

HAWAI‘I CLEAN ENERGY

FINAL

PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

SUMMARY

U.S. DEPARTMENT OF ENERGY

Office of Electricity Delivery and Energy Reliability
Office of Energy Efficiency and Renewable Energy

(DOE/EIS-0459)

SEPTEMBER 2015

COVER SHEET

TITLE: Hawai‘i Clean Energy Final Programmatic Environmental Impact Statement (Final PEIS)

RESPONSIBLE FEDERAL AGENCY: U.S. Department of Energy (DOE), Offices of Electricity Delivery and Energy Reliability (OE) and Energy Efficiency and Renewable Energy (EERE)

COOPERATING AGENCIES: State of Hawai‘i (Department of Business, Economic Development, and Tourism), U.S. Environmental Protection Agency, Bureau of Ocean Energy Management, National Park Service, Natural Resources Conservation Service, U.S. Marine Corps, U.S. Navy, and Federal Aviation Administration

LOCATION: State of Hawai‘i (Islands of O‘ahu, Hawai‘i, Kaua‘i, Lāna‘i, Maui, and Molokai)

CONTACTS: For additional information on this PEIS contact:

Dr. Jane Summerson, National Environmental Policy Act (NEPA) Document Manager

ABSTRACT: DOE decided to prepare this PEIS, which is not required under NEPA, to evaluate DOE's proposed action to develop guidance that can be used to support the State of Hawai‘i in achieving the Hawai‘i Clean Energy Initiative (HCEI) goal of meeting 70 percent of the State’s energy needs by 2030 through clean energy (the preferred alternative). For the PEIS, DOE and the State of Hawai‘i grouped 31 clean energy technologies and activities into five categories: (1) Energy Efficiency, (2) Distributed Renewable Energy Technologies, (3) Utility-Scale Renewable Energy Technologies, (4) Alternative Transportation Fuels and Modes, and (5) Electrical Transmission and Distribution. For each activity or technology, the PEIS identifies potential impacts to 17 environmental resource areas and potential best management practices that could be used to minimize or prevent those potential environmental impacts. The PEIS is available from the Hawai‘i Clean Energy PEIS and DOE NEPA websites:

<http://hawaiiicleanenergypeis.com> and <http://energy.gov/nepa/nepa-documents>.

PUBLIC COMMENTS: The Final PEIS considers comments submitted during the 90-day public comment period on the Draft PEIS and from eight public hearings held on six islands in Hawai‘i between May 12 and 22, 2014. A Comment-Response Document, which includes all comments received on the Draft PEIS and DOE’s responses to those comments, is included as Chapter 9 of the Final PEIS. Written and oral comments were given equal weight, and all comments submitted after the comment period closed were considered. The Final PEIS contains revisions and new information based in part on comments received on the Draft PEIS. Vertical bars in the margins marking changed text indicate the locations of these revisions and new information. Deletions are not indicated.

S.1 Introduction

The *Hawai‘i Clean Energy Programmatic Environmental Impact Statement* (PEIS) analyzes the potential environmental impacts, and best management practices that could minimize or prevent those potential environmental impacts, associated with 31 clean energy technologies and activities grouped into five categories: (1) Energy Efficiency, (2) Distributed Renewable Energy Technologies, (3) Utility-Scale Renewable Energy Technologies, (4) Alternative Transportation Fuels and Modes, and (5) Electrical Transmission and Distribution. The information in the PEIS could help DOE, the public, other Federal and State agencies, Native Hawaiian and other organizations, and future energy developers better understand and plan for greater use of renewable energy and energy efficiency in Hawai‘i.

With about 85 percent of its energy derived from imported petroleum and petroleum products, the State of Hawai‘i remains the most oil-dependent State in the Nation. Roughly equal amounts of petroleum are used for electricity generation, ground transportation, and commercial aviation (about 28 percent each), with the rest used for marine transport, military, and other uses. Unlike other states, Hawai‘i relies heavily on imported oil to meet its electricity generation needs. Whereas less than 1 percent of electricity on the U.S. mainland is generated using oil, in Hawai‘i, the figure is 74 percent. Furthermore, electricity prices in the State are three times higher than the United States national average. Section 355 of the [Energy Policy Act of 2005 \(EPAAct 2005\)](#) directs the U.S. Department of Energy (DOE) to assess the economic implications of Hawai‘i’s dependence on imported oil as the principal source of energy and to explore the technical and economic feasibility of increasing the contribution of renewable energy resources for both electricity generation and fuel for various modes of transportation.

In furtherance of the provisions of Section 355 of EPAAct 2005, DOE and the State of Hawai‘i entered into a Memorandum of Understanding (MOU) in January 2008¹. This MOU established a long-term partnership known as the [Hawai‘i Clean Energy Initiative \(HCEI\)](#) to transform the way in which energy efficiency and renewable energy resources are planned and used in the State. When it was established, HCEI set a goal of meeting 70 percent of Hawai‘i’s energy needs by 2030 through clean energy, which refers to a combination of 40 percent from renewable energy generation and 30 percent from energy efficiency and conservation measures. In addition to State-mandated renewable energy and energy efficiency goals, the HCEI set a goal to reduce oil used for ground transportation by 70 percent by 2030, and a goal to meet as much of in-State demand for transportation fuels with renewables as feasible by 2030². In support of HCEI goals, the Hawai‘i State Legislature passed and the Governor signed into law [House Bill \(HB\) 1464](#) in 2009, establishing the Renewable Portfolio Standard (RPS) and Energy Efficiency Portfolio Standard in the State of Hawai‘i. In the 2015 Legislative Session, the Hawai‘i State Legislature amended the State’s RPS by passing [HB 623](#), which increases the RPS to 30 percent by December 31, 2020; 70 percent by December 31, 2040, and 100 percent by December 31, 2045. Governor David Ige signed the nation’s first 100 percent RPS into law on June 8, 2015; Act 97 (Session Laws of Hawaii, 2015).

¹ In September 2014, DOE and the State of Hawai‘i signed another MOU to reaffirm their commitment to the HCEI (<http://dbedt.hawaii.gov/blog/hawaii-and-u-s-department-of-energy-reaffirm-commitment-to-clean-energy-initiative/>).

² Unlike the electricity generation sector, the transportation sector does not currently have statute-mandated goals. With this in mind, the State of Hawai‘i is reestablishing goals and timelines to reduce petroleum-based fuels for transportation as a priority of the next phase of the HCEI. The Hawai‘i State Energy Office completed a series of stakeholder consultations in June 2015, culminating with a final report offering a set of actionable tactics (see <http://www.hawaii-clean-energy-initiative.org/>). The Hawai‘i State Energy Office intends to re-engage stakeholders to create a new energy-in-transportation road map, using the new report as a guide.

S.2 Purpose and Need

The purpose and need for DOE action is based on the 2008 MOU (reaffirmed in the 2014 MOU) with the State of Hawai‘i that established the long-term HCEI partnership. Consistent with this MOU, DOE’s purpose and need is to support the State of Hawai‘i in its efforts to meet 70 percent of the State’s energy needs by 2030 through clean energy.

DOE’s primary purpose in preparing this PEIS, which is not required under NEPA, is to provide information to the public, Federal and State agencies, Native Hawaiian and other organizations, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support the HCEI. This environmental information could be used by decision-makers, developers, and regulators in determining the best activities and technologies to meet future energy needs. The public could use this PEIS to better understand the types of potential impacts associated with the various technologies and activities.

The State of Hawai‘i’s intent regarding the Clean Energy PEIS is for the Federal, State, and county governments, the general public, and private developers to use the PEIS as a reference document when project-specific environmental impact statements (EISs) are prepared. The PEIS can support the environmental review of future clean energy initiatives in Hawai‘i by identifying common impacts from a variety of clean energy technologies, local resources that could be potentially impacted, local entities that should be consulted, regulatory processes in place, and available best management practices to minimize foreseen environmental impacts. The State of Hawai‘i acknowledges that the PEIS does not serve to recommend or prioritize any specific clean energy technology or policy.

DOE prepared this PEIS pursuant to the *National Environmental Policy Act of 1969* (NEPA), as implemented by the Council on Environmental Quality (CEQ) NEPA regulations ([40 CFR Parts 1500 through 1508](#)) and DOE NEPA implementing procedures ([10 CFR Part 1021](#)).

S.3 Proposed Action

DOE’s proposed action is to develop guidance that can be used in making decisions to support the State of Hawai‘i in achieving the goal established in the HCEI to meet 70 percent of the State’s energy needs by 2030 through energy efficiency activities and renewable energy technologies.

Most clean energy projects have the potential to cause environmental impacts, especially if not implemented properly. However, careful adherence to Federal, State, and county laws, regulations, and permitting requirements; implementation of well-planned best management practices and mitigation measures; along with early consideration of local community concerns about the projects could alleviate or mitigate many of the potential environmental impacts.

Early consideration of such guidance, especially in project planning and development, could substantially streamline the project-specific environmental review, permitting processes, and community interactions, as well as lessen the potential for controversy over specific projects. DOE application of this guidance would be limited to those actions where DOE has authority for a Federal decision-making role; however, the information in this PEIS and in any forthcoming guidance could be potentially useful for any proposed project whether Federal, State, or private.

For this PEIS, DOE and the State of Hawai‘i identified 31 clean energy technologies and activities associated with potential future actions and grouped them into five clean energy categories. These are listed in Table S-1 and briefly described below. Activities and technologies were selected for clean energy categories based on their ability to make a timely contribution to the reduction of Hawai‘i’s reliance on

fossil fuels and their stage of technical development, which makes the technology more likely to advance to the implementation or commercialization stage. Four of these technologies or activities are only described in Chapter 2 and not carried forward for detailed impacts analyses. The reasoning for this treatment is provided in the descriptions below.

This PEIS analyzes each of these technologies and activities at a programmatic level for the islands of Kaua‘i, O‘ahu, Molokai, Lāna‘i, Maui, and Hawai‘i. Potential impacts are analyzed on an island-by-island basis when feasible. DOE is not proposing to develop any specific project, activity, or technology at this time and, therefore, cannot and does not analyze impacts of specific projects.

In the absence of specific, proposed projects, DOE defined “representative projects” for each activity and technology to allow the PEIS to evaluate and present the typical impacts (beneficial and adverse) associated with the respective activity or technology at the scale of a hypothetical project. The representative projects for each activity and technology characterize projects that could be implemented in Hawai‘i by 2030 based on realistic capacity factors and feasibility. The representative projects are hypothetical and not intended to represent any real or proposed project and are provided for analytical purposes only.

Table S-1. Clean Energy Categories and Associated Technologies or Activities

Clean Energy Category	Technology or Activity
Energy Efficiency	Energy Efficient Buildings
	Energy Conservation
	Ground Source Heat Pumps
	Initiatives and Programs
	Sea Water Air Conditioning
	Solar Water Heating
Distributed Renewables	Biomass
	Hydroelectric
	Hydrogen Fuel Cells
	Photovoltaic
	Wind
Utility-Scale Renewables	Biomass
	Geothermal
	Hydroelectric
	Municipal Solid Waste
	Marine Hydrokinetic Energy
	Ocean Thermal Energy Conversion
	Photovoltaic
	Solar Thermal
	Wind (Land-based)
	Wind (Offshore)
Alternative Transportation Fuels and Modes	Biofuels
	Electric Vehicles
	Hybrid Electric Vehicles
	Hydrogen
	Compressed and Liquefied Natural Gas and Liquefied Petroleum Gas
	Multi-Modal Transportation
Electrical Transmission and Distribution	On-Island Transmission
	Undersea Cables
	Smart Grid
	Energy Storage

Clean Energy Categories

Energy Efficiency

Energy efficiency refers to reducing the energy used for a given purpose or service while maintaining the same results; for example, replacing an incandescent light bulb with a different type of lighting technology that uses less energy to produce the same amount of light. Energy efficient technologies reduce the need for energy while energy efficient activities require less energy or save energy. This PEIS addresses the following energy efficient technologies and activities:

Energy Efficient Buildings

Residential and commercial buildings use energy for many purposes such as cooling, lighting, water heating, and use of appliances and electronics. Today's buildings consume more energy than any other sector of the U.S. economy including the transportation industry. In an effort to decrease energy consumption, energy efficiency measures are incorporated into building construction and retrofits.

Energy Conservation

Energy conservation is the act of reducing or going without a service or task in order to save energy; for example, turning off a light. Using less energy generally has positive potential environmental consequences. There would be no adverse environmental impacts associated with energy conservation; therefore, this activity is not carried forward for detailed impacts analyses.

Ground Source Heat Pumps

Underground temperatures are less variable than air temperatures. A ground source heat pump is an electrical-powered heating and cooling system that takes advantage of the relatively constant ground or groundwater temperature to transfer energy for space heating/cooling and water heating. Because of the moderate climate, ground source heat pumps are not currently deployed widely in Hawai'i and would be unlikely by 2030; therefore, this technology is not carried forward for detailed impacts analyses. Heat pump water heaters are an efficient heat transfer method used in construction. The PEIS addresses heat pump water heaters under *Energy Efficient Buildings*.

Initiatives and Programs

Utility- and government-sponsored clean energy initiatives and programs can help to make renewable energy, energy efficiency, and conservation practices attractive to consumers and communities. There are several ways to provide incentives to individuals, businesses, and communities that could result in a reduced overall demand for imported fossil fuels. These range from education and training to financial incentives for using energy efficient appliances and equipment at home and in commercial operations. The State of Hawai'i, island utilities, counties, and the Federal Government have employed several energy efficiency and renewable energy initiatives and programs for specific State-, island-, and community-level projects. There would be no adverse environmental impacts associated with initiatives and programs; therefore, this activity is not carried forward for detailed impacts analyses.

Sea Water Air Conditioning

Sea water air conditioning, also known as deep water cooling, uses the temperature differences (gradients) between deep and surface water to chill water for individual buildings or for use in larger (district) cooling air conditioning systems. This energy efficiency technology replaces the conventional electric chiller component of a cooling system with a deep, cold sea water cooling station or heat exchanger to cool a closed-loop air conditioning system that is significantly less energy-intensive.

Solar Water Heating

Solar water heating is a technology that uses the sun to heat water. It is generally considered for use in residential rooftop applications. This PEIS focuses on its use in single-family homes; however, it is

scalable to multi-family residences. Solar water heating technology has the potential to reduce household energy consumption by up to 40 percent.

Distributed Renewables

Distributed renewables refer to the use of renewable energy resources for an electricity generator that is located close to the end user or even onsite. The generating capacity of a distributed generation source can range from generation at a single residence to larger installations for commercial or multi-unit housing applications. This PEIS addresses the following distributed renewable technologies and activities:

Biomass

Biomass energy encompasses multiple energy production technologies that use organic matter from trees, agricultural crops, and animal waste as well as biogenic material in urban waste streams to produce a variety of potential energy end products. Biomass energy to produce electricity and heat is discussed under both distributed renewable and utility-scale renewable energy. Biomass energy used for transportation fuels is discussed under Alternative Transportation Fuels and Modes.

Hydroelectric

Hydroelectric power, or hydropower, utilizes the energy in flowing water to spin a turbine attached to a generator to produce electricity. Hydropower plants require a water source in a geographic area generally characterized by uneven terrain such as hills or mountains to have sufficient power-generation potential. There are three common types of hydropower plant designs: impoundment, diversion, and pumped storage hydropower (the latter is discussed in the context of Energy Storage technology in the clean energy category of Electrical Transmission and Distribution).

Hydrogen Fuel Cells

A fuel cell is a device that converts the chemical energy from a fuel into electricity through a chemical reaction with oxygen or another oxidizing agent. A hydrogen fuel cell uses the chemical energy of hydrogen to react with oxygen to produce electricity. Fuel cells can be used for almost any application typically powered by batteries or internal combustion engines, and they can scale to provide energy to a laptop computer or to a utility power station. Fuel cells produce no criteria air pollutants or greenhouse gas emissions at the point of operation. However, they are heavily dependent on a cost-efficient supply of hydrogen.

Photovoltaics

Photovoltaic (PV) cells convert sunlight to electricity. Photovoltaic cells are assembled into a solar module or group of PV cells. Solar modules are placed in an area or added to a larger system to generate and supply electricity for homes and businesses. A system typically includes one or more solar modules (sometimes referred to as an array), equipment to convert direct current electricity to alternating current electricity (i.e., inverters), and connecting wiring. Some systems are designed with batteries to store the generated electricity for later use and/or sun tracking devices to increase the amount of solar energy collected.

Wind

Wind turbines convert the kinetic energy of the wind to mechanical power. The wind turbine blades are designed to act like an airplane wing. The wind causes a pocket of low-pressure air on one side of the blade, which generates “lift” and pulls the blade toward it, causing the blade to move and the rotor to turn. The rotor turns a shaft and, through a gearbox, spins a generator to make electricity. Small wind turbines generally are those with capacities ranging from 20 watts to 100 kilowatts. At the low end of this range, units with capacities of 20 to 500 watts are often referred to as micro-turbines. At the high end of the range, small wind turbines can have a similar configuration and appearance to utility-sized wind turbines.

Utility-Scale Renewables

Utility-scale renewables refer to the use of renewable energy resources from a centrally located regional power plant. Utility-scale renewable technologies include the same kinds of renewable energy resources as distributed renewables, as well as other resources whose use at the distributed scale is impractical. The generating capacities for utility-scale technologies are typically at least an order of magnitude larger than for distributed applications. This PEIS addresses the following utility-scale technologies and activities:

Biomass

Biomass energy sources for utility-scale projects are the same as those for distributed renewable energy projects. Some types of biomass resources are more or less suited for utility-scale projects. The cost-effective acquisition (i.e., collecting, processing, and transportation) of biomass resources is a key component to implementing a utility-scale biomass energy system.

Geothermal

Geothermal energy recovery systems use heat that radiates naturally from the earth. These geothermal systems can be used directly for heating buildings or in industrial processes, or they can be used to generate electricity. Because it is difficult to transport heat over any large distance, both direct use and electricity production must take place at, or very near, the geothermal system. Once converted to electricity, the energy can be transported great distances over transmission lines.

Hydroelectric

Utility-scale hydroelectric, or hydropower, is the same technology as described in Distributed Renewables but on a larger scale. According to a U.S. Army Corps of Engineers evaluation, the State of Hawai‘i has limited potential for large-scale, river-based hydropower projects; therefore, this utility-scale technology is considered to have a low feasibility and is not carried forward for detailed impacts analyses.

Municipal Solid Waste

Municipal solid waste, more commonly known as trash or garbage, consists of everyday items used and then thrown away. This technology includes options available for converting municipal solid waste and other forms of waste to energy. Municipal solid waste-to-energy projects use similar technologies as those described for biomass facilities but also include the collection and use of methane gas released from existing landfills.

Marine Hydrokinetic Energy

Marine hydrokinetic technologies use the kinetic energy from moving water (such as waves, tides, and ocean currents) to generate electricity. The amount of energy that can be extracted from a wave is a function of the wave’s height and frequency. That is, the higher and more frequent the waves, the more power that can be extracted. Marine hydrokinetic devices can be situated on the shoreline or offshore depending on the technology. This technology is in the early stages of development; consequently, there are numerous designs in various stages of viability for commercial deployment or product testing.

