lāna'i.

Under State law (HRS 195D), all new wind farms in Hawai'i that "take" or harm protected (avian) species are required to develop and implement a Habitat Conservation Plan for the lifetime of the project to mitigate impacts to protected (avian) species and their habitats. Any action could also be subject to the Endangered Species Act.

Comment 7-1:

I'm a physicist (energy expert), and longtime (30± years) environmental advocate, who is extensively involved with energy and environmental matters. I've been to Hawai'i several times (six islands) and am very concerned about the wind energy situation there.

I've put together an informal all-volunteer coalition of some 10,000 individuals, and about 700 of them are PhDs or experts. The name of our group is Alliance for Wise Energy Decisions (AWED).

AWED's focus has been on the science. For instance, after talking to a LOT of people about renewables (like wind power), the inescapable conclusion is that almost everyone has only a superficial understanding of this very technical matter. Additionally, the public and political perception of things like wind energy are being driven by special interest lobbyists, and by "environmentalists" who are well-intentioned but misguided.

In essence, our alliance is trying to improve state and federal policies, and our position is simply this:

- 1 - we do have environmental and energy issues, and
- 2 - such technical matters should be resolved by using real Science.

Instead our energy and environmental policies have essentially being written by those who stand to economically or politically profit from

them. As a result of our current methodology, anything genuinely science-based in these policies is inadvertent and accidental.

A key element of our efforts is to get the public up-to-speed, and our website (WiseEnergy.org) is an unparalleled educational resource. There you will find our model ordinance, plus references to several other communities that have enacted good wind laws.

Another example of our education campaign is that I have put on numerous free community presentations about our energy future (10± states), with a focus on the question of whether we want our energy policies to be determined by lobbyists or by science. This is now online at EnergyPresentation.Info. This has been called one of the most thorough energy presentations on the planet.

The expanded version of my recent talk to Congress, Science Under Assault is now online at ScienceUnderAssault.Info. Please look at that closely, as that is our underlying theme. This is really the core issue of the whole energy matter.

I will add you to our network of science-oriented persons. Here is the most recent issue of my newsletter — I hope you'll find several of the articles to be of interest. Periodically (once every three weeks or so) I also send out informal energy and environmental information to this group.

Response:

Thank you for the additional information. DOE's primary purpose in preparing the Hawai'i Clean Energy PEIS is to provide information to the public, Federal and State agencies, Native Hawaiian and other organizations, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support the HCEI. This environmental information could be used by decision-makers, developers, and regulators in determining the best activities and technologies to meet future energy needs. The public could use this PEIS to better understand the types of potential impacts associated with the various technologies.

Likewise, the State of Hawai'i's intent regarding the Clean Energy PEIS is for the Federal, State, and county governments, the general public, and private developers to use the PEIS as a reference document when project- and location-specific EISs for renewable energy projects are prepared. The information can be used in concert with other data (economic and engineering feasibility) for specific projects in the future to maximize the benefits for the residents and businesses in Hawai'i while minimizing the potential environmental impacts.

Comment 9-3: We don't have a lot of land between the mountains and the ocean and [wind turbines] will visually pollute our landscape. They belong in open planes and deserts where there is lots of room and no human life around.

Response: Section 6.8.8 notes that some individuals object to the appearance of wind turbines, feeling they are an unnatural intrusion to the natural scenery and viewshed. Conversely, some people consider wind turbines to be graceful and modernistic and are not opposed to their presence. The PEIS also considers the natural beauty and solitude of the islands in its impacts analyses of land and submerged land use (Sections 5.5.5, 6.8.5, and 6.9.5), cultural and historic resources (Sections 5.5.6, 6.8.6, and 6.9.6), scenic and visual resources (Sections 5.5.8, 6.8.8, and 6.9.8), and recreation resources (Sections 5.5.9, 6.8.9, and 6.9.9).

Comment 29-2: I am a mother of two boys on the Autism spectrum who have sensory issues. The effects of the low frequency noise on children with sensory issues is very concerning. Not to mention the health risks for children and people susceptible to seizures and other health conditions. And Champlin wants to place these wind turbines close to our schools and residential area??? The potential impact this would have on our students and residents is very concerning. Kahuku is already a poor, rural community that lacks resources and services that many other communities have access to. As a special needs parent, I know this all too well in fighting for services for my children. Please consider that in your environmental impact study.

Response: Although the PEIS does not address potential impacts of actual projects in specific locations, Section 6.8.8.1 includes a discussion on the long-term visual impacts that are associated with wind turbine operations, including shadow flicker and blade glinting. In Section 6.8.12.1, the PEIS also addresses the potential impacts of low frequency sound, but recognizes that its effects on humans are not well understood. Sections 6.8.8.1 and 6.8.17.1 were modified to further describe the potential visual and health effects, respectively, from shadow flicker and blade glint or glare from utility-scale wind turbines and to provide references for additional information.

DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. DOE is not proposing any specific project, activity, or technology, nor is DOE attempting to establish a preference or hierarchy of technologies in comparison to others.

The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to

Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

Comment 29-3: Not only do Kahuku residents have to deal with health risks, the physical safety concerns of the close proximity of placement is alarming. There is no real guarantee of safety during hurricane season or in case of fires (as it has happened with First Wind).

Response: Although rare, fires have occurred in utility-scale wind turbines. The generator housing at the top of the tower (known as the nacelle) contains powered electronic equipment, so there is both an energy source and some amount of combustible material. Also, there have been historical instances of wind turbines collapsing. However, utility-scale wind turbines are now better designed and certified to meet international engineering standards and, as applicable, include ratings for withstanding hurricane force winds and other criteria. As described in several sections of the PEIS, the use of appropriate setback criteria for siting wind turbines restricts them to locations where dwellings would be outside the wind turbine's fall zone to minimize the rare potential for these impacts (See Section 6.8.17.2)

Comment 53-1: For the "Air Quality" category, the PEIS Summary states that wind projects will have "[n]o operation impacts" on air quality. However, to the extent that a wind project reduces reliance on fossil-fuel plants which release air pollutants, the wind project has the potential to positively impact air quality. The PEIS Summary recognizes this phenomenon in the "climate change" row, but fails to recognize it in the "air quality" row.

Response: The comment is correct in that the summary of air quality impacts of wind projects in Tables S-9b and 2-41b, as well as in the discussions of impacts in the Sections 6.8.2 (for land-based wind) and 6.9.2 (for offshore wind), could note the positive impact to air quality that would result from a corresponding decrease in air emissions from fossil fuel plants. However, because this document does not evaluate an actual project at a specific location, it was deemed inappropriate to attempt comparisons to site-specific conditions, such as the specific manner in which electricity is currently produced in an area. Also, addressing only the local and direct operational impacts of wind technologies to air quality is more consistent with evaluations for other resource areas. Climate change, on the other hand, is recognized as a global concern with goals and standards established in terms of the reducing rates of greenhouse gas emissions from large, geo-political areas. In this case, DOE believes it is appropriate to discuss the reduction of greenhouse gases that would result from

implementation of wind technologies even if it is the result of typical offsets from fossil fuel plants.

Comment 53-2: For the “Marine Transportation” category, the PEIS Summary states that wind projects have “[m]inor impacts on marine transportation from shipment via marine cargo ship.” It is not clear what impacts if any are being referenced aside from increased demand for shipping services, but Castle & Cooke believes any such impacts are not necessarily greater than the impacts associated other technology categories, such as Photovoltaic Systems, Solar Thermal Systems, and Ocean Thermal Energy Conversions. Thus, if this item is listed for the Wind category, it should also be listed for other technology categories.

Response: The comment is well taken. Implementation of large renewable energy technologies of any type would be expected to require shipping of large quantities of materials into the islands and, in relation to the existing level of shipping activities, impacts to marine transportation would be minor. The wind technology is somewhat singled out for the identified summary language because DOE addresses the perception of many people that wind turbine components, because of their size, would represent unusual shipping difficulties. DOE does not believe this to be the case (i.e., impacts would be minor), so included the language.

Comment 53-3: For the “Environmental Justice” category, the PEIS Summary states that wind projects have “[p]otentially adverse impacts to minority populations or to low-income population associated with potential visual and scenic, noise and vibration, or other resource impacts in the affected areas.” This notation is not included for other technology categories, such as Photovoltaic Systems, Geothermal, Biomass, and Municipal Solid Waste-to-Energy. While it is true that land prices are often lower in low-income areas and that such areas therefore attract disproportionately high investment in infrastructure, this is true for all categories of infrastructure, not just wind projects. In fact, since wind projects must be sited where there is an adequate wind resource whereas thermal facilities may be sited where land prices are most favorable, this concern is even greater for non-wind technology categories than for the wind category. Accordingly, this notation should be removed from the wind category, or should be included for other categories as well.

Response: The statements regarding potential adverse impacts to minority or low-income populations from land-based and offshore utility-scale wind project development were removed from Table S-9b in the PEIS Summary and Tables 6-10 and 6-11, which summarize the potential environmental impacts and best management practices/mitigation for land-based and offshore wind systems, respectively. Section 3.16.1 has

been updated to address the potential for any renewable energy project to cause environmental justice impacts.

Comment 58-32: You display maps of geothermal resources for the entire state (P. 2-106 to 108), yet only wind maps for Maui County (P. 2-144 to 145). Please explain why O'ahu and Hawai'i were excluded.

Response: Figure 2-40 depicts wind resources, based on average wind speeds at a height of 80 meters, for the entire state. The figures identified in the comment (i.e., those on pages 2-144 to 2-145 of the Draft PEIS) show results from a specific study referenced in the PEIS. As indicated in the associated PEIS text, that study considered only the islands of Molokai, Lāna'i, and Maui. The PEIS has been modified to clarify the reason for including information from the study even though it did not cover other islands.

Wind energy resource maps for all Hawaiian islands can be found at the Hawai'i Office of Planning State GIS Program website (see "Downloadable Layers, Atmospheric and Climate" at <http://planning.hawaii.gov/gis/download-gis-data/>).

Comment 58-36: You say data on 161 wind projects determined that "average land requirements" were 84 acres per MW. (P. 2-141), then say that empirical evidence in Hawai'i shows a maximum of 23.8 acres per MW for existing Hawai'i facilities. (P. 2-142) Please reconcile, and explain which figure is more accurate for future planning purposes.

Response: Although not provided in the PEIS, it may be relevant to this comment to note that the data on the 161 wind projects provided a range of area requirements that extended from slightly more than 20 acres per megawatt to almost 250 acres per megawatt. As one might expect, the data vary because wind turbine spacing can depend greatly on site-specific characteristics such as the size and configuration of the land available, uses of adjacent land, and direction and dominance of the prevailing wind. The information on the area requirements for the 161 wind farm projects was presented in Section 2.3.3.9.1 to provide a more complete picture of the type of land requirements often associated with wind farms and that could be applicable to projects in Hawai'i, depending on the nature of the wind farm project and the proposed location. That said, DOE also felt it was appropriate to consider similar information reported for wind projects within the islands, even though that information is based on a limited set of data points. Again, it is difficult to say which data set would be more appropriate for planning Hawaiian projects because the layout for wind turbines in a wind farm is so site-specific. It should be noted, however, that for the representative wind

technology project (Section 2.3.3.9.5), DOE chose to assume a land requirement more typical of existing projects in Hawai‘i.

Comment 64-17: The statement “if the three anchor points avoid high value habitats such as coral reefs and are anchored in mud sediments, the potential disturbance impact would be small and localized” is not necessarily accurate. [6.9.4.1]

Response: Text in Section 6.9.4.1 has been modified to better characterize the potential impacts.

Comment 76-3: I think wind and solar for sure, and if we can get involved with ocean thermal and all of that would be great.

Response: The comment is noted as is the support for implementation of renewable energy technologies.

Comment 106-2: And I would like to just give a very short description. For instance, you start out with 200 megawatts of name plate capacity on a wind project in Maui that you're trying to get to O‘ahu. First off, your actual capacity factor is about 24 percent in Hawai‘i. That takes you down to 48 megawatts. I just scribbled this right now on the back of my pad here -- by the time you're done by the time you take in the transmission loss, the curtailment by HECO of power coming from this wind project on Maui or wherever that they can't use for curtailment, by the time you consider the cost of the fuel for the spinning reserve that you have to run constantly because wind is so erratic and going up and down, you need to have a constant back-up of fossil fuel generation. Then, when you add in the purchases by wind projects when they are forced to keep their rotors turning, you have to buy electricity to do so when the wind is uncooperative. That's just a few of the many disasters associated with a wind project.

And I'll give you an example. In California, hundreds of thousands of acres of California are covered by wind projects. They slaughter birds and bats by the millions. There's 13,000 wind turbines in California. They can be replaced by one single gas-fired combined-cycle power plant on about 45 acres; 555 megawatts would replace hundreds of thousands of acres of bird cuisinarts, which is what the renewable energy people call wind mills.

Response: This comment correctly notes that there are inefficiencies associated with the operation of wind turbines and in the transmission of electricity; wind turbines typically do not operate year-round at their full rated capacity and there are energy losses, typically in the form of heat. However, some of the numbers cited in the comment are not consistent with those identified by DOE in the PEIS. As the primary example, data described

in Section 2.3.3.9.1 show the capacity factor for wind turbines installed between 2004 through 2010 in the United States ranged from 30 to 35 percent, compared with the 24 percent cited by the commenter. Further, the PEIS describes capacity factors reported for wind farms in Hawai‘i as ranging from 45 to 65 percent (per 2013 data). The commenter further states that a single gas-fired, combined-cycle power plant, producing 555 megawatts, could replace all of the wind turbines in California. The National Renewable Energy Laboratory’s *Renewable Electricity Futures Report* states that the current installed wind power capacity for California, as of September 30, 2014, was 5,832 megawatts (see http://apps2.eere.energy.gov/wind/windexchange/wind_installed_capacity.asp for data updates). So even if the California wind turbines have an average capacity factor of 24 percent, a single 555 megawatt power plant would not duplicate their output. More significantly, the gas-fired power plant would not provide the same benefits (i.e., reduction of imported fossil fuels and greenhouse gas emissions) as a renewable energy source. With regard to the comments about bird fatalities, Sections 6.8.4 and 6.9.4 discuss the potential impacts on wildlife and possible mitigation strategies. It is also important to note that under State law (HRS 195D), all new wind farms in Hawai‘i that “take” or harm protected (avian) species are required to develop and implement a Habitat Conservation Plan for the lifetime of the project to mitigate impacts to protected (avian) species and their habitats.

Comment 118-2: For wind, it uses a representative 25 megawatt facility consisting of 10 2.5 megawatt wind turbines. So, a 400 megawatt project on Lāna‘i would be 16 times larger than the representative facility. The assumption in the study is that the larger project here would simply involve more turbines, take up more land, take longer to build, etc. I don't think it's that simple.

Response: DOE developed the PEIS to provide a broad perspective of the potential environmental impacts for the various renewable energy technologies that could be employed to achieve the HCEI goals. It does not evaluate specific scenarios or proposals and is not meant to characterize all potential scales of implementation of individual or groups of technologies. The information provided in the PEIS could be used to guide future environmental analyses of specific projects. The analysis of impacts in some resource areas are more appropriate for scaling from the representative projects than others. These data are provided to give a perspective; not to provide the exact impacts for any specific project size.

The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a

project-specific environmental review subject to Federal and State environmental laws and regulations.

Comment 118-4: The PEIS states a foundation for one 2.5 megawatt turbine could require 450 cubic yards of concrete. How large a hole does that one turbine require? How much dirt will that displace if it's going to accommodate the turbine tower and 450 cubic yards of concrete? Then multiply that by 160. The chart says the impact on Geology and Soils is "general construction impacts from land disturbance/ soil erosion."

Response: The 450 cubic yards of concrete identified in the PEIS for a wind turbine foundation is a typical value based on data collected from several sources. For an actual wind farm project in Hawai'i, the amount of concrete and size of the associated hole required would depend on the site-specific characteristics and the site-specific design of the wind turbine foundation. However, for illustration purposes, the base of a 360-foot-tall wind turbine tower (as assumed for the PEIS' representative project) would likely be about 15 feet in diameter at the base. If it is assumed the foundation extended out about 10 feet in all directions from the tower (i.e., a foundation diameter of 35 feet), a foundation depth of about 13 feet would be required to accommodate 450 cubic yards of concrete. It is expected that much of the excavated materials would be used as fill material within the project site for work such as leveling ground or building access roads, but the material could also be sent offsite for use as fill material in other locations.

Comment 118-5: The impact on land use says "Potential Land Use Impacts including Land Disturbance During site preparation and turbine insulation." That's the problem with the PEIS - everything is so down played. How can even a 10-wind turbine facility have only a potential land use impact.

Response: Use of the word "potential" to describe land use impacts is not an attempt to downplay the concern; rather, the terminology is commonly used in environmental evaluations, such as a PEIS, that estimate what future impacts could be before a decision has been made to proceed with a Federal action.

Comment 119-1: I went to all this hoop-la in Honolulu. I was one of the delegates of the Puho when the Akamai Advisory Council. [*transcriber*: not sure of the Hawaiian spelling] I was nominated by the governor to represent the Akamai Advisement Council. Okay, now it's come about the wind mill. We have, on this island, we have 13 Akumawahu. [*transcriber*: not sure of the Hawaiian spelling] We have two moku, the Kūhalono and the Puna. Now, you want to put in 170 wind mills on the Akapoi on the Kaaha area. [*transcriber*: not sure of the Hawaiian spellings] We are against them.

Why? Because they would bring the cable from Lānaʻi, Molokaʻi and Maui to ship to Honolulu under the ocean. And it's going to ruin the coral.

Response:

Potential impacts from wind turbines, whether distributed, utility-scale land-based, or utility-scale offshore, are addressed in Sections 5.5, 6.8, and 6.9, respectively. With respect to utility-scale land-based wind turbines, DOE has addressed these types of concerns in resources areas such as land use, cultural and historic resources, scenic and visual resources, recreation resources, and others. These are difficult questions to evaluate because they are generally heart-felt, personal concerns pertaining to an individual's quality of life and expectations with regard to that quality. A goal of the environmental assessment process, however, is to at least identify such concerns so they can be considered in the decision-making process.

The potential for impacts to corals is an identified concern for an undersea cable, as well as other marine technologies, and is addressed in multiple locations in the PEIS. Section 2.3.5.2.4 identifies avoiding coral reefs as one of the associated challenges of laying undersea cable. The representative project for the undersea cable technology would use horizontal directional drilling, or a similar approach, to install cables beneath sensitive nearshore coral zones.

Comment 121-3:

It's split the community right in half. It was deplorable. You folks come here, you didn't see that. David Murdoch split the whole community in half, four wind mills, and that was only because they bribed somebody here before. So I'll end with that. I'm a happy guy. Have a wonderful day. But I'm very strong on this. It's had a real impact on me. I don't want it and I will do anything I have to do that it doesn't exist. Thank you for your time. Thank you for your visit.

Response:

This comment describes a strong opposition to wind turbines particularly as a result of a specific set of existing land-based turbines. With respect to how the PEIS handled impacts from utility-scale land-based wind turbines, DOE addressed these types of concerns in resources areas such as land use, cultural and historic resources, scenic and visual resources, recreation resources, and others (see Section 6.8). These sections of the document also describe best management practices that could minimize adverse impacts. This document, however, cannot be expected to change actions already undertaken.

Comment 124-2:

Windmills are a disaster waiting to happen. The DOE can place a 75 feet windmill adjacent to it's main headquarters and regional offices and next to the schools and subdivision in the neighboring community. We could experiment on how much savings the government and communities could reap. Of course these windmills would have to be fully functional with a shelf life of 50 years. After 50 years of experimentation in your

workplace and communities

then the DOE can decide was it worth it. I do not think for a second the clogging up of growing communities masterplan by placing windmills within 100 miles of any kind of development including agricultural lacks the vision of growing communities, many by leaps and bounds.

Response: Potential impacts from wind turbines, whether distributed, utility-scale land-based, or utility-scale offshore, are addressed in Sections 5.5, 6.8, and 6.9, respectively. With respect to utility-scale land-based wind turbines, DOE has addressed these types of concerns in resources areas such as land use, cultural and historic resources, scenic and visual resources, recreation resources, and others. These are difficult questions to evaluate because they are generally heart-felt, personal concerns pertaining to an individual's quality of life and expectations with regard to that quality. A goal of the environmental assessment process, however, is to at least identify such concerns so they can be considered in the decision-making process.

9.3.4 ENVIRONMENTAL RESOURCE

9.3.4.1 Airspace Management

Comment 54-1: Proposed projects should take into consideration the impacts to air navigation and ensure that it is not an obstruction or hazards to aircraft.

Response: Section 3.11 discusses airspace management from the perspective of commercial airport systems and military airbase operations. In particular to this comment, Section 3.11.1.1 addresses requirements regarding potential obstructions to air navigation, Section 3.11.4 provides best management practices, one of which states that developers of potential energy projects should coordinate and comply with the Federal Aviation Administration's Obstruction and Evaluation process early in the project development process, particularly if projects involve tall structures, reflective surfaces, are near airfields, and may involve State or other Federal agencies. Chapters 4 through 8 address the potential environmental impacts to air navigation for the analyzed energy technologies and activities.

Comment 54-2: Photovoltaic (PV) systems can create a hazardous condition for a pilot due to possible glint and glare reflected from the PV array. All PV projects must agree to the following condition: If glint or glare from the PV array creates a hazardous condition for pilots, the company must be prepared to immediately mitigate the hazard, upon notification by the Department of Transportation, Airports Division (DOT-A) or the Federal Aviation Administration (FAA).

Response: Section 6.6.11.2 identifies a best management practice that states the project proponents should coordinate with the Federal Aviation Administration and the Hawai'i Department of Transportation-Airports Division during the siting process to minimize potential impacts. In addition, PV cells are especially designed to maximize solar absorption, thus reducing glare and glint (<http://energy.gov/eere/energybasics/articles/photovoltaic-cell-conversion-efficiency-basics>).

9.3.4.2 Biological Resources

Comment 64-3: Address effects of the higher level of nutrients inherently present in cooler water brought up from depth in evaluating where to discharge the return water. Not only temperature needs to be considered in locating an appropriate discharge point of the return water to match the ambient, also nutrient levels. Higher levels of nutrient discharge in shallow areas at a high volume/minute can, for example, trigger algal blooms and change community dynamics. [2.3.1.5, 4.2]

In BMP bullet 3, add that sensitive EFH should be avoided. Add a new BMP that the discharge/effluent point should be located to match the environmental conditions of the ambient environment (similar temperature, nutrient level, etc.). [4.2.4.2]

Response: Section 4.2.3.1.1 addresses impacts to nutrient levels and the potential for unusual algal blooms, and Section 4.2.4.1 addresses the potential impact on marine productivity. Text has been added to more specifically address algal blooms, and two new BMPs were added to Section 4.2.4.2 to consider sensitive essential fish habitat (EFH) and recommend matching the discharge/effluent point to the surrounding environment.

Comment 64-4: An EFH consultation will be required for this type of action; the earlier the conversation starts the better. [2.3.3.5.3, 2.3.3.6.3, 2.3.3.10.3, 2.3.5.2.3]

Response: Section 2.3.3.5.3 includes the following statement regarding permitting, "The developers also would consult with the USFWS and the NOAA NMFS on projects impacting protected species, critical habitat, and essential fish habitat."

In response to the comment, a similar statement will be added to ocean thermal energy conversion (Section 2.3.3.6.3), offshore wind power (Section 2.3.3.10.3), and undersea cables (Section 2.3.5.2.3) discussions to reflect the general EFH consultation requirements for energy development in marine environments. A statement also will be added in Section 2.2.5.1 to define the general consultation requirement for EFH

under Section 305(b) of the *Magnuson-Stevens Fishery Conservation and Management Act*.

Comment 64-5: The section may give the impression that seagrass is uncommon, hence not a resource of concern for project proponents. Seagrass BEDS per se may not be common, however seagrass in varying densities is present across the islands in the shallow sediment bottom areas hence need to be taken into account as a resource that can be impacted by in-water activities. [3.4.2.1.6]

Response: Section 3.4.2.1.6 was modified to clarify that seagrass is abundant in the area of concern.

Comment 64-6: Cite source for depth estimate of benthic community, can likely extend deeper. [3.4.2.1.7]

Response: The citation was provided in the opening paragraph of the section in question: Maragos (1998) (Atlas of Hawai‘i, Marine Ecosystems). The text acknowledges that the depth of this zone can extend deeper than “...160 feet or more within the euphotic zone of the ocean.” Various authors use different classification systems and therefore depths.

Comment 64-7: Cite source for information stated; it is unclear if this information has been crafted specific to Hawai‘i’s resources or whether these are generic terms. Often times, mesophotic reefs or deep sea sponge habitats are the used terms in Hawai‘i and the Pacific Islands for these deeper resources. [3.4.2.1.8, 3.4.2.1.9, 3.4.2.1.10, 3.4.2.1.11]

Response: The citation was provided in the opening paragraph of the sections in question: Maragos (1998) (Atlas of Hawai‘i, Marine Ecosystems). Dr. Maragos presented a classification and description of Hawai‘i’s marine ecosystems. The PEIS acknowledges that other terms and classification schemes could be used, but Dr. Maragos’ information was used because the information was readily available, easy to understand, and applicable to the entire affected area.

Comment 64-8: There are actually 5, not 4 as stated, Management Unit Species (MUS) groups that are managed by NMFS: bottomfish, coral reef ecosystem, precious corals, crustaceans and importantly pelagics. Correct “coral reef fisheries” to state “coral reef ecosystem” MUS. [3.4.2.4, 3.4.3.4]

EFH has been designated for 5, not 4 as stated, Management Unit Species (MUS) groups that are managed by NMFS: bottomfish, coral reef ecosystem, precious corals, crustaceans and pelagics. These designations are found not only in the Fishery Ecosystem Plan for the Hawai‘i Archipelago, but also in the Pelagic Fishery Ecosystem Plan (for Pelagics). Include description of EFH for Pelagics. Correct “coral reef fisheries” to state “coral reef ecosystem” MUS. State that coral reef

ecosystem EFH is all bottom down to 100m depth” rather than 300 feet. Suggest providing a summary table of all EFH designation depth boundaries (can copy and paste from Fishery ecosystem plan).

Response: Section 3.4.2.4 has been updated to include the fifth management unit species, Pelagic Fisheries, which was inadvertently omitted. The other text changes were made as suggested. A summary table of EFH designations was not added. The PEIS directs the reader to the specific fisheries management plan for more details.

Comment 64-10: The release of water warmed by running it through a hydroelectric plant into the marine environment will be a hazard for corals in the area/ Outflow needs to be in an area that has no coral cover. Suggest adding language that addresses this to the appropriate section. [5.2.3.1.1]

Response: The releases of potentially warmed water as discussed in Section 5.2.3.1.1 would occur in freshwater streams and would be diluted by stream flow and ocean water before reaching areas of coral. If specific projects were identified in the future that had the potential for releasing warmed water into the marine environment, additional consultation and analysis would be required for that specific installation.

Comment 64-13: Language states that alteration of the environment could impact EFH. Alteration of the environment is an impact to EFH. Language should reflect the certainty of the impact to EFH. [6.4.4.1]

Response: Section 6.4.4.1 has been modified to reflect the certainty of impacts to EFH from alteration of the environment.

Comment 64-21: An increase in offshore facilities for the storage or import of LNG and LPG is referred to as not impacting biological resources. Any new offshore construction would result in loss of EFH, the extent would depend on location and the type of facility put in place. Language should reflect the potential loss. [7.5.4.1]

Response: The statement in the section actually states that upgrading and expanding onshore infrastructure would not impact biological resources as they would likely occur in previously developed areas. The section acknowledges that some localized disturbance to marine communities would occur during construction of offshore facilities. Language has been added to Section 7.5.4.1 to indicate that offshore development could result in loss of EFH.

Comment 64-22: Many more BMPs will be recommended on a project specific basis for the installation of undersea cables to protect EFH including: scheduling construction outside of coral spawning periods, relocate corals found in the cable path and monitor over time, locate HDD breakout points at locations that would minimize the impact on coral resources, develop a

maintenance and replacement plan that considers impacts to EFH. [8.2.1.2]

Response: Comment noted. All representative type projects discussed in the PEIS would be subject to project-specific environmental reviews if actual projects were proposed. Section 8.2.4.2 was modified to include this sampling of potential BMPs for specific projects.

Comment 64-23: Impacts to seafloor would also involve impacts to EFH in areas where the cable is shallower than 400m depth, and/or traversing other designated EFH such as precious corals beds. [8.2.4.1]

Response: Section 8.2.4.1 has been revised to include potential impacts to EFH in deeper waters. The section acknowledges potential impacts to deepwater corals.

Comment 64-24: Add in BMP bullet # that consultation should occur with NMFS Pacific Islands Regional Office also regarding impacts to Essential Fish Habitat. [8.2.4.2]

Response: Consultation on impacts to EFH is not considered a BMP; it is a regulatory requirement. This has been clarified in Section 2.1.1 and 2.7. It should be noted that EFH consultations can be combined with other environmental reviews, such as NEPA, Clean Water Act, or Fish and Wildlife Coordination Act.

Comment 107-7: It's very easy to be cavalier about daily life underwater. I am one of few individuals who has had an opportunity to live and work underwater. After ten days living in an underwater habitat and spending many hours in the water, I came to realize that the undersea world is complex and fragile, and that the Hawaiian concept that the ocean is a mirror image of the land is correct. Let's not go backwards on marine resource protection as this document can be interpreted to suggest.

Response: The PEIS recognizes the importance of the marine environment and analyzes potential impacts that could occur from renewable energy technologies and activities accordingly. The PEIS also assesses potential impacts to the marine environment from actions taken on land. The programmatic nature of the PEIS does not allow for a detailed analysis or presentation. Any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

Comment 122-11: 3.4.1.3.3 Freshwater Aquatic Species Pg 3-121

In the Hawai'i Clean Energy Draft Programmatic Environmental Impact Statement Summary (DOE/EIS-0459), April 2014, in reference to

Freshwater Section is 3.4.1.3.3 Pg 3-121 and the Estuaries Section is 3.4.2.1.3 Pg 3-125 see below:

Freshwater aquatic species, watershed and stream ranking and characteristics data should be updated with more recent references:

Parham, J. E. et al, Atlas of Hawaiian Watersheds & Their Aquatic Resources, Bishop Museum & Division of Aquatic Resources, April 2008. <http://www.hawaiiwatershedatlas.com/>

Response: DOE has reviewed the suggested reference and added information to the PEIS as appropriate. However, the atlas contains considerable detail on watersheds and aquatic systems and is much more extensive and detailed than what is appropriate for a PEIS. The *Atlas of Hawaiian Watersheds & Their Aquatic Resources* has been added as a reference to the PEIS.

Comment 122-12: 3.4.2.1.3 Estuaries Pg 3-125

This is a generic description of estuaries with no details provided specific to Hawaiian estuaries or the species that utilize these estuaries. Refer to: Juvik and Juvik (eds). Atlas of Hawai‘i. University of Hawai‘i Press. 3rd Edition.

Response: The general description was taken from Juvik and Juvik (eds). Atlas of Hawai‘i. University of Hawai‘i Press. 3rd Edition. The text in question has been modified to include a description specific to Hawai‘i and to include a discussion of the general species groups that live in estuaries.

Comment 122-13: 3.4.2.1.6 Seagrasses

There are 3 species of seagrasses native to Hawai‘i. The report is missing *Halophila decipiens*, which occurs in lower light conditions relative to other two species. Light attenuation is related to water depth and/or turbidity. *Halophila decipiens* is found in harbors (turbidity) and deepwater (>15 m) and is the most widely distributed seagrass in Hawai‘i, forming extensive meadows in deep-water. There is an endemic snail that is dependent on both *Halophila* species. Missing from this report entirely are the extensive *Halimeda kanaloana* meadows found in Maui nui. This macroalga is an endemic species that roots in sediment. Turtles consume this species. It is also an important fish habitat.

Response: The PEIS has been updated to include DLNR’s input and clarification. Maragos (1998) Atlas of Hawai‘i only included the one endemic seagrass species; the PEIS has been updated to include the second species of seagrass (*Halophila decipiens*) reported in the scientific literature in 2002 (McDermid et al. 2002). Discussion of the macroalgae (*Halimeda kanaloana*) meadows in the shallow benthic communities and offshore deep reefs has also been added. Because it grows in much the same form

as seagrasses, the section title has been changed to “Seagrasses and Macroalgae”.

Comment 125-3: The report indicates only “short-term impacts” to whales if the proposed cable runs through the Humpback Whale Sanctuary. That is ridiculous. The impacts of a thirty-year cable are not short term. And little reference is made to the critical issues of maintenance and repair for the cable. It would be easy to promise no laying of the cable during whale season. Can the same restriction apply to repairs, should the cable need them during whale season?

Response: Based on studies conducted on existing undersea power cables around the world (Normandeau et al. 2011; see <http://www.boem.gov/Environmental-Stewardship/Environmental-Studies/Pacific-Region/Studies/2011-09-EMF-Effects.aspx>), impacts to whales are not anticipated once a cable is laid. Any effects of electromagnetic fields are expected to be localized near the cable or completely attenuated if buried. While there could be impacts if repairs are required, such impacts would be relatively short-term and confined to the time required to complete repairs. Section 8.2 has been revised to reflect potential impacts from maintenance activities.

The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. That is, any decision by DOE or other Federal agency to provide funding to a particular project would be preceded by a project-specific environmental review subject to Federal and State laws and regulations.

Comment 135-2: Recently I was talking to an older surfer from the Pooiki surfing area (the plant is on Pooiki Rd.). He commented that the bay was full of turtles for decades. Now there are none. I am concerned that this is due to contamination from the wells into the ocean.

Response: As a programmatic EIS, the PEIS does not discuss the impacts from any specific facilities in Hawai‘i. Potential contaminants associated with the various technologies are included in the impacts analysis for water resources. Sea turtles as an endangered species and the impacts of utility-scale projects on turtle populations are discussed throughout the PEIS (see Section 3.4.3.2.1 and Tables S-8, S-9a, and S-9b). Any future site-specific renewable energy projects must adhere to Federal, State and local regulatory processes and requirements, including those involving threatened and endangered species and marine mammals.

9.3.4.3 Climate and Air Quality

Comments 64-18: Describe using crops for biofuels being carbon neutral. If land is being converted from some other use to crops for biofuel (especially thousands of acres), I don't think it's correct to call it carbon neutral. [7.1.2.1.2]

Response: The commenter is correct that the cultivation of feedstock crops and conversion to biofuels would have a carbon imprint; however, the degree of impact would be heavily dependent on the specifics of a given project, such as crop type and harvest/refinery techniques. The section states that the GHG reduction is based on the "concept" that burning biofuels would be carbon neutral. The section (and also in Section 5.1.2.1.2) clearly states that the premise of carbon neutrality is an unsettled issue. It is more fully discussed in Section 5.1.2.1.2. Land that is producing biomass takes up carbon from the atmosphere thereby reducing GHGs but then is returned upon combustion (i.e., no net change if production equals or exceeds harvest). Oil combustion always adds GHG emissions. Therefore, the PEIS assumes that if biomass replaces oil, there would be a reduction in GHGs. The reference to Section 5.1.2.1 in this Section has been changed to 5.1.2.1.2, which is the specific section with referenced discussion.

Comment 65-12: Access the data available at EPA's GHG Reporting Program to retrieve GHG emission data from 2012. See <http://ghgdata.epa.gov/ghgp/main.do>.

Response: The PEIS uses a study prepared by ICF International study in 2008, under the commission of DBEDT, that reported GHG emissions for each Hawaiian island for the year 2007 and provided relative points of comparison for presenting carbon dioxide equivalent statistics for the state. The data and relative points of comparison are considered useful for the programmatic level of analysis in the climate and air quality sections of the PEIS. EPA's GHG Reporting Program for more recent years does not sort the data in a consistent manner as the ICF study and is not an equivalent comparison between years because different reporting parameters and source categories have been added since 2011. It is noted, however, that GHG emissions continue to decline across the state of Hawai'i. Section 3.2.3.3 has been updated to include a description of EPA's GHG Reporting Program and a statement that GHG emissions have been declining through 2013.

Comment 65-13: Consider EPA's proposed Clean Power Plan in the Final PEIS and, if known, discuss state actions that are consistent with the Plan.

Response: Section 3.2.3.3 has been updated to include a description of EPA’s proposed Clean Power Plan and the State of Hawai‘i’s position of support regarding the program.

9.3.4.4 Cultural and Historic Resources

Summary Comment SC037 (4-1, 32-1, 34-1, 40-1, 41-1, 48-1, 66-1): Several comments advised that requirements for protection of cultural resources pursuant to Section 106 of the *National Historic Preservation Act* (NHPA) must be addressed and followed for future, site-specific renewable energy projects tiering from the PEIS.

Response: References within the PEIS to NHPA Section 106 compliance refer to the requirement for applicable, site-specific renewable energy projects on any of the islands to evaluate and adhere to the regulations. The commenters are correct, in that any future renewable energy projects that may tier from the PEIS will have to properly comply with Section 106 requirements and evaluate any potential adverse effects to historic properties from a federal undertaking.

Summary Comment SC038 (13-1, 70-2, 70-3, 70-4, 70-5, 58-52): Some commenters suggested that the PEIS designate geographical areas that are rich in cultural resources as exclusion zones from renewable energy development. Others felt that cultural landscapes should be identified and evaluated for effects by the different renewable energy technology approaches. Some comments stated that the PEIS must reveal the specific impacts of the construction and operation of utility-scale wind projects on traditional Hawaiian access rights of cultural practitioners to use trails and roads and other culturally significant sites and to conduct gathering activities and religious practices.

Response: While utility-scale energy project exclusion zones for rich cultural resources may address some issues, the general programmatic nature of this EIS, lack of detailed data on such cultural resources, as well as confidentiality of resource locations make identification of exclusion zones inappropriate for the scope of the document. The PEIS is meant to be used as a reference document when project- and location-specific EISs for renewable energy projects are prepared, calling out impacts to be considered, such as impacts to site access and visual corridors for cultural uses. The programmatic scope of the PEIS does not allow for identification and impact evaluation of all known cultural resources on any of the Hawaiian islands; rather, it identifies known examples of cultural resources and practices on the six Hawaiian islands with electrical infrastructure so the reader (e.g., the public, government agencies, and developers) may have an appreciation and context for potential impacts from renewable energy efforts that could be considered.

As presented in Section 3.6.3, to a large extent, an overwhelming majority of cultural resources and practices are integral components of

cultural landscapes within a geographical area that also includes wildlife and other natural resources. Therefore, identification of specific cultural landscapes would require comprehensive cultural evaluations, which is beyond the scope of the PEIS. Any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review, including detailed evaluations of cultural resources.

Access to locations for traditional and customary practices could be impacted by several renewable energy technologies and activities, not just utility-scale wind projects. The types and magnitudes of access impacts would be highly dependent on the siting location for a particular project. Any potential impacts would be evaluated in a site-specific analysis. For the purposes of the PEIS, the analysis of cultural resource impacts was limited to common construction and operation impacts. See Section 3.6.6 for this information.

The Office of Hawaiian Affairs' (OHA's) Papakilo database consists of varied collections of data pertaining to historically and culturally significant places, events, and documents in Hawai'i's history. This online repository of data will greatly increase OHA's ability to preserve and perpetuate cultural and historical information and practices, thus providing an invaluable resource to educate other regulatory agencies, OHA's Native Hawaiian beneficiaries, and the general public. See <http://www.papakilodatabase.com/main/main.php>.

Comment 52-2: [Chapter 3] list of best management practices should include survey and inventory of project areas. Identification of cultural and historic resources within the project area facilitates the avoidance, minimization, or mitigation of impacts to the resources, as well as clarifies and streamlines consultation and review processes.

Response: Section 3.6.7 was updated to include a BMP addressing project site survey and inventory.

Comment 52-3: Installation of solar water heaters in section 4.3.6 should also include [Section 4.1.6 best management practice: applying Secretary of Interior's Standards for the Treatment of Historic Properties] in best management practices. Additionally, it should be noted that following the Secretary of Interior's Standards for the Rehabilitation of Historic Properties allows for change such as energy retrofits and installation of water heaters and photovoltaic panels while ensuring retention of historic characteristics.

Response: Section 4.1.6.2 was updated to include the benefit of complying with the Secretary of the Interior guidance, and Section 4.3.6.2 was updated to include a bullet with the same text.

Comment 56-2: OHA respectfully requests that more ardent language be added in the “CULTURAL AND HISTORIC RESOURCES” - “Potential Impacts” - “Best Management Practices and Mitigation Measures” sections for each and every technology listed. For instance, Draft PEIS “Section 3.6.7” is merely referenced under all the technologies where that section specifically reads: “Avoidance of impacts is the primary objective; however, when avoidance is not possible or practicable, then BMPs and/or mitigation would be applied.” In other words, this important “Avoidance” admonition is only mentioned once among the entire 1,350 pages of the Draft PEIS.