Ocean Thermal Energy Conversion

Ocean thermal energy conversion is a technology that relies on temperature gradients in the ocean to generate electricity. By utilizing colder deep water and warmer surface waters, it is possible to alternately condense and evaporate a fluid to drive a turbine. In general, the larger the temperature difference between the shallow and deep water, the more power a system will be able to produce.

Photovoltaics

As discussed in Distributed Renewables, PV modules convert the sun’s energy directly into electricity. This technology also is currently applied to larger, utility-scale generating facilities as arrays of solar modules.

Solar Thermal

Solar thermal energy systems convert solar energy into thermal energy (heat) that can be used for the production of electricity. One big difference from solar PV technology is that solar thermal power plants generate electricity indirectly. Heat from the sun's rays is collected and used to heat a fluid. The steam produced from the heated fluid powers a generator that produces electricity.

Land-Based Wind

As discussed above for distributed wind, wind turbines convert the kinetic energy of the wind to mechanical power. Utility-scale wind projects include multiple, larger turbines in an array to maximize the available wind resource. Typical land-based wind turbines for utility-scale applications range from 1.5 to 3.5 megawatts with rotor diameters of 200-300 feet on towers about 250 feet to over 350 feet tall, dependent on the particular installation.

Offshore Wind

Offshore, utility-scale wind turbines function in the same manner as land-based wind turbines. That is, they convert the kinetic energy of the wind to mechanical power and the turning rotor spins a generator to make electricity. Most manufacturers of offshore wind turbines are currently testing prototypes with capacities of 5 to 7 megawatts with rotor diameters roughly 400 to 500 feet or larger. A primary difference between land-based and offshore wind turbine technology is the substructure upon which the wind turbine and tower is mounted. Depending on the depth of the water, offshore turbines are mounted on either shallow-water substructures (less than about 100 feet), transitional technology substructures (100 to 200 feet), or floating platforms (greater than 200 feet).

Alternative Transportation Fuels and Modes

Alternative transportation fuels and modes encompass those fuel types and methods of transportation that are different than conventional gasoline-powered automobiles. This PEIS addresses the following alternative transportation fuels, alternative transportation modes, and alternative types and methods of transportation:

Biofuels

Biofuels are fuels derived from biomass or waste feedstocks. Biomass includes wood, agricultural crops, herbaceous and woody energy crops, and municipal organic wastes such as manure. Biofuels from waste feedstocks can also be derived from food wastes, including fats, oils, and grease (FOG). Converting restaurants' recycled fats, oils, and grease into biodiesel diverts waste, reduces pollution, and supports local businesses. These feedstocks can be transformed using a variety of conversion technologies into conventional biofuel products (such as ethanol and biodiesel), and advanced biofuel products (such as cellulosic ethanol, biobutanol, Green Diesel, synthetic gasoline, and renewable jet fuel).

Electric Vehicles

Electric vehicles operate with an electric motor (or motors) powered by rechargeable battery packs. Some electric vehicles run solely on electrical power from the grid while others use a combination of gasoline and electricity.

Hybrid Electric Vehicles

Hybrid-electric vehicle powertrains combine a conventional combustion engine (either gasoline or diesel), a battery, and an electric motor. The wheels are driven by the internal combustion engine, the electric motor, or a combination of the two.

Hydrogen

Hydrogen is the simplest and most abundant element in the universe and can be produced from fossil fuels including oil, coal, or natural gas as well as biomass, organic waste, water, or salt water. As a

transportation fuel, the energy content in 2.2 pounds of hydrogen gas is about the same as the energy content in 1 gallon of gasoline. Hydrogen can be used in internal combustion engines or in combination with hydrogen fuel cells to power electric motors.

Compressed and Liquefied Natural Gas and Liquefied Petroleum Gas

Natural gas as an alternative transportation fuel for vehicles comes in two forms: compressed natural gas and liquefied natural gas. The fuel is used in natural gas vehicles and more commonly in compressed natural gas-powered vehicles. These vehicles are similar to gasoline or diesel vehicles with regard to power, acceleration, and cruising speed.

Multi-Modal Transportation

Multi-modal transportation options reduce the number of miles traveled by personal vehicles for work commuting and personal trips. Multi-modal transportation options include public transportation (e.g., bus, rail, and marine), ridesharing, car sharing, bike sharing, active transit (walking and biking), telecommuting/teleworking, and alternative work schedules. A comprehensive, well-connected multi-modal transportation system allows tourists and residents to easily access multiple transportation options so that they can get to where they need to go quickly and without as much dependence on single occupancy vehicles.

Electrical Transmission and Distribution

Electrical transmission and distribution refers to the transmission of electrical power from a point of generation and the means by which it is stored and distributed to electricity users. Electricity transmission and distribution systems form an electrical grid or network that is used to manage and distribute electricity in a geographic region. While electrical transmission and distribution is not specifically addressed in the HCEI, implementation of new renewable energy technologies and/or improving the existing electrical network in Hawai'i would directly affect transmission of such electricity and is therefore analyzed in this PEIS. This PEIS addresses the following electrical transmission and distribution technologies and activities:

On-Island Transmission

On-island transmission of electricity includes connections from the power generation source, transmission over a short or long distance, and connection to the power user. This system is often referred as the island electrical grid or simply "power grid." The power grid is how the majority of people and companies get their electricity.

Undersea Cable

Undersea power cables, also called submarine cables, transmit power across large bodies of water; whether from one island to another or from an offshore energy facility (e.g., an offshore wind turbine platform) to an on-island electrical network. Undersea cables lie on the sea bed and connect to on-island power grids via a land-sea cable transition site. Any type of electrical power can transmit across undersea cables including that from renewable energy sources such as solar, wind, and biomass.

Smart Grid

A smart grid is a modernized electrical grid that uses analog or digital information and communications technology to gather and act on information, such as information about the behaviors of suppliers and consumers, in an automated fashion to improve the efficiency, reliability, economics, and sustainability of the production and distribution of electricity. DOE describes the smart grid as an integration of five fundamental technologies: (1) integrated communications, (2) advanced components, (3) advanced control methods, (4) sensing and measurement, and (5) improved interfaces and decision support.

Energy Storage

Energy storage can take electricity that is generated at one point in time and store it for use at a different time. Incorporating energy storage in the electricity distribution chain allows utilities to decouple generation from demand which has several benefits including improved use of generated energy. The primary uses for energy storage include energy management, bridging power, and power quality and reliability.

S.4 Public Participation and Agency Coordination

S.4.1 PUBLIC PARTICIPATION

S.4.1.1 PEIS Scoping Process

In 2010, DOE announced its intent to prepare a PEIS for the wind phase of the now-defunct Hawai‘i Interisland Renewable Energy Program (HIREP). The Notice of Intent (NOI) appeared on December 14, 2010, in the *Federal Register* ([75 FR 77859](#)), and it referred to the PEIS as the HIREP: Wind PEIS (DOE/EIS-0459). The NOI identified the State of Hawai‘i as a joint lead agency.

In February 2011, DOE held scoping meetings in Honolulu, Kahului, Kaunakakai, and Lāna‘i City. In meetings and submitted comments, commenters expressed concern that DOE and the State of Hawai‘i would not analyze energy efficiency measures, distributed renewable energy assets, or the full range of potential renewable energy technologies. Commenters also expressed concern about the construction of interisland electricity transmission connections and cables; the potential disparity of impacts on islands that could host wind development projects versus those that would use the electricity; and potential impacts to cultural resources, among other issues. In response to public scoping comments received on the HIREP: Wind PEIS, DOE consulted with the State of Hawai‘i and broadened the range of energy efficiency and renewable energy activities and technologies to be analyzed as well as the number of islands to be evaluated. The result was a more comprehensive programmatic EIS renamed the Hawai‘i Clean Energy PEIS.

A new scoping process began with DOE’s publication of an Amended NOI in the *Federal Register* ([77 FR 47828, August 10, 2012](#)), with the State of Hawai‘i as a cooperating agency instead of a joint lead agency. The Amended NOI identified the five clean energy categories under the expanded range of activities and technologies to be analyzed. DOE held eight public scoping meetings in September 2012 on six islands in the cities of Honolulu, Līhu‘e, Kailua-Kona, Hilo, Kahului, Lāna‘i City, Kaunakakai, and Kāne‘ohe.

In addition to the Amended NOI, DOE announced the scoping meetings to encourage public participation in the PEIS process through publishing notices in six local newspapers, issuing a press release, sending postcards or emails to individuals and groups that had previously shown interest in the HIREP: Wind PEIS, and creating the Hawai‘i Clean Energy PEIS Website (www.hawaiicleanenergypeis.com).

DOE received and reviewed more than 700 comment documents as part of the Hawai‘i Clean Energy PEIS scoping process. Issues raised most often were related to island energy independence and self-sufficiency (e.g., opposition to generating electricity on other islands for transmission to O‘ahu); Native Hawaiian issues (e.g., to avoid impacts on subsistence lifestyle, spirituality, and traditions); cultural and historic resources; socioeconomics and communities; land use; biological resources; utility-scale land-based wind and geothermal renewables; undersea cable corridors; and concerns about health effects of smart meters. DOE prepared the *Scoping Summary Report for the Hawai‘i Clean Energy Programmatic Environmental Impact Statement* that contains a five-page summary of these comments (available online

from <http://hawaiienergy.com/eis-documents/>). DOE also considered these comments during the preparation of the Draft PEIS.

S.4.1.2 Areas of Controversy

Through discussions with the cooperating agencies, other agency coordination efforts, and the public involvement process— DOE solicited input, including the identification of any potential areas of controversy. This input came both during the public scoping process and the comments received during the public review of the Draft PEIS. The following potential areas of controversy were identified in the Draft PEIS and remain unchanged after review of public comments received on the Draft EIS. Changes to the PEIS that resulted from comments are addressed in [Section S.4.1.3](#):

- Island energy independence and self-sufficiency – Concerns were raised about islands being self-sufficient and energy-independent versus using local resources to generate energy for use on other islands.
- Native Hawaiian issues – Concerns, based on traditional beliefs, were raised about the use of island resources, such as using geothermal energy, to generate energy.
- Land use – Concerns were raised about the use of this finite resource for energy generation.
- Transmission lines including undersea cable – In addition to island energy dependence and self-sufficiency, concerns were raised about the overall cost and relative benefit of an interisland transmission grid.
- Analysis was too limiting – Concerns were raised about the proposal for a major project using a single technology (e.g., wind power) without adequate study of all the options and their appropriateness for use in specific locations.

As a result of considering all scoping comments and comments received on the Draft PEIS, the PEIS is a programmatic evaluation of the energy efficiency activities and renewable energy technologies that could reasonably be implemented in Hawai‘i. The scope includes an assessment of the viability of implementation in the State of Hawai‘i and the associated potential environmental impacts. As discussed in [Section S.3](#) above, the PEIS does not evaluate any specific or proposed project. Implementation of these activities and technologies and the ultimate ability to achieve the goals established by the HCEI should include input from all stakeholders.

S.4.1.3 Draft PEIS Public Review and Comment Period

On April 18, 2014, DOE published in the *Federal Register* its Notice of Availability for the *Hawai‘i Clean Energy Draft Programmatic Environmental Impact Statement* (DOE/EIS-0407D) (79 FR 21909). DOE’s Notice of Availability invited the public to comment on the Draft PEIS during a 90-day public comment period that ended on July 17, 2014, and described how the public could submit oral and written comments on the Draft PEIS. DOE’s Notice also announced that it would hold a total of eight public hearings from May 12 through May 22, 2014, in Lihue on Kaua‘i, Kailua-Kona and Hilo on Hawai‘i Island, Kahului on Maui, Kaunakakai on Molokai, Lāna‘i City on Lāna‘i Island, and in Honolulu and Kāne‘ohe on O‘ahu.

DOE used notification methods similar to those used during the scoping period to notify the public and applicable Federal, State, and county agencies of the public review and comment period for the Draft PEIS. These notification methods included posting advertisements soliciting comments on the Draft PEIS

and announcing the public hearings in local newspapers both one week and then two days (as possible) prior to the hearing dates; sending an email to individuals who had signed up on the PEIS website to receive email notifications related to the development of the PEIS as well as to scoping meeting attendees who had signed up to receive such notification; and mailing postcards through the U.S. postal service to those interested individuals who had not provided an email addresses.

DOE made the Draft PEIS available on the Internet at the Hawai‘i Clean Energy PEIS Website (www.hawaii-clean-energy-peis.com) and on the DOE NEPA Website (www.energy.gov/nepa) and provided a CD or bound copy of the Draft PEIS upon request. The State of Hawai‘i DBEDT distributed bound copies of the Draft PEIS to eight public libraries throughout Hawai‘i.

DOE received 151 comment documents (emails, letters, hearing transcripts, etc.) consisting of 582 comments on the Draft PEIS from Federal, State, and local government agencies, Native Hawaiian and other organizations, and members of the public. Examples of some changes in the Final PEIS that were driven by public or agency comments include the following:

- Expansion on the programmatic nature of the Hawaii Clean Energy PEIS
- Expansion of the background of the HCEI goals
- Expansion of the roles and responsibilities of various Hawai‘i state agencies
- Addition of heat pump water heaters as an element within energy-efficient buildings
- Addition of information related to interconnection standards; primarily as they relate to distributed solar PV generation
- Update of renewable portfolio standards based on recent legislation
- Additional permitting details for OTEC and sea water air conditioning
- Expansion of the discussion on multi-modal transportation
- Clarification of permitting and potential impacts associated with an undersea cable
- Enhancement of the discussion of cultural resources impacts, and
- Update of the National Marine Fisheries listing of candidate marine species.

DOE considered all comments on the Draft PEIS received or postmarked during the public comment period in preparing this Final PEIS. Comments received after the close of the public review and comment period were also considered in the preparation of the Final PEIS.

S.4.2 AGENCY COORDINATION

When implementing NEPA, a lead agency is strongly encouraged to involve Federal, State, and local government agencies. DOE benefitted in the preparation of the PEIS from the contributions of several cooperating and participating agencies.

The CEQ regulations define a lead agency as the agency or agencies preparing or having taken primary responsibility for preparing the environmental impact statement (40 CFR 1501.5 and 40 CFR 1508.16) and a cooperating agency as any other Federal agency having jurisdiction by law or special expertise with respect to any environmental impact involved in a proposal (or a reasonable alternative) for legislation or other major Federal action significantly affecting the quality of the human environment (40 CFR 1501.6 and 40 CFR 1508.5). A State or local governmental agency may also become a cooperating agency. Participating (or consulting) agencies are those with an interest in defining the scope of an impact assessment and collaborating with lead and cooperating agencies in determining the methodologies and level of detail to be used in analyzing the alternatives.

DOE sent invitations to various Federal agencies and the State of Hawai‘i Department of Business, Economic Development and Tourism (DBEDT) to be cooperating agencies for this PEIS. DBEDT agreed to represent the State of Hawai‘i as the sole cooperating agency for the State. Table S-2 lists the Federal and State agencies that agreed to be a cooperating agency or participating agency for this PEIS, followed by brief descriptions of the expertise, permitting authority, and responsibilities of each cooperating agency.

Table S-2. Cooperating and Participating Agencies

Agency	Department/Office
Cooperating Status	
U.S. Department of the Interior	National Park Service
	Bureau of Ocean Energy Management
U.S. Department of Agriculture	Natural Resources Conservation Service
U.S. Environmental Protection Agency	Region 9
U.S. Department of Defense	U.S. Marine Corps
	U.S. Navy
U.S. Department of Transportation	Federal Aviation Administration
State of Hawai‘i	DBEDT
Participating Status	
U.S. Department of the Interior	U.S. Geological Survey
	U.S. Fish and Wildlife Service
Advisory Council on Historic Preservation	N/A
U.S. Department of Agriculture	Farm Services Agency
U.S. Department of Commerce	National Marine Fisheries Service
	National Oceanic and Atmospheric Administration, National Ocean Service – Office of National Marine Sanctuaries
U.S. Department of Transportation	Federal Highway Administration
U.S. Department of Homeland Security	U.S. Coast Guard
U.S. Department of Defense	U.S. Army Corps of Engineers

Several of the listed agencies submitted comments on the Draft PEIS, which were resolved as documented in the Comment Response-Documents. The agencies were all contacted relative to release of the Final PEIS and raised no additional concerns.

National Park Service

The U.S. National Park Service (NPS) has expertise in natural and cultural resources and is charged with protecting the U.S. National Park System including resources for future generations. In addition, the NPS monitors the condition of National Historic Trails and Landmarks and National Natural Landmarks outside of the park system, and it may provide technical preservation assistance to owners of landmarks. NPS also maintains the *National Register of Historic Places*.

S.4.2.1 Bureau of Ocean Energy Management

The Bureau of Ocean Energy Management (BOEM) has expertise in and the responsibility for permitting leases and rights-of-way for renewable energy development activities on the Outer Continental Shelf and other offshore Federal waters. It also has expertise in coastal and marine biological and physical sciences, as well as marine archaeological and cultural resources. Under EPCA 2005, BOEM was granted (through its predecessor agency) the authority for regulating the production, transportation, and transmission of renewable energy resources on the Outer Continental Shelf and other offshore Federal waters. Pursuant to the *Outer Continental Shelf Lands Act* ([43 U.S.C. §§ 1331–1356](#), [Public Law 113-212](#)), BOEM has been

vested with jurisdictional authority for submerged lands greater than 3 miles seaward of the Hawaiian coastline. BOEM has no jurisdictional authority in Hawaiian waters from the coastline out to the 3-mile State/Federal boundary. This authority does not apply to any area on the OCS within the boundaries of any unit of the National Park System, National Wildlife Refuge system, National Marine Sanctuary system, or any National Monument.

S.4.2.2 Natural Resources Conservation Service

The Natural Resources Conservation Service (NRCS) has expertise in conservation planning assistance to private landowners and in the soil sciences. NRCS derives its regulatory and permitting authority under the *Soil Conservation and Domestic Allotment Act* ([16 U.S.C. § 590a et seq.](#)) and the *Food, Conservation, and Energy Act of 2008* ([Public Law 110-234](#); known as the “Farm Bill”), as well as subsequent Farm Bills using programs such as the Conservation Stewardship Program ([7 CFR Part 1470](#)); *Environmental Quality Incentives Program in the Food, Conservation, and Energy Act of 2008* ([Public Law 110-246](#)); and the Wildlife Habitat Incentive Program ([7 CFR Part 636](#)).

S.4.2.3 U.S. Environmental Protection Agency

The EPA administers the programmatic and regulatory aspects of 11 pollution control statutes including the *Clean Air Act* ([42 U.S.C. § 7401 et seq.](#)) and *Clean Water Act* ([33 U.S.C. § 1251 et seq.](#)). EPA has interest in all environmental resource areas, activities, and technologies. As a cooperating agency, EPA assisted in the independent review of both the Draft and Final PEISs.

S.4.2.4 Federal Aviation Administration

The Federal Aviation Administration has expertise in airport land and airspace issues and permitting authority for matters related to hazards to air navigation.

S.4.2.5 U.S. Marine Corps and U.S. Navy

The U.S. Marine Corps and the Department of the Navy both have expertise related to U.S. military installations and training, including radar, restricted areas, airspace, and training areas. All branches of the military are present on O‘ahu. The branches of the military coordinate with the U.S. Department of Defense (DoD) on renewable energy project compatibility through the DoD Siting Clearinghouse in the Office of the Deputy Undersecretary of Defense for Installations and Environment. The Clearinghouse formal review process applies to projects filed with the U.S. Secretary of Transportation under 49 U.S.C. § 44718 as well as other projects proposed for construction within military training routes or special use airspace, whether on private, State, or Federal property.

S.4.2.6 State of Hawai‘i

State of Hawai‘i agencies have expertise in all matters related to State energy policy, land use, Native Hawaiian culture, aquatic resources, ocean recreation, forestry and wildlife, land and coastal land management and conservation, historic preservation, and parklands. On behalf of all State of Hawai‘i agencies, DBEDT is serving as a cooperating agency for this PEIS. The State agencies have permitting authority and will serve as information sources for many entities, including but not limited to the public and developers of future projects in Hawai‘i.

S.5 Permitting and Regulatory Requirements

DOE prepared this PEIS pursuant to NEPA, as implemented by the CEQ NEPA regulations ([40 CFR Parts 1500 through 1508](#)) and DOE NEPA implementing procedures ([10 CFR Part 1021](#)). This PEIS considers, among other regulatory items, the requirements of the *Hawai‘i Environmental Policy Act* ([Chapter 343, Hawai‘i Revised Statutes](#)). This PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be eligible for funding or other forms of support by DOE or other Federal agencies. To the extent that DOE proposes to fund or undertake particular projects or activities that may fall within the scope of this PEIS, project-specific NEPA reviews for such projects and activities are expected to build on, or tier from, this PEIS. Moreover, any such projects and activities would be subject to compliance with obligations under other environmental laws such as the *Endangered Species Act of 1973* ([16 U.S.C. § 1531–1544 et seq.](#)) and the *National Historic Preservation Act of 1966* ([54 U.S.C. § 300101 et seq.](#)). For those projects that do not have any connection to Federal actions, State-level environmental reviews would still have to occur as required under Hawai‘i Revised Statutes, such as the *Hawai‘i Environmental Policy Act* and other statutes and administrative rules.

The Hawai‘i State Energy Office has developed and made available online a comprehensive list of Federal, State, and county-specific permits that are generally required for the activities that typically accompany clean energy projects. These include permits related to siting, construction, operation, and other phases. This information is available at <https://energy.Hawaii.gov> and includes a link to a single downloadable document called the *Guide to Renewable Energy Facility Permits in the State of Hawai‘i*. Permit packets associated with each permit also are available for download at the above website. In addition, many Federal, State, and county permitting agencies in Hawai‘i have developed their own guidance materials describing various permitting processes, procedures, and requirements. The links to these agency websites are included in Section 2.2 of the PEIS.

To supplement these tools, a free interactive online permitting tool, the Hawai‘i Renewable Energy Permitting Wizard, is also available from the Hawai‘i State Energy Office (<http://wizard.hawaiiicleanenergyinitiative.org>). The Wizard allows users (such as a would-be renewable energy developer) to identify the Federal, State, and county permits that may be required for a specific renewable energy project in Hawai‘i based on input provided by the user. Designed for renewable energy projects, the Wizard can create a permit plan for a proposed project based on the type of renewable energy technology proposed. The permit plan also includes the recommended sequence—with estimated timelines—in which the permits may be obtained.

S.6 Structure of the Hawai‘i Clean Energy PEIS

This PEIS is arranged into a summary; nine chapters, each containing a separate, chapter-specific reference list; and three appendices:

- This Summary summarizes the contents of the PEIS. In accordance with [40 CFR 1502.12](#), the Summary stresses the major conclusions and areas of controversy (including issues raised by agencies and the public). [Title 40 CFR 1502.12](#) also requires that a summary stress the issues to be resolved (including the choice among alternatives). However, since this PEIS focuses on a range of technologies and activities and analyzes their potential impacts rather than setting up a choice from among them, neither the body of the PEIS nor this Summary present issues to be resolved.

- Chapter 1, “Introduction,” provides background information on the HCEI, an overview of the NEPA process, the purpose and need for agency action, and information on public and agency coordination.
- Chapter 2, “Proposed Action,” describes each of the five clean energy categories and the associated 31 technologies and activities. The chapter discusses, from a programmatic perspective, the permitting and regulatory requirements needed to implement the technologies and activities associated with the different clean energy categories. It provides a brief primer of each activity/technology that includes a description of a representative project. The chapter includes a discussion of a no-action alternative and tables that summarize potential environmental impacts associated with the technologies and activities in each clean energy category. The chapter concludes with brief explanations of the PEIS’s treatment of cumulative impacts, irreversible and irretrievable commitment of resources, the relationship between short-term uses and long-term productivity, unavoidable adverse impacts, and DOE’s preferred alternative. This chapter also contains the glossary.
- Chapter 3, “Affected Environment,” provides the existing conditions for each of the potentially affected environmental resource areas. It considers these resource areas at the State level and on an island-by-island basis for six islands (Kaua‘i, O‘ahu, Molokai, Lāna‘i, Maui, and Hawai‘i). In order to avoid redundancy in later chapters focused on technology-specific impacts, this chapter includes a discussion of the environmental impacts most often associated with construction and operation activities regardless of the clean energy activity or technology. The chapter organizes and discusses these impacts and associated best management practices in relation to the impacted resource, not the particular activity or technology. The environmental resource areas addressed in Chapter 3 include:
 - Geology and Soils – The geologic characteristics of the area at and below the ground surface, the frequency and severity of seismic activity, and the kinds and quality of soils.
 - Climate and Air Quality – Climatic conditions such as temperature and precipitation, ambient air quality, and criteria pollutant and greenhouse gas emissions.
 - Water Resources – Marine, surface-water, and groundwater features, water quality and availability, floodplains, and wetlands.
 - Biological Resources – Flora and fauna of the region and the occurrence and protection of special-status species.
 - Land and Submerged Land Use – Land and submerged land use practices and land ownership information.
 - Cultural and Historic Resources – Cultural, historic, and archaeological resources and the importance of those resources.
 - Coastal Zone Management – The existing regulatory process for consistency with coastal zone management plans, special management areas, and shoreline setbacks.
 - Scenic and Visual Resources – Scenic and visual resources in terms of land formations, vegetation, and color, and the occurrence of unique natural views.

- Recreation Resources – Existing recreation areas and uses, both on land and in the marine environment.
 - Land and Marine Transportation – The existing transportation systems in the area.
 - Airspace Management – Existing airport systems and military air bases and operation as well as the processes for managing the safe utilization of the airspace for intended uses.
 - Noise and Vibration – Ambient noise and vibration levels, analytical techniques, and the identification of sensitive receptors.
 - Utilities and Infrastructure – Existing electric utilities and electrical transmission and distribution services.
 - Hazardous Materials and Waste Management – Solid and hazardous waste generation and management practices, wastewater services, the types of waste from current activities, the means by which waste is disposed, and pollution prevention practices.
 - Socioeconomics – The labor market, population, housing, public services, and personal income.
 - Environmental Justice – The identification of low-income and minority populations that could be subject to disproportionately high and adverse environmental impacts.
 - Health and Safety (including Accidents and Intentional Destructive Acts) – The existing public and occupational safety conditions, including information on health and safety regulations and worker safety and injury data. The impacts chapters also provide a perspective of potential impacts from accidents and intentional destructive acts.
- Chapters 4 through 8 present the environmental impact analyses, by environmental resource, for the activities/technologies carried forward for detailed analysis. Energy Conservation and Initiatives and Programs are not associated with adverse environmental impacts, and Utility-Scale Hydroelectric is considered to have low feasibility; these are not analyzed in detail.) The analyses are based on the potential programmatic-level impacts from the representative projects (Chapter 2) on the affected environment (Chapter 3) to provide potential impact perspectives. Each section within each chapter also presents best management practices and mitigation measures specific to an activity or technology.
 - Chapter 4, “Environmental Impacts from Energy Efficiency”
 - Chapter 5, “Environmental Impacts from Distributed Renewables”
 - Chapter 6, “Environmental Impacts from Utility-Scale Renewables”
 - Chapter 7, “Environmental Impacts from Alternative Transportation Fuels and Modes”
 - Chapter 8, “Environmental Impacts from Electrical Transmission and Distribution”
 - Chapter 9, “Comment-Response Document,” presents a description of the comment-response process, the comments received, and DOE’s responses to those comments.

This PEIS includes three appendixes:

- Appendix A, “Public Notices”
- Appendix B, “Distribution List”

- Appendix C, “List of Preparers”

S.7 Potential Environmental Impacts and Best Management Practices

As identified in [Section S.3](#), DOE is not proposing any specific projects associated with this PEIS. Therefore, this PEIS uses representative projects to evaluate the potential environmental impacts from the various activities and technologies that could be implemented to assist the State in meeting the Renewable Portfolio Standard and Energy Efficiency Portfolio Standard established as part of the HCEI. This PEIS also describes best management practices that could be implemented to keep those impacts to a minimum or prevent them altogether.

Additionally, because of its programmatic nature, the PEIS cannot present the same comparative analyses of each activity or technology as an evaluation of a specific project at a known location. The criteria used for such a specific analysis could include reliability, schedule-ability, economic feasibility, lifecycle analysis, potential for and scale of emergency/disaster impacts, and relative ease of integration onto each island’s grid. These criteria could be included in a future project-specific environmental review.

Chapter 2 presents several summary tables that provide an overview of the potential environmental impacts for the energy efficiency activities and renewable energy technologies associated with each of the five clean energy categories. Each table presents the following:

- A reference to specific sections in Chapter 3 for those impacts that would be common among most construction and operation activities. (These impacts are set forth in one place in Chapter 3 to avoid repeating them for each distinct activity or technology in later chapters.)
- The potential environmental impacts specific to the stated activity/technology.

Accompanying each summary table is a chart that illustrates the resource areas that could be affected by each activity/technology. The clear circles indicate that no potential impacts would be expected for the activity/technology in that resource area. The light-gray circles indicate that the activity/technology would be expected to result in impacts similar to those common among most construction and operation activities (described in Chapter 3). The black circles indicate that there could be potential impacts specific to an activity or technology for that resource area. These charts are also presented below as Tables S-3 through S-7.

Best management practices and mitigation measures are identified in several places in the PEIS. For those potential impacts common among construction and operation activities, and not technology-specific, best management practices are presented in Chapter 3 for each resource area. For the activity/technology-specific impacts, the best management practices and mitigation measures are presented in Chapters 4 through 8 with the impacts analysis for that activity/technology. Implementation of these best management practices and mitigation measures are important to prevent or minimize the potential environmental impacts to that resource.

Table S-3. Characterization of the Potential for Environmental Impacts – Energy Efficiency

S.8 Overview of Potential Environmental Impacts from Technologies and Activities in the Clean Energy Categories

This section (1) provides an overview of the major conclusions about potential impacts from the five clean energy categories and (2) presents tables that summarize the potential environmental impacts associated with the clean energy technologies with the highest potential for adverse environmental impacts (based on the representative projects analyzed in this PEIS). Table S-8 summarizes impacts for On-Island Transmission, Undersea Cables, and Sea Water Air Conditioning. Potential environmental impacts for Utility-Scale Renewable technologies are summarized for Biomass-Fueled Steam Turbine Generation, Biodiesel Plant and Electric Power Plant, Geothermal, Municipal Solid Waste-to-Energy Facility, and Marine Hydrokinetic Energy in Table S-9a, and for Ocean Thermal Energy Conversion, Photovoltaic Systems, Solar Thermal Systems, Land-based Wind, and Offshore Wind in Table S9b. The other activities and technologies (generally the energy efficiency activities, distributed renewable technologies, and the alternative transportation fuels and modes) are not listed in these tables because they have the smallest potential for adverse environmental impacts. Chapter 2 contains a complete set of the tables that summarize potential impacts from all renewable energy technologies and energy efficiency activities for all resource areas (see Tables 2-37 through 2-46).

Major Conclusions

Many of the technologies and activities evaluated in this PEIS have the potential benefit of reducing greenhouse gas and other criteria pollutant emissions due to the reduced need for and use of fossil fuels as

an energy source. The potential for other environmental impacts varies across the different energy categories depending on the technology, size, and location of the analyzed projects, but generally can be characterized as follows:

- Activities and technologies in the Energy Efficiency category would have the smallest potential for notable environmental impacts. The small size and, in most cases, minimally disruptive nature of these activities and technologies would result in no or minimal potential impacts across the resource areas. However, sea water air conditioning could potentially impact water quality and biological resources, due to the return of warmer water for discharge. These potential impacts can be minimized or eliminated through the consideration and implementation of the various best management practices identified and discussed in this PEIS.
- Activities and technologies in the Distributed Renewables category typically would involve small projects; therefore, potential impacts from these technologies are not likely to be significant. Implementation of renewable energy projects at the residential scale (particularly solar photovoltaic, which can be deployed quickly in multiple locations) can exceed the capacity of a local power grid or utility. This can cause delays in bringing new energy sources to the electrical grid, require system upgrades, and have other consequences on local circuits. These and other potential adverse impacts can be minimized or eliminated through the implementation of interconnection standards and the use of best management practices identified and discussed in the PEIS.
- Among the technologies and activities analyzed in this PEIS, the greatest potential for environmental impacts is associated with the Utility-Scale Renewables category since it would include those technologies with the largest physical footprint and generation of the largest amount of electricity. All of these technologies would have the potential to impact numerous resource areas. Such potential impacts generally would be highest during construction and include noise, increased air emissions, changes to scenic and visual landscapes, and potential impacts to biological and cultural resources. The most common potential long-term impacts associated with these technologies would include changes to land and submerged land use and scenic and visual resources. These potential impacts would be location-dependent and could be minimized or eliminated through the use of the location-specific best management practices identified and discussed in the PEIS.
- Activities and technologies in the Alternative Transportation Fuels and Modes category would have a moderate potential for notable environmental impacts. Increased use of the alternative fuels would result in a reduction of criteria pollutants and greenhouse gas emissions as well as a reduction in the use of fossil fuels. The development of certain biofuels, however, could have adverse impacts related to using large land areas for the production of feedstock, the application of herbicides and fertilizers, and the introduction of invasive species. These and other potential adverse impacts can be minimized or eliminated through the use of best management practices such as proper handling, storage, and use of chemicals and the screening of plant species for invasive characteristics. A comprehensive, connected multi-modal transportation system in Hawai‘i likely would result in reductions in petroleum used for ground transportation, reductions in nonpoint source pollution, and improved air quality.
- In the Electrical Transmission and Distribution category, the two technologies with the greatest potential for environmental impacts on valuable resources are on-island transmission and undersea cables. These projects are long and linear, and the potential impacts are predominantly associated with construction activities and the route of the transmission lines/cables. Potential

construction and routing impacts can be minimized or eliminated through the use of construction- and location-specific best management practices.

In addition, during project siting, all of these activities—but especially the Electrical Transmission and Distribution and the Utility-Scale Renewables categories—share the characteristic of encountering one or more host communities that could be impacted in numerous ways. In Hawai‘i, this almost always includes the potential to impact Native Hawaiian communities, lifestyles, and values. The potential for project acceptance and success can be greatly enhanced by early and sincere involvement of the various communities in project planning and concern for “fairness” in project definition.

In addition to impacts from a technology standpoint, the State of Hawai‘i has indicated particular interest in the potential impacts to four environmental resource areas.

- Biological resources due to the large number of threatened and endangered species and unique island habitat;
- Land and submerged land use based on the finite characteristics of this resource to the islands’ environments;
- Cultural and historic resources because of the strong and long standing beliefs of the native population and their relationship with the islands’ physical environment; and
- Scenic and visual resources because of both the cultural and historic aspects, as well as the importance to the tourism appeal of the islands.

Table S-8. Summary of Impacts for Selected Technologies and Activities

Resource Area	On-Island Transmission	Undersea Cables	Sea Water Air Conditioning
Geology and Soils			
	General impacts during construction.	<p>Onshore General impacts during construction.</p> <p>Offshore Potential disturbance of marine sediments during construction (short-term) with minor impacts:</p> <ul style="list-style-type: none"> • Sediment disturbance at the horizontal directional drilling breakout point • Drilling mud/slurry release at the horizontal directional drilling breakout point • Sediment disturbance at trenching locations. <p>No impacts to geology and soils during operation.</p>	<p>Onshore Potential soil erosion and contamination during construction (short-term).</p> <p>Offshore Potential disturbance of marine sediments during construction (short-term) and operations.</p>
Climate and Air Quality			
Air Quality	General impacts during construction	<p>General impacts during construction.</p> <p>Beneficial impacts resulting from higher penetration of renewable generation on each connected island grid.</p>	<p>General impacts during construction (short-term).</p> <p>The use of a sea water air conditioning system would require 75 percent less electricity than a standard cooling system; therefore, there would be a beneficial impact to air quality from a reduction of criteria pollutants resulting from electricity generated by fossil fuels.</p>
Climate Change	General impacts during construction	General impacts during construction.	<p>Minor impacts during construction.</p> <p>Reductions in greenhouse gas emissions as a result of reduction of electricity generation using fossil fuels.</p>

Table S-8. Summary of Impacts for Selected Technologies and Activities (continued)

Resource Area	On-Island Transmission	Undersea Cables	Sea Water Air Conditioning
Water Resources			
Surface Water	<p>General impacts during construction.</p> <p>Operation impacts include possible alteration of stormwater runoff along transmission corridor as vegetation is reestablished. Any single drainage path expected to experience minimal alteration.</p> <p>Potential application of herbicides to maintain transmission corridor could produce negative environmental impacts if they reach surface waters.</p>	<p><u>Onshore</u> General impacts during construction.</p> <p>Potential impacts if increase in impermeable surfaces at built up land-sea transition sites.</p> <p><u>Offshore</u> Sediment disturbance/dispersal and increased turbidity during horizontal directional drilling.</p> <p>Potential site-specific impacts may occur to habitats or communities of concern.</p> <p>No operation impacts.</p>	<p><u>Onshore</u> General impacts during construction (short-term).</p> <p>No operation impacts.</p> <p><u>Offshore</u> Sediment disturbance/ dispersal and increased turbidity.</p> <p>Potential site-specific impacts may occur to habitats or communities of concern.</p> <p>Potential increase in nutrient levels (nitrate and phosphates).</p> <p>Potential for sea water temperature variability impact.</p>
Groundwater	<p>General impacts during construction.</p> <p>No adverse operation impacts unless herbicides applied to maintain transmission corridor.</p>	<p>General impacts during construction.</p>	<p>General construction impacts.</p> <p>No adverse operation impacts.</p> <p>Potential fresh water (groundwater) savings if wastewater is used as the cooling medium.</p> <p>Potentially beneficial; fresh water savings compared to a facility with an open cooling system.</p>

Table S-8. Summary of Impacts for Selected Technologies and Activities (continued)

Resource Area	On-Island Transmission	Undersea Cables	Sea Water Air Conditioning
Biological Resources			
	<p>General impacts to terrestrial ecosystems during construction, including potential access roads.</p> <p>Operational maintenance of cleared areas around towers and vegetation height along transmission corridor.</p> <p>Potential bird and bat collisions with towers and lines, especially nocturnal flying species.</p>	<p>General impacts to terrestrial and marine ecosystems during construction (short-term impacts to benthic communities and marine mammals if construction occurred in the Hawaiian Islands Humpback Whale National Marine Sanctuary).</p> <p>Potential localized disturbance impacts to benthic communities at the horizontal directional drilling breakout point and along cable route during construction due to direct displacement or indirect sedimentation.</p> <p>Potential operation impacts on sensitive species by electromagnetic fields along undersea cable route.</p>	<p>General impacts to terrestrial and marine ecosystems during construction (short-term impacts to benthic communities and marine mammals if construction occurred in the Hawaiian Islands Humpback Whale National Marine Sanctuary).</p> <p>Minimal and localized impacts to marine organisms from water discharge temperature.</p> <p>Potential increase in nutrient levels resulting in increased marine productivity and possible creation of unusual algal blooms.</p> <p>Potential localized disturbance impacts to benthic communities at discharge point.</p> <p>Potential entrainment of smaller organisms at the intake pipe.</p>
Land and Submerged Land Use			
Land Use	Transmission line corridors and location of substations and switching yards could result in changes of land ownership patterns and land use.	General impacts during construction and operation.	Short-term land disturbance impacts at the cooling station locations and along distribution line routes during construction.
Submerged Land Use	None; the on-island transmission project would not extend offshore.	<p>Short-term submerged land disturbance impacts along the undersea cable corridor during construction.</p> <p>Potential temporary impacts during maintenance/expansion activities.</p> <p>Potential land use impacts along undersea cable corridor.</p>	Potential land use impacts related to expansions/maintenance of the cooling stations and/or distribution network.