Whereas, on the other hand, the Draft PEIS repeats language (in every section describing a technology) that belies the role of avoidance of impacts in historic preservation review, and merely counsels: “...to minimize impacts to cultural and historic resources...” or “...to reduce potential impacts to cultural, historic, and related resources...” OHA asserts that a statement about “avoidance of impacts” should be expressed also as a possible outcome under the appropriate Section X.X.6.2 for every technology discussed. Such ardent language is material and relevant for balancing the goals of the Aloha+ Challenge and for providing clarity. OHA applauds this Draft PEIS for helping guide Hawai'i to a secure and sustainable future.

Response: While DOE respects OHA's position and subject matter expertise, the PEIS was purposefully designed to reduce repetitive language. While every effort was made to this end, as the commenter points out, there are still sections of redundancy in the document. Rather than repeat “avoidance of impacts” as a primary objective in all technology description and impact analysis sections, the reader is referred to the cultural resources-related common impacts and best management practice (BMP) discussions in Sections 3.6.6 and 3.6.7, respectively. The way the PEIS is constructed, sections in Chapters 4 through 8 (potential impacts) refer back to the appropriate section in Chapter 3 (affected environment) unless there are unique impacts associated with a particular technology. In the case of cultural and historic resources, the types of impacts and BMPs are site-specific and follow a process; they are not unique to the technology.

An assessment of the specific impacts (and description of pertinent BMPs) associated with any future, proposed project to cultural and historic resources would be included in that project's environmental review documents (environmental impact statement or environmental assessment).

Comment 70-6: The draft EIS recognizes that a utility-scale wind project will impact access in its analysis of recreation impacts. See page 3-229, Section 3.9.4 (“In addition, access restrictions to recreation areas may occur if

construction is located near the recreation areas"). A similar assessment must be done in the cultural impact section of the final EIS.

Response: Section 3.6.6 includes the requested text. Specifically, the section reads, "Also, access by Native Hawaiians to traditional and customary cultural and natural resources for gathering rights, including religious practices, during construction can be limited or disallowed when areas are closed for safety reasons." An assessment of the specific impacts of a proposed project to cultural practices, including access, must be done in any project-specific environmental review documents (environmental impact statement or environmental assessment).

Comment 102-1: One of the things that -- I just came here to get information and see what you all were actually up to and basically my feeling is when I look at the whole plan of using alternative energy in Hawai'i and what's gone -- I've been here ten years and I've seen the windmills go up and I'm sure to the dismay of maybe the Hawaiian people. That's where I have a concern there, when you look at the cultural practice and whether you're -- the state of Hawai'i is really cognizant of the feelings of the Hawaiian people.

Response: The State of Hawai'i takes very seriously the feelings and input of the Hawaiian people from concerns raised as residential members of the state as well as cultural sensitivities regarding traditional practices, beliefs, and locations among the islands and surrounding waters. The State's Office of Hawaiian Affairs, State Department of Land and Natural Resources, local non-government organization, civic groups, and active practitioners help ensure native peoples and their concerns are addressed. Hawai'i's energy policy directive is to balance technical, economic, environmental, and cultural considerations when assessing possible energy projects and initiatives. See Section 3.6.7.

Comment 125-4: Lastly, the report references the undersea cable as having minimal impact to cultural and historic resources. That is false. The impact to those treasures would in fact be irrevocable destruction. We saw that the proposed Big Wind cable's entry to land on Lāna'i, for example, would have run through a beach rich with historic and cultural artifacts — it would have been impossible to construct the cable's on-land infrastructure without significantly and permanently altering, if not destroying, those resources.

Response: Section 3.6.6 has been modified to specifically identify beach, nearshore, and offshore locations as further examples where impacts could occur.

9.3.4.5 Coastal Zone Management

Comment 143-1: I wanted to bring up, coastal zoning management, get involved. Coastal zoning management, I've been attending those meetings only because

after World War II the ships dumped all the ordnance off Maili Beach, and just recently, they went out, the DoD came out, took their boats out there and cleaned up 236 acres of ordnance, and there was millions and millions of acres of ordnance being dumped right off Maili Beach. So that got cleaned up and the fishermen are happy, so that's why I pay attention to coastal zoning management. Coastal zoning management is really important because of our relationship to the ocean and to thousands of years of relationship with the ocean, so that's important.

Response: The PEIS identifies coastal zone management as one of the environmental resource areas (Section 3.7) discussed and evaluated for potential impacts. The past disposal and location of Department of Defense ordnance and munitions is addressed in the discussion on submerged land use (Section 3.5.3.4).

9.3.4.6 Environmental Justice

Comment 62-2: Sections 5.4.15 and 5.4.16 of the PEIS on Photovoltaics conclude that there would be “no potential impacts” in the Socioeconomic and Environmental Justice resource areas. However, the decoupling initiative has the potential to impact specific groups that cannot afford or who are not in a position to effect the implementation of this technology (e.g., residential or commercial renters). We recognize that the PUC is currently reexamining decoupling; however, in its present form, the mechanism appears to effectively reduce the pool of utility ratepayers, thus creating increased economic distress for those who cannot afford or avail themselves of these technologies (i.e., rooftop solar). Decoupling is an issue the PEIS does not mention or analyze, but MEDB believes is fraught with socioeconomic and environmental justice impacts. MEDB encourages the inclusion of this issue as a part of the PEIS analysis of Photovoltaics.

Response: Your comment on this issue is well taken. DOE’s primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in support of the HCEI. DOE is not assessing the impacts of clean energy ratemaking policies in this PEIS. Therefore, such inclusion of potential impacts from the decoupling initiative is beyond the scope of this PEIS.

Comment 70-7: The draft EIS provides no basis whatsoever for its conclusion that land-based utility scale wind would have "small" environmental justice impacts. See Page 6-142. This cursory conclusion has no support in the draft's description of the "affected environment." See Page 3-301 through 3-302. There are no facts at all to support the draft EIS' faulty analysis of

the environmental justice impacts of a utility-scale land-based wind project. See page 6-154 at section 6.8.16.

The draft EIS states that under state and federal law, an environmental justice analysis must be done for many reasons, including this one: "Cultural traditions suggests that many locations could host populations dependent on subsistence hunting and fishing." See Page 3-302 (citing HI Act 294). The draft EIS, however, does not identify areas like Lānaʻi and Molokaʻi as locations where populations are dependent on subsistence hunting and fishing. In fact, there is no information about any such locations in the state.

The final EIS should identify the environmental justice impacts of utility-scale wind projects proposed for Lānaʻi and Molokaʻi that are designed to benefit urban Honolulu. The final EIS should evaluate how supporting such projects would disproportionately impact the ability of Native Hawaiian communities on these islands to perpetuate their constitutionally protected subsistence, religious, and cultural practices.

The draft EIS does not recognize the impact on Native Hawaiian sacred sites like burials as an environmental justice issue. The final EIS should also evaluate and study the impact of these projects on Native Hawaiian burial sites as part of the environmental justice analysis.

Response:

The statement that environmental justice impacts are expected to be small has been removed from the environmental justice discussion in Sections 3.16.1 and 6.8.16.1. Additional text has been added that states that there may be a higher potential for environmental justice impacts due to the larger-scale aspect of land-based wind energy projects and the possibility of being located in rural areas considered important to environmental justice populations.

The PEIS addresses Native Hawaiian populations that depend on subsistence hunting and fishing practices in Sections 3.6.2, 3.6.4, and 3.6.7 and the applicable impacts sections in Chapters 4 through 8. Section 3.6.2 has been modified to address additional subsistence-based community information and to identify the Aha Moku Councils on each Hawaiian island as being useful resources in identifying subsistence-based communities and issues as they relate to potential renewable energy projects in Hawaii. In addition, general statements acknowledging that cultural traditions and practices may be evaluated as environmental justice concerns were added to the common construction and operation impacts discussions for cultural and historic resources and environmental justice (Sections 3.6.6 and 3.16.1, respectively).

DOE recognizes communities on Lānaʻi, Molokaʻi, and other Hawaiian islands depend on subsistence hunting and gathering; however, these

communities are not specifically identified in the PEIS. The PEIS does not address specific renewable energy technology and activity projects proposed for Lāna‘i, Molokai, or any specific location; such discussion is beyond the scope of the PEIS. Any future site-specific renewable energy projects must adhere to Federal, State and local regulatory processes and requirements, including those related to environmental justice issues. This would include identifying and consulting with subsistence-living communities potentially impacted by the individual project being proposed in order to fully understand the potential impacts of a given project.

The environmental justice discussion in Section 3.16 has been modified to include a general statement that environmental justice analyses can include Native Hawaiian cultural resources, beliefs, and practices and to include a reference to the cultural resources section for more detail.

Comment 111-6: I also noticed that -- and I have to admit I got a little offended by it, okay -- which was the area of the impact on social, economics, and how the impact wasn't that big because it was a minority or it impacted -- there was the minority of individuals in low-income situations. That was offensive because Molokai, that's the majority of the people that live here, that will be impacted.

Response: Any statements made relating to minimal socioeconomic impacts due to an area having a minority or low-income peoples were not intended to discount the magnitude or severity of these impacts. The PEIS does not address specific renewable energy technology and activity projects proposed for Lāna‘i, Molokai, or any specific location. The PEIS presents an independent assessment of the potential environmental impacts of the renewable energy technologies listed in Chapter 2 by analyzing “representative projects,” which generically characterize a project that could be implemented in the state of Hawai‘i. Any future site-specific renewable energy projects must adhere to Federal, State and local regulatory processes and requirements, including those that require proponents to address environmental justice issues and socioeconomic impacts on minority and low-income communities.

Comment 138-3: One should also consider the environmental justice of generating power with all its waste, noise, hazards, and environmental degradation on outlying islands for the purpose of sending power to O‘ahu. There would be no justice in this

Response: The analysis of environmental justice in this PEIS is based on Executive Order 12898, *Federal Action to Address Environmental Justice in Minority Populations and Low-Income Populations* and State of Hawaii Act 294. Accordingly, this PEIS identifies and addresses 31 activities and technologies and the potential for disproportionately high and adverse

human health or environmental effects of 14 environmental resource areas, including waste management, noise, hazardous materials, and the many areas concerning the ocean environment, on minority populations and low-income populations. The commenter's assertion that environmental justice impacts exist as a result of generating power on outlying islands for the purpose of sending power to O'ahu would need to be evaluated if such a proposal were presented. This PEIS does not consider specific proposals.

9.3.4.7 Hazardous Materials and Waste Management

Comment 64-20 There may be an increase in the storage of hazardous substances close to the coast in order to ease transport off island or temporary storage for those brought on island. Competent response plans need to be in place to deal with any spills or leaks that could impact the marine environment. [Comment cited 7.14.1.1; section does not exist]

Response: Section 7.1.14.1.1 of the PEIS has been revised to include additional language regarding the preparation and adherence to safety response plans in the event of a spill or emergency.

Comment 122-7 2.3.1.1.4 Representative Project Pg 2-34

Table 2-5. Projected Energy Savings with the Representative Project

General comment. There should be somewhere in this document that addresses how/where to dispose of the LED light bulbs that are being proposed for replacing the incandescent bulbs. The LED bulbs are more energy efficient than the incandescent bulbs ... BUT they are toxic to the environment.

To date ... NO BODY ... NO AGENCY ... NO ORGANIZATION ... NO BUSSINESS ... is addressing disposal of the highly toxic energy efficient bulbs ... fuel cells from the HYBRID AUTOMOBILES. This is an important issue to address ... the plan encourages use of these products .. . the plan also needs to address RESPONSIBLE and safe disposal of them ... Has anyone researched this issue? Where and how is the toxic material going to be disposed? Will it be a local land fill? Will the toxic substances contaminate the water table? Will the toxic material be shipped to a mainland disposal site? Ocean dumping or shipping the material to the numerous coral atolls or islets in the Pacific CANNOT be an option. What is the cost for disposal?

There also needs to a section to address public education and outreach ... during the conversion and disposal phases.

Response: Sections 4.1.14.1.1 and 4.1.14.1.2 were modified to include additional discussion of these topics. As mentioned, special handling and disposal

requirements would be required for disposal of LED lamps at their end of life.

Comment 133-2: Clean energy is important to our communities not just to 'get off oil' but to protect ourselves from aggregated nuclear isotopes.

Response: The comment is noted.

9.3.4.8 Health and Safety

Comment 37-3: My concern today is a lack of adequate evacuation routes, inadequate water storage facilities, and inadequate road access. Prior to expanding energy interest, please consider the many lives of innocent people are at risk, and plan accordingly for their safety. Have in place proper road ways, adequate evacuation routes, and sources of water on Hawai'i Island.

Response: Individual, technology- and location-specific renewable energy projects that may be implemented in Hawai'i in the future would go through appropriate environmental review that would address health and safety impacts to populations, including available natural resources and evacuation routes should a severe accident occur.

Comment 44-1: Folks on Kaua'i, through a PUC complaint process, were able to stop KIUC from shoving smart meters down their throats without homeowner's explicit permission to install them. There are health issues to be considered in everything our utility companies are doing to expose our bodies to more and more electro-magnetic radiation without thinking about the long term consequences to our progeny.

www.stopkiuc.com

Are HECO, MECO, and HELCO going to attempt to force these so-called smart meters on everyone like KIUC tried, but failed to do? Having one of the most energy and water efficient homes in the state, I certainly don't need one or want one. I may even be off the grid sometime next year with battery backup. At the rate we are going, a lot of homeowners may elect to go off grid too because it will be cheaper, safer, more reliable, and because they are fed up with our crooked monopoly that no one dares to question, except the PUC on very rare occasions this past year, but It keeps giving it chance after chance, protecting and supporting it, in a useless effort to resuscitate it on its death bed. It is time for the PUC to pull the plug and to end its life support - decoupling, more stock sales, more rate increases, Etc. - and bury it with a tombstone epitaph - Here lies Wolf Electric Industries that dared to think of itself as a god amongst us.

Does anyone even care to include EMF issues in an EIS before blindly approving everything for the sole benefit of our crooked utility monopoly's profits, excessive dividends, and excessive executive salaries, and for the benefit of others like the CHOO CHOO people (HART, Etc.) who, like Wolf Electric Industries, worship money and power so much that they have a total disregard for the long term consequences to our island, our environment, and our children and grand children's future?

I certainly would not want to live near HECO's high voltage power lines and transformers, or ride the CHOO CHOO near them or sit at a nearby station waiting for it, and I'll bet none of you would dare live near them either, or want your children to do so, or even use the CHOO CHOO, but you let the wolf do whatever it damn well pleases because of its power over you. Shame on those of you who bow your heads and genuflect before your false god in idolatrous worship. You continue to do what is best for the wolf and its profits instead of what is best for the public for which you were elected to serve.

People are talking more and more talk about the dangers of wireless radiation, cell towers, cell phones, WiFi, smart meters...but EMFs from power lines (otherwise known as electrical transmission lines) are just, if not more, dangerous. What Do The Studies Say About EMFs From Power Lines? Powerline EMFs have been linked to:

- leukemia (especially in children) - breast cancer - brain cancer - reproductive problems and birth defects
- depression, - blood disorders, - heart disease, sleeping complaints and a host of other ailments.

Dozens of studies have found links between living near power lines and poor health:

- as far back as 1979 the Wertheimer and Leeper study found that children living near ordinary power lines had 3 times the likelihood of developing cancer....large gauge transmission lines are worse.
- the Savitz study (1980s) concluded 10-15 percent of all child cancers resulted from magnetic field exposure from powerlines.
- the Wall Street Journal reported in 1993 that the real estate resale value of homes decreased by as much as 30%, if exposed to electromagnetic fields
- according to a 2005 study published in the British Medical Journal, babies who live near high-voltage power lines are almost twice as likely as others to develop leukemia during childhood And yet despite this

evidence people are still being subjected to EMFs from power lines which are installed too close to people's homes.

What Kind of EMFs do Power Lines Create? There are two types of electromagnetic field produced by powerlines.

- an electric field is always present when the powerline is switched on. Its strength depends on the voltage.

- a magnetic field is caused by the electric current flowing in the line when people use electricity. This can vary considerably and is considered the most dangerous. Electric fields are stopped by most building materials. The real problem with power lines are the magnetic fields. Magnetic fields penetrate practically everything.

The main factor that reduces magnetic fields is distance from the source. In other words the further away you can get from these powerlines the better. But if its your home that is situated too close to a power line this is not easily resolved. Watch this video presentation by Dr. Martin Blank for a scientific explanation of magnetic fields: -

<http://www.electricsense.com/4637/emfs-from-power-lines-the-facts/#sthash.rVUNHyD6.dpuf>

Are Underground Power Lines Safer? The EMFs from underground powerlines are slightly different. The electric fields will usually be negligible because they are screened by soil, concrete, sand etc. But because underground cables tend to be buried close to the surface the magnetic fields at ground level are often very high, higher than from overhead cables because they are closer to you. But the EMFs fall off more rapidly than those from overhead wires because the cables are closer together and they cancel out each other's effects more effectively.

Response: General EMF evaluations and potential impacts are discussed under health and safety in Section 3.17 of the PEIS and in the appropriate technology sections in Chapters 6 and 8. Detailed discussion of potential impacts of a specific project would be accomplished during the review of that specific proposal.

Comment 134-5: 4. (Unaddressed issue) The electrical grid is very susceptible to distribution point terrorist attacks that could cause continuing and widespread outages. One way to address this issue is to consider different grid design. For example, using decentralized power generation would lesson [sic] the impact. Such security issues are not evaluated in the PEIS.

Response: Potential impacts from terrorist attacks associated with the electrical grid in general are beyonnd the scope of the PEIS; rather, this PEIS addresses potential environmental impacts from a wide variety of representative

renewable energy technologies and activities. Decentralized renewable power generation is discussed in a category in the PEIS (Sections 2.3.2 and Chapter 5) referred to as “distributed” renewable energy (e.g., rooftop solar or small-scale wind turbines), where the power is generated for an individual home or business.

9.3.4.9 Land and Marine Transportation

Comment 54-3: Table S-3 on Page S-16 mentioned Sea Water Air Conditioning (SWAC). There are a couple of issues regarding SWAC or any other technology that requests space within the commercial harbors.

- Any tenant improvements within the commercial harbor is subject to approval by Harbors and are evaluated on a case-by-case basis.
- Water-based facilities, whether within or outside of the commercial harbors, are subject to the US Department of the Army (DA) permit to conduct work in navigable waters.
- Other possible permits may include Conservation District Use Permit and Special Management Area/Coastal Zone Management Permit. The EIS should disclose all of the approval and permit processes necessary before construction on any improvement can begin.

Response: Section 2.3.1.5.3 has been updated to include additional information regarding development requirements for sea water air conditioning within commercial harbors. The PEIS’s purpose is to discuss potential impacts of this technology, and proponents of any specific project would be required to obtain the permits mentioned in the comment.

Comment 54-4: Table S-6 on Page S-19 mentioned a range of fuels that could be used in Hawai‘i. Harbors' Kalaeloa 2040 Master Plan and Fuel Pier Development Plan are looking at range of fuels that would be transported to the harbor, including biofuels and Liquid Hazardous Gas (LHG, and this group includes CNG/LNG/LPG as indicated below). The transfer of LHG requires special "zones of concern" imposed by various regulatory authorities, such as USCG, FERC, etc. The EIS should include a discussion of the various zones of concern because this could be a potential public safety issue. Also, LHG storage also requires large land areas to contain these zones.

Response: Section 2.3.4.5.3 discusses the permitting and guidelines for hazardous liquid gas facilities. Additional text was added to the PEIS to state that potential hazards (e.g., toxic, flammable, overpressure) to the surrounding area would have to be considered in the development and siting of such facilities. Text was also added to Section 7.5.17.1 (Health and Safety impacts) to clarify the potential hazards of handling, storing, and distributing liquid hazardous gas. Further examination of impacts

upon any particular zone would take place if specific project proposals are presented.

9.3.4.10 Land and Submerged Land Use

Summary Comment SC039 (145-4, 149-1, 151-1): Commenters expressed concern that photovoltaic systems were tying up land from other uses, particularly with respect to agricultural land.

Response: The PEIS was not developed to promote one technology, project, or site location over another. Rather the PEIS describes renewable energy technologies that could be used to achieve the HCEI goals and the potential environmental impacts associated with those technologies. Any future site-specific renewable energy projects must adhere to Federal, State, and local regulatory processes and requirements, including those related to land use.

Any future environmental review of a specific proposal will evaluate competing interests and land uses. This issue is not unique to solar PV or any other technology. The PEIS acknowledges the common land use impacts in Section 3.5.4.1: “Longer-term impacts from project operation could result in changes to land use and land ownership patterns, and could have potential compatibility issues with existing zoning and other local regulations if sited near coastal zones or other sensitive land use features.”

Comment 33-1: NPS Park land transferred to profit making HCDA solar farm insiders.