Table S-8. Summary of Impacts for Selected Technologies and Activities (continued)

Resource Area	On-Island Transmission	Undersea Cables	Sea Water Air Conditioning
Cultural and Historic Resources			
	<p>General impacts during construction and operation.</p> <p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	<p>Potential direct impacts from onshore and offshore construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	<p>General construction and operation impacts to cultural resources.</p> <p>Potential adverse impacts to cultural, historic, and related natural resources during construction and operation (both on and offshore).</p>
Coastal Zone Management			
	<p>General impacts during construction and operation.</p> <p>Potential impacts to coastal zone resources (site-specific).</p>	<p>Potential effects to special management areas established to protect specific coastline resources and limit shorefront access (project/site-specific).</p>	<p>Potential effects to special management areas established to protect specific coastline resources and limit shorefront access (project- and/or site-specific).</p>

Table S-8. Summary of Impacts for Selected Technologies and Activities (continued)

Resource Area	On-Island Transmission	Undersea Cables	Sea Water Air Conditioning
Scenic and Visual Resources			
	<p>General impacts during construction.</p> <p>Long-term visual impacts associated with towers, transmission lines, cleared transmission corridors, substations, and switching yards.</p>	<p>Short-term impacts to visual resources during construction.</p> <p>Short-term visibility of cable-laying ships.</p> <p>Long-term visual impacts associated with the new transition sites.</p>	<p>Short-term impacts to visual resources during construction.</p> <p>Long-term visual impacts associated with the new cooling station.</p>
Recreation Resources			
	<p>General impacts during construction.</p> <p>Long-term obstruction to some recreational activities; conversely, some activities could be enhanced by improved access (e.g., from access roads for installed transmission infrastructure).</p>	<p>General impacts during construction.</p> <p>Short-term impacts during construction; limited to no impacts during operations.</p>	<p>General impacts during construction.</p> <p>Potential short-term impacts to offshore recreation during installation of the subsurface piping.</p> <p>The short-term impacts could include: (1) restricted access to recreation areas near the area of installation of the underwater piping and on-shore facility, and (2) possible visual impairment from areas near the construction of the facilities that could have a negative effect on the ongoing recreational activities.</p>

Table S-8. Summary of Impacts for Selected Technologies and Activities (continued)

Resource Area	On-Island Transmission	Undersea Cables	Sea Water Air Conditioning
Land and Marine Transportation			
Land Transportation	<p>Potential traffic congestion during construction from wide-load hauling of transmission line components (e.g., towers and tower foundations).</p> <p>Short-term impacts during line stringing.</p> <p>Impacts during construction if transmission line installation required road crossings.</p>	<p>Potential traffic congestion during construction from wide-load hauling of transmission line components (e.g., cables and installation equipment).</p> <p>General impacts during construction of the land-sea transition sites</p>	<p>General impacts including localized short-term traffic impacts during construction and/or if road crossings are needed.</p>
Marine Transportation	<p>None; the on-island transmission project would not extend offshore.</p>	<p>Potential short-term impacts on harbor operations, local marine transportation, and military marine (including submarine) operations.</p>	<p>Potential short-term (temporary) impacts on harbor operation, local marine transportation, and military marine operations</p> <p>Potential impacts to military submarine operations.</p>
Airspace Management			
	<p>Potential air traffic impacts during construction if helicopters are used to transport supplies or for line stringing.</p> <p>Potential construction and operation impacts and hazards to civilian and military aviation due to topography and high presence of low-altitude aviation.</p> <p>Potential long-term impacts from radio frequency interference.</p>	<p>None; construction and operation of undersea cable and land-sea transition sites would not require any tall structures and therefore would not impact airspace management.</p>	<p>None; construction and operation of sea water air conditioning would not require any tall structures and therefore would not impact airspace management.</p>

Table S-8. Summary of Impacts for Selected Technologies and Activities (continued)

Resource Area	On-Island Transmission	Undersea Cables	Sea Water Air Conditioning
Noise and Vibration			
	<p>Short-term noise and vibration impacts during construction.</p> <p>Potential vibration and humming noise during operation from loose hardware.</p> <p>Sizzles, crackles, hissing noises possible, especially during periods of higher humidity.</p>	<p>Short-term noise and vibration impacts to sensitive noise receptors, including potential impacts to marine mammals and sea turtles.</p> <p>Long-term noise and vibration impacts from operation of undersea cables would be negligible.</p> <p>Noise and vibration impacts from land-based converter stations would be dependent on the location and compatibility with the existing noise levels and land uses.</p>	<p>Short-term noise and vibration impacts during construction. Noise levels could temporarily exceed regulatory levels. Exposure to elevated noise and vibration levels may result in temporary impacts to marine & mammal behavior and marine mammal prey species.</p> <p>No long-term ambient noise or vibration impacts are expected during operation.</p> <p>A positive benefit could be the elimination of noise currently generated from cooling towers as buildings convert to sea water air conditioning systems.</p>
Utilities and Infrastructure			
	<p>Potential impacts related to adding electricity capacity to the grid.</p>	<p>Potential impacts related to adding electricity capacity to the local power grid.</p> <p>Connecting the electrical grids of two or more islands would:</p> <ul style="list-style-type: none"> • Enable the transmission of power and ancillary services in both directions and allow the two networks to operate in a coordinated fashion; • Improve the power system economics and reliability on each island; • Increase system flexibility in resource planning, operations, and reliability; • Add flexibility in siting and interconnection of renewable energy generation; • Reduce renewable energy curtailments; and • Reduce oil usage for electricity generation. 	<p>Potential reduction in energy consumption (may require modification of the utility structure to meet the Renewable Portfolio Standard).</p>

Table S-8. Summary of Impacts for Selected Technologies and Activities (continued)

Resource Area	On-Island Transmission	Undersea Cables	Sea Water Air Conditioning
Hazardous Materials and Waste Management			
Hazardous Materials	General impacts from exposure to hazardous materials during construction. Potential impacts from exposure to hazardous materials during operation and maintenance from use of herbicides to maintain transmission corridor.	General impacts during construction and operation, particularly during development of converter stations.	General impacts from exposure to hazardous materials during construction. No adverse operation impacts.
Waste Management	None; any vegetation cleared likely would be composted or reused.	Any waste generated onboard the construction vessels and barges would be disposed of at the appropriate landfill.	General waste management impacts during construction.
Wastewater	General impacts during construction.	General impacts during construction and operation, particularly during development of converter stations.	General wastewater impacts during construction. No adverse operation impacts. Potential beneficial impacts may occur if wastewater were utilized in place of sea water. This would minimize the amount of wastewater from other sources that would have to be treated by the local municipality.
Socioeconomics			
	Minimal beneficial impacts during construction and operation.	Minimal beneficial impacts during construction and operation.	Beneficial – few jobs created.
Environmental Justice			
	Small environmental justice impacts. Site-specific evaluation of impacted populations required.	Small environmental justice impacts. Site-specific evaluation of impacted populations required.	Depending on siting, impacts to visual and scenic resources could have the potential to be disproportionately high and adverse with respect to environmental justice communities.

	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
			Potential groundwater impacts from geothermal fluids removed from the subsurface.		
Biological Resources					
	<p>Potential for general construction impacts.</p> <p>Potential impacts to vegetation or wildlife (including to the wide-ranging Hawaiian hawk and the Hawaiian hoary bat) species (site-specific).</p> <p>Potential beneficial impacts – may create a market for selective harvesting of invasive woody species, such as albizia trees.</p> <p>Potential impacts from the introduction of new, invasive plant species.</p> <p>Potential impacts associated with use of genetically modified plants.</p>	<p>General construction impacts.</p> <p>Potential for loss of wildlife habitat.</p> <p>Potential impacts from the introduction of new, invasive plant species from commercial feedstock production.</p> <p>Potential impacts associated with use of genetically modified plants.</p>	<p>General construction impacts.</p> <p>Potential impacts to biological resources including land disturbance and disturbance by human activity.</p> <p>Potential increase in invasive species establishment in disturbed sites.</p> <p>Potential biological impacts on flights of marine birds (such as shearwaters and petrels) from facility lighting (site-specific).</p>	<p>General construction impacts.</p> <p>Potential for construction impacts including land disturbance to wildlife in adjacent habitats, particularly near important nesting and feeding areas, wetlands, or roost sites (site-specific).</p> <p>Potential for impacts to biological resources during operations (site-specific).</p>	<p>Potential construction impacts include displacement of marine mammals, reptiles, and fish both from physical activity and noise transmission through ocean waters.</p> <p>Potential marine habitat impacts including to marine pools, beaches (both rocky and sand), coral reefs, and essential fish habitat.</p> <p>Potential loss of beach nesting habitat for sea turtles and marine birds; and resting sites for the Hawaiian monk seal.</p> <p>Potential collision hazards to marine mammals and reptiles during anchor cabling.</p> <p>Potential localized noise (sound waves) impacts (potential auditory injury), avoidance, physical injury to marine mammals, fish, or other species, and alteration of water dynamics from submerged oscillating or rotating components.</p>

Table S-9a. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste-to-Energy Facility	Marine Hydrokinetic Energy
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
					Potential electromagnetic field impacts from the undersea power cable.
Land and Submerged Land Use					
Land Use	Potential change in landownership patterns if the site is acquired by purchase or land use easement. Potential conversion of undeveloped land or land under current land uses.	Potential change in landownership patterns if the site is acquired by purchase or land use easement. Undeveloped land or land under current land uses could be converted to energy uses.	Potential change in land use or ownership by purchase or through land leases. Potential impacts to undeveloped land or land with current uses from conversion to an energy facility. Potential land use easement impacts.	Potential change in landownership patterns if the site is acquired by purchase or land use easement. Potential land use conversion impacts (i.e., the creation of transmission corridors).	Potential land disturbance impacts during construction.
Submerged Land use	Biomass projects would be land-based and not impact submerged land uses.	Biomass projects would be land-based and not impact submerged land uses.	Geothermal projects would be land-based and not impact submerged land uses.	Because the representative project would be entirely land-based, there would be no impacts to submerged land use.	Potential localized impacts to the ocean floor from tethering and power cable installation, including obstruction of local marine habitats.
Cultural and Historic Resources					
	General construction and operation impacts. Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities. Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.	General construction and operation impacts. Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities. Land and Marine Transportation					
Land Transportation	Potential increase in truck traffic for biomass delivery. Potential increased wear on paved roads and road maintenance.	Potential increase in truck traffic for biomass delivery. Potential increased wear on paved roads and road maintenance.	Potential short-term impacts on roadway traffic during project construction.	Potential for localized transportation impacts from transporting municipal solid waste.	None.
Marine Transportation	None; it is unlikely that bulk biomass would be shipped between islands.	None; it is unlikely that bulk biomass would be shipped between islands.	None identified.	Because the representative project would be entirely land-based, there would be no impacts to marine transportation. Transfer of municipal solid waste between islands is not anticipated.	Potential obstruction impacts to marine navigation including to tourist cruises, passenger ferries, fishing vessels (recreational and commercial), and large commercial cargo ships. Potential impacts to military marine operations, surface and subsurface navigation from both floating and submerged structures.
Airspace Management					
	Potential hazards to aircrafts from emission stacks for those project locations nearby airports.	Minimal potential hazards to aircrafts from emission stacks for those project locations nearby airports.	None; the development and operation of a geothermal facility would not result in any tall structures or steam exhausts that would require further consultation on airspace management impacts.	Potential impacts if emission stacks are less than 200 feet.	None; the marine hydrokinetic energy representative project would not include any tall structures and therefore would not impact airspace management.

Table S-9a. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste-to-Energy Facility	Marine Hydrokinetic Energy
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
Noise and Vibration					
	<p>Short-term noise and vibration construction impacts.</p> <p>Potential long-term impacts to existing noise and vibration levels, depending on the location of facilities and compatibility with existing noise levels and land uses.</p> <p>Noise impacts from truck traffic delivery (site-specific).</p>	<p>Short-term noise and vibration construction impacts.</p> <p>Long-term noise and vibration operation impacts (site-specific).</p> <p>Noise impacts from truck traffic delivery (site-specific).</p>	<p>Short-term and long-term noise and vibration impacts would result from exploration, construction, and operation. Potential impacts from noise and vibration would be wholly dependent on sound levels and the proximity of sensitive receptors to the source. Noise and vibration levels would be reduced with implementation of best management practices.</p>	<p>General impacts during construction and operation.</p>	<p>Short-term noise and vibration impacts to sensitive noise receptors, including potential impacts to marine mammals and sea turtles. Unless deployed in large arrays of generators, long-term noise and vibration impacts from marine hydrokinetic energy technologies would be minimal with implementation of best management practices.</p>
Utilities and Infrastructure					
	<p>General construction and operation impacts.</p> <p>Varying impacts to utilities (site/island-specific i.e., small effects to O'ahu, larger effects to Lāna'i), requiring potential adjustment/ management of power grids and overall power production.</p>	<p>General construction and operation impacts.</p> <p>Varying impacts to utilities (site/island-specific i.e., small effects to O'ahu, large effects to Lāna'i), requiring potential adjustment/ management of power grids and overall power production.</p>	<p>General construction impacts.</p> <p>Potential for minor to moderate impacts to electric utilities (site-specific, i.e., moderate effects to Maui and minor effects to Hawaii's utilities).</p>	<p>General construction and operation impacts.</p> <p>Varying impacts to utilities (site/island-specific i.e., small effects to O'ahu, larger effects to Lāna'i), requiring potential adjustment/ management of power grids and overall power production.</p>	<p>General construction impacts.</p>

Table S-9a. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste-to-Energy Facility	Marine Hydrokinetic Energy
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
Hazardous Materials and Waste					
Management Hazardous Materials	General construction impacts. Potential exposure to high quantities of fertilizers (primarily nitrogen), herbicides, and pesticides.	General construction impacts. Potential exposure to high quantities of fertilizers, herbicides, and pesticides. Potential hazardous materials exposure impacts from biodiesel leaks or accidents.	General construction impacts. Potential impact from exposure to hazardous materials if chemicals used during exploration/flow testing or from drilling fluids that were improperly handled or released into the environment. Potential impact from exposure to hazardous materials if an accidental spill or chemical release were to occur during operations from lubricating oils, hydraulic fluids, coolants, solvents, and/or cleaning agents. Potential impact from exposure associated with naturally occurring hydrogen sulfide.	General construction impacts. Potential exposure to hazardous materials from municipal solid waste delivered to the site. Potential impact from exposure to hazardous materials associated with the flammability of syngas production.	General construction impacts. Potential exposure to hazardous materials including fuels from boats, marine vessels, barges, lubricants and hydraulic fluids contained in the wave or tidal energy devices during operations and maintenance.
Waste Management	General construction impacts.	General construction impacts. Potential increase in byproduct waste generated	General construction impacts. Potentially adverse impacts if additional waste were generated on the island of Hawai'i. Minor amounts of hazardous waste may be generated including paints, coatings, and spent solvents.	General construction impacts. Potential exposure to hazardous waste (i.e., infectious waste, electronics, lead acid batteries, firearms, propane tanks, sludge, agricultural wastes, soil, and some noncombustible inorganic materials (such as concrete, stone).	Potential landfill impacts to O'ahu and Hawai'i (pending the resolution of existing landfill capacity constraints) if non-recyclable materials add to existing landfill capacity constraints.

Table S-9a. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste-to-Energy Facility	Marine Hydrokinetic Energy
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
				<p>Potential waste management impacts from ash waste byproducts.</p> <p>Potentially beneficial impacts resulting from decreased municipal solid waste in landfills.</p>	
Wastewater	Potential impacts to wastewater services from trace amounts of chemicals and elevated temperatures during blowdown from the steam cycle and cooling system.	<p>General construction impacts.</p> <p>Potential impacts to wastewater services from trace amounts of chemicals and elevated temperatures during the blowdown from the steam cycle and cooling system.</p>	<p>General construction impacts.</p> <p>Potential wastewater impacts in the event of a leak containing geothermal waste fluids.</p>	<p>General construction impacts.</p> <p>Potential impacts to wastewater services from blowdown.</p>	<p>Potential impacts to wastewater services from vessel effluent during construction.</p> <p>No operation impacts.</p>
Socioeconomics					
	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.
Environmental Justice					
	<p>Small potential impacts to the general population.</p> <p>Site-specific evaluation of impacted populations required.</p>	<p>Small potential impacts to the general population.</p> <p>Site-specific evaluation of impacted populations required.</p>	<p>Small environmental justice impacts.</p> <p>Site-specific evaluation of impacted populations required.</p>	<p>Small potential impacts to the general population.</p> <p>Site-specific evaluation of impacted populations required.</p>	<p>No effects identified. Because of the uncertainty of the marine hydrokinetic energy designs and the low potential for adverse impacts, there would be no disproportionately high and adverse impacts to minority or low-income populations. There would be no environmental justice impacts from the marine hydrokinetic energy representative project.</p>

Table S-9a. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste-to-Energy Facility	Marine Hydrokinetic Energy
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
Health and Safety	General construction and operation impacts.	<p>General construction and operation impacts.</p> <p>Health risks from the use of pesticides, herbicides, and fertilizers.</p> <p>Additional risks of traffic accidents associated with the transport of biomass materials.</p>	<p>General construction and operation impacts.</p> <p>Potential health and safety effects from drilling including hydrogen sulfide worker exposure.</p> <p>Potential health and safety impacts from physical, thermal, and chemical hazards such as hydrogen sulfide exposure.</p>	General construction and operation impacts.	<p>General construction and operation impacts.</p> <p>Potential for public health and safety effects including to boats, both civilian and military marine vessels, and to the public onshore in the event the device were destroyed, damaged or if the loss of mooring/ spatial stabilization were to occur.</p>

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
Geology and Soils					
	None; the only potential impacts to geology and soils would be the interface of the undersea cable to connect the ocean thermal energy conversion facilities with the grid.	General construction impacts from land disturbance/soil erosion. No operation impacts.	General construction impacts from land disturbance. Potential for soil contamination in the event of a leak or accidental release of the heat transfer fluids (such as synthetic oil or even molten salt) used in the system.	General construction impacts from land disturbance/soil erosion. No operation impacts.	General onshore construction impacts from land disturbance/soil erosion. Potential impacts to marine sediments (e.g., natural migration of sand) from anchor/mooring devices, undersea cables, and land/sea transition zones. No operation impacts.
Climate and Air Quality					
Air Quality	General construction impacts. Limited, intermittent, and short-term air quality impacts during construction. Potential land disturbance and related fugitive dust at nearby onshore construction related areas, including areas where offshore electrical lines connect with the onshore regional electric grid.	General construction impacts. No operation impacts.	General construction impacts. No operation impacts.	General construction impacts. No operation impacts.	General construction impacts. Potential increased criteria pollutants from construction equipment including marine vessels (powered by fossil fuels, e.g., diesel, or gasoline) during construction. Potential for fugitive dust at nearby onshore construction-related areas.

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
	<p>Potential increase in criteria pollutant emissions during construction from equipment or marine vessels powered by fossil fuels.</p> <p>Potential operational emissions from auxiliary diesel generators on the platform.</p>				
Climate Change	<p>Potential increase in greenhouse gas emissions from construction equipment and operation of diesel generators on the platform.</p> <p>Potential greenhouse gas emissions reduction from a mix of technologies used to produce electricity using fossil fuels.</p>	<p>Potential greenhouse gas emissions reduction from a mix of cleaner technologies used to produce electricity using fossil fuels.</p>	<p>Potential greenhouse gas emissions reduction from a mix of different technologies used to produce electricity using fossil fuels.</p>	<p>Potential greenhouse gas emissions reduction from a mix of cleaner technologies used to produce electricity using fossil fuels.</p>	<p>Potential greenhouse gas emissions reduction from a mix of cleaner technologies used to produce electricity using fossil fuels.</p>
Water Resources					
Surface Water	<p>Potential ocean sediment disturbance resulting in increased turbidity and impacts to coral or other bottom communities of concern.</p> <p>Potential water quality impacts from discharge not meeting water quality criteria for marine waters (i.e., nutrient levels such as nitrite plus nitrate, phosphate, and phosphorous.).</p>	<p>General construction impacts.</p> <p>Potential stormwater runoff from the site (dependent on the amount of impermeable surface/nature of the preconstruction site).</p>	<p>General construction impacts.</p> <p>Potential stormwater runoff contamination in the event of leaks or accidental releases of the heat transfer fluids (such as synthetic oil or even molten salt) used in the system.</p>	<p>General construction impacts.</p> <p>Potential for increased stormwater runoff as a result of increased impermeable surfaces (wind turbine foundations, electrical support buildings, and paved roads or parking areas) – (site-specific).</p>	<p>General construction impacts including horizontal directional drilling for electrical cables and for the construction of a substation.</p> <p>No potential onshore effects during operations.</p> <p>Potential for increased turbidity at breakout point from drilling mud or slurries used during horizontal directional drilling.</p>

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
	<p>Potential increased algal bloom impacts from increased nutrient levels.</p> <p>Potential impacts from temperature variation and elevated chlorine levels of discharge.</p>				Potential impacts to coral or other bottom communities of concern from high turbidity (site-specific).
Groundwater	Minimal groundwater impacts during construction and operation.	<p>General construction impacts.</p> <p>Potential changes in runoff to the site and potential associated change in groundwater recharge.</p>	<p>Minor groundwater impacts during construction.</p> <p>Potential changes in runoff to the site and potential associated change in groundwater recharge.</p>	General construction impacts.	<p>General construction impacts.</p> <p>No operation impacts.</p>
Floodplains and Wetlands	None identified.	Potential impacts during construction and operation (site-specific).	Potential impacts during construction and operation (site-specific).	Potential impacts during construction and operation (site-specific).	Potential impacts during construction (site-specific).
Biological Resources					
	<p>Potential for short-term and small disturbances during placement of the cabling lines, moors, and anchors.</p> <p>Potential disturbance to deep and shallow marine habitats and shorelines (including marine pools, sandy and rocky beaches, seagrass habitat, shallow benthic communities, and coral reefs at multiple depths) during construction (site-specific).</p>	<p>General construction impacts.</p> <p>Potential impacts to biological resources including migratory birds, threatened and endangered plants and animals, critical habitat, protected land areas, and wetlands from habitat loss during site development (site-specific). For locations near the ocean, potential impacts may occur to marine anchialine pools.</p>	<p>General construction impacts.</p> <p>Potential impacts to biological resources including migratory birds, threatened and endangered plants and animals, critical habitat, protected land areas, and wetlands) from habitat loss during site development (site-specific). For locations near the ocean, potential impacts may occur to marine anchialine pools.</p>	<p>General construction and operation impacts.</p> <p>Potential impacts to biological resources including loss of vegetation and wildlife (migratory birds, threatened and endangered plants and animals, critical habitat, and other high value areas such as wetlands and native plant communities) from site development (site-specific).</p> <p>Potential for mortality of avian species and bats (site-specific).</p>	<p>General construction and operation impacts.</p> <p>Potential disturbance impacts to the ocean floor and marine communities/ habitats (i.e., coral reefs, shallow benthic communities, seagrass habitat, beaches, and possibly marine pools) during installation of anchors, undersea cables (site-specific).</p> <p>Potential impacts to marine animals from temporary construction noise impacts.</p>

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
	<p>Potential impacts to the marine environment from introduction of an electromagnetic field along the undersea cable.</p> <p>Potential attraction of marine fish, mammals, and seabirds to structures and for biofouling organisms.</p> <p>Potential impacts to marine communities from nutrient rich discharge waters.</p> <p>Potential impacts to marine organisms due to intake pipes.</p> <p>Potential collision hazards to marine mammals from mooring lines.</p>			<p>Potential impacts to seabirds by attracting/disorienting them from onsite lighting.</p>	<p>Potential for increase in marine mammal collisions from ships and boats during construction.</p> <p>Potential increase for hazards to marine mammals congregating in marine subsurface structures.</p> <p>Potential for increased collision hazard for large marine mammals (i.e., whales) from mooring cables.</p> <p>Potential hazards (increased risk for mortalities by rotor blade collision) to seabirds in areas surrounding wind turbines due to potential aggregation of forage fish near submarine structures, tower safety lighting, and potential use of aboveground platform structures as resting areas.</p> <p>Potential introduction of an electromagnetic field into the marine environment along the cable resulting in potential impacts to marine mammals with electrosensory systems.</p>

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
Land and Submerged Land Use					
Land Use	Typical land use impacts associated with the interface of an undersea cable and the electrical grid.	<p>Potential land use impacts including land disturbance and possible conversion of undeveloped land and land in other current use to an energy generating facility.</p> <p>Potential change in land ownership patterns and/or easements required for the project (i.e., project site, access roads, corridors to the nearest electrical grid).</p> <p>Potential impacts to adjacent land uses (roads, residential/commercial areas, historic sites, scenic locations, and airports) from the glint and glare of the solar panels.</p>	<p>Potential change in land ownership patterns through purchase and or land use leases for both the solar thermal project site and any linear corridors required to tie-in to the existing electrical grid.</p> <p>Potential impacts to undeveloped land or land currently used for other uses could be converted to energy uses.</p>	<p>Potential land use impacts including land disturbance during site preparation and turbine installation, as well as access road construction and support structures.</p> <p>Potential conversion of undeveloped land or land with other current land uses for energy use.</p> <p>Potential landownership changes and obtainment of land use easements.</p>	<p>Potential change in local landownership patterns.</p> <p>Potential land disturbance during construction of the tie-in to the existing transmission grid.</p>
Submerged Land Use	Potential for large obstructions in the ocean floor from structures.	None; PV projects would be land-based and not impact submerged land uses.	None; solar thermal projects would be land-based and not impact submerged land uses.	None; land-based wind turbines would have no potential effects to submerged land use.	Potential impacts to sea floor requiring a submerged lands lease.
Cultural and Historic Resources					
	<p>General construction and operation impacts.</p> <p>Potential direct impacts from onshore and offshore construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p>	<p>General construction and operation impacts.</p> <p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p>	<p>General construction and operation impacts.</p> <p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p>	<p>General construction and operation impacts.</p> <p>The visual impact of wind turbines may be unacceptable near cultural and historic areas.</p>	<p>General construction and operation impacts.</p> <p>The visual impact of wind turbines may be unacceptable near cultural and historic areas.</p>

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
	<p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	<p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	<p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p>	<p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p> <p>The visual impact of wind turbines may be unacceptable near cultural and historic areas where the historic integrity (setting, feeling, association, viewsheds) plays an important role in the value of the resource.</p>	<p>Potential direct impacts from onshore and offshore construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p> <p>Potential for visual, noise, or restricted access effects on sensitive cultural and historic resources and activities.</p> <p>Potential impact on a historical building, structure, or district by facilities being incompatible with the historic context of a structure or area.</p> <p>The visual impact of wind turbines may be unacceptable near cultural and historic areas where the historic integrity (setting, feeling, association, viewsheds) plays an important role in the value of the resource.</p>

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
Coastal Zone Management					
	<p>Potential impacts to designated special management areas from the cable crossing the shoreline (site-specific).</p> <p>Potential shorefront access impacts from the cable crossing the shoreline (site-specific).</p> <p>Potential shoreline erosion impacts from the cable crossing the shoreline (site-specific).</p>	<p>Potential impacts to designated special management areas, shorefront access, and shoreline erosion (site-specific).</p>	<p>Potential impacts to designated special management areas, shorefront access, and shoreline erosion (site-specific);</p> <p>Potential for adverse impacts to those locations near the shoreline.</p> <p>Potential for increase in runoff and sedimentation and impacts to coastal water habitats from land clearing.</p>	<p>Potential impacts to designated special management areas, shorefront access, and shoreline erosion (site-specific).</p>	<p>Potential impacts to designated special management areas, shorefront access, and shoreline erosion (site-specific).</p>
Scenic and Visual Resources					
	<p>General visual impacts during construction.</p> <p>Potential long-term visual impacts onshore from the introduction of a transition site.</p>	<p>General visual impacts during construction.</p> <p>Potential long-term visual impacts from solar panels, including in association with new facilities and associated buildings.</p> <p>Potential glinting, glare, and visual effects depending on the panel orientation, sun angle, viewing angle, viewer distance, and other visibility factors; may also be dependent on individual viewer sensitivity.</p> <p>Potential long-term visual effects from routine maintenance activities.</p>	<p>General visual impacts during construction.</p> <p>Potential long-term dynamic visual impacts from parabolic troughs/mirrors (glare/reflected light), thermal storage tanks, steam condenser, cooling towers (plumes) and generator as well as road access, parking, maintenance facilities, and transmission line tie-in.</p> <p>Potential for individual discomfort from glare effects, depending on viewer sensitivity, viewer location, viewer movement, and time of day.</p>	<p>General short-term visual impacts during construction including site preparation activities such as clearing, construction of access and onsite roads, equipment laydown areas, installation of turbine foundations, erection of turbines, and connection to the grid.</p> <p>Potential long-term visual impacts from wind turbine operations including the presence of the wind turbines, movement of the rotor blades, shadow flicker, blade glinting, flashing aviation warning lights (nighttime in particular), roads, vehicles, and workers conducting maintenance activities.</p>	<p>Potential long-term visual impacts from wind turbine operations including the presence of the wind turbines, the sweeping movement of the blades, lighting for the marine and aviation navigation, and the land/sea transition site.</p> <p>Depending on viewer sensitivity, potential for long-term impacts to viewers due to the strong vertical lines/ large sweep of turbines/ moving blades that can dominate views or command visual attention.</p>

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
			<p>Potential increase in light pollution impacts (skyglow, light trespass, and glare) from security lighting and other exterior lighting around buildings, parking areas, work areas and during maintenance activities (vehicle-mounted lights).</p>	<p>Depending on viewer sensitivity, potential for long-term impacts to viewers nearby due to the strong vertical lines/ large sweep of turbines/ moving blades that can dominate views or command visual attention.</p> <p>Depending on viewer sensitivity, potential for long-term shadow flicker impacts for viewers close enough to fall within the shadows cast by the turbines.</p>	
Recreation Resources					
	<p>General construction impacts.</p> <p>Potential long-term impacts in the vicinity of onshore and offshore facilities from access restrictions and potential visual impacts from the facilities.</p>	<p>General construction impacts.</p> <p>Potential long-term impacts such as land cover required for the arrays and associated facilities required for the project resulting in access restrictions to area as well as visual impacts created by the presence of the facilities and maintenance activities.</p> <p>Potential impacts to nearby recreation areas from panels and other components that reflect and result in glinting, glare, and other visual effects.</p>	<p>General construction impacts.</p> <p>Potential long-term impacts from access restrictions to the site and visual impacts associated with the new facilities.</p> <p>Potential impacts to recreation resources from light pollution, particularly those areas where a dark night sky is valued (i.e., campgrounds).</p>	<p>General construction impacts.</p> <p>Potential long-term impacts such as access restrictions due to the presence of wind turbines, movement of the rotor blades, shadow flicker, blade glinting, aviation warning lights, roads, vehicles, and workers conducting maintenance activities.</p> <p>Potential impacts to nearby recreation areas from strong vertical lines of the turbines dominating views and large sweep of moving blades commanding visual attention.</p>	<p>General construction impacts.</p> <p>Potential long-term impacts including access restrictions due to the presence of the wind turbines, the sweeping movement of the rotor blades, lighting for marine and aviation navigation, and the land/sea transition site.</p>

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
				Potential intrusion to the natural scenery and viewshed depending on the viewer sensitivity. Potential impacts to the night sky for nearby recreation areas (i.e., campgrounds) from aviating warning lights.	
Land and Marine Transportation					
Land Transportation	None.	Short-term transportation impacts associated with construction traffic.	Short-term transportation impacts associated with construction traffic.	Potential short-term impacts on roadway traffic during project development (i.e., transportation of wind turbine components such as the blades and turbines to the construction site).	Potential short-term impacts on roadway traffic during project development (i.e., transportation of wind turbine components such as the blades and turbines to the harbor for transport to the construction site).
Marine Transportation	Potential obstruction impacts to marine navigation including to tourist cruises, passenger ferries, fishing vessels (recreational and commercial), and large commercial cargo ships. Potential impacts to military marine operations, surface and subsurface navigation from both floating and submerged structures.	None; installation and operation of a utility-scale PV system would not impact marine transportation.	None; installation and operation of a solar thermal system would not have any marine transportation impacts as it would be totally land-based.	Minor impacts on marine transportation from shipment via marine cargo ship.	Potential navigation hazards to domestic and military marine transportation including to military submarine operations from undersea structures (mooring cables and power lines extending down to the ocean floor).
Airspace Management					
	Potential impacts to military transportation operations (marine surface and aviation operations).	Potential hazards to aircraft and pilots from sunlight reflection; dependent on the magnitude of reflection (glint and glare) from solar power systems.	Potential hazards to both military and civilian aircraft from reflections of the concentrated solar power facility.	Potential hazards to airspace navigation, both military (training and operations) and civilian (including tourist industry helicopters/fix-winged aircraft).	Potential hazards to airspace navigation, both military (training and operations) and civilian (including tourist industry helicopters/fix-winged aircraft).

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
	Potential impacts on approach paths to airports.		Potential air turbulence hazards to both military and civilian aircraft (likely limited to low altitude aircraft i.e., helicopters or during take-offs and landings) from Conservation Stewardship Program plants employing a dry cooling system.	Potential impacts to aviation navigation and communication systems such as radar. Potential hazards to aircrafts downwind of rotor induced turbulence.	Potential impacts to aviation navigation and communication systems such as radar. Potential hazards to aircrafts downwind of rotor-induced turbulence.
Noise and Vibration					
	Short-term noise and vibration impacts to sensitive noise receptors, including potential impacts to marine mammals and sea turtles. Long-term noise and vibration impacts from operation of an ocean thermal energy conversion facility 3.5 miles off-shore would be minimal with implementation of best management practices.	General construction impacts.	General construction impacts.	General construction impacts. Operational noise and vibration impacts from land-based wind turbines would occur when wind conditions are favorable, day or night.	Short-term noise and vibration impacts to sensitive noise receptors, including potential impacts to marine mammals and sea turtles. Long-term noise and vibration impacts from operation of wind turbines located 5 miles offshore would be minimal with implementation of best management practices.
Utilities and Infrastructure					
	General construction impacts. Potentially moderate effects to electric utilities (site-specific).	General construction impacts. Potential minimal impacts to electric utilities (site-specific).	General construction impacts. Potential minimal impacts to electric utilities (site-specific).	General construction impacts. Potential minor impacts to electric utilities (site-specific).	General construction impacts. Potential impacts to electric utilities (site-specific).
Hazardous Materials and Waste Management					
Hazardous Materials	General construction impacts.	General construction and operation impacts.	General construction impacts.	General construction impacts.	General construction impacts.

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
	<p>Potential exposure to hazardous materials during operations from large quantities of ammonia and/or chlorine gas/liquid, including through accidental releases or leaks.</p> <p>Potential for fires or explosions from chlorine and gaseous ammonia combinations.</p>	<p>Potential exposure to trace amounts of hazardous materials (i.e., cadmium, selenium, arsenic) if panels were broken.</p>			<p>Potential hazardous materials impacts associated with construction from munition response sites and the potential use of batteries for energy storage.</p>
Waste Management	<p>General construction impacts.</p>	<p>General construction and operation impacts.</p> <p>Potential hazardous waste impacts resulting from trace amounts of cadmium, selenium, or arsenic if solar panels are broken and/or during solar panel decommissioning/disposal.</p>	<p>General construction impacts.</p>	<p>General construction impacts.</p>	<p>General construction impacts.</p> <p>Minimal construction and demolition waste.</p> <p>Potential impacts during the decommissioning and dismantling of the wind turbine as result of turbine removal.</p>
Wastewater	<p>Potential impacts to wastewater effluent from added chlorine.</p>	<p>General construction impacts.</p> <p>Potential impacts from wastewater discharge resulting from disposal of PV modules at their end-life, particularly from potential leaching or contamination from cadmium containing materials.</p>	<p>General construction impacts.</p>	<p>General construction impacts.</p>	<p>Minor and limited wastewater impacts from construction and during operations/maintenance activities from personnel and machinery operations.</p>
Socioeconomics					
	<p>Very small population and economic benefits (i.e., few</p>	<p>Very small population and economic benefits (i.e., few</p>	<p>Very small population and economic benefits (i.e., few</p>	<p>Very small population and economic benefits (i.e., few</p>	<p>Very small population and economic benefits (i.e., few</p>

Table S-9b. Summary of Impacts for Utility-Scale Renewable Technologies and Activities (continued)

Resource Area	Ocean Thermal Energy Conversion	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
	net new jobs) during construction and operation.	net new jobs) during construction and operation.	net new jobs) during construction and operation.	net new jobs) during construction and operation.	net new jobs) during construction and operation.
Environmental Justice					
	Small potential impacts to the general population. Site-specific evaluation of impacted populations required.	Small environmental justice impacts. No disproportionately high and adverse impacts to minority populations or to low-income populations from solar photovoltaic panels operations.	Minimal potential for environmental justice impacts due to small environmental impacts to general population.	Potential environmental justice impacts depending on siting location.	Small potential for environmental justice impacts.
Health and Safety					
	General construction and operation impacts. Potential worker exposure to chlorine and ammonia gases.	General construction and operation impacts.	General construction and operation impacts.	General construction and operation impacts.	General construction and operation impacts. Potential for public health and safety impacts including to boats, both civilian and military marine vessels, and to the public onshore in the unlikely event the device were destroyed, damaged or if the loss of mooring/ spatial stabilization were to occur.