...
West O‘ahu's future park lands could become the next UNDER THE TABLE LAND DEAL if West O‘ahu citizens aren't willing to STEP UP and SPEAK OUT about this!

...
SUPPORT WEST O‘AHU PARKS in Kalaeloa-- or they will be GIVEN AWAY to developers!

Response: While the PEIS discusses the land use impacts of each clean energy technology, the prioritization of land use is outside the scope of the PEIS. DOE developed the PEIS to present the potential environmental impacts associated with energy efficiency activities and renewable energy technologies that could be used to comply with the HCEI. Other agencies participated in its development and review. The PEIS was not developed to promote one technology, project, or site location over another. Any future site-specific renewable energy projects must adhere to Federal, State and local regulatory processes and requirements, including those related to land use.

Comment 58-50: On P. 3-186 DOE lists known munitions disposal sites for O'ahu, but DOE does not list sites for Lānaʻi and Molokaʻi. See below e.g., and then correct this omission:

http://www.usace.army.mil/Portals/2/docs/Environmental/FUDS/FUDS_Inventory/FUDS_Inventory_Hawaii.pdf

Response: The PEIS has been updated to include a general statement that other submerged munition sites may exist near Lānaʻi and Molokai from past military activity. The PEIS currently contains the appropriate reference (<http://www.denix.osd.mil/mmrp/MRSI/index.cfm>) where detailed information and maps for those sites can be located.

Comment 64-9: States no impacts to submerged lands, but does not mention possible shoreline erosion (due to plan location or runoff is unclear). Increased sedimentation would be a concern and an impact to submerged lands. [5.1.5.1.2]

Response: Shoreline erosion and the potential for increased runoff is consistently addressed for geology and soils (Section 3.1.3), water resources (Section 3.3.5), and wastewater (Section 3.14.3). These common impacts also have common best management practices to prevent or minimize potential impacts. Otherwise, the potential for shoreline erosion to impact submerged land use would depend on the location of the specific project being evaluated, which would undergo a separate, site-specific environmental analysis.

Comment 64-15: Under BMPs for submerged lands the comment is None noted. The BMPs for submerged lands should be the same marine BMPs referred to in 3.4.6.2 [6.4.5.2]

Response: Best management practices for submerged land use are identified in Section 3.5.5.2. Since these BMPs are common to technologies involving potential impacts to submerged lands, they were not repeated in Section 3.4.6.2. A proper cross-reference has been added to Section 3.5.5.2.

Comment 65-4: Describe how Hawaiʻi could better use contaminated lands, landfills, mine sites, and other disturbed and degraded lands as a component of renewable energy development and the extent that these lands could be identified and prioritized to achieve the goals of the HCEI. Include a list of the above identified sites in the Final PEIS.

Response: Section 3.5.5.1 has been expanded to provide additional details on the EPA RE-Powering America Program and efforts by Hawaii to identify and redevelop formerly disturbed and contaminated sites including examples of the types of site that could be considered.

9.3.4.11 Recreation Resources

Summary Comment SC040 (120-1, 127-1): Utility-scale projects can impact hunting and fishing habitat and/or access; this can be a recreational resource impact and/or a socioeconomic impact on those families relying on hunting and fishing for food.

Response: Impacts to hunting and fishing are a potential impact of any utility-scale project, and will depend on the siting and arrangement of specific projects. This is an important consideration when planning and evaluating future projects. In this PEIS, potential access restrictions are identified for recreation resources (Section 3.9) and in the impacts discussions for each utility-scale technology (Sections 6.X.9).

9.3.4.12 Scenic and Visual Resources

Comment 58-43: In discussing "on-island transmission" you say "Proximity to cultural and scenic resources, including national parks; any NPS park units within the viewshed of the proposed solar power facility (and associated facilities and transmission corridors) should be consulted early in the planning process." (P. 2-217) Please explain why only solar is included in this statement.

Response: Section 2.3.5.1.3 has been revised to remove this specific permitting consideration. This consideration is a general consideration that applies to all technologies and is covered in Table 2-2.

9.3.4.13 Socioeconomics

Comment 45-2: The Draft Statement omitted the consumers & businesses that purchase and pays for the Electrical Power. The consumers pay for all Electrical Power costs, including research, employees pay employees benefit accounts, etc.

Response: The PEIS was developed to identify potential environmental impacts of renewable energy technologies. The costs for any power generation will ultimately be borne by the consumers (both residential and commercial). This information, coupled with the engineering and economic feasibility studies for specific projects, should improve the overall energy planning in Hawai'i.

Comment 58-51: On P. 3-299 DOE states that "Historical analysis indicates that Hawai'i energy consumers do not alter consumption habits as the price of electricity and gasoline fluctuates." This is blatantly untrue. See P. 1-2 of your own document: energy consumption decreased by 14.5% since 2008. See also PUC Docket 2012-0036, HECO's IRP Plan, which details the decrease in energy consumption.

Response: The decrease in energy consumption discussed on P. 1-2 of the Draft PEIS, is a result of increases in energy efficiency measures and use of renewable energy resources that were a part of the HCEI. The statement in Section 3.15.1.2 is supported by a DBEDT analysis (reference provided in Section 3.15.1.2).

Comment 94-1: Renewable energy brings sustainable employment along with it, and you can look this up. So if there's concerns about bringing jobs to the island, these are truly sustainable clean employment. So for those people that are interested in that too, I forgot to put that in my statement.

Response: Thank you for the comment. The PEIS addresses potential change in employment from each renewable energy technology in the socioeconomics sections in Chapters 4 through 8.

Comment 107-4: Additionally, can we claim that it is in the public interest when it would be built if it were connecting industrial-scale "renewable projects" which are subsidized by Federal grants that add to our Federal deficit? This is especially egregious here in Hawai'i where there are other alternatives described in the Draft that are more economically and more environmentally safe.

Response: The "public interest" statement in Section 2.3.5.1.2 has been removed since it is not relevant to the evaluation of potential environmental impacts.

Comment 118-6: The same down-played impacts are seen for biological resources, cultural and historical resources, scenic and visual resources and many others. And under socioeconomics, there's absolutely no mention of the impact on our high-end tourism.

Response: The PEIS recognizes the importance of the stated resource areas and analyzes potential impacts that could occur from renewable energy technologies and activities accordingly. However, a programmatic EIS analyzes impacts on a regional scale, which does not allow for a detailed analysis or presentation of any specific sites. Any decision by DOE or other Federal agency to provide funding to a specific project would be preceded by a project-specific environmental review subject to Federal and State environmental laws and regulations.

9.3.4.14 Utilities and Infrastructure

Comment 64-16: Under Utilities and Infrastructure there is no mention of the mooring and anchoring that would be required for the offshore facilities. The impacts from these components are likely to be as great (or greater) than those from running the cables for the produced electricity mentioned. [6.4.13]

Response: Anchoring/mooring would be considered a part of the overall technology deployment, and the impacts are covered under all sections without separate distinction; the utilities and infrastructure section is instead related to a technology's impacts to utilities and infrastructure, themselves. For instance, the discussion on impacts from marine hydrokinetic technologies addresses potential impacts to subsurface geology from anchoring (Section 6.4.1), potential impacts to biological resources from anchoring (Section 6.4.4), potential noise and vibration impacts from mooring lines (Section 6.4.12), and the potential impacts to marine vessels from the loss of mooring stabilization (Section 6.4.17).

9.3.4.15 Water Resources

Comment 58-49: From Section 3.3.1 Water Use, the following statements appear: "Three-quarters of the State's water usage is for thermoelectric purposes. The thermoelectric designation is for water, all of which is saline, used in generating electricity. If water used in production of electricity is excluded, municipal water supplies represents by far the greatest water use in the State, and irrigation, at about 21 percent, is the next largest water user."

The table also shows that the total amount of water used on Kaua'i is less than 2 percent of the water used in the State. If the thermoelectric category were to be excluded from the totals, Kaua'i's percentage would increase to more than 4 percent of the State's value.

The table also shows that the total amount of water used on O'ahu is more than 83 percent of the water used in the State. If the thermoelectric category were to be excluded from the totals, O'ahu's percentage would decrease to about 48 percent of the State's value.

The table also shows that the total amount of water used on Lāna'i is about 0.1 percent of the water used in the State. If the thermoelectric category were to be excluded from the totals, Lāna'i's percentage would increase to about 0.4 percent of the State's value. The table also shows that the total amount of water used on Maui is less than 9 percent of the water used in the State. If the thermoelectric category were to be excluded from the totals, Maui's percentage increases to about 24 percent of the State's value."

Apparently, Lāna'i, Maui, Kaua'i and Moloka'i increase without thermoelectric calculated in, but O'ahu goes down. Please specifically explain what this means and why it is important.

Response: The PEIS describes water use in Hawai'i with and without thermoelectric uses simply as a means of providing a more complete characterization. Thermoelectric power generation requires large quantities of cooling

water, much of which generally goes back to the source, and all of the water is saline in Hawai‘i. For all these reasons, including the amount of water used in thermoelectric power generation in the water use figures acts to significantly skew the data for those that may be more interested in how the State’s fresh water is used. At the same time, DOE did not want to omit the information; hence, the discussion with and without the thermoelectric category. The reason that the percentage of water used on Lāna‘i, Maui, Kaua‘i and Molokai (as compared to the State) all increase when thermoelectric is not included is because the majority of the thermoelectric generation occurs on O‘ahu, Hawai‘i, and Maui.

Comment 64-1: Most of the technologies will require the building of facilities and infrastructure that will increase the amount of impervious surfaces around the islands, this will lead to more stormwater runoff and would lead to more sediment reaching the coasts. As mentioned, BMP's for construction and for plant designs should consider including ditches and retention ponds to catch sediment. [general comment]

Response: Section 3.3.5.1 addresses common construction and operation impacts to surface water. Consistent with the comment, this section addresses the potential impacts of increased impermeable surfaces and the need to design new facilities with appropriate features for the management of stormwater runoff. Similarly, the Chapter 5 and 6 discussions of water resource impacts of distributed and utility-scale renewable energy technologies, respectively, include the issue of proper management of increased quantities of stormwater runoff.

Comment 64-2: Due to the nature of the generality of this document, the reader may get the impression that some of these activities, which can be large in scope, are associated with only minor permits and regulations. This will likely not be the case. Any in-water activities will trigger significant scrutiny, it is important that the reader, especially a project proponent, be aware and prepared for this.

Response: Agreed. Section 2.2.5 notes the complex and time-consuming nature of many of the permits that would be required of renewable energy projects. Because of this comment; however, the section was modified to specifically mention those projects involving “in-water” activities.

Comment 65-8: Revise the text on page 6-98 to note that state CWA Section 401 certification is not required for discharges into federal waters, and that although state WQS would not strictly apply in federal waters, EPA could, nevertheless, consider using them in developing limits for its own permit.

- Response: Section 6.5.3.1.1 was revised to include information regarding the non-applicability of the Section 401 certification for discharges in Federal waters.
- Comment 65-9: Add further information in the Final PEIS supporting the assumption that chlorine would be effectively diluted. Note that dilution values will need to be estimated at various distances from the representative OTEC facility.
- Response: Section 6.5.3.1.1 was modified to provide additional information with regard to determining or estimating chlorine concentrations.
- Comment 65-10: The Final PEIS should discuss the problems associated with discharging into already impaired waters, including NPDES permitting issues, and should discuss treatment options and discharge alternatives in greater detail.
- Response: Section 3.3.5.1 was modified to note that NPDES permits involving discharges to impaired waters normally carry added requirements. The PEIS discusses general potential impacts of discharge into impaired waters, while specific project proposals will likely be required to address treatments and alternatives in greater detail, pursuant to state and federal laws.
- Comment 65-11: The Final PEIS should note that sea water air conditioning will likely require an entrainment analysis and monitoring plan to assess any impacts from water intakes pipes in conjunction with compliance with CWA Section 316(b).
- Response: Section 2.3.1.5.3 was modified to include the likely requirement for an entrainment analysis.
- Comment 111-4: And we need issues such as what's going to happen, how smart is it really to put anything in the ocean, whether it's wind power or the cable in the ocean, when we're dealing with issues such as radiation from the Japan incident. Nobody is thinking about those things. How is it going to affect that cable or any wind mill stations out in the ocean.
- Response: Radiation levels in the ocean are being tracked by several groups, including the University of Hawai'i's School of Ocean and Earth Science and Technology (SOEST) (http://www.soest.Hawaii.edu/GG/FACULTY/hdulaiov/Fukushima_Mar_2012.htm), the associated Pacific Islands Ocean Observing System (PacIOOS) (http://oos.soest.Hawaii.edu/pacioos/projects/fukushima/oceanic_discharges.php), and the Woods Hole Oceanographic Institution (<http://www.whoi.edu/>). The Woods Hole website states that, with the exception of sites near the Fukushima nuclear power plant, radiation

released to the ocean poses little risk to human health. For example, Woods Hole has tested seawater samples from various Pacific locations including Hawai‘i (Kāne‘ohe Bay) shown to contain cesium-137 that can be traced back to the Fukushima incident, but at concentrations thousands of times less than the radioactivity produced by naturally occurring isotopes. At these small concentrations that pose no risk to human health, there would be no reason to suspect adverse impacts to the components of any marine-based renewable energy systems.

Comment 114-7: The last comment I am going to make -- and since Isaac brought it up is about desalination not just here, but in Hawai‘i in general. I understand it requires quite a bit of power. And as I went through the Table of Contents, I didn't see that. And maybe it's not as much energy, but I think it will be a growing energy need in Hawai‘i on O‘ahu as you begin to run out of water. So I would like to see a little bit of a study about the Energy Department's and the desal. on this island. They're thinking of using liquid natural gas. That creates a whole other issue. And I know there's some components of your study that addressed liquid natural gas. But that's one that makes sense that I think we have to decide here, if that's the best way to pursue it. So I thank you very much. I hope all of the students stick with it.

Response: Desalination is mentioned in the discussion about ocean thermal energy conversion (Section 2.3.3.6) as a possible beneficial by-product of specific configurations of the technology. Also, in general terms, the renewable energy technologies addressed in the PEIS could be used to support the energy needs of a desalination plant or plants. However, forecasts of future availability of freshwater in Hawai‘i and associated needs for desalination plants is beyond the scope of the PEIS.

9.3.5 PEIS PROCESS AND STRUCTURE

9.3.5.1 Cooperating Agencies

Comment 79-2: Also, on the cooperating agencies, I wish you folks would get comments from the Department of Land and Natural Resources because they will have a different perspective, being very protective of the land, and they're very knowledgeable about it.

Response: The State of Hawai‘i is a cooperating agency and participated in the development and review of the Draft PEIS. The Department of Land and Natural Resources (DLNR), along with numerous other State agencies, were consulted during the preparation of the Draft PEIS and were given the opportunity to comment during the public comment period. DLNR provided comments on the Draft PEIS.

Comment 93-3: So, I'm concerned that by partnering with DBEDT, the Department of Business, Economic Development and Tourism, there is an implicit bias in this PEIS with regards to the interisland cable, centralized power generation, and the small grid. DBEDT's objective is to make policy determinations with respect to economic development. DBEDT does not appear to have any interest in environmental, cultural or cost impacts.

Response: The DOE does not set policy for the State of Hawai'i. The inclusion of the State Energy Office and DBEDT as a cooperating agency is provided for under NEPA since DBEDT has special expertise in matters relating to renewable energy in Hawai'i. DBEDT's participation in the PEIS did not limit or constrain DOE's evaluation of potential environmental resources in any of the resource areas. Further, the State of Hawai'i's participation was not limited to DBEDT; other State agencies, including the Department of Land and Natural Resources, were involved with the PEIS process. DOE is not proposing any specific project, activity, or technology, nor is DOE attempting to establish a preference or hierarchy of technologies in comparison to others.

9.3.5.2 Informational Request

Comment 71-1: Request copy of Draft PEIS

Response: A copy of the Draft PEIS was provided to the commenter.

Comment 91-1: Before I start my stuff, I just want to do some housekeeping stuff. I have been on you guys' list, and I just got the notice yesterday. Okay?

None of the I am the spokesperson for Na Kupuna Moku O Keawe. I have kapuna from all six major districts of this island.

So I want to try to copy -- first of all, I don't have the capacity to download it, the size of your files -- but I need to be able to take those to these other districts that I communicate with so I can share that information. But I can't do it on a disk, you can't change the pages and throw this to that -- you know how that goes -- so I'm requesting a hard copy. I left my information on how to get it to me. And as quickly as you possibly can, because apparently this deadline thing is right around the corner.

Response: A copy of the Draft PEIS was provided to the commenter.

Comment 133-1: I am requesting for an extension for public comment.

Response: An extension of the 90-day public comment period was not provided; however, all comments received after the close of the comment period were evaluated and equally included in this comment response document.

9.3.5.3 Public Involvement

Summary Comment SC041 (38-3, 67-2, 103-1): Several commenters indicated that the comments provided in 2012 during the NEPA scoping process for the PEIS were not addressed by DOE in the Draft PEIS.

Response: Comments provided in 2012 during the NEPA scoping process were used by DOE to develop the scope of the Draft PEIS. DOE prepared a scoping comment summary report after the completion of the scoping process and posted this report on the PEIS Website (<http://hawaii-clean-energy-peis.com>). Draft PEISs typically do not present and respond to specific scoping comments. Any comments received, however, on the Draft PEIS have been specifically addressed in the Final EIS as part of the Comment-Response Document.

Summary Comment SC042 (43-1, 49-1, 50-1): Several comments provided background materials or requested environmental reviews for specific projects that have already been implemented. They do not identify any questions or concerns related to any specific topic covered in the PEIS.

Response: These comments do not identify any questions or comments specifically related to the material covered in the Draft PEIS and are therefore considered out-of-scope.

Comment 46-1: I received this information today June 4th, 2014. I have noticed that the 90 [day] comment period began in April. We are just now receiving this information and therefore request a change or an extension of the comment period to properly reflect [the] receipt date. This will provide the same allotment of time given others.

Response: The request for a copy of the Draft PEIS was made at the May 15, 2014, public hearing in Kahului on Maui, a hard copy of the Draft PEIS was mailed from Arizona on May 16th, and was delivered to the requestor's P.O. Box on May 31st. DOE provided a CD of the Draft PEIS to the requestor at the public hearing.

Public involvement is a key component of the NEPA process. DOE made the entire PEIS available by posting it on the Internet (<http://hawaii-clean-energy-peis.com> and <http://energy.nepa.gov>) and by supplying the printed document to County and University libraries throughout Hawai'i. All comments received before the end of the 90-day comment period were included in this comment-response chapter and considered in preparation of the Final PEIS. All comments DOE received after the 90-day comment period also were considered.

Comment 46-2: I was just as surprised as you when we met in the Hilo meeting, with myself receiving only a one day notice. You mentioned that you too were surprised with the low turnout at the other meetings. As I said then, it is

the fault of the State and Federal agencies for not giving proper notice or conducting proper consultations.

Response:

In accordance with DOE NEPA practices, the notice of the public comment period and public hearings were sent to Federal, State, and local agencies as well as local interest groups and individuals who signed up to the PEIS mailing list either via the scoping meetings or the Hawai'i PEIS Website, at the start of the comment period in April. Additionally, each public hearing was advertised with a display ad in local newspapers for each venue one week and then two days prior to the hearing dates (as available).

Comment 61-8:

These issues were raised in public comments already submitted for the PEIS process yet the Draft PEIS does not address or answer any of those points. Critical comments you received prior to publishing the draft were not evaluated and or incorporated. Therefore, the Draft PEIS is biased against the community, unrealistically favors geothermal, that lead to fatally flawed conclusions.

Political support for geothermal development has been well in Hawai'i since the 1970's, deriving from personally driven agendas, extensive federal funding, and failure to see and appreciate the reality of opposition from residents of impacted neighborhoods.

A glaring example of the problems with the PEIS presents itself in a 2008 DOE document that erroneously concluded community opposition resulted from poor communication, project planning, aesthetics and similar dainty topics. While the facts actually show, the people most strongly opposing geothermal have been personally injured by exposure to toxic gases, have seen their plants and animals similarly damaged, have endured evacuations during emergency situations, suffered long nights disturbed by loud drilling noise, and fear contamination of their land and water. How could any credible document ignore the thoughts of the people that have lived with and known geothermal in Hawai'i for 30 years? This is a fully engaged population with decades of strong opposition to impacts they have suffered, and yet the Draft PEIS does not give their concerns a voice. Why is that? Could there be a political factor at play?

Response:

The comments provided in 2012 during the NEPA scoping process were used by DOE to develop the scope of the Draft PEIS. DOE prepared a scoping comment summary report after the completion of the scoping process and posted this report on the PEIS Website (http://hawaiiicleanenergypeis.com/wp-content/uploads/2012/12/Scoping-Summary-Report_Final.pdf). EISs typically do not present and respond to specific scoping comments. Any

comments received, however, on the Draft PEIS have been specifically addressed in the Final PEIS as part of the CRD.

The PEIS evaluates each activity and technology equally and does not present a preference for any one or group of technologies. The power to decide upon the final combination of energy sources used in the state of Hawai'i does not rest with the Federal Government.

Comment 91-6:

There are a lot of things Jim talks about. But, you know, this just blows my mind. The last time you guys were here was two years ago. Who did you talk to in the meantime? I spent all night last night reading the testimonies. That was just the testimonies, that wasn't even the stuff that you got on your stuff because I can't download it. It would cost me too much money and I just don't have the facilities to do that. But, where is that information? I mean, guys like us, we're on the list, you know. Why aren't we getting the little updates? What, it took you two years to come out and say, hey, guess what, here's what else I got for you. You have three minutes to make a ***** comment, excuse my language. You have three minutes to make a comment. That's not correct. You know, I would love to be able to sit here and dissect this stuff and tell it to you. I'll read it. I actually do read this stuff because it concerns me in a great deal. If it affects me, it affects every one of you. I'm just the first in the line. So, I would really like to ask the Department of Energy, communicate with the local people, especially the Kanaka Maoli. Just as a matter of point, the United States does not have jurisdiction in Hawai'i. This is my country, this is my resources. I am not going to debate you on this because we can't decide this in this room. I am asking you to consider this matter when you start talking about this, okay? And believe me, you guys got to -- you even have it on your power points -- the historic and customary values of this -- who are you going to ask about it? Nobody has asked us yet. You talk about us, about how caring you're going to be for us. Never once did you ever call us. So, you know, I'm not trying to be a Jack Ass here, I am trying to tell you that -- look, I'm alive, I'm here. I have been around for 45 years doing this stuff. It's very annoying. But I have to keep doing it. But, see, some of you die and don't ask me a question. Gees, I have been doing this too long. At least ask me a question. Thank you very much.

Response:

DOE developed the PEIS to present the potential environmental impacts associated with energy efficiency activities and renewable energy technologies that could be used to comply with the HCEI. Other agencies, including the State of Hawai'i, participated in its development and review. The PEIS was not developed to promote one technology, project, or site location over another. Any future site-specific renewable energy projects must adhere to Federal, State and local regulatory processes and requirements.

Public involvement is a key component of the NEPA process. DOE encourages interested parties to continue communicating with Federal, State, and local governments by participating in forums such as public meetings.

DOE provided multiple opportunities to participate in this process. It began with the HIREP:Wind PEIS scoping period, which resulted in an Amended Notice of Intent and change in the scope of the PEIS to this Clean Energy PEIS. Then DOE hosted eight scoping meetings to hear from agencies and the public, and followed those up with eight public hearings to hear comments on the Draft PEIS. These meetings and hearings were held on six different islands.

Comment 100-3: But anyway, it's like you have to talk to the people that are on the ground. You've got to get away from the state agencies that pretend they know everything because they don't do a damn thing. They run out and have these meetings that have two-minute comment periods like you're supposed to be a genius and be able to summarize it in three minutes. Nobody -- nobody in this room can summarize what they're thinking in three minutes. So, why expect the public to do so? I don't understand. But there's people like myself -- there's several parties in this room who are very consistent in coming out to these meetings. I would like to see the Department come out and reach out to them and let them do some speaking to really give some input that's not connected to a Federal Agency, a State Agency or a big corporate entity. It would be very, very helpful, it would sure calm down a lot of nerves around here. Because right now we're looking at it -- we're like, you know, those roads going down to Pohoia, that's not for us. They're putting those roads down there because it's going to industrialize that whole area which means -- tell me -- what is the purpose of you if they are going to make all these things in the way in the first place. The cable is already being laid. You know, it's not like a decisive thing going on here whether we're going to do it. All the and the cables are -- they're doing it. They're just coming in to ask us, did it hurt yet? You know, what I mean? And so, I'm asking you to reach out to the people who are actually on the ground that have to live through this who have unbelievable ideas. We have great green ideas that are functional. But you have to include us in that program and not listen to us. I mean, I spent almost all night last night just reading the testimonies from the last scoping meeting. And that's just a handful of people that really want to know. I don't know anybody in my circle that knows about this meeting tonight. I don't. That's not good. Because there's a lot of people here being affected.

Response: DOE developed the PEIS to present the potential environmental impacts associated with energy efficiency activities and renewable energy technologies that could be used to comply with the HCEI. Other agencies, including the State of Hawai'i, participated in its development and

review. The PEIS was not developed to promote one technology, project, or site location over another. Any future site-specific renewable energy projects must adhere to Federal, State and local regulatory processes and requirements.

Public involvement is a key component of the NEPA process. DOE encourages interested parties to continue communicating with Federal, State, and local governments by participating in forums such as public meetings.

Comment 106-8: Please don't be confused by the small number of people that are here tonight. Any time anything important comes down and we think we're at risk, you're going to find the entire population of Moloka'i is going to be out to stop you. And that goes for the cable and that goes for anything touching Moloka'i.

Response: Public involvement is a key component of the NEPA process. DOE encourages interested parties to continue communicating with Federal, State, and local governments by participating in forums such as public meetings.

Comment 111-3: we need more responses to our concerns

Response: DOE's primary purpose in preparing the PEIS is to provide information on potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that are currently or could reasonably be deployed in Hawai'i. The PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be funded or supported by DOE or other Federal agencies in the future or subject to Federal or State permits. All public comments submitted during the PEIS process appear in this comment-response document and were considered in preparation of the Final PEIS.

Comment 114-1: I kind of want to address the students. Thank you for coming. Really important to them. I think what you're seeing in my lifetime -- I'm almost 75, I don't think I've ever seen a Federal Agency respond to a community by changing what it did to the degree that this report has. You probably maybe weren't here in 2011 when we had the first one. But, I thank you very much. I think -- I've never seen a Federal Agency and the State Agency respond to a community, very unusual in my lifetime anyway. Maybe I kind of lived that long.

Response: Public involvement is a key component of the NEPA process. DOE encourages interested parties to continue communicating with Federal, State, and local governments by participating in forums such as public meetings.

Comment 129-1: Can comments and questions be submitted to you as an attachment to an email. Maui Economic Development Board, Inc. Board of Directors would like to submit comments, but our schedule of gathering and forwarding these comments would preclude sending an official letter via USPS. The online comment option would probably not afford the best way of communicating considering the importance of the issue. Your guidance on this would be appreciated.

Response: The Maui Economic Development Board submitted comments via email (see Comment 62), which are responded to in the following sections in this CRD:

9.3.1.4, Energy Efficiency
9.3.3.10, Environmental Justice
9.3.3.24, PEIS Scope
9.3.4.6, Undersea Cable

Additionally, DOE responded to all comments received directly or forwarded by the State of Hawai'i and gave equal weight to all comments received regardless of receipt method or sender.

9.3.5.4 General

Comment 35-1: We reviewed the subject application and have no comments at this time.

Response: Thank you for the written confirmation.

Comment 57-4: The DPEIS does not clearly distinguish firm power alternatives from intermittent alternatives. The reliability and ease of integrating firm and intermittent alternatives into each island's grid vary considerably and should be more fully described, preferably in a separate section.

Response: The PEIS (Chapter 2) has been revised to indicate which of the generation technologies could be considered firm (or baseline) power and which are intermittent.

Comment 58-6: Please specifically identify what "regulatory and policy developments" since the failed HIREP:Wind draft PEIS was terminated caused DOE to re-do this process. (P. 1-3)

Response: The key element associated with the subject sentence is that DOE and the State of Hawai'i reacted to the comments provided during the initial scoping period for HIREP:Wind and significantly broadened the range of energy efficiency and renewable energy activities and technologies to be considered in the Hawai'i Clean Energy PEIS. Additionally, there was a decision by the State and DOE to go from a HEPA/NEPA document (like

HIREP) and proceed only as a PEIS under NEPA. The subject phrase has been removed from Section 1.1.2.

Comment 65-1: Provide and discuss the baseline or current energy usage, anticipated growth, and anticipated demand for energy in the state of Hawai‘i, and for each island.

Response: Section 2.1.1 has been updated to include the requested information.

Comment 65-2: Quantify the amount of renewable energy generation that will be needed to meet the HCEI goals.

Response: Section 2.1.1 has been updated to include the requested information.

Comment 65-3: Discuss current levels of renewable energy generation for each technology in the state of Hawai‘i, and for each island, and provide estimates for the amount of renewable energy that could be developed for each technology presented. Include estimates for rooftop solar on residential and commercial buildings.

Response: Section 2.1.2 has been updated to include the requested information.

Comment 65-16: Provide a qualitative discussion of potential impacts from construction and operation activities each technology/activity, highlighting the extent and range of potential impacts.

Response: The PEIS includes a discussion of the potential environmental impacts of construction in two areas (combined into the Summary tables, S-8 and S-9). Chapter 3 includes a discussion of the environmental impacts most often associated with construction and operation activities regardless of the clean energy activity or technology. Chapters 4 through 8 present the environmental impact analyses of each activity/technology from and/or to each environmental resource area. The discussion in these chapters is organized by type of impact (biological, environmental) rather than by project phase (i.e., construction, operation, and maintenance). Thus, rather than specifically discussing construction and operation, Chapters 4 through 8 typically refer back to Chapter 3. These impacts are presented for a representative project. Providing an extent and range for all activities associated with each technology and activity would be a larger effort and outside the scope of the Final PEIS.

Comment 118-3: For example, the impact chart says that for Land Transportation, there would be "potential short-term impacts on roadway traffic during project development." Many of the resource categories just say "general construction impacts." Nowhere is there a concern about long-term damage to our roads. The main road from Kaumalapau Harbor was built to accommodate trucks hauling bins of pineapples. Perhaps hauling megaton loads with 30 blades that are 190 feet long and 10 tours for the

representative 25 megawatt facility may not do much permanent damage. What happens when you haul 480 blades in and 160 towers slowly over our old roads? The roads will also have to be widened because the blades won't go around the turns.

Response: DOE developed the PEIS to provide a broad perspective of the potential environmental impacts for the various renewable energy technologies that could be employed to achieve the HCEI goals. The PEIS analyzes these potential environmental impacts through the use of representative projects. The PEIS does not evaluate specific scenarios or proposals and is not meant to characterize all potential scales of implementation of individual or groups of technologies. The information provided in the PEIS could be used to guide future environmental analyses of specific projects. Chapter 3 discusses the various impacts that could occur to each of the "main" Hawaiian islands, including Lānaʻi, based on each island's unique characteristics.

Comment 118-7: Not only are the impacts down-played, but the PEIS doesn't address how the impacts are magnified when you have a gigantic project on a small island like Lānaʻi.

Response: DOE developed the PEIS to provide a broad perspective of the potential environmental impacts for the various renewable energy technologies that could be employed to achieve the HCEI goals. The PEIS analyzes these potential environmental impacts through the use of representative projects. The PEIS does not evaluate specific scenarios or proposals and is not meant to characterize all potential scales of implementation of individual or groups of technologies. The information provided in the PEIS could be used to guide future environmental analyses of specific project proposals on each island.

9.3.5.5 Comments on Document

Comment 58-53: The following pages have typographical errors: the front cover misspells "Hawaii;" "pursing" instead of "pursuing" on P. 2-105; extra period on P. S-47 (chart); the "a" should be removed from 4th line, P. 2-6; "and" should be inserted on P. 2-16 after PUC "operating in the State and ... "; there is an extra period on P. 2-28 at the end of the third line; a dash should be inserted on P. 2-52 at "electricity:chilled air;" there is a missing period at the end of the 4th full paragraph on P. 2-55; there is an unnecessary period at the end of section 2.3.2. P. 2-56 above the bullet points; P. 2-71, should be "decommission!ng"; the underlined period on P. 2-81, 4th full para. should be removed; P. 2-85, "if the wind turbine system~ connected ... "; P 2-113, is it "on Hawaii" or "in Hawaii", Sec. 2.3.3.3; P. 2-117, a period should be inserted after "gas projects" P2-165 there is an extra "would" in 4th line from top of page; P. 2-182 "U niteQ_State~" P. 2-190 should be "on" Molokaʻi, not "in"; p. 2-194 you

have two ""however, it is noted that natural gas primarily consists of methane"; P. 2-197, line 12, remove "is used as-for passenger ... "; P. 2-216, "Permits or utility coordination that may be ... "; there is an extra period at end of last line on P.2-219; P. 2-228 "that" should be removed from last line; P. 2-229, add space between "abovementioned"; P. 2-239, remove "the" from in front of "MECO"; P. 2-286, extra period should be removed after "resource".

Response: Thank you for this comment. The Final PEIS reflects the editorial corrections as indicated.

Comment 65-17: Ensure that the Summary provides adequate attention to those activities and technologies that were examined in detail within the Final PEIS.

Response: The summary of the PEIS has been reviewed and reevaluated to ensure that the necessary level of detail addressing the technologies, actions, and impacts is appropriately presented in the Final PEIS.

Comment 117-1: it's wonderful that I can say that some of the Department of Energy people that are back with us. Some of the State people are truly my friends. So I hope you will not take this personally. But I am going to take my time to point out how this document...is schizophrenic.

Response: Thank you for your hospitality and detailed review of the PEIS. The PEIS is organized in a similar manner as other DOE PEIS's.

9.3.6 OUT OF SCOPE COMMENTS (INCLUDES RATIONALE)

Summary Comment SC043 (37-1, 102-2): Two comments stated that Native Hawaiian rights that were lost over time have not been restored and that letters submitted to the U.S. State Department in May 2014 regarding the legality of Hawaiian statehood be addressed such that DOE can remain in compliance and move forward without prejudice.

Response: The scope of the PEIS does not include an evaluation of Native Hawaiian land rights that historically may have been lost or the legality of Hawaiian statehood. The PEIS evaluates potential impacts from representative renewable energy technologies and activities that could be implemented in Hawai'i. The PEIS does evaluate; however, cultural resources and Hawaiian practices as they relate to potential impacts from renewable energy development in Hawai'i.

Summary Comment SC044 (145-5, 146-1, 147-3, 149-4, 151-5): Several commenters expressed general distrust for the utility companies or a concern that politics and corporate greed will have undue influence on the development of renewable energy projects and that the right people are often not listened to.

Response: The PEIS was developed to provide the public with a broad range of information on renewable energy technologies that might be used in Hawai'i to achieve HCEI goals and the potential environmental impacts associated with those technologies. The PEIS is not intended to promote any specific technology, project, or organization. Decisions on which activities and technologies are implemented will be determined by the State of Hawai'i and the Public Utilities Commission with input from other organizations and the public. Whether these future decisions might be unduly influenced by political-based interests or a bias for higher corporate profits is well beyond the scope of the PEIS. However, it is an objective of the PEIS, as well as the NEPA process, to help the public be better informed so it might be better able to determine what energy technologies and strategies are in the best interest of the local communities, the state, and the environment.

Summary Comment SC045 (143-2, 149-2, 149-5, 151-4): Commenters discussed past public meetings on different topics, concerns with past and current military activities in the area, state policies on water resource management and coastal zone management, and the need for mitigation actions as a result of past activities.

Response: The comments do not provide any comment or suggestion regarding the PEIS and therefore are considered outside the scope of the PEIS.

Comment 38-4: What environmental studies were done for the Hawai'i Renewable Development Venture, which is funded by the U.S. Department of Energy and awards thousands of dollars to private businesses?

Response: The comment does not provide any comment or suggestion regarding the PEIS and therefore is considered outside the scope of the PEIS.

Comment 38-10: Evaluate the pros and cons of energy service companies that help consumers maintain their systems (solar panels and batteries, hydro power, wind power, etc.)

Response: Evaluating different energy service companies to maintain the systems once installed is beyond the scope of the PEIS since it discusses types of technology rather than specific providers.

Comment 51-1: We have had enough of this company's [HECO's] abuse of power, and we will not tolerate it anymore! We, the ratepayers of Hawai'i, demand that this company be totally dismantled, its non-exclusive franchise revoked for failure to comply with franchise requirements, its management fired, especially Constance Lau, its financial assets frozen, and its other assets converted, or condemned by eminent domain if necessary, to ownership by and for the benefit of the people of Hawai'i. No other solution is acceptable to ratepayers.

Response: The comment document does not provide any comment or suggestion regarding the PEIS and therefore is considered outside the scope of the PEIS.

Comment 51-2: Julie Ann Wrigley, Global Institute of Sustainability, ASU LightWorks, and ASU Utility of the Future Center, mentioned in this document & included on the Bcc line of this message, therefore has an obligation to provide additional modeling and analytical tools for the benefit of ALL ratepayers of Hawai‘i to help us develop a plan for the orderly dismantling of this company and its conversion to the publicly owned, nonprofit utilities.

Response The comment does not provide any comment or suggestion regarding the PEIS and therefore is considered outside the scope of the PEIS.

Comment 51-3: The ratepayers are fed up with the PUC giving the company chance after chance, after chance, instead of just pulling the plug on its life support system and letting it die in favor of public power. HECO has been in violation of its non-exclusive utility franchise for many years, charged with price fixing, especially by tying geothermal prices to the cost of oil, and possibly violating anti-trust laws, so the only course of action is to rescind that franchise. Hawai‘i is the ONLY state without public power according to the American Public Power Association. A public power utility will do a much better job serving the military and civil defense than HECO. Some in the military are fed up with the company too. KIUC is not public power. It is controlled by Touchstone Energy.

Response: The comment does not provide any comment or suggestion regarding the PEIS and therefore is considered outside the scope of the PEIS.

Comment 51-4: Folks on O‘ahu, Molaka‘i, and Maui are already working on public power issues, and one public power article by a Hawai‘i resident is being updated for republication. I think the people will soon reach the breaking point and start marching in the streets and / or stop paying their electric bills en mass, to force the issue if necessary, and a TV ad may be in the works to help educate the people during election time to force the candidates to talk about energy issues, including public power, since our news media refuses to let the public know what is going on behind the scenes. They all simply run HECO's propaganda ads and TV commercials portraying itself as our holier than thou, angelic saint and savior, when it is, in fact, nothing more than a wolf in sheep's clothing, the fox guarding the hen house, fleecing and financially raping the ratepayers because of its idolatry of money and power, stealing from the poor to give to the rich.

Response: The comment does not provide any comment or suggestion regarding the PEIS and therefore is considered outside the scope of the PEIS.

Comment 55-1: In case you have not noticed:
<http://www.tfhawaii.org/cols/2014/071314.shtml>

Taxes, taxes and more taxes. [in response to Ed Wagner email]. [Linked content indicates taxes are part of the reason why energy prices are high in Hawai'i.]

Response: The comment does not provide any comment or suggestion regarding the PEIS and therefore is considered outside the scope of the PEIS.

Comment 58-23: DOE says "it is anticipated that the State will continue to progress toward its end goal of zero net energy consumption for new construction." (P. 2-32) What is the timeline?

Response: This comment regarding the State's timeline on zero net energy consumption is beyond the scope of this PEIS.

Comment 58-41: Please specifically provide how much funding DOE and related agencies have provided to the State of Hawai'i and the state's utilities under the guise of supporting the HCEI and Energy Agreement since January 2008 up and through this PEIS process, including the costs associated with HIREP:Wind.

Response: The information requested by the commenter is not within the scope of the PEIS and has no bearing on the types or magnitude of potential environmental impacts. If the information is still desired, the commenter can obtain these data through a request under the Freedom of Information Act or Hawai'i's Uniform Information Practices Act (<http://oip.hawaii.gov/laws-rules-opinions/uipa/uniform-information-practices-act-uipa/>).

Comment 73-1: Aloha,

I am a power plant engineer and I would like to make a recommendation.

Who can I contact and send informations?

Mahalo

Response: This submittal did not contain any questions or comments relative to the Draft PEIS and is considered out-of-scope.

Comment 75-8: I think the legislature has considered, and I encourage them to allow landowners to develop power generation on one property and distribute it across TMK boundaries to sell to tenants. Right now you can do that on one TMK, but you can't cross TMK boundaries and sell to tenants, and I

think we should be able to do that if the landowner owns adjacent properties and do that without being considered a public utility.

Response: Analysis of utility practices in the state is outside the scope of the PEIS; however, demand for such services could well lead to private-sector, civil-society, or public provision of such analysis.