S.9 Alternatives Considered by DOE

DOE NEPA implementing regulations require that a PEIS analysis include a no-action alternative, which provides a baseline for comparison against the impacts of the proposed action. Under the no-action alternative, DOE would continue to support, through funding and other actions, the State of Hawai‘i in meeting its HCEI goals on a case-by-case basis, but without guidance to integrate and prioritize funding decisions and other actions.

Implementation of the HCEI in Hawai‘i will occur whether or not DOE develops guidance to assist in making decisions or other actions related to clean energy in Hawai‘i. Therefore, the potential environmental impacts associated with each of the renewable energy technologies likely would also occur under the no-action alternative; however, there may not be formal guidance in place that would assist DOE in taking actions that maximize the benefits of certain technologies while minimizing the potential adverse environmental impacts in important resource areas. If the goals of the HCEI are not met, the State of Hawai‘i would remain heavily dependent on fossil fuels and statutory greenhouse gas targets probably would not be met.

Preferred Alternative

CEQ regulations [[40 CFR 1502.14\(e\)](#)] require DOE to identify its preferred alternative in this Final PEIS. DOE plans to incorporate the information presented in this PEIS into guidance that could build upon the permitting requirements, best management practices, and potential mitigation measures identified to minimize potential environmental impacts for future development of renewable energy projects and energy efficiency activities. Therefore, DOE’s proposed action is also the preferred alternative.

HAWAI'I CLEAN ENERGY

FINAL

PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

U.S. DEPARTMENT OF ENERGY

Office of Electricity Delivery and Energy Reliability
Office of Energy Efficiency and Renewable Energy

(DOE/EIS-0459)

SEPTEMBER 2015

COVER SHEET

TITLE: Hawai'i Clean Energy Final Programmatic Environmental Impact Statement (Final PEIS)

RESPONSIBLE FEDERAL AGENCY: U.S. Department of Energy (DOE), Offices of Electricity Delivery and Energy Reliability (OE) and Energy Efficiency and Renewable Energy (EE)

COOPERATING AGENCIES: State of Hawai'i (Department of Business, Economic Development and Tourism), U.S. Environmental Protection Agency, Bureau of Ocean Energy Management, National Park Service, Natural Resources Conservation Service, U.S. Marine Corps, U.S. Navy, and Federal Aviation Administration

LOCATION: State of Hawai'i (Islands of O'ahu, Hawai'i, Kaua'i, Lāna'i, Maui, and Molokai)

CONTACTS: For additional information on this PEIS contact:

Dr. Jane Summerson, National Environmental Policy Act (NEPA) Document Manager

U.S. Department of Energy - NNSA

P.O. Box 5400, Bldg 401 KAFB East

Albuquerque, NM 87185

ABSTRACT: DOE decided to prepare this PEIS, which is not required under NEPA, to evaluate DOE's proposed action to develop guidance that can be used to support the State of Hawai'i in achieving the Hawai'i Clean Energy Initiative (HCEI) goal of meeting 70 percent of the State's energy needs by 2030 through clean energy (the preferred alternative). For the PEIS, DOE and the State of Hawai'i grouped 31 clean energy technologies and activities into five categories: (1) Energy Efficiency, (2) Distributed Renewable Energy Technologies, (3) Utility-Scale Renewable Energy Technologies, (4) Alternative Transportation Fuels and Modes, and (5) Electrical Transmission and Distribution. For each activity or technology, the PEIS identifies potential impacts to 17 environmental resource areas and potential best management practices that could be used to minimize or prevent those potential environmental impacts. The PEIS is available from the Hawai'i Clean Energy PEIS and DOE NEPA websites:

<http://hawaiiicleanenergypeis.com> and <http://energy.gov/nepa/nepa-documents>.

PUBLIC COMMENTS: The Final PEIS considers comments submitted during the 90-day public comment period on the Draft PEIS and from eight public hearings held on six islands in Hawai'i between May 12 and 22, 2014. A Comment-Response Document, which includes all comments received on the Draft PEIS and DOE's responses to those comments, is included as Chapter 9 of the Final PEIS. Written and oral comments were given equal weight, and all comments submitted after the comment period closed were considered in their entirety. The Final PEIS contains revisions and new information based in part on comments received on the Draft PEIS. Vertical bars in the margins marking changed text indicate the locations of these revisions and new information. Deletions are not indicated.

SUMMARY

The Summary for this Hawai‘i Clean Energy PEIS is a separate, stand-alone volume. Detailed and more technical information is provided in the main body of the PEIS and appendices.

S.1 Introduction.....	S-1
S.2 Purpose and Need	S-2
S.3 Proposed Action.....	S-2
S.4 Public Participation and Agency Coordination.....	S-9
S.4.1 Public Participation.....	S-9
S.4.1.1 PEIS Scoping Process.....	S-9
S.4.1.2 Areas of Controversy.....	S-10
S.4.1.3 Draft PEIS Public Review and Comment Period	S-10
S.4.2 Agency Coordination.....	S-11
S.4.2.1 National Park Service	S-12
S.4.2.2 Bureau of Ocean Energy Management.....	S-12
S.4.2.3 Natural Resources Conservation Service.....	S-13
S.4.2.4 U.S. Environmental Protection Agency.....	S-13
S.4.2.5 Federal Aviation Administration	S-13
S.4.2.6 U.S. Marine Corps and U.S. Navy.....	S-13
S.4.2.7 State of Hawai‘i	S-13
S.5 Permitting and Regulatory Requirements.....	S-14
S.6 Structure of the Hawai‘i Clean Energy PEIS.....	S-14
S.7 Potential Environmental Impacts and Best Management Practices.....	S-17
S.8 Overview of Potential Environmental Impacts from Technologies and Activities in the Clean Energy Categories.....	S-22
S.9 Alternatives Considered by DOE	S-57

LIST OF TABLES

<u>Table</u>	<u>Page</u>
S-1 Clean Energy Categories and Associated Technologies or Activities	S-3
S-2 Cooperating and Participating Agencies	S-12
S-3 Characterization of the Potential for Environmental Impacts – Energy Efficiency	S-18
S-4 Characterization of the Potential for Environmental Impacts – Distributed Renewables.....	S-19
S-5 Characterization of the Potential for Environmental Impacts – Utility-Scale Renewables	S-20
S-6 Characterization of the Potential for Environmental Impacts – Alternative Transportation Fuels and Modes	S-21
S-7 Characterization of the Potential for Environmental Impacts – Electrical Transmission and Distribution	S-22
S-8 Summary of Impacts for Selected Technologies and Activities	S-25
S-9 Summary of Impacts for Utility-Scale Renewable Technologies and Activities.....	S-34

CHAPTER 1 – INTRODUCTION

1 INTRODUCTION.....	1-1
1.1 Background.....	1-1
1.1.1 Hawai‘i Clean Energy Initiative Goals and Implementing Legislation.....	1-1
1.1.2 Notice of Intent and Amended Notice of Intent	1-3
1.2 Environmental Review Process	1-4
1.2.1 Purpose and Need for Agency Action	1-4
1.2.2 Proposed Action	1-5
1.2.3 Environmental Resource Areas	1-6
1.3 Agency Coordination.....	1-7
1.3.1 NEPA Process.....	1-7
1.3.2 Cooperating and Participating Agencies	1-7
1.3.2.1 National Park Service (NPS).....	1-8
1.3.2.2 Bureau of Ocean Energy Management (BOEM)	1-8
1.3.2.3 Natural Resources Conservation Service (NRCS)	1-8
1.3.2.4 U.S. Environmental Protection Agency (EPA)	1-9
1.3.2.5 Federal Aviation Administration (FAA)	1-9
1.3.2.6 U.S. Marine Corps and U.S. Navy	1-9
1.3.2.7 State of Hawai‘i.....	1-10
1.4 Scope of the PEIS	1-10
1.4.1 Defining Scope	1-10
1.4.2 Scoping Process.....	1-10
1.4.3 Hawai‘i Clean Energy PEIS Scoping Process	1-11
1.4.4 Summary of Hawai‘i Clean Energy PEIS Scoping Comments	1-12
1.5 Hawaii Clean Energy Draft PEIS	1-12
1.6 Structure of Hawai‘i Clean Energy PEIS	1-13

CHAPTER 5 – ENVIRONMENTAL IMPACTS FROM DISTRIBUTED RENEWABLES

5 ENVIRONMENTAL IMPACTS FROM DISTRIBUTED RENEWABLES.....	5-1
5.1 Biomass.....	5-1
5.1.1 Geology and Soils.....	5-5
5.1.1.1 Potential Impacts.....	5-5
5.1.1.2 Best Management Practices and Mitigation Measures.....	5-5
5.1.2 Climate and Air Quality.....	5-5
5.1.2.1 Potential Impacts.....	5-5
5.1.2.1.1 Air Quality.....	5-5
5.1.2.1.2 Climate Change.....	5-6
5.1.2.2 Best Management Practices and Mitigation Measures.....	5-6
5.1.3 Water Resources.....	5-7
5.1.3.1 Proposed Impacts.....	5-7
5.1.3.1.1 Surface Water.....	5-7
5.1.3.1.2 Groundwater.....	5-7
5.1.3.1.3 Floodplains and Wetlands.....	5-8
5.1.3.2 Best Management Practices and Mitigation Measures.....	5-8
5.1.4 Biological Resources.....	5-8
5.1.4.1 Potential Impacts.....	5-8
5.1.4.2 Best Management Practices and Mitigation Measures.....	5-8
5.1.5 Land and Submerged Land Use.....	5-9
5.1.5.1 Proposed Impacts.....	5-9
5.1.5.1.1 Land Use.....	5-9
5.1.5.1.2 Submerged Land Use.....	5-9
5.1.5.2 Best Management Practices and Mitigation Measures.....	5-9
5.1.6 Cultural and Historic Resources.....	5-9
5.1.6.1 Potential Impacts.....	5-9
5.1.6.2 Best Management Practices and Mitigation Measures.....	5-9
5.1.7 Coastal Zone Management.....	5-9
5.1.7.1 Potential Impacts.....	5-9
5.1.7.2 Best Management Practices and Mitigation Measures.....	5-9
5.1.8 Scenic and Visual Resources.....	5-10
5.1.8.1 Potential Impacts.....	5-10
5.1.8.2 Best Management Practices and Mitigation Measures.....	5-10
5.1.9 Recreation Resources.....	5-10
5.1.10 Land and Marine Transportation.....	5-10
5.1.10.1 Potential Impacts.....	5-10
5.1.10.1.1 Land Transportation.....	5-10
5.1.10.1.2 Marine Transportation.....	5-10

5.1.10.2 Best Management Practices and Mitigation Measures	5-11
5.1.11 Airspace Management	5-11
5.1.12 Noise and Vibration	5-11
5.1.12.1 Potential Impacts	5-11
5.1.12.2 Best Management Practices and Mitigation Measures	5-11
5.1.13 Utilities and Infrastructure	5-11
5.1.13.1 Potential Impacts	5-11
5.1.13.2 Best Management Practices and Mitigation Measures	5-11
5.1.14 Hazardous Materials and Waste Management	5-12
5.1.14.1 Potential Impacts	5-12
5.1.14.1.1 Hazardous Materials	5-12
5.1.14.1.2 Waste Management	5-12
5.1.14.1.3 Wastewater	5-12
5.1.14.2 Best Management Practices and Mitigation Measures	5-12
5.1.15 Socioeconomics	5-12
5.1.15.1 Potential Impacts	5-12
5.1.15.2 Best Management Practices and Mitigation Measures	5-13
5.1.16 Environmental Justice	5-13
5.1.16.1 Potential Impacts	5-13
5.1.16.2 Best Management Practices and Mitigation Measures	5-13
5.1.17 Health and Safety	5-13
5.1.17.1 Potential Impacts	5-13
5.1.17.2 Best Management Practices and Mitigation Measures	5-13
5.2 Hydroelectric	5-13
5.2.1 Geology and Soils	5-18
5.2.1.1 Potential Impacts	5-18
5.2.1.2 Best Management Practices and Mitigation Measures	5-18
5.2.2 Climate and Air Quality	5-18
5.2.2.1 Potential Impacts	5-18
5.2.2.2 Best Management Practices and Mitigation Measures	5-19
5.2.3 Water Resources	5-19
5.2.3.1 Potential Impacts	5-19
5.2.3.1.1 Surface Water	5-19
5.2.3.1.2 Groundwater	5-20
5.2.3.1.3 Floodplains and Wetlands	5-20
5.2.3.2 Best Management Practices and Mitigation Measures	5-20
5.2.4 Biological Resources	5-20
5.2.4.1 Potential Impacts	5-20
5.2.4.2 Best Management Practices and Mitigation Measures	5-21
5.2.5 Land and Submerged Land Use	5-21
5.2.5.1 Potential Impacts	5-21
5.2.5.1.1 Land Use	5-21
5.2.5.1.2 Submerged Land Use	5-22
5.2.5.2 Best Management Practices and Mitigation Measures	5-22
5.2.6 Cultural and Historic Resources	5-22
5.2.6.1 Potential Impacts	5-22
5.2.6.2 Best Management Practices and Mitigation Measures	5-22
5.2.7 Coastal Zone Management	5-22
5.2.8 Scenic and Visual Resources	5-22
5.2.8.1 Potential Impacts	5-22
5.2.8.2 Best Management Practices and Mitigation Measures	5-23

5.2.9	Recreation Resources	5-23
5.2.9.1	Potential Impacts	5-23
5.2.9.2	Best Management Practices and Mitigation Measures	5-23
5.2.10	Land and Marine Transportation	5-23
5.2.11	Airspace Management	5-24
5.2.12	Noise and Vibration	5-24
5.2.12.1	Potential Impacts	5-24
5.2.12.2	Best Management Practices and Mitigation Measures	5-24
5.2.13	Utilities and Infrastructure	5-24
5.2.13.1	Potential Impacts	5-24
5.2.13.2	Best Management Practices and Mitigation Measures	5-24
5.2.14	Hazardous Materials and Waste Management	5-24
5.2.14.1	Potential Impacts	5-24
5.2.14.2	Best Management Practices and Mitigation Measures	5-25
5.2.15	Socioeconomics	5-25
5.2.15.1	Potential Impacts	5-25
5.2.15.2	Best Management Practices and Mitigation Measures	5-25
5.2.16	Environmental Justice	5-25
5.2.16.1	Potential Impacts	5-25

CHAPTER 7 – ENVIRONMENTAL IMPACTS FROM ALTERNATIVE TRANSPORTATION FUELS AND MODES

7 ENVIRONMENTAL IMPACTS FROM ALTERNATIVE TRANSPORTATION FUELS AND MODES	7-1
7.1 Biofuels.....	7-1
7.1.1 Geology and Soils.....	7-7
7.1.1.1 Potential Impacts	7-7
7.1.1.1 Best Management Practices and Mitigation Measures	7-8
7.1.2 Climate and Air Quality	7-8
7.1.2.1 Potential Impacts	7-8
7.1.2.1.1 Air Quality	7-8
7.1.2.1.2 Climate Change.....	7-8
7.1.2.2 Best Management Practices and Mitigation Measures	7-9
7.1.3 Water Resources	7-9
7.1.3.1 Potential Impacts	7-9
7.1.3.1.1 Surface Water.....	7-9
7.1.3.1.2 Groundwater.....	7-10
7.1.3.1.3 Floodplains and Wetlands	7-10
7.1.3.2 Best Management Practices and Mitigation Measures	7-11
7.1.4 Biological Resources	7-11
7.1.4.1 Potential Impacts	7-11
7.1.4.2 Best Management Practices and Mitigation Measures	7-12
7.1.5 Land and Submerged Land Use.....	7-12
7.1.5.1 Potential Impacts	7-12
7.1.5.1.1 Land Use	7-12
7.1.5.1.2 Submerged Land Use	7-12
7.1.5.2 Best Management Practices and Mitigation Measures	7-12
7.1.6 Cultural and Historic Resources	7-12
7.1.6.1 Potential Impacts	7-12
7.1.6.2 Best Management Practices and Mitigation Measures	7-12
7.1.7 Coastal Zone Management	7-12
7.1.7.1 Potential Impacts	7-12
7.1.7.2 Best Management Practices and Mitigation Measures	7-13
7.1.8 Scenic and Visual Resources	7-13
7.1.8.1 Potential Impacts	7-13
7.1.8.2 Best Management Practices and Mitigation Measures	7-13
7.1.9 Recreation Resources	7-13
7.1.9.1 Potential Impacts	7-13
7.1.9.2 Best Management Practices and Mitigation Measures	7-14
7.1.10 Land and Marine Transportation.....	7-14
7.1.10.1 Potential Impacts	7-14
7.1.10.1.1 Land Transportation.....	7-14
7.1.10.1.2 Marine Transportation.....	7-14
7.1.10.2 Best Management Practices and Mitigation Measures	7-14
7.1.11 Airspace Management.....	7-14
7.1.12 Noise and Vibration.....	7-15
7.1.12.1 Potential Impacts	7-15
7.1.12.2 Best Management Practices and Mitigation Measures	7-15
7.1.13 Utilities and Infrastructure.....	7-15
7.1.13.1 Potential Impacts	7-15