Comment 90-1: I want to give you the simple story here. We never wanted to hook into HELCO in the beginning. We wanted to live a little life over here. But without our requesting it, HELCO sent us an estimate of what it would cost to bring electric poles to our farm. It was \$20,000. In 33 years, we haven't spent \$20,000 on solar. And I have lights, computers, refrigeration, freezers, even a big freezer. I put all my wild pig meat in to share with people in need. That's in 33 years. So, what we need today, I think, and this will be something for Russell Ruderman and others to think about, we need a finance mechanism, but what Richard Ha calls it, a rubber slippery crap. Because we had to start small scale with two batteries. And little by little as we farmed and raised enough money, we could expand our solar system, our panels and things like this. Today, the battery storage is maintenance free, you know. But we need a finance mechanism. So that's something for the rural people, decentralized, that we need to work on.

Response: While finance mechanisms may allow deeper penetration into the renewable energy market for a larger number of people, analysis of such is beyond the scope of the PEIS.

Comment 90-2: I want to make a comment about the Department of Energy. Before I came here, I googled the DOE to see what their budget was for clean energy. It's \$6.3 billion a year they spend. But the same DOE, Department of Energy, spends \$7.6 billion to maintain the nuclear weapons systems in the United States. Now, we need to change the priorities here. I speak as a peace activist. Let's put more money into clean energy than we are into nuclear weapons.

Response: Comment noted. The PEIS doesn't address congressional appropriation actions.

Comment 93-5: [The PEIS] does not address the problem that continued growth is not sustainable. It's irresponsible to simply enable business interests and continued growth of consumption under the banner of green energy.

Response: It is beyond the scope of the PEIS to analyze the broader question of sustainability of growth.

Comment 98-3: I would like to see the option evaluated of energy service companies that help consumers maintain their systems like maintaining solar panels, maintaining their batteries, whatever they've got.

Response: Analysis of energy services companies is beyond the scope of the PEIS; however, demand for such services could lead to private-sector, civil-society, or public provision of such services. The PEIS's purpose is to discuss types of technologies and their potential impacts rather than specific practices by energy companies.

Comment 114-4: And we need your help, students. This report, by the way, is 1,353 pages long, I looked at it today. So, you can divide it up among yourselves, everybody can read it. Do a report next year, read the summary for the student pages. But I saw that 1,350 pages, one part of the environmental study.

Response: The comment does not provide any comment or suggestion for DOE's action regarding the PEIS and therefore is considered outside the scope of the PEIS.

Comment 126-1: My company is the North American distributor of all electric vehicles including All Electric EV Bus passenger buses, LSV all electric cars and mini vans. Hawai'i seems to be the greenest state and I would like to see the buses transporting passengers from airports etc. Please send me to the correct person.

Response: This comment did not include any questions or concerns regarding information provided in the Draft PEIS and is considered out-of-scope.

Comment 128-1: I am wondering whether you are affiliated with the research site on the Big Island, between Waikoloa and the Kona Airport? Driving past the ocean, I saw a Clean Energy Research Center and was wondering whether you are affiliated with this?!

Response: This comment did not include any questions or concerns regarding information provided in the Draft PEIS and is considered out-of-scope.

Comment 134-1: The significant errors, omissions, and unaddressed issues will prevent the Draft PEIS from expediting specific EIS for clean energy initiatives.

Response: This comment did not contain specific topics that could be addressed in a response and is considered out-of-scope.

Comment 136-4: The commenter provided an excerpt from an article in the July 2014 edition of *Business in Vancouver* entitled, "Drilling down to the economic realities of geothermal power."

Response: This comment was an excerpt from an article that did not contain any questions or concerns specific to the Draft PEIS and therefore is considered out-of-scope.

Comment 150-1: I live in Kalihi and I'm a civil engineer, construction. I would like to suggest to the state to look into acquiring the roof of -- at Waiiau Power Plant. On the mauka side is a Sears Roebuck distribution center, and it has a roof there of about 25 to 50 acres. That would be ideal for putting solar panels and make arrangement with Sears to lease that -- lease that right to put solar there and you're right across street from the Waiiau Power Plant.

Also, on the Pearl Harbor side of Waiiau Power Plant is Pearl Harbor east lock or west lock, east lock or middle lock, and the Navy cannot use that for any ships at all because it requires a lot of dredging, and that's ideal area to put in a lot of panels and put a solar field over there and you have hundreds of acres there that the Navy can't use anyway.

I would suggest the state department look into those two places and expand a very enlarged solar panel field.

Response: The commenter has identified two specific facilities for the potential placement of photovoltaic systems. Although these suggestions may be good, viable projects, such actions are outside the scope of the PEIS. The PEIS was not developed to promote one technology, project, or site location over another, or to evaluate any site-specific project. Rather, the PEIS describes renewable energy technologies that could be used to comply with the HCEI and the potential environmental impacts associated with those technologies.

Comment 151-3: And Luwella actually kind of brought up about, well, who is going to use this energy that's being developed on the west side? Is it going to be for the community? And it doesn't appear that way.

Response: The PEIS is not intended to promote one technology, project, or site location over another, or to evaluate any site-specific project. As a result, any specific current or planned energy project, including where the energy from such a project may be routed, is outside the scope of the PEIS.

9.3.7 DUPLICATE COMMENTS

Summary Comment SC046 (130-1, 63-1, 69-3, 136-1, 36-1, 36-2, 113-1, 114-2, 132-1, 79-1, 79-3, 79-4, 79-5, 79-6, 79-7, 79-8, 115-1, 117-5, 117-6, 117-8, 117-9, 117-3, 117-4, 117-2): Several comments were received in duplicate. Twenty of these were cases in which commenters made written submissions along with oral statements that duplicated points made in their written submissions. Two of the duplicate comments were oral testimony that simply "seconded" what was said by previous speakers without elaboration.

Response: Responses can be found under the original comments; see Tables 9-1 and 9-2 for comment cross-references.

APPENDIX A

Public Notices

Notices about the Draft Programmatic EIS

The following Notice of Availability appeared in the Federal Register on April 18, 2014.

ACTION: Notice of availability and public hearings.

SUMMARY: The U.S. Department of Energy (DOE) announces the availability of the *Hawaii Clean Energy Draft Programmatic Environmental Impact Statement* (Hawaii Clean Energy Draft PEIS or Draft PEIS) (DOE/EIS-0459). DOE also announces eight public hearings to receive comments on the Draft PEIS. The Draft PEIS evaluates the potential environmental impacts associated with 31 energy efficiency activities and renewable energy technologies that could assist the State of Hawaii in meeting the goals established under the Hawaii Clean Energy Initiative (HCEI).

DATES: DOE invites comments on the Draft PEIS during a 90-day period, which ends July 17, 2014. Comments submitted after this date will be considered to the extent practicable during preparation of the Hawaii Clean Energy Final PEIS. The Department will hold eight public hearings at the locations, dates, and times listed in **SUPPLEMENTARY INFORMATION** below.

ADDRESSES: Comments on the Draft PEIS may be submitted:

- Orally or in writing at a public hearing.
- By email to hawaii-clean-energy-peis@ee.doe.gov.
- Through the PEIS Web site at <http://hawaii-clean-energy-peis.com>.
- By mail to Dr. Jane Summerson, Hawaii Clean Energy PEIS Document Manager, DOE NNSA, POB 5400 Bldg 401, KAFB East, Albuquerque, NM 87185.

FOR FURTHER INFORMATION CONTACT: For additional information on the Hawaii Clean Energy Draft PEIS, contact Dr. Jane Summerson at the address above or send an email to hawaii-clean-energy-peis@ee.doe.gov. For general information regarding the DOE National Environmental Policy Act (NEPA) process, contact: Ms. Carol M. Borgstrom, Director, Office of NEPA Policy and Compliance (GC-54), U.S. Department of Energy, 1000 Independence Ave. SW., Washington, DC 20585, telephone 202-586-4600 or leave a message at 800-472-2756.

SUPPLEMENTARY INFORMATION:

Background

DOE and Hawaii entered into a Memorandum of Understanding (MOU) in January 2008 that established a long-term partnership to assist Hawaii in its efforts to transform the way in which energy efficiency and renewable energy resources are planned and used in the State. The MOU established working

groups to address key sectors of the energy economy (e.g., electricity, end-use efficiency, transportation, and fuels), which led to the establishment of the Hawaii Clean Energy Initiative (HCEI). A goal of the HCEI is to meet 70 percent of Hawaii's energy needs by 2030 through energy efficiency and renewable energy (collectively "clean energy").

PEIS Scoping

On December 14, 2010, DOE issued a notice of intent to prepare a PEIS, with the State of Hawaii as a joint lead, on the wind phase of the Hawaii Interisland Renewable Energy Program (75 FR 77859). In light of scoping comments and regulatory and policy developments, DOE broadened the range of reasonable energy efficiency and renewable energy activities and technologies to be analyzed in the PEIS and issued an amended notice of intent to prepare the Hawaii Clean Energy PEIS (77 FR 47828; August 10, 2012). In preparing the PEIS, DOE considered scoping comments received on the initial and amended notices of intent.

The Hawaii Clean Energy Draft PEIS was prepared with the following cooperating agencies: State of Hawaii (Department of Business, Economic Development and Tourism), U.S. Environmental Protection Agency Region 9, Bureau of Ocean Energy Management, National Park Service, Natural Resources Conservation Service, U.S. Marine Corps, U.S. Navy, and Federal Aviation Administration.

Purpose and Need for Agency Action

The purpose and need for DOE's action is based on the 2008 MOU with the State of Hawaii that established the long-term HCEI partnership. Consistent with this MOU, DOE's purpose and need is to support the State of Hawaii in its efforts to meet 70 percent of the State's energy needs by 2030 through clean energy. DOE's primary purpose in preparing this PEIS is to provide information to the public, Federal and State agencies, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could support the HCEI. This environmental information could be used by decisionmakers, developers, and regulators in determining the best activities and technologies to meet future energy needs. The public could use this PEIS to better understand the types of potential impacts associated with the various technologies.

DEPARTMENT OF ENERGY

Hawaii Clean Energy Draft Programmatic Environmental Impact Statement

AGENCY: U.S. Department of Energy.

Proposed Action

DOE's Proposed Action is to develop guidance that can be used in making decisions to support the State of Hawaii in achieving the HCEI's goals.

For the Hawaii Clean Energy Draft PEIS, DOE and the State of Hawaii identified 31 clean energy technologies and activities associated with potential future actions and grouped them into five clean energy categories:

- Energy efficiency,
- Distributed renewable energy technologies,
- Utility-scale renewable energy technologies,
- Alternative transportation fuels and modes, and
- Electrical transmission and distribution.

For each activity or technology, the Draft PEIS identifies potential impacts to 17 environmental resource areas and potential best management practices that could be used to minimize or prevent those potential environmental impacts.

Document Availability

The Hawaii Clean Energy Draft PEIS is posted at <http://hawaii-cleanenergypeis.com> and <http://energy.gov/nepa/eis-0459-hawaii-clean-energy-programmatic-environmental-impact-statement>. To obtain a compact disk (CD) of the Draft PEIS, contact Dr. Summerson at the address under **ADDRESSES** above, online at <http://hawaii-cleanenergypeis.com>, or by email to hawaii-cleanenergypeis@ee.doe.gov. Printed copies of the complete PEIS are available at:

- Hawaii State Library, 478 South King Street, Honolulu, HI 96813.
- Lanai Public and School Library, 555 Fraser Ave, Lanai City, HI 96763.
- Wailuku Public Library, 251 High Street, Wailuku, HI 96793.
- Molokai Public Library, 15 Ala Malama, Kaunakakai, HI 96748.
- Hilo Public Library, 300 Waianuenue Ave, Hilo, HI 96720.
- Kailua-Kona Public Library, 75-138 Hualalai Road, Kailua-Kona, HI 96740.
- Lihue Public Library, 4344 Hardy Street, Lihue, HI 96766.
- Kaneohe Public Library, 45-829 Kamehameha Highway, Kaneohe, HI 96744.

DOE will provide a printed copy of the Summary or complete Draft PEIS upon request. However, due to the size of the document (approximately 60 pages for the Summary and 1,300 pages for the complete Draft PEIS), DOE recommends that interested parties take advantage of the download or CD options. If a printed copy is required,

contact Dr. Jane Summerson at the address above or by email to hawaii-cleanenergypeis@ee.doe.gov.

Public Hearings

The Department invites interested parties to provide comments on the Draft PEIS at public hearings to be held May 12 through May 22, 2014, at:

- May 12: Kauai, Kauai War Memorial, Convention Hall, 4191 Hardy Street, Lihue, HI 96766.
- May 13: Hawaii, Kealahoe High School, 74-5000 Puohuluhuli Street, Kailua-Kona, HI 96740.
- May 14: Hawaii, Aunty Sally Kaleohano's Luau Hale, 799 Piilani Street, Hilo, HI 96720.
- May 15: Maui, Pomaikai Elementary School, 4650 South Kamehameha Avenue, Kahului, HI 96732.
- May 19: Molokai, Kaunakakai Elementary School, 30 Ailooa Street, Kaunakakai, HI 96748.
- May 20: Lanai, Lanai High & Elementary School, 555 Fraser Avenue, Lanai City, HI 96763.
- May 21: Oahu, Kawanakoa Middle School, 49 Funchal Street, Honolulu, HI 96813.
- May 22: Oahu, James B. Castle High School, 45-386 Kaneohe Bay Drive, Kaneohe, HI 96744.

Each hearing will begin at 5:00 p.m. and end at 8:30 p.m. Each hearing will start with an open house (5:00-5:45), when Federal and State personnel and their contractors will be available to answer questions in an informal setting. The open house will be followed by a presentation (5:45-6:00) by Dr. Summerson, who will describe the PEIS, the NEPA process, and the methods that can be used to submit comments. During the remainder of the hearing, interested parties may present oral comments to DOE. A court reporter will transcribe the comments presented at each hearing. Individuals wishing to speak at a hearing should register when they arrive. DOE will initially allot three minutes to each commenter to ensure that as many people as possible have the opportunity to speak. More time may be provided, as circumstances permit. Written comments may be submitted at the hearing or by the other methods described in **ADDRESSES** above. DOE will give equal consideration to oral and written comments in preparing the Hawaii Clean Energy Final PEIS.

Issued in Washington, DC, April 14, 2014.

Patricia A. Hoffman,

Assistant Secretary, Office of Electricity Delivery and Energy Reliability.

[FR Doc. 2014-08848 Filed 4-17-14; 8:45 am]

BILLING CODE 6450-01-P

DEPARTMENT OF ENERGY**Proposed New Program in Stewardship of Accelerator Technologies for Energy and Environmental Applications**

AGENCY: Office of High Energy Physics, Office of Science, Department of Energy.

ACTION: Notice of request for information (RFI).

SUMMARY: The Office of High Energy Physics, as DOE's lead office for long-term accelerator R&D, invites interested parties to provide input on a possible new program to perform R&D leading to advances in particle accelerator technology used in energy and environmental applications.

DATES: Written comments and information are requested on or before May 19, 2014.

ADDRESSES: Interested persons may submit comments by email only.

Comments must be sent to EnergyEnvironmentRFI@science.doe.gov with the subject line "Stewardship RFI Comments".

FOR FURTHER INFORMATION CONTACT: Dr. Eric R. Colby, (301)-903-5475, Eric.Colby@science.doe.gov.

SUPPLEMENTARY INFORMATION:**The Challenge**

With world energy consumption predicted to grow by 56% between 2010 and 2040,¹ innovations that reduce pollutants from energy production, improve energy efficiency of industrial processes, and develop cost-effective techniques to clean up water and destroy environmental toxins will become increasingly important both to sustaining economic growth, and to protecting the environment.

Accelerator technologies have been demonstrated to have significant impact in each of these areas,^{2 3 4 5} but have not reached a sufficient level of technical maturity and economy to be widely adopted.

U.S. Department of Energy
HAWAI'I CLEAN ENERGY
DRAFT PROGRAMMATIC
ENVIRONMENTAL IMPACT STATEMENT

PUBLIC HEARING
Monday, May 12, 2014
Kaua'i War Memorial • 4191 Hardy Street, Lihue
5:00 pm – 8:30 pm

The U.S. Department of Energy (DOE) invites public comments on the Hawai'i Clean Energy Draft PEIS, in which DOE proposes to develop guidance that can be used in making decisions to support the State of Hawai'i in achieving its goal of 70% clean energy by 2030. The PEIS analyzes, at a programmatic level, the potential environmental impacts of activities in the categories of energy efficiency, distributed renewables, utility-scale renewables, alternative transportation fuels and modes, and electrical transmission and distribution.

DOE is holding a total of eight hearings on six islands from May 12-22, 2014; dates and locations are listed on the Hawaii Clean Energy Website: <http://www.hawaii-clean-energy-peis.com>.

Comments can be submitted through June 17, 2014 via:

- Internet - <http://www.hawaii-clean-energy-peis.com>
- Email - hawaii-clean-energy-peis@ee.doe.gov
- Public hearings being held throughout the Islands
- U.S. mail addressed to: Jane Summerson, U.S. Department of Energy,
P.O. Box 5400, Bldg 401 KAFB East, Albuquerque, NM 87185

The Draft PEIS is available for download from <http://hawaii-clean-energy-peis.com> and <http://energy.gov/NEPA>. Copies are available at area public libraries; see the Draft PEIS Website for locations.

PUBLIC HEARING
Tuesday, May 20, 2014
Lāna'i High & Elementary School, 555 Fraser Avenue, Lāna'i City
5:00 pm – 8:30 pm

The U.S. Department of Energy (DOE) invites public comments on the Hawai'i Clean Energy Draft PEIS, in which DOE proposes to develop guidance that can be used in making decisions to support the State of Hawai'i in achieving its goal of 70% clean energy by 2030. The PEIS analyzes, at a programmatic level, the potential environmental impacts of activities in the categories of energy efficiency, distributed renewables, utility-scale renewables, alternative transportation fuels and modes, and electrical transmission and distribution.

DOE is holding a total of eight hearings on six islands from May 12-22, 2014; dates and locations are listed on the Hawaii Clean Energy Website: <http://www.hawaii-clean-energy-peis.com>.

Comments can be submitted through June 17, 2014 via:

- Internet - <http://www.hawaii-clean-energy-peis.com>
- Email - hawaii-clean-energy-peis@ee.doe.gov
- Public hearings being held throughout the Islands
- U.S. mail addressed to: Jane Summerson, U.S. Department of Energy, P.O. Box 5400, Bldg 401 KAFB East, Albuquerque, NM 87185

The Draft PEIS is available for download from <http://hawaii-clean-energy-peis.com> and <http://energy.gov/NEPA>. Copies are available at area public libraries; see the Draft PEIS Website for locations.

PUBLIC HEARINGS

Wednesday, May 21, 2014, 5:00 pm - 8:30 pm

Kawananakoa Middle School • 49 Funchal Street, Honolulu

Thursday, May 22, 2014, 5:00 pm - 8:30 pm

James B. Castle High School • 45-386 Kaneohe Bay Drive, Kaneohe

The U.S. Department of Energy (DOE) invites public comments on the Hawai'i Clean Energy Draft PEIS, in which DOE proposes to develop guidance that can be used in making decisions to support the State of Hawai'i in achieving its goal of 70% clean energy by 2030. The PEIS analyzes, at a programmatic level, the potential environmental impacts of activities in the categories of energy efficiency, distributed renewables, utility-scale renewables, alternative transportation fuels and modes, and electrical transmission and distribution.

DOE is holding a total of eight hearings on six islands from May 12-22, 2014; dates and locations are listed on the Hawaii Clean Energy Website: <http://www.hawaiicleanenergypeis.com>.

Comments can be submitted through June 17, 2014 via:

- Internet - <http://www.hawaiicleanenergypeis.com>
- Email - hawaiicleanenergypeis@ee.doe.gov
- Public hearings being held throughout the Islands
- U.S. mail addressed to: Jane Summerson, U.S. Department of Energy, P.O. Box 5400, Bldg 401 KAFB East, Albuquerque, NM 87185

The Draft PEIS is available for download from <http://hawaiicleanenergypeis.com> and <http://energy.gov/NEPA>. Copies are available at area public libraries; see the PEIS Website for locations.

DOE- Hawai'i mailed the following notice to the Hawai'i mailing list.

NOTICE OF AVAILABILITY

Hawai'i Clean Energy Draft Programmatic Environmental Impact Statement (DOE/EIS-0459)

The U.S. Department of Energy (DOE) is pleased to announce the availability of the *Hawaii Clean Energy Draft Programmatic Environmental Impact Statement* (Draft PEIS) and invitation to comment on the PEIS DOE prepared the Draft PEIS in accordance with the Council on Environmental Quality's National Environmental Policy Act (NEPA) implementing regulations (40 CFR Parts 1500 through 1508) and DOE's NEPA implementing procedures (10 CFR Part 1021).