7.1.13.2 Best Management Practices and Mitigation Measures	7-15
7.1.14 Hazardous Materials and Waste Management	7-15
7.1.14.1 Potential Impacts	7-15
7.1.14.1.1 Hazardous Materials.....	7-15
7.1.14.1.2 Waste Management.....	7-16
7.1.14.1.3 Wastewater.....	7-16
7.1.14.2 Best Management Practices and Mitigation Measures.....	7-17
7.1.15 Socioeconomics.....	7-17
7.1.15.1 Potential Impacts	7-17
7.1.15.2 Best Management Practices and Mitigation Measures.....	7-17
7.1.16 Environmental Justice	7-17
7.1.16.1 Potential Impacts	7-17
7.1.16.2 Best Management Practices and Mitigation Measures.....	7-17
7.1.17 Health and Safety	7-17
7.1.17.1 Potential Impacts	7-17
7.1.17.2 Best Management Practices and Mitigation Measures.....	7-18
7.2 Plug-In Electric Vehicles (PEVs).....	7-18
7.2.1 Geology and Soils.....	7-21
7.2.1.1 Potential Impacts	7-21
7.2.1.2 Best Management Practices and Mitigation Measures.....	7-21
7.2.2 Climate and Air Quality	7-21
7.2.2.1 Potential Impacts	7-21
7.2.2.1.1 Air Quality	7-21
7.2.2.1.2 Climate Change.....	7-21
7.2.2.2 Best Management Practices and Mitigation Measures.....	7-22
7.2.3 Water Resources	7-22
7.2.3.1 Potential Impacts	7-22
7.2.3.1.1 Surface Water.....	7-22
7.2.3.1.2 Groundwater.....	7-22
7.2.3.1.3 Floodplains and Wetlands	7-22
7.2.3.2 Best Management Practices and Mitigation Measures.....	7-22
7.2.4 Biological Resources	7-22
7.2.5 Land and Submerged Land Use.....	7-23
7.2.5.1 Potential Impacts	7-23
7.2.5.1.1 Land Use	7-23
7.2.5.1.2 Submerged Land Use	7-23
7.2.5.2 Best Management Practices and Mitigation Measures.....	7-23
7.2.6 Cultural and Historic Resources	7-23
7.2.6.1 Potential Impacts	7-23
7.2.6.2 Best Management Practices and Mitigation Measures.....	7-23
7.2.7 Coastal Zone Management	7-23
7.2.8 Scenic and Visual Resources	7-23
7.2.9 Recreation Resources	7-24
7.2.10 Land and Marine Transportation.....	7-24
7.2.10.1 Potential Impacts	7-24
7.2.10.1.1 Land Transportation.....	7-24
7.2.10.1.2 Marine Transportation.....	7-24
7.2.10.2 Best Management Practices and Mitigation Measures.....	7-24
7.2.11 Airspace Management.....	7-24
7.2.12 Noise and Vibration.....	7-24
7.2.12.1 Potential Impacts	7-24

7.2.12.2 Best Management Practices and Mitigation Measures	7-24
7.2.13 Utilities and Infrastructure.....	7-25
7.2.13.1 Potential Impacts	7-25
7.2.13.2 Best Management Practices and Mitigation Measures	7-25
7.2.14 Hazardous Materials and Waste Management	7-25
7.2.14.1 Potential Impacts	7-25
7.2.14.1.1 Hazardous Materials.....	7-25
7.2.14.1.2 Waste Management.....	7-25
7.2.14.1.3 Wastewater.....	7-26
7.2.14.2 Best Management Practices and Mitigation Measures	7-26
7.2.15 Socioeconomics.....	7-26
7.2.15.1 Potential Impacts	7-26
7.2.15.2 Best Management Practices and Mitigation Measures	7-27
7.2.16 Environmental Justice	7-27
7.2.17 Health and Safety	7-27
7.3 Hybrid Electric Vehicles (HEVs).....	7-27
7.3.1 Geology and Soils.....	7-29
7.3.2 Climate and Air Quality	7-29
7.3.2.1 Potential Impacts	7-29
7.3.2.1.1 Air Quality	7-29
7.3.2.1.2 Climate Change.....	7-30
7.3.2.2 Best Management Practices and Mitigation Measures	7-30
7.3.3 Water Resources	7-30
7.3.4 Biological Resources	7-30
7.3.5 Land and Submerged Land Use.....	7-30
7.3.6 Cultural and Historic Resources	7-30
7.3.7 Coastal Zone Management	7-30
7.3.8 Scenic and Visual Resources	7-30
7.3.9 Recreation Resources	7-30
7.3.10 Land and Marine Transportation.....	7-31
7.3.10.1 Potential Impacts	7-31
7.3.10.1.1 Land Transportation	7-31
7.3.10.1.2 Marine Transportation.....	7-31
7.3.10.2 Best Management Practices and Mitigation Measures	7-31
7.3.11 Airspace Management.....	7-31
7.3.12 Noise and Vibration.....	7-31
7.3.13 Utilities and Infrastructure.....	7-31
7.3.14 Hazardous Materials and Waste Management	7-31
7.3.14.1 Potential Impacts	7-31
7.3.14.1.1 Hazardous Materials.....	7-31
7.3.14.1.2 Waste Management.....	7-32
7.3.14.1.3 Wastewater.....	7-32
7.3.14.2 Best Management Practices and Mitigation Measures	7-32
7.3.15 Socioeconomics.....	7-33
7.3.16 Environmental Justice	7-33
7.3.17 Health and Safety	7-33
7.4 Hydrogen	7-33
7.4.1 Geology and Soils.....	7-38
7.4.1.1 Potential Impacts	7-38
7.4.1.2 Best Management Practices and Mitigation Measures	7-38
7.4.2 Climate and Air Quality	7-38

7.4.2.1	Potential Impacts	7-38
7.4.2.1.1	Air Quality	7-38
7.4.2.1.2	Climate Change.....	7-39
7.4.2.2	Best Management Practices and Mitigation Measures.....	7-39
7.4.3	Water Resources	7-39
7.4.3.1	Potential Impacts	7-39
7.4.3.1.1	Surface Water.....	7-39
7.4.3.1.2	Groundwater.....	7-39
7.4.3.1.3	Floodplains and Wetlands	7-40
7.4.3.2	Best Management Practices and Mitigation Measures.....	7-40
7.4.4	Biological Resources	7-40
7.4.5	Land and Submerged Land Use.....	7-40
7.4.5.1	Potential Impacts	7-40
7.4.5.1.1	Land Use	7-40
7.4.5.1.2	Submerged Land Use	7-40
7.4.5.2	Best Management Practices and Mitigation Measures.....	7-41
7.4.6	Cultural and Historic Resources	7-41
7.4.6.1	Potential Impacts	7-41
7.4.6.2	Best Management Practices and Mitigation Measures.....	7-41
7.4.7	Coastal Zone Management	7-41
7.4.7.1	Potential Impacts	7-41
7.4.7.2	Best Management Practices and Mitigation Measures.....	7-41
7.4.8	Scenic and Visual Resources	7-41
7.4.8.1	Potential Impacts	7-41
7.4.8.2	Best Management Practices and Mitigation Measures.....	7-42
7.4.9	Recreation Resources	7-42
7.4.9.1	Potential Impacts	7-42
7.4.9.2	Best Management Practices and Mitigation Measures.....	7-42
7.4.10	Land and Marine Transportation.....	7-42
7.4.10.1	Potential Impacts	7-42
7.4.10.1.1	Land Transportation.....	7-42
7.4.10.1.2	Marine Transportation.....	7-42
7.4.10.2	Best Management Practices and Mitigation Measures.....	7-43
7.4.11	Airspace Management.....	7-43
7.4.12	Noise and Vibration.....	7-43
7.4.12.1	Potential Impacts	7-43
7.4.12.2	Best Management Practices and Mitigation Measures.....	7-43
7.4.13	Utilities and Infrastructure.....	7-43
7.4.13.1	Potential Impacts	7-43
7.4.13.2	Best Management Practices and Mitigation Measures.....	7-43
7.4.14	Hazardous Material and Waste Management.....	7-44
7.4.14.1	Potential Impacts	7-44
7.4.14.1.1	Hazardous Materials.....	7-44
7.4.14.1.2	Waste Management.....	7-44
7.4.14.1.3	Wastewater.....	7-45
7.4.14.2	Best Management Practices and Mitigation Measures.....	7-45
7.4.14.2.1	Hazardous Materials.....	7-45
7.4.14.2.2	Waste Management.....	7-45
7.4.14.2.3	Wastewater.....	7-45
7.4.15	Socioeconomics.....	7-45
7.4.15.1	Potential Impacts	7-45

7.4.15.2 Best Management Practices and Mitigation Measures	7-46
7.4.16 Environmental Justice	7-46
7.4.16.1 Potential Impacts	7-46
7.4.16.2 Best Management Practices and Mitigation Measures	7-46
7.4.17 Health and Safety	7-46
7.4.17.1 Potential Impacts	7-46
7.4.17.2 Best Management Practices and Mitigation Measures	7-46
7.5 Compressed and Liquefied Natural Gas, and Liquefied Petroleum Gas	7-46
7.5.1 Geology and Soils	7-51
7.5.1.1 Potential Impacts	7-51
7.5.1.2 Best Management Practices and Mitigation Measures	7-52
7.5.2 Climate and Air quality	7-52
7.5.2.1 Potential Impacts	7-52
7.5.2.1.1 Air Quality	7-52
7.5.2.1.2 Climate Change	7-52
7.5.2.2 Best Management Practices and Mitigation Measures	7-52
7.5.3 Water Resources	7-52
7.5.3.1 Potential Impacts	7-52
7.5.3.2 Best Management Practices and Mitigation Measures	7-53
7.5.4 Biological Resources	7-53
7.5.4.1 Potential Impacts	7-53
7.5.4.2 Best Management Practices and Mitigation Measures	7-53
7.5.5 Land and Submerged Land Use	7-53
7.5.5.1 Potential Impacts	7-53
7.5.5.1.1 Land Use	7-53
7.5.5.1.2 Submerged Land Use	7-53
7.5.5.2 Best Management Practices and Mitigation Measures	7-53
7.5.6 Cultural and Historic Resources	7-54
7.5.6.1 Potential Impacts	7-54
7.5.6.2 Best Management Practices and Mitigation Measures	7-54
7.5.7 Coastal Zone Management	7-54
7.5.7.1 Potential Impacts	7-54
7.5.7.2 Best Management Practices and Mitigation Measures	7-54
7.5.8 Scenic and Visual Resources	7-54
7.5.8.1 Potential Impacts	7-54
7.5.8.2 Best Management Practices and Mitigation Measures	7-54
7.5.9 Recreation Resources	7-55
7.5.9.1 Potential Impacts	7-55
7.5.9.2 Best Management Practices and Mitigation Measures	7-55
7.5.10 Land and Marine Transportation	7-55
7.5.10.1 Potential Impacts	7-55
7.5.10.1.1 Land Transportation	7-55
7.5.10.1.2 Marine Transportation	7-56
7.5.10.2 Best Management Practices and Mitigation Measures	7-56
7.5.11 Airspace Management	7-56
7.5.12 Noise and Vibration	7-56
7.5.12.1 Potential Impacts	7-56
7.5.12.2 Best Management Practices and Mitigation Measures	7-56
7.5.13 Utilities and Infrastructure	7-56
7.5.13.1 Potential Impacts	7-56
7.5.13.2 Best Management Practices and Mitigation Measures	7-56

7.5.14	Hazardous Materials and Waste Management	7-57
7.5.14.1	Potential Impacts	7-57
7.5.14.1.1	Hazardous Materials.....	7-57
7.5.14.1.2	Waste Management.....	7-57
7.5.14.1.3	Wastewater.....	7-57
7.5.14.2	Best Management Practices and Mitigation Measures.....	7-57
7.5.15	Socioeconomics.....	7-57
7.5.15.1	Potential Impacts	7-57
7.5.15.2	Best Management Practices and Mitigation Measures.....	7-58
7.5.16	Environmental Justice	7-58
7.5.16.1	Potential Impacts	7-58
7.5.16.2	Best Management Practices and Mitigation Measures.....	7-58
7.5.17	Health and Safety	7-58
7.5.17.1	Potential Impacts	7-58
7.5.17.2	Best Management Practices and Mitigation Measures.....	7-58
7.6	Multi-Modal Transportation.....	7-58
7.6.1	Geology and Soils.....	7-63
7.6.1.1	Potential Impacts	7-63
7.6.1.2	Best Management Practices and Mitigation Measures.....	7-63
7.6.2	Climate and Air Quality	7-63
7.6.2.1	Potential Impacts	7-63
7.6.2.1.1	Air Quality	7-63
7.6.2.1.2	Climate Change.....	7-63
7.6.2.2	Best Management Practices and Mitigation Measures.....	7-64
7.6.3	Water Resources	7-64
7.6.3.1	Potential Impacts	7-64
7.6.3.1.1	Surface Water.....	7-64
7.6.3.1.2	Groundwater.....	7-64
7.6.3.1.3	Floodplains and Wetlands	7-65
7.6.3.2	Best Management Practices and Mitigation Measures.....	7-65
7.6.4	Biological Resources	7-65
7.6.4.1	Potential Impacts	7-65
7.6.4.2	Best Management Practices and Mitigation Measures.....	7-65
7.6.5	Land and Submerged Land Use.....	7-65
7.6.5.1	Potential Impacts	7-65
7.6.5.1.1	Land Use	7-65
7.6.5.1.2	Submerged Land Use.....	7-65
7.6.5.2	Best Management Practices and Mitigation Measures.....	7-66
7.6.6	Cultural and Historic Resources	7-66
7.6.7	Coastal Zone Management	7-66
7.6.8	Scenic and Visual Resources	7-66
7.6.8.1	Potential Impacts	7-66
7.6.8.2	Best Management Practices and Mitigation Measures.....	7-66
7.6.9	Recreation Resources	7-66
7.6.10	Land and Marine Transportation.....	7-66
7.6.10.1	Potential Impacts	7-66
7.6.10.1.1	Land Transportation.....	7-66
7.6.10.1.2	Marine Transportation.....	7-67
7.6.10.2	Best Management Practices and Mitigation Measures.....	7-67
7.6.11	Airspace Management.....	7-67
7.6.12	Noise and Vibration.....	7-67

7.6.12.1 Potential Impacts	7-67
7.6.12.2 Best Management Practices and Mitigation Measures	7-67
7.6.13 Utilities and Infrastructure.....	7-68
7.6.14 Hazardous Materials and Waste Management	7-68
7.6.14.1 Potential Impacts	7-68
7.6.14.1.1 Hazardous Materials.....	7-68
7.6.14.1.2 Waste Management.....	7-68
7.6.14.1.3 Wastewater.....	7-69
7.6.14.2 Best Management Practices and Mitigation Measures.....	7-69
7.6.15 Socioeconomics.....	7-69
7.6.15.1 Potential Impacts	7-69
7.6.15.2 Best Management Practices and Mitigation Measures.....	7-69

CHAPTER 8 – ENVIRONMENTAL IMPACTS FROM ELECTRICAL TRANSMISSION AND DISTRIBUTION

8 ENVIRONMENTAL IMPACTS FROM ELECTRICAL TRANSMISSION AND DISTRIBUTION	8-1
8.1 On-Island Transmission.....	8-1
8.1.1 Geology and Soils.....	8-7
8.1.1.1 Potential Impacts	8-7
8.1.1.2 Best Management Practices and Mitigation Measures.....	8-7
8.1.2 Climate and Air Quality	8-8
8.1.2.1 Potential Impacts	8-8
8.1.2.1.1 Air Quality	8-8
8.1.2.1.2 Climate Change.....	8-8
8.1.2.2 Best Management Practices and Mitigation Measures.....	8-8
8.1.3 Water Resources	8-8
8.1.3.1 Potential Impacts	8-8
8.1.3.1.1 Surface Water.....	8-8
8.1.3.1.2 Groundwater.....	8-8
8.1.3.1.3 Floodplains and Wetlands	8-9
8.1.3.2 Best Management Practices and Mitigation Measures.....	8-9
8.1.4 Biological Resources	8-9
8.1.4.1 Potential Impacts	8-9
8.1.4.2 Best Management Practices and Mitigation Measures.....	8-10
8.1.5 Land and Submerged Land Use.....	8-10
8.1.5.1 Potential Impacts	8-10
8.1.5.1.1 Land Use	8-10
8.1.5.1.2 Submerged Land Use	8-10
8.1.5.2 Best Management Practices and Mitigation Measures.....	8-11
8.1.6 Cultural and Historic Resources	8-11
8.1.6.1 Potential Impacts	8-11
8.1.6.2 Best Management Practices and Mitigation Measures.....	8-11
8.1.7 Coastal Zone Management	8-11
8.1.7.1 Potential Impacts	8-11

8.1.7.2	Best Management Practices and Mitigation Measures	8-11
8.1.8	Scenic and Visual Resources	8-12
8.1.8.1	Potential Impacts	8-12
8.1.8.2	Best Management Practices and Mitigation Measures	8-12
8.1.9	Recreation Resources	8-12
8.1.9.1	Potential Impacts	8-12
8.1.9.2	Best Management Practices and Mitigation Measures	8-12
8.1.10	Land and Marine Transportation	8-13
8.1.10.1	Potential Impacts	8-13
8.1.10.1.1	Land Transportation	8-13
8.1.10.1.2	Marine Transportation	8-13
8.1.10.2	Best Management Practices and Mitigation Measures	8-13
8.1.11	Airspace Management	8-13
8.1.11.1	Potential Impacts	8-13
8.1.11.2	Best Management Practices and Mitigation Measures	8-14
8.1.12	Noise and Vibration	8-14
8.1.12.1	Potential Impacts	8-14
8.1.12.2	Best Management Practices and Mitigation Measures	8-14
8.1.13	Utilities and Infrastructure	8-14
8.1.13.1	Potential Impacts	8-14
8.1.13.2	Best Management Practices and Mitigation Measures	8-14
8.1.14	Hazardous Materials and Waste Management	8-15
8.1.14.1	Potential Impacts	8-15
8.1.14.1.1	Hazardous Materials	8-15
8.1.14.1.2	Waste Management	8-15
8.1.14.1.3	Wastewater	8-15
8.1.14.2	Best Management Practices and Mitigation Measures	8-15
8.1.15	Socioeconomics	8-15
8.1.15.1	Potential Impacts	8-15
8.1.15.2	Best Management Practices and Mitigation Measures	8-15
8.1.16	Environmental Justice	8-16
8.1.16.1	Potential Impacts	8-16
8.1.16.2	Best Management Practices and Mitigation Measures	8-16
8.1.17	Health and Safety	8-16
8.1.17.1	Potential Impacts	8-16
8.1.17.2	Best Management Practices and Mitigation Measures	8-17
8.2	Undersea Cables	8-17
8.2.1	Geology and Soils	8-24
8.2.1.1	Potential Impacts	8-24
8.2.1.2	Best Management Practices and Mitigation Measures	8-25
8.2.2	Climate and Air Quality	8-26
8.2.2.1	Potential Impacts	8-26
8.2.2.2	Best Management Practices and Mitigation Measures	8-26
8.2.3	Water Resources	8-26
8.2.3.1	Potential Impacts	8-26
8.2.3.1.1	Surface Water	8-26
8.2.3.1.2	Groundwater	8-27
8.2.3.1.3	Floodplains and Wetlands	8-27
8.2.3.2	Best Management Practices and Mitigation Measures	8-27
8.2.4	Biological Resources	8-28
8.2.4.1	Potential Impacts	8-28