DOE's proposed action is to develop guidance to aid in making decisions about future funding or other actions to support the State of Hawaii in its efforts to meet the Hawaii Clean Energy Initiative's goal, which is to meet 70 percent of the State's energy needs by 2030 through clean, renewable energy. The Draft PEIS identifies 31 clean energy technologies and activities associated with potential future actions that could require an environmental review and groups them into five clean energy categories:

- Energy efficiency,
- Distributed renewable energy technologies,
- Utility-scale renewable energy technologies,
- Alternative vehicle fuels and modes, and
- Electrical transmission and distribution.

For each activity or technology, the Draft PEIS identifies potential impacts to 17 environmental resource areas and discusses best management practices that could be used to avoid, minimize, or reduce those potential environmental impacts.

The Draft PEIS can be accessed for download at <http://hawaii-clean-energy-peis.com> or <http://energy.gov/nepa/eis-0459-hawaii-clean-energy-programmatic-environmental-impact-statement>. A CD can be requested from DOE by email to hawaii-clean-energy-peis@ee.doe.gov, online at <http://hawaii-clean-energy-peis.com>, or by contacting DOE's NEPA Document Manager.

Dr. Jane Summerson, Ph.D.
U.S. Department of Energy - NNSA
PO Box 5400, Bldg 401 KAFB East
Albuquerque, NM 87185

In the CD and download version, each chapter includes links to access glossary terms, tables, figures, and references to help the reader to review the document electronically.

DOE will issue a Notice of Availability in the *Federal Register* on April 18, 2014, that announces a 90-day public comment period from April 18 through July 16, 2014. The Notice also will be posted on the above websites. DOE will consider comments received after the end of the comment period date to the extent practicable. DOE has scheduled eight public hearings in Hawai'i from May 12 to 22, 2014; locations, dates, and times will be provided in the Notice of Availability and on the PEIS Website. Comments on the Draft EIS may be provided orally or in writing at a public hearing, by email to hawaii-clean-energy-peis@ee.doe.gov, through the PEIS website at <http://hawaii-clean-energy-peis.com>, or by mail to the address above. DOE appreciates your participation in this NEPA process.

Sincerely,

A handwritten signature in cursive script that reads "Jane Summerson".

Jane Summerson, Ph.D.
NEPA Document Manager

Notices about Public Scoping

The following Amended Notice of Intent appeared in the *Federal Register* on August 10, 2012.

47828

Federal Register / Vol. 77, No. 155 / Friday, August 10, 2012 / Notices

DEPARTMENT OF ENERGY**Amended Notice of Intent To Prepare the Hawai'i Clean Energy Programmatic Environmental Impact Statement**

AGENCY: Department of Energy (DOE).
ACTION: Amended Notice of Intent (NOI) to prepare a Programmatic Environmental Impact Statement (PEIS).

SUMMARY: In 2010, DOE announced its intent to prepare a *PEIS for the Hawai'i Interisland Renewable Energy Program (HIREP): Wind* (DOE/EIS-0459) (HIREP: Wind PEIS). In response to public scoping comments on the HIREP: Wind PEIS, as well as regulatory and policy developments since the scoping meetings, DOE proposes to broaden the range of energy efficiency and renewable energy activities and technologies to be analyzed in the PEIS and, accordingly, has renamed it the *Hawai'i Clean Energy PEIS*. DOE's proposal will involve the development of guidance to use in future funding decisions and other actions to support Hawai'i in achieving the goal established in the Hawai'i Clean Energy Initiative (HCEI) to meet 70% of the State's energy needs by 2030 through energy efficiency and renewable energy. Achieving the HCEI goal could involve a diverse range of activities. Accordingly, this PEIS will analyze the potential environmental impacts of activities in the following clean energy categories: (1) Energy Efficiency, (2) Distributed Renewables, (3) Utility-Scale Renewables, (4) Alternative Transportation Fuels and Modes, and (5) Electrical Transmission and Distribution. The State of Hawai'i and the U.S. Department of the Interior's Bureau of Ocean Energy Management (BOEM) are cooperating agencies in preparing this PEIS.

DATES: DOE invites public comment on the scope of the PEIS during a 60-day public scoping period ending on October 9, 2012. See *Public Participation: Scoping, EIS Distribution, Schedule* in the **SUPPLEMENTARY INFORMATION** section below for public scoping meeting dates and locations. DOE will consider all comments received or postmarked by the end of the scoping period, and will consider comments received or postmarked after the ending date to the extent practicable.

ADDRESSES: Written comments on the scope of the PEIS or a request to be added to the PEIS distribution list may be submitted as follows:

- Email to hawaiiicleanenergypeis@ee.doe.gov.

- Electronic comments via the PEIS Web site at <http://www.hawaiiicleanenergypeis.com>.

- Facsimile (fax) to (808) 541-2253.

Attention: Hawai'i Clean Energy PEIS.

- U.S. mail to Jim Spaeth, U.S. Department of Energy, 300 Ala Moana Blvd., P.O. Box 50247, Honolulu, HI 96850-0247.

FOR FURTHER INFORMATION CONTACT: For information on DOE's proposed action, contact Jane Summerson, Ph.D., DOE National Environmental Policy Act (NEPA) Document Manager, Office of Energy Efficiency and Renewable Energy, U.S. Department of Energy, 1000 Independence Avenue SW., Washington, DC 20585, or Jim Spaeth, U.S. Department of Energy, 300 Ala Moana Blvd., P.O. Box 50247, Honolulu, HI 96850-0247, or send an email to hawaiiicleanenergypeis@ee.doe.gov. Information on the Hawai'i Clean Energy PEIS is available on the PEIS Web site at <http://www.hawaiiicleanenergypeis.com> and at the public libraries listed under *Public Participation: Scoping, EIS Distribution, Schedule* in the **SUPPLEMENTARY INFORMATION** section below.

For general information about the DOE NEPA process, contact Carol Borgstrom, Director, Office of NEPA Policy and Compliance (GC-54), U.S. Department of Energy, 1000 Independence Avenue SW, Washington, DC 20585, or (800) 472-2756 or askNEPA@hq.doe.gov.

SUPPLEMENTARY INFORMATION:**1. Background***DOE and the State of Hawai'i Coordination and Collaboration*

DOE and Hawai'i entered into a Memorandum of Understanding (MOU) in January 2008 that established a long-term partnership to transform the way in which energy efficiency and renewable energy resources are planned and used in the State. The MOU established working groups to address key sectors of the energy economy (e.g., electricity, end-use efficiency, transportation, and fuels), which led to the establishment of the HCEI. The goal of the HCEI is to meet 70% of Hawai'i's energy needs by 2030 through energy efficiency and renewable energy (collectively "clean energy").

To support this goal, in 2009, Hawai'i's legislature established a Renewable Portfolio Standard of 15% by 2015, 25% by 2020, and 40% by 2030. [See Haw. Rev. Stat. Sections 269-91 to 296-95 (2012) and Haw. Rev. Stat. Section 196 (2012).] Hawai'i also has established an Energy Efficiency Portfolio Standard that calls for the

statewide reduction in electricity use of 4,300 gigawatt hours via efficiency measures by 2030. [Haw. Rev. Stat. Section 269–96 (2012).]

Meanwhile, DOE has helped advance Hawai'i's clean energy goals by providing technical research and analysis, direct staff involvement, competitive solicitations, and funding. For example, DOE has provided funding for distributed photovoltaics on O'ahu and Maui; a wind farm on O'ahu; smart grid projects on Maui and Kaua'i; electric vehicle public charging networks; efficient appliance rebates; solar water heating rebates; and low-interest loans. Also, in accordance with Section 355 of the Energy Policy Act of 2005, DOE assessed the economic implications of Hawai'i's dependence on oil as a principal source of energy, including the technical and economic feasibility of increasing the use of renewable energy resources for the generation of electricity on an island-by-island basis. The report concluded that Hawai'i has many opportunities to diversify energy use through greater utilization of renewable energy for electricity and transportation applications.¹

2010 Notice of Intent for the HIREP: Wind PEIS

On December 14, 2010, DOE issued a NOI to prepare a PEIS, with the State of Hawai'i as a joint lead, on the wind phase of the Hawai'i Interisland Renewable Energy Program (75 FR 77859). That NOI referred to the PEIS as the HIREP: Wind PEIS. Scoping meetings were held in Honolulu, Kahului, Kaunakakai, and Lāna'i City in February 2011. Commenters expressed concern that DOE and the State would not analyze energy efficiency measures, distributed renewable energy, or the full range of potential renewable energy technologies. Commenters also expressed concern about the construction of interisland electricity transmission connection(s) and cable(s), the potential disparity of impacts on islands that could host wind development projects versus those that would use the electricity, and potential impacts to cultural resources, among other issues. In light of these comments, as well as regulatory and policy developments since the scoping meetings, DOE consulted with the State and decided to broaden the range of energy efficiency and renewable energy activities and technologies to be

¹U.S. Department of Energy. *Assessment of Dependence of State of Hawaii on Oil*. (December 2008); available at http://hawaiiicleanenergypeis.com/wp-content/uploads/2012/07/Hawaii_Oil_Dependency.pdf.

analyzed in the PEIS. In preparing the PEIS, DOE will consider scoping comments already received on the initial NOI, along with comments received in response to this amended NOI.

2. Environmental Review Process

The Hawai'i Clean Energy PEIS will be prepared pursuant to the National Environmental Policy Act (NEPA), as amended, the Council on Environmental Quality (CEQ) NEPA regulations (40 CFR Parts 1500 through 1508), and the DOE NEPA implementing procedures (10 CFR Part 1021). The PEIS also will consider, among other regulatory items, the requirements of the Hawai'i Environmental Policy Act (Hawai'i Revised Statutes [HRS] chapter 343).

DOE invites Federal, State, and local government agencies, Native Hawaiian and other organizations, and members of the public to submit comments and participate in public meetings on the scope of the PEIS—that is, the proposed action, the range of reasonable alternatives, and potential environmental impacts and other issues to be considered. DOE also invites government agencies with jurisdiction by law or special expertise to be cooperating agencies in EIS preparation. The State of Hawai'i and BOEM have agreed to be cooperating agencies.

The PEIS will not eliminate the need for project-specific environmental review of individual projects or activities that may be eligible for funding or other support by DOE. To the extent that DOE proposes to fund or undertake particular projects or activities that may fall within the scope of the PEIS, project-specific NEPA review for such projects and activities is expected to be tiered from the PEIS and to be more effective and efficient because of the PEIS. Moreover, such projects and activities will be subject to compliance with obligations under other environmental laws such as the Endangered Species Act and National Historic Preservation Act.

3. DOE Purpose and Need for Agency Action

DOE's purpose and need for agency action is based on the 2008 MOU with Hawai'i that established a long-term partnership to transform the way in which energy efficiency and renewable energy resources are planned and used in the State. Consistent with this MOU, DOE's purpose and need is to support the State in its efforts to meet 70% of the State's energy needs by 2030 through clean energy.

4. DOE's Proposed Action

DOE's proposed action is to develop guidance that it can use in making decisions about future funding or other actions to support Hawai'i in achieving the goal established in the HCEI to meet 70% of the State's energy needs by 2030 through energy efficiency and renewable energy. For purposes of this PEIS, DOE has divided these potential future actions into five clean energy categories and will analyze, at a programmatic level, the potential environmental impacts of future DOE actions that would fall within these categories and be subject to DOE's proposed guidance.

Energy Efficiency
Buildings (new construction and retrofits)
Energy Conservation
Ground Source Heat Pumps
Initiatives and Programs (e.g., tax incentives and rebates)
Sea Water Cooling
Solar Water Heating
Distributed Renewables
Biomass (small systems)
Hydroelectric (small systems)
Hydrogen Fuel Cells
Solar Photovoltaic Panels
Wind (small systems)
Utility-Scale Renewables
Biomass Geothermal
Hydroelectric
Municipal Solid Waste (including landfill gas)
Ocean Energy (wave and tidal)
Ocean Thermal Energy Conversion
Solar Photovoltaic Arrays
Solar Thermal Systems
Wind (land-based)
Wind (offshore)
Alternative Transportation Fuels and Modes
Biofuels
Electric Vehicles
Hybrid Electric Vehicles
Hydrogen
Liquefied Natural Gas
Mass Transportation
Electrical Transmission and Distribution
On Island Transmission
Land/Sea Cable Transition Sites
Undersea Cable Corridors
Smart Grid
Energy Storage
The PEIS will analyze the potential environmental impacts of only those clean energy activities and technologies that are eligible under Hawai'i's Renewable Portfolio Standard or Energy Efficiency Portfolio Standard. It will analyze these potential impacts, as

appropriate, on an island-by-island basis for the islands of Hawai'i, Kaua'i, Lāna'i, Maui, Moloka'i, and O'ahu. The PEIS will build upon the environmental and technical studies and public comments and outreach conducted to date.

The energy efficiency activities and renewable energy technologies and resources available in Hawai'i, including distributed and utility-scale renewable energy, vary by island and in commercial availability and economic viability. Furthermore, as in all utility systems, Hawai'i's ability to incorporate clean energy into individual island grids can be limited by the capacity of the power transmission system. Thus, DOE will consider several factors in determining the appropriate level of detail for analyzing the potential environmental impacts of each form of clean energy in the PEIS. These factors may include the potential to make a timely contribution to the HCEI goal; stage of technical development; commercial availability; and potential for significant environmental impacts. Similarly, DOE will consider the conditions on an individual island to help determine the appropriate level of detail for analysis of potential impacts on that island. In other words, the PEIS will not assume that each energy efficiency activity or renewable energy technology has the same potential for use on each island or that it would result in the same potential environmental impacts on each island.

The PEIS may identify (a) general geographical areas suitable for development of renewable energy resources, (b) combinations of energy efficiency activities and renewable energy technologies that may be both feasible and efficient in helping Hawai'i meet its HCEI goal, and (c) selection criteria and priorities that DOE could consider when reviewing project-specific proposals. In addition, the PEIS will provide information needed to consider the potential environmental impacts from clean energy activities and technologies. As a result, DOE will have information relevant to prioritizing future funding or other decisions. This could help DOE avoid redundancies and inefficiencies in future project development and decision-making.

The PEIS also will analyze, as connected actions or for cumulative impacts, on-going and reasonably foreseeable actions by other entities that could contribute to meeting Hawai'i's clean energy goals. Such energy efficiency and renewable energy actions could be proposed or undertaken by other federal agencies, state or local government agencies, or private parties.

No-Action Alternative

Under the no-action alternative, DOE would continue to support, through funding and other actions, Hawai'i in meeting the HCEI goal on a case-by-case basis, but without guidance to integrate and prioritize funding decisions and other actions.

5. Preliminary Identification of Environmental Issues

The PEIS will evaluate the full range of potential environmental, including cultural and socioeconomic, impacts associated with implementing clean energy activities and technologies on the islands of Hawai'i, Kaua'i, Lāna'i, Maui, Moloka'i, and O'ahu.

The following environmental resource areas have been tentatively identified for consideration in the EIS:

- Cultural and historical resources.
- Air quality (including climate change and greenhouse gas emissions).
- Water resources.
- Floodplains and wetlands.
- Coastal zone management.
- Geology and soils.
- Land and submerged land use.
- Biological resources (including threatened and endangered species, special status species, and related sensitive resources).
- Land and marine transportation.
- Airspace management.
- Public health and safety.
- Noise.
- Natural hazards.
- Hazardous materials and waste management.
- Accidents and intentional destructive acts.
- Recreational resources.
- Visual resources.
- Socioeconomics.
- Environmental justice (disproportionately high and adverse impacts to minority and low-income populations).
- Utilities and infrastructure.
- Cumulative impacts (past, present, and reasonably foreseeable future actions).
- Irreversible and irretrievable commitments of resources.

6. Public Participation: Scoping, EIS Distribution, Schedule

Public scoping meetings will be conducted at the following times and locations:

- September 11, 2012, 5:00–8:30 p.m. at O'ahu, McKinley High School, 1039 South King Street, Honolulu, HI 96814
- September 12, 2012, 5:30–9:00 p.m. at Kaua'i, Kaua'i War Memorial Convention Hall, 4191 Hardy Street, Lihue, HI 96766

- September 13, 2012, 5–8:30 p.m. at Hawai'i, Kealahou High School, 74–5000 Puohuluhuli Street, Kailua-Kona, HI 96740
- September 14, 2012, 5–8:30 p.m. at Hawai'i, Hilo High School, 556 Waianuenue Avenue, Hilo, HI 96720
- September 17, 2012, 5:30–9 p.m. at Maui, Pomaika'i Elementary School, 4650 South Kamehameha Avenue, Kahului, HI 96732
- September 18, 2012, 5–8:30 p.m. at Lāna'i, Lāna'i High & Elementary School, 555 Fraser Avenue, Lanai City, HI 96763
- September 19, 2012, 5:30–9 p.m. at Molokai, Mitchell Pau'ole Community Center, 90 Ainoa Street, Kaunakakai, Molokai, HI 96748
- September 20, 2012, 5–8:30 p.m. at O'ahu, James B. Castle High School, 45–386 Kaneohe Bay Drive, Kaneohe, HI 96744

Each scoping meeting will involve: a presentation that describes the NEPA process and the concept of a Programmatic EIS; a question and answer session; and a formal commenting session, which will be transcribed by a court reporter to ensure that all comments are available to DOE for consideration during preparation of the draft PEIS. The meetings will provide opportunities to view exhibits on potential clean energy approaches, ask questions, and submit comments orally or in writing. Representatives from DOE, Hawai'i, BOEM, and any other involved agencies will be available to answer questions and provide additional information to participants. Individuals who submit comments during the scoping process and provide their contact information will receive copies of the draft PEIS. The format of the draft PEIS provided could be a printed summary and CD of the complete document, a CD of the document, Web site access to the document, or a complete printed document, according to the commenter's format preference. Persons who do not submit comments during scoping, but would like to receive a copy of the draft PEIS when it is issued, should submit a request as provided in the ADDRESSES section and specify their format preference.

Information on the Hawai'i Clean Energy PEIS is available on the PEIS Web site at <http://www.hawaiiicleanenergypeis.com>. Materials relating to this PEIS also will be available at the public libraries listed below and several additional public libraries across the State of Hawai'i (for a complete list, see the PEIS Web site):

- Hawai'i State Library, 478 South King Street, Honolulu, HI 96813.

- Lānaʻi Public and School Library, 555 Fraser Ave, Lānaʻi City, HI 96763.
- Wailuku Public Library, 251 High Street, Wailuku, HI 96793.
- Molokaʻi Public Library, 15 Ala Malama, Kaunakakai, HI 96748.
- Hilo Public Library, 300 Waianuenue Ave, Hilo, HI 96720.
- Kailua-Kona Public Library, 75–138 Hualalai Road, Kailua-Kona, HI 96740.
- Lihuʻe Public Library, 4344 Hardy Street, Lihuʻe, HI 96766.

In preparing the draft PEIS, DOE will consider comments received during the scoping period and will consider late comments to the extent practicable. DOE plans to issue the draft PEIS in 2013. The U.S. Environmental Protection Agency (EPA) will publish a Notice of Availability (NOA) of the draft PEIS in the **Federal Register**, which will begin a minimum 45-day public comment period. DOE will announce how to comment on the draft PEIS and will hold public hearings during the public comment period, but no sooner than 15 days after the NOA of the draft PEIS is published.

In preparing the final PEIS, DOE will respond to comments received on the draft PEIS. DOE plans to issue the final PEIS in 2014. No sooner than 30 days after EPA publishes a NOA of the final PEIS, DOE may issue its Record of Decision regarding its actions considered in the PEIS.

Issued in Washington, DC, on August 3, 2012.

Patricia Hoffman,

Assistant Secretary for Electricity Delivery and Energy Reliability.

The PEIS will analyze, at a programmatic level, the potential environmental impacts of activities in the categories of energy efficiency, distributed renewables, utility-scale renewables, alternative transportation fuels and modes, and electrical transmission and distribution.

Meetings will be held on Moloka'i, Lāna'i, Maui, and Hawai'i Island; please check the website for the specific schedule.

PUBLIC SCOPING MEETING
Thursday, September 13, 2012
Kealakehe High School • 74-5000 Puohuluhuli Street, Kailua-Kona
5:00 pm – 8:30 pm

The U.S. Department of Energy (DOE) invites public comment on the scope of the Hawai'i Clean Energy PEIS, in which DOE proposes to develop guidance to use in future funding decisions and other actions to support Hawai'i in achieving its goal of 70% clean energy by 2030. The PEIS will analyze, at a programmatic level, the potential environmental impacts of activities in the categories of energy efficiency, distributed renewables, utility-scale renewables, alternative transportation fuels and modes, and electrical transmission and distribution.

Meetings will be held in Hilo and on O'ahu, Kaua'i, Moloka'i, Lāna'i, and Maui; please check the website for the specific schedule.

Comments can be submitted through October 9, 2012 via:

The Amended Notice of Intent and information about the 60-day public scoping period can be found at <http://www.hawaiicleanenergypeis.com>

DOE- Hawai'i mailed the following postcard to the Hawai'i mailing list.

NOTICE OF PUBLIC SCOPING

The U.S. Department of Energy (DOE) and the State of Hawai'i have established a long-term partnership to transform the way in which renewable energy and energy efficiency resources are planned and used in the state. In 2010, DOE announced its intent to prepare a programmatic environmental impact statement (PEIS) with the State as a joint lead for wind energy development under the Hawai'i Interisland Renewable Energy Program (HIREP). In response to public comments, as well as regulatory and policy developments, DOE has broadened the scope of the PEIS to now include energy efficiency, distributed renewables, utility-scale renewables, alternative transportation fuels and modes, and electrical transmission and distribution.

DOE invites public comments on the revised scope of the PEIS, now called the Hawai'i Clean Energy PEIS. The State of Hawai'i and the U.S. Department of the Interior's Bureau of Ocean Energy Management (BOEM) are cooperating agencies in preparing this PEIS. DOE will hold eight public scoping meetings on six islands from September 11–20, 2012. The public is invited to attend and participate in these meetings. Meeting details, information about the PEIS, the Amended Notice of Intent, and instructions for commenting on the PEIS can be found on the following website:

<http://www.hawaiiicleanenergypeis.com>

Notice about Past Action

The following Notice of Intent appeared in the *Federal Register* on December 14, 2010.

DEPARTMENT OF ENERGY

Notice of Intent To Prepare a Programmatic Environmental Impact Statement for the Hawai'i Interisland Renewable Energy Program: Wind (DOE/EIS-0459)

AGENCY: Department of Energy (DOE).

ACTION: Notice of intent to prepare a Programmatic Environmental Impact Statement (EIS).

SUMMARY: DOE announces its intention to prepare a Programmatic EIS with the State of Hawai'i as joint lead agencies pursuant to the National Environmental Policy Act (NEPA) of 1969 and the Hawai'i Environmental Policy Act. The Hawai'i Interisland Renewable Energy Program: Wind Programmatic Environmental Impact Statement (hereinafter referred to as the Hawai'i Wind EIS or the EIS) will assess the foreseeable environmental impacts which may arise from wind energy development under the Hawai'i Interisland Renewable Energy Program (HIREP). Hawai'i proposes to facilitate the development of wind-generated electric energy and the required improvements to the existing electric transmission infrastructure in Hawai'i. This EIS is the first phase of a programmatic environmental review of developing and increasing renewable energy technologies in Hawai'i.

DATES: The public scoping period starts with the publication of this Notice in the **Federal Register**. Comments on the

scope of the EIS should be submitted by March 1, 2011. Comments e-mailed or postmarked after that date will be considered to the extent practicable. DOE and Hawai'i will hold public scoping meetings in the first quarter of 2011. Dates will be announced in the **Federal Register**, on the DOE NEPA Web site at <http://www.nepa.energy.gov>, on the EIS Web site at <http://www.hirep-wind.com>, and in local media at least 15 days before each meeting.

ADDRESSES: DOE and Hawai'i will announce locations of scoping meetings as indicated in **DATES**. Send comments on the scope of the Hawai'i Wind EIS or a request to be added to the EIS distribution list:

- By e-mail to comments@hirep-wind.com.
- By submitting electronic comments on the EIS Web page at <http://www.hirep-wind.com>.
- By facsimile (fax) to 808-586-2536, Attention Allen G. Kam.
- By mail to Allen G. Kam, Esq., AICP, HIREP EIS Manager, State of Hawai'i, Department of Business, Economic Development and Tourism, Renewable Energy Branch, State Energy Office, P.O. Box 2359, Honolulu, HI 96804.

Information on the HIREP: Wind Phase is available at the EIS Web site at <http://www.hirep-wind.com>. This Notice of Intent, and the draft and final EIS when issued, also will be posted on the DOE NEPA Web site at <http://www.nepa.energy.gov>. These documents and additional materials relating to this EIS will be available at:

- Hawai'i State Library, 478 South King Street, Honolulu HI 96813.
- Lāna'i Public and School Library, 555 Fraser Ave, Lāna'i City, HI 96763.
- Wailuku Public Library, 251 High Street, Wailuku, HI 96793.
- Moloka'i Public Library, 15 Alamalama, Kaunakakai, HI 96748.
- Edwin H. Mo'okini Library, University of Hawai'i-Hilo, 200 West Kāwili Street, Hilo, HI 96720-4091.
- Kailua-Kona Public Library, 75-138 Hualālai Road, Kailua-Kona, HI 96740-1704.
- Lihu'e Public Library, 4344 Hardy Street, Lihu'e, HI 96766.
- DOE Freedom of Information Act Public Reading Room, 1000 Independence Avenue, SW., Washington, DC 20585.

FOR FURTHER INFORMATION CONTACT: For information on DOE's proposed action, contact Anthony J. Como, DOE NEPA Document Manager, Office of Electricity Delivery and Energy Reliability (OE-20), U.S. Department of Energy, 1000 Independence Avenue, SW.,

Washington, DC 20585; or at anthony.como@hq.doe.gov. For general information about the DOE NEPA process, contact Carol Borgstrom, Director, Office of NEPA Policy and Compliance (GC-54), U.S. Department of Energy, 1000 Independence Avenue, SW., Washington, DC 20585; or at 800-472-2756 or askNEPA@hq.doe.gov.

For information on the Hawai'i Interisland Renewable Energy Program, contact Mr. Allen G. Kam, Esq., AICP, HIREP EIS Manager, State of Hawai'i, Department of Business, Economic Development and Tourism, Renewable Energy Branch, State Energy Office, P.O. Box 2359, Honolulu, HI 96804; or at 808-587-9023 or hirep@dbedt.hawaii.gov.

SUPPLEMENTARY INFORMATION:

1. Background

Section 355 of the Energy Policy Act of 2005 (EPAct) requires the Secretary of Energy to assess the economic implications of the dependence of the State of Hawai'i on oil as a principal source of energy, including the technical and economic feasibility of increasing the contribution of renewable energy resources for the generation of electricity on an island by island basis. Such an assessment is to include, among other factors, siting and facility configuration, the effects on utility system reliability, and environmental considerations. In furtherance of the provisions of section 355 of EPAct, DOE and Hawai'i executed a Memorandum of Understanding (MOU) in January 2008 that established the Hawai'i Clean Energy Initiative (HCEI) and a long-term partnership between DOE and Hawai'i to implement the initiative. HCEI has a goal of providing 70 percent of the state's primary energy from clean energy sources by 2030 by replacing 40 percent of fossil fuel use with renewable energy and reducing energy consumption by 30 percent through energy efficiency measures. Of the alternative renewable energy sources available in Hawai'i—including wind, geothermal, solar, biomass, ocean thermal energy conversion, and wave—wind power has been identified as the most commercially available and economically viable option at the present time. The island of O'ahu, with 80 percent of the state's population, is the island with the greatest energy demand; however, the island does not contain sufficient renewable energy potential to meet the HCEI's goals. The islands of Maui, Lāna'i, and Moloka'i have the most abundant and viable wind resources of those islands closest to O'ahu. The analysis provided in the

O'ahu Wind Integration and Transmission Study (November 2010) (additional information at <http://www.nrel.gov/wind/systemsintegration/owits.html>), prepared by DOE's National Renewable Energy Laboratory, concluded that bringing 400 megawatts (MW) of wind-generated power to O'ahu via undersea cable (*i.e.*, the Hawai'i Interisland Wind Program) is technically feasible and should be considered an important part in reaching the HCEI's goals. Subsequent environmental reviews may address non-wind renewable technologies.

2. Environmental Review Process

The Hawai'i Wind EIS will be prepared pursuant to NEPA, as amended, the Council on Environmental Quality (CEQ) NEPA regulations (40 CFR parts 1500–1508), the DOE NEPA implementing procedures (10 CFR part 1021), and the Hawai'i Environmental Policy Act (Hawai'i Revised Statutes (HRS) chapter 343). The EIS will assess the potential environmental impacts from the development of wind generation facilities, the transmission required to deliver the wind-generated energy to O'ahu, and the required improvements to the existing electric transmission infrastructure on O'ahu. Because the proposed actions and alternatives may involve activities in floodplains and wetlands, the draft EIS may include a floodplain and wetland assessment prepared in accordance with 10 CFR part 1022. Compliance with Floodplain and Wetland Environmental Review Requirements. The proposed actions and alternatives will involve undersea transmission cables that will transect federal Outer Continental Shelf waters, where the Department of the Interior's Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE) has exclusive authority over right-of-way grants for undersea renewable energy transmission cables.

DOE and Hawai'i invite agencies, Native Hawaiian and other organizations, and members of the public to participate in developing the scope of the EIS—that is, the proposed actions, the range of reasonable alternatives and environmental impacts and other issues to be considered—by submitting written comments and by participating in public scoping meetings that DOE and Hawai'i will conduct jointly. DOE and Hawai'i also invite those agencies with jurisdiction by law or special expertise to be cooperating agencies in EIS preparation.

3. DOE Purpose and Need for Agency Action and Proposed Action

DOE's purpose and need for agency action is to meet its obligations under section 355 of EPAct and the 2008 MOU with Hawai'i to transform the way in which renewable energy and efficiency resources are planned and used in the State. DOE's proposed action is to work with and support Hawai'i in the implementation of the HCEI.

4. Hawai'i's Purpose and Need for State Action and Proposed Action

Hawai'i's purpose and need for action is to determine how to use its wind energy resources to meet the 2030 goals set forth in the HCEI. Hawai'i's proposed action is to facilitate renewable energy development that will be required for the State of Hawai'i to meet the HCEI renewable energy goals, including the development of wind resources on the islands of Maui, Lāna'i, and/or Moloka'i and the required improvements to the existing electric transmission infrastructure, including undersea cables to transmit renewable energy generation to O'ahu.

5. Alternatives

Alternatives to be analyzed in this EIS include the proposed action, which would provide for the implementation of an oversight program to develop up to 400 MW of wind energy on the Maui County islands of Maui, Lāna'i, and/or Moloka'i and transmission of that energy to O'ahu. A range of wind development projects could be pursued under the proposed action, and include varying power capacities and configurations among the islands, undersea cable corridors and routes, and locational criteria for landing sites (see www.hirep-wind.com for additional information including conceptual maps). The EIS will address scenarios under the proposed action that consider a programmatic approach to all wind energy deriving from a single island in Maui County (*i.e.*, Maui, Lāna'i, or Moloka'i) and all wind energy deriving from a combination of generation on two or more islands in Maui County, along with associated programmatic approaches to cable corridors and routes and landing site locations. The EIS will also analyze a no-action alternative.

6. Preliminary Identification of Environmental Issues

The EIS will evaluate the full range of potential environmental, social, cultural, and economic impacts associated with a proposed wind energy program encompassing the islands of Maui, Lāna'i and Moloka'i and use areas on O'ahu. The EIS also will include a

cultural impact assessment prepared in accordance with Hawai'i law, specifically Act 50, SLH 2000.

Impacts will be analyzed across a number of resource areas, including:

- Air quality (including climate change and greenhouse gas emissions).
- Water resources and drainage.
- Coastal zone resources.
- Geography, geology, and soils.
- Land and submerged land use.
- Threatened and endangered

species, special status species, and related sensitive resources such as the Hawaiian Islands Humpback Whale National Marine Sanctuary.

- Land transportation.
- Marine transportation and commerce.
- Airspace utilization.
- Public health and safety.
- Noise.
- Natural hazards.
- Hazardous materials.
- Accidents and intentional destructive acts.
- Cultural and historical resources.
- Recreational resources.
- Visual resources.
- Socioeconomic impacts, community services and infrastructure.
- Environmental justice considerations (disproportionately high and adverse impacts to minority and low income populations).
- Cumulative impacts (past, present, and reasonably foreseeable future actions).
- Irreversible and irretrievable commitments of resources.

The programmatic analysis will identify best management practices, outline regulatory procedures, address mitigation of environmental impacts and support the development of general guidance for major components of an interisland undersea cable energy grid for the transmission of wind energy.

7. Public Participation: Scoping, EIS Distribution, Schedule

As indicated in the **DATES** section, public scoping meetings will be conducted in early 2011. Each scoping meeting will be structured in two parts: first an informal "workshop" discussion period that will not be recorded, then a formal commenting session, which will be transcribed by a court stenographer. The meetings will provide interested parties the opportunity to view exhibits on the HIREP: Wind, ask questions, and submit comments orally or in writing. Representatives from DOE, Hawai'i, and any cooperating agencies will be available to answer questions and provide additional information to participants. Individuals who submit comments during the scoping process

will receive paper or electronic copies of the draft EIS, according to their preference. Persons who do not wish to submit comments or suggestions at this time, but would like to receive a copy of the draft EIS when it is issued should submit a request as provided in the **ADDRESSES** section and include their preference for a paper or electronic copy.

In preparing the draft EIS, DOE and Hawai'i will consider comments received during the scoping period. The agencies plan to issue the draft EIS by October 2011. After the agencies issue the draft EIS, the U.S. Environmental Protection Agency will publish a notice of availability of the draft EIS in the **Federal Register**, which will begin a minimum 45-day public comment period. In addition to and concurrent with this NOI publication in the **Federal Register**, the State of Hawai'i is preparing a state-level environmental review notice. That notice along with this NOI will be published in the State of Hawai'i Environmental Notice consistent with all state requirements.

The agencies will announce how to comment on the draft EIS and will hold public hearings during the public comment period, but no sooner than 15 days after the notice of availability is published. In preparing the final EIS, the agencies will respond to comments received on the draft EIS. The agencies plan to issue the final EIS by April 2012. No sooner than 60 days after the Environmental Protection Agency publishes a Notice of Availability of the final EIS, DOE and Hawai'i will each issue its Record of Decision regarding their actions considered in the EIS.

Issued in Washington, DC, on December 8, 2010.

Patricia A. Hoffman,

Assistant Secretary, Office of Electricity Delivery and Energy Reliability.

[FR Doc. 2010-31310 Filed 12-13-10; 8:45 am]

BILLING CODE 6450-01-P

APPENDIX B

Distribution List

DISTRIBUTION LIST

DOE provided electronic copy (CD-ROM) of this Hawai'i Clean Energy PEIS to Federal, State, and county elected and appointed government officials and agencies as well as libraries throughout the State of Hawai'i and the DOE Freedom of Information Act Reading Room. As it did with the Draft PEIS, DOE sent email notice of availability of the Final PEIS to the same mailing list that received such notice about the Draft PEIS. That is, DOE sent email notice to individuals who had previously signed up to receive a copy of the Draft PEIS, those who had provided an email address at a public scoping meeting held September 2012, requests received through the Hawai'i Clean Energy PEIS online mailing list application, via direct email to the PEIS email address, or through personal communication with a project representative. In addition, DOE sent email notification of availability of the Final PEIS to those individuals who requested and provided an email address at a public hearing held May 2014. For those individuals who requested notification but who provided only a postal mailing address, DOE sent the same notice of available through the U.S. postal service.

DOE will provide copies of the Final PEIS upon request and has made it available online at the Hawai'i Clean Energy PEIS Website (<http://www.hawaiicleanenergyPEIS.com>) and on the DOE NEPA Website (<http://energy.gov/nepa/eis-0459-hawaii-clean-energy-programmatic-environmental-impact-statement>).

APPENDIX C

List of Preparers

LIST OF PREPARERS

This appendix lists the individuals and organizations that filled primary roles in the preparation of this *Hawai'i Clean Energy Programmatic Environmental Impact Statement* (DOE/EIS-0459; Hawai'i Clean Energy PEIS). Dr. Jane Summerson of the U.S. Department of Energy (DOE) was the federal National Environmental Policy Act (NEPA) Document Manager and directed the preparation of this document. The Hawai'i Clean Energy PEIS contractor team was led by New West Technologies LLC through contracts with DOE and the State of Hawai'i. New West was assisted by JAD Environmental LLC and Rivers Consulting (for the Final PEIS), which provided project management, public participation, and technical assistance support. The PEIS contractor team was led by Joe Rivers of Rivers Consulting.

DOE provided direction to the PEIS contractor team, which was responsible for developing the analytical methodology and alternatives, coordinating the work tasks, collecting the required data, performing the impact analyses, and producing the document. DOE was responsible for data quality, the scope and content of the PEIS, and issue resolution.

Pursuant to the Council on Environmental Quality (CEQ) regulations that implement NEPA, DOE invited agencies that could have jurisdiction by law or special expertise with respect to any environmental issue to be addressed in the PEIS (40 CFR 1501.6) to be involved with its preparation as cooperating agencies. Eight of those agencies agreed to participate as cooperating agencies: State of Hawai'i, Department of Business, Economic Development, and Tourism; two bureaus within the Department of the Interior (Bureau of Ocean Energy Management and National Park Service); U.S. Department of Agriculture, Natural Resources Conservation Service; U.S. Department of Transportation, Federal Aviation Administration, Western-Pacific Region; two bureaus within the Department of Defense (U.S. Marine Corps and Navy); and U.S. Environment Protection Agency, Region 9.

As the lead agency, DOE used the analyses and proposals of the cooperating agencies to the maximum extent possible consistent with its responsibility. Accordingly, cooperating agencies accepted obligations to contribute staff to the PEIS team, developed and reviewed analyses for which they have particular expertise, and funded their own participation. Ultimately, DOE retained the responsibility for determining the appropriateness and adequacy of incorporating any data, analyses, and results of other work by these organizations for this PEIS. The PEIS contractor team was responsible for integrating such work in the document.

As required by Federal regulations [40 CFR 1506.5(c)], New West, JAD Environmental, and Rivers Consulting signed NEPA Disclosure Statements in relation to the work they performed on this PEIS. These statements are included at the end of the table.

List of Preparers

Name	Education	Experience	Project Responsibilities
U.S. Department of Energy			
Jane Summerson DOE	<ul style="list-style-type: none"> • Ph.D., Geology • M.S., Geobiology • M.A., Anthropology • B.A, Anthropology 	<ul style="list-style-type: none"> • 14 years of experience as a DOE NEPA Compliance Office and NEPA Document Manager • 20 years of DOE project management experience 	NEPA Document Manager
Contractor Team Management

**NEPA DISCLOSURE STATEMENT FOR PREPARATION OF THE
HAWAII CLEAN ENERGY
PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT**

The Council on Environmental Quality regulations (CEQ) at Title 40 of the *Code of Federal Regulations* (CFR) Section 1506.5(c), which have been adopted by the U.S. Department of Energy (10 CFR Part 1021), require contractors and subcontractors who will prepare an environmental impact statement to execute a disclosure statement specifying that they have no financial or other interest in the outcome of the project.

“Financial or other interest in the outcome of the project” is defined as any direct financial benefit such as a promise of future construction or design work in the project, as well as indirect financial benefits the contractor is aware of (e.g., if the project would aid proposals sponsored by the firm’s other clients).

In accordance with these requirements, Spike Bighorn, on behalf of the company and its employees, hereby certifies as follows, to the best of its knowledge as of the date set forth below:

(a) New West Technologies has no financial or other interest in the outcome of the project.

(b) _____ has the following financial or other interest in the outcome of the project and hereby agrees to divest itself of such interest prior to aware of this contract, or agrees to the attached plan to mitigate, neutralize or avoid any such conflict of interest.

Financial or Other Interests

- 1.
- 2.

**NEPA DISCLOSURE STATEMENT FOR
PREPARATION OF THE HAWAII CLEAN ENERGY PROGRAMMATIC ENVIRONMENTAL
IMPACT STATEMENT (DOE/EIS-0459)**

**Prime Contract No. Z10003265
Subcontract No. HNE1213_SUB01**

Council on Environmental Quality regulations at 40 CFR 1506.5(c), which have been adopted by DOE (10 CFR Part 1021), require contractors who will prepare an EIS to execute a disclosure specifying that they have no financial or other interest in the outcome of the project. The term "financial interest or other interest in the outcome of the project" for purpose of this disclosure is defined in the March 23, 1981, guidance "Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations" (46 FR 18026, Question 17a and b).

"Financial or other interest in the outcome of the project" includes "any financial benefit such as a promise of future construction or design work in the project, as well as indirect benefits the contractor is aware of (e.g., if the project would aid proposals sponsored by the firm's other clients)" (see 46 FR 18026).

In accordance with these requirements, Rivers Consulting, Inc. hereby certifies to the best of its knowledge and belief, it has no financial or other interest in the outcome of the project.