8.2.4.2	Best Management Practices and Mitigation Measures	8-29
8.2.5	Land and Submerged Land Use.....	8-29
8.2.5.1	Potential Impacts	8-29
8.2.5.1.1	Land Use	8-29
8.2.5.1.2	Submerged Land Use	8-30
8.2.5.2	Best Management Practices and Mitigation Measures.....	8-30
8.2.6	Cultural and Historic Resources	8-30
8.2.6.1	Potential Impacts	8-30
8.2.6.2	Best Management Practices and Mitigation Measures.....	8-30
8.2.7	Coastal Zone Management	8-31
8.2.7.1	Potential Impacts	8-31
8.2.7.2	Best Management Practices and Mitigation Measures.....	8-31
8.2.8	Scenic and Visual Resources	8-31
8.2.8.1	Potential Impacts	8-31
8.2.8.2	Best Management Practices and Mitigation Measures.....	8-31
8.2.9	Recreation Resources	8-31
8.2.9.1	Potential Impacts	8-31
8.2.9.2	Best Management Practices and Mitigation Measures.....	8-32
8.2.10	Land and Marine Transportation.....	8-32
8.2.10.1	Potential Impacts	8-32
8.2.10.1.1	Land Transportation.....	8-32
8.2.10.1.2	Marine Transportation.....	8-32
8.2.10.2	Best Management Practices and Mitigation Measures.....	8-33
8.2.11	Airspace Management.....	8-33
8.2.12	Noise and Vibration.....	8-33
8.2.12.1	Potential Impacts	8-33
8.2.12.2	Best Management Practices and Mitigation Measures.....	8-34
8.2.13	Utilities and Infrastructure.....	8-34
8.2.13.1	Potential Impacts	8-34
8.2.13.2	Best Management Practices and Mitigation Measures.....	8-35
8.2.14	Hazardous Materials and Waste Management	8-35
8.2.14.1	Potential Impacts	8-35
8.2.14.1.1	Hazardous Materials.....	8-35
8.2.14.1.2	Waste Management.....	8-36
8.2.14.1.3	Wastewater.....	8-36
8.2.14.2	Best Management Practices and Mitigation Measures.....	8-36
8.2.15	Socioeconomics.....	8-36
8.2.15.1	Potential Impacts	8-36
8.2.15.2	Best Management Practices and Mitigation Measures.....	8-36

8.3.1	Geology and Soils.....	8-40
8.3.2	Climate and Air Quality	8-40
8.3.3	Water Resources	8-40
8.3.4	Biological Resources	8-40
8.3.5	Land and Submerged Land Use.....	8-40

8.3.6 Cultural and Historic Resources	8-41
8.3.7 Coastal Zone Management	8-41
8.3.8 Scenic and Visual Resources	8-41
8.3.9 Recreation Resources	8-41
8.3.10 Land and Marine Transportation	8-41
8.3.11 Airspace Management	8-41
8.3.12 Noise and Vibration	8-41
8.3.13 Utilities and Infrastructure	8-41
8.3.13.1 Potential Impacts	8-41
8.3.13.2 Best Management Practices and Mitigation Measures	8-41
8.3.14 Hazardous Materials and Waste Management	8-42
8.3.14.1 Potential Impacts	8-42
8.3.14.1.1 Hazardous Materials	8-42
8.3.14.1.2 Waste Management	8-42
8.3.14.1.3 Wastewater	8-42
8.3.14.2 Best Management Practices and Mitigation Measures	8-42
8.3.15 Socioeconomics	8-42
8.3.15.1 Potential Impacts	8-42
8.3.15.2 Best Management Practices and Mitigation Measures	8-42
8.3.16 Environmental Justice	8-42
8.3.17 Health and Safety	8-43
8.3.17.1 Potential Impacts	8-43
8.3.17.2 Best Management Practices and Mitigation Measures	8-44
8.4 Energy Storage	8-45
8.4.1 Geology and Soils	8-50
8.4.1.1 Potential Impacts	8-50
8.4.1.1.1 Flywheel – Distributed Energy Source	8-50
8.4.1.1.2 Sodium-Sulfur Batteries – Utility-Scale Energy Source	8-50
8.4.1.2 Best Management Practices and Mitigation Measures	8-50
8.4.2 Climate and Air Quality	8-51
8.4.2.1 Potential Impacts	8-51
8.4.2.1.1 Air Quality	8-51
8.4.2.1.2 Climate Change	8-51
8.4.2.2 Best Management Practices and Mitigation Measures	8-51
8.4.3 Water Resources	8-52
8.4.3.1 Potential Impacts	8-52
8.4.3.1.1 Surface Water	8-52
8.4.3.1.2 Groundwater	8-52
8.4.3.1.3 Floodplains and Wetlands	8-52
8.4.3.2 Best Management Practices and Mitigation Measures	8-53
8.4.4 Biological Resources	8-53
8.4.5 Land and Submerged Land Use	8-53
8.4.6 Cultural and Historic Resources	8-53
8.4.6.1 Potential Impacts	8-53
8.4.6.1.1 Flywheel – Distributed Energy Source	8-53
8.4.6.1.2 Sodium Sulfur Batteries – Utility-Scale Energy Source	8-53
8.4.6.2 Best Management Practices and Mitigation Measures	8-53
8.4.7 Coastal Zone Management	8-53
8.4.7.1 Potential Impacts	8-53
8.4.7.1.1 Flywheel – Distributed Energy Source	8-53
8.4.7.1.2 Sodium-Sulfur Batteries – Utility-Scale Energy Source	8-53

8.4.7.2	Best Management Practices and Mitigation Measures	8-53
8.4.8	Scenic and Visual Resources	8-54
8.4.8.1	Potential Impacts	8-54
8.4.8.1.1	Flywheel – Distributed Energy Source	8-54
8.4.8.1.2	Sodium-Sulfur Batteries – Utility-Scale Energy Source	8-54
8.4.8.2	Best Management Practices and Mitigation Measures	8-54
8.4.9	Recreation Resources	8-54
8.4.10	Land and Marine Transportation	8-54
8.4.11	Airspace Management	8-54
8.4.12	Noise and Vibration	8-54
8.4.12.1	Potential Impacts	8-54
8.4.12.1.1	Flywheel – Distributed Energy Source	8-54
8.4.12.1.2	Sodium-Sulfur Batteries – Utility-Scale Energy Source	8-55
8.4.12.2	Best Management Practices and Mitigation Measures	8-55
8.4.13	Utilities and Infrastructure	8-55
8.4.13.1	Potential Impacts	8-55
8.4.13.2	Best Management Practices and Mitigation Measures	8-55
8.4.14	Hazardous Materials and Waste Management	8-55
8.4.14.1	Potential Impacts	8-55
8.4.14.1.1	Hazardous Materials	8-55
8.4.14.1.2	Waste Management	8-55
8.4.14.1.3	Wastewater	8-56
8.4.14.2	Best Management Practices and Mitigation Measures	8-56
8.4.15	Socioeconomics	8-56
8.4.15.1	Potential Impacts	8-56
8.4.15.2	Best Management Practices and Mitigation Measures	8-57
8.4.16	Environmental Justice	8-57
8.4.17	Health and Safety	8-57
8.4.17.1	Potential Impacts	8-57
8.4.17.1.1	Flywheel Technology	8-57
8.4.17.1.2	Sodium-Sulfur Batteries – Utility-Scale Energy Source	8-57
8.4.17.2	Best Management Practices and Mitigation Measures	8-57

CHAPTER 9 – COMMENT-RESPONSE DOCUMENT

9	COMMENT-RESPONSE DOCUMENT	9-1
9.1	Introduction	9-1
9.1.1	Background	9-1
9.1.2	Hawai‘i Clean Energy Draft PEIS	9-1
9.1.3	How DOE Considered Public Comments	9-2
9.1.4	Methodology	9-2
9.2	Organization of the Comment-Response Document	9-3
9.3	Comments and Responses	9-21
9.3.1	Policy	9-21
9.3.2	Regulatory	9-53
9.3.3	Technology/Activity	9-61
9.3.4	Environmental Resource	9-128
9.3.5	PEIS Process and Structure	9-155
9.3.6	Out of Scope Comments (includes rationale)	9-165
9.3.7	Duplicate Comments	9-171

LIST OF TABLES

<u>Table</u>	<u>Page</u>
1-1	Clean Energy Categories and Associated Technologies or Activities 1-5
1-2	Cooperating and Participating Agencies..... 1-7
2-1	Clean Energy Categories and Associated Technologies or Activities 2-5
2-2	Federal, State, and County Permitting and Regulatory Agencies and Their Roles 2-9
2-3	Energy Efficiency Measures 2-28
2-4	Energy Usage Baseline Projection Summary for Buildings, Statewide 2-35
2-5	Projected Energy Savings with the Representative Project 2-38
2-6	Energy Conservation Measures 2-40
2-7	HECO Rebate Program..... 2-41
2-8	Steam Boiler Electricity Generation 2-72
2-9	Operational Parameters for a 5-kilowatt Fuel Cell Power System 2-83
2-10	Small Wind Turbine Projects..... 2-94
2-11	Estimated Acreage of Permanent Surface Disturbance for Utility-Scale Renewable Technologies for the Representative Project by Nameplate Capacity, Total Acreage, and per Megawatt 2-96
2-12	Biomass Steam Boiler Electricity Generation 2-102
2-13	Biodiesel Production Plant and Electrical Power Plant 2-104
2-14	Typical Land Disturbances Associated with Geothermal Resource Development..... 2-107
2-15	Candidate Landfill Gas-to-Energy Landfills in Hawai‘i..... 2-123
2-16	Wind Speed Regions in Comparison with Wind Turbine Operations 2-147
2-17	Summary of Land Areas Associated with Hawai‘i Wind Project..... 2-148
2-18	Utility-Scale Wind Turbine Projects..... 2-151
2-19	Hawai‘i Wind Resource Potential by Wind Speed Interval, Water Depth, and Distance from Shore 2-161
2-20	Per Vehicle Fuel Consumption Comparison of Conventional, Hybrid-Electric, and Electric Vehicles 2-180
2-21	Estimated 2030 Electric Vehicle Fleet Composition and Gasoline Reduction Potential..... 2-183
2-22	Summary of Electricity Capacity Required To Charge the 2030 Electric Vehicle Fleet..... 2-184
2-23	Power Generation Capacity in Hawai‘i 2-184
2-24	Comparison of Hybrid System Types..... 2-186
2-25	Per Vehicle Fuel Consumption Comparison of Conventional and Hybrid-Electric Vehicles .. 2-188
2-26	Estimated 2030 Hybrid-Electric Vehicle Statewide Composition and Petroleum Reduction Potential 2-191
2-27	Multi-Modal Option Summary for Commuters by County 2-206
2-28	Diesel Transit Bus Increases Needed to Meet 20-Million-Gallon Fuel Use Reduction Target 2-218
2-29	Expected Transmission and Interconnection Voltages 2-221
2-30	Typical Transmission Line Voltage Levels, Corridor Width, and Tower or Pole Height 2-221
2-31	Features of Major Undersea Power Cable Systems 2-225
2-32	Energy Storage Technology Characteristics 2-247
2-33	Benefits and Drawbacks Associated with Energy Storage Locations 2-249
2-34	Advantages and Disadvantages of Energy Storage Technologies 2-250
2-35	Energy Storage Technologies and Their Level of Maturity..... 2-250
2-36	Representative Project Characteristics..... 2-253
2-37	Summary of the Potential Environmental Impacts – Energy Efficiency 2-256
2-38	Characterization of the Potential for Environmental Impacts – Energy Efficiency..... 2-263
2-39	Summary of the Potential Environmental Impacts – Distributed Renewables 2-264

2-40	Characterization of the Potential for Environmental Impacts – Distributed Renewables.....	2-275
2-41	Summary of the Potential Environmental Impacts – Utility-Scale Renewables.....	2-276
2-42	Characterization of the Potential for Environmental Impacts – Utility-Scale Renewables	2-300
2-43	Summary of the Potential Environmental Impacts – Alternative Fuels and Transportation Modes	2-301
2-44	Characterization of the Potential for Environmental Impacts – Alternative Transportation Fuels and Modes.....	2-319
2-45	Summary of the Potential Environmental Impacts – Electrical Transmission and Distribution.....	2-320
2-46	Characterization of the Potential for Environmental Impacts – Electrical Transmission and Distribution	2-334
3-1	High-Level Summary of the NRCS Soil Survey Data for Kaua‘i	3-8
3-2	High-Level Summary of the NRCS Soil Survey Data for O‘ahu	3-11
3-3	High-Level Summary of the NRCS Soil Survey Data for Molokai.....	3-14
3-4	High-Level Summary of the NRCS Soil Survey Data for Lāna‘i.....	3-16
3-5	High-Level Summary of the NRCS Soil Survey Data for Maui.....	3-19
3-6	High-Level Summary of the NRCS Soil Survey Data for Hawai‘i Island	3-24
3-7	Destructive Earthquakes in Hawai‘i since 1868	3-25
3-8	National and State of Hawai‘i Ambient Air Quality Standards.....	3-39
3-9	Air Emissions Reported for Counties within the State of Hawai‘i, for Calendar Year 2008	3-41
3-10	Greenhouse Gas Emission Summary by Island, for Calendar Year 2007	3-42
3-11	Large Streams in Hawai‘i	3-47
3-12	Inland and Marine Water Classification Criteria from HAR Chapter 11-54	3-50
3-13	Summary of State of Hawai‘i Inland Waters Considered Impaired	3-51
3-14	Summary of State of Hawai‘i Marine Waters Considered Impaired	3-52
3-15	2010 Water Use (in million gallons per day) by Category and Source for the State of Hawai‘i.....	3-53
3-16	Summary of Kaua‘i Inland and Marine Waters Considered Impaired	3-58
3-17	2010 Water Use by Category and Source on Kaua‘i and for the State of Hawai‘i.....	3-59
3-18	Summary of O‘ahu Inland and Marine Waters Considered Impaired	3-63
3-19	2010 Water Use by Category and Source on O‘ahu and for the State of Hawai‘i.....	3-65
3-20	Summary of Molokai Inland and Marine Waters Considered Impaired.....	3-67
3-21	2005 Water Use by Category and Source on Molokai and for the State of Hawai‘i	3-69
3-22	Summary of Lāna‘i Marine Waters Considered Impaired.....	3-71
3-23	2010 Water Use by Category and Source on Lāna‘i and for the State of Hawai‘i	3-71
3-24	Summary of Maui Inland and Marine Waters Considered Impaired.....	3-76
3-25	2010 Water Use by Category and Source on Maui and for the State of Hawai‘i	3-77

RISE	Rewarding Internships for Sustainable Employment
RPS	Renewable Portfolio Standards
SBCC	State Building Code Council
SHPD	State Historic Preservation Division
SHWB	Solid and Hazardous Waste Branch
SMES	Superconducting Magnetic Energy Storage
SPIDERS	Smart Power Infrastructure Demonstration for Energy Reliability and Security
TMDLs	Total Maximum Daily Loads
USACE	U.S. Army Corps of Engineers
USCG	U.S. Coast Guard
USDA	U.S. Department of Agriculture
USDOT	U.S. Department of Transportation
USFWS	U.S. Fish and Wildlife Service
USGS	U.S. Geological Survey
USMC	U.S. Marine Corps
U.S. PACOM	United States Pacific Command
V	Volt
VCR	Videocassette Recorder
VDC	Volts Direct-Current
VRB	Vanadium Redox Battery
ZnBr	Zinc Bromide

UNDERSTANDING SCIENTIFIC NOTATION

DOE has used scientific notation in this PEIS to express numbers that are so large or so small that they can be difficult to read or write. Scientific notation is based on the use of positive and negative powers of 10. The number written in scientific notation is expressed as the product of a number and a positive or negative power of 10. Examples include the following:

Positive powers of 10	Negative powers of 10
$10^1 = 10 \times 1 = 10$	$10^{-1} = 1 \div 10 = 0.1$
$10^2 = 10 \times 10 = 100$	$10^{-2} = 1 \div 100 = 0.01$
and so on, therefore,	and so on, therefore,
$10^6 = 1,000,000$ (or 1 million)	$10^{-6} = 0.000001$ (or 1 in 1 million)

Probability is expressed as a number between 0 and 1 (0 to 100 percent likelihood of the occurrence of an event). The notation 3×10^{-6} can be read 0.000003, which means that there are 3 chances in 1 million that the associated result (for example, a fatal cancer) will occur in the period covered by the analysis.

METRIC PREFIXES

Prefix	Symbol	Multiplication factor	Scientific notation
tera-	T	1,000,000,000,000	= 1×10^{12}
giga-	G	1,000,000,000	= 1×10^9
mega-	M	1,000,000	= 1×10^6
kilo-	k	1,000	= 1×10^3
deca-	D	10	= 1×10^1
deci-	d	0.1	= 1×10^{-1}
centi-	c	0.01	= 1×10^{-2}
milli-	m	0.001	= 1×10^{-3}
micro-	μ	0.000001	= 1×10^{-6}
nano-	n	0.000000001	= 1×10^{-9}
pico-	p	0.000000000001	= 1×10^{-12}

1 INTRODUCTION

Chapter 1 provides an overview of the *Hawai‘i Clean Energy Programmatic Environmental Impact Statement* (DOE/EIS-0459; Hawai‘i Clean Energy PEIS). The chapter is divided into five main sections: [Section 1.1](#) includes background information about the State of Hawai‘i’s clean energy goals; [Section 1.2](#) describes the environmental review process pursuant to the *National Environmental Policy Act of 1969* (NEPA; [42 U.S.C. § 4321 et seq.](#)) and the U.S. Department of Energy’s (DOE’s) purpose and need for agency action; [Section 1.3](#) addresses the *cooperating agency* process and those entities with a role in the development of the Hawai‘i Clean Energy PEIS; [Section 1.4](#) discusses the *scope* of this PEIS and the public *scoping process* DOE used to obtain input on the issues it should address in the PEIS; [Section 1.5](#) discusses the release of the Draft PEIS and the opportunity for public comment; and [Section 1.6](#) provides a summary of the organizational structure of this PEIS.

1.1 Background

With about 85 percent of its energy derived from imported petroleum and petroleum products, the State of Hawai‘i remains the most oil-dependent State in the nation ([EIA 2012](#)). Roughly equal amounts of petroleum are used for electricity generation, ground transportation, and commercial aviation (about 28 percent each), with the rest used for marine transport, military, and other uses ([DBEDT 2013a](#)). Unlike other states, Hawai‘i relies heavily on imported oil to meet its electricity generation needs. Whereas less than 1 percent of electricity on the mainland is generated using oil, in Hawai‘i, the figure is 74 percent ([DBEDT 2013a](#)). Furthermore, even though per capita energy usage in Hawai‘i is among the lowest in the nation (in part due to its tropical climate), electricity prices in the State are three times higher than the United States national average ([DBEDT 2013a](#)). Hawai‘i’s heavy dependence on imported oil is due in part to the State’s geographical isolation in the Pacific Ocean. Section 355 of the *Energy Policy Act of 2005* (EPAAct 2005; [Public Law 109–58](#)) directs DOE to assess the economic implications of Hawai‘i’s dependence on imported oil as the principal source of energy and to explore the technical and economic feasibility of increasing the contribution of *renewable energy* resources for both electricity generation and fuel for various modes of transportation.

1.1.1 HAWAI‘I CLEAN ENERGY INITIATIVE GOALS AND IMPLEMENTING LEGISLATION

In furtherance of the provisions of Section 355 of EPAAct 2005, DOE and the State of Hawai‘i entered into a Memorandum of Understanding (MOU) in January 2008. This MOU established a long-term partnership known as the *Hawai‘i Clean Energy Initiative* (HCEI) to transform the way in which energy efficiency and renewable energy resources are planned and used in the State. When it was established, HCEI set a goal of meeting 70 percent of Hawai‘i’s energy needs by 2030 through clean energy, which refers to a combination of renewable energy generation and energy efficiency and conservation measures. The 70-percent goal related to the State’s total estimated energy needs in 2030 compared with a business-as-usual scenario, and comprises 40 percent from renewable energy resources and 30 percent from multiple energy efficiency and conservation measures. In addition to State-mandated renewable energy and energy efficiency goals, the HCEI set a goal to reduce oil used for ground transportation by 70 percent by 2030, and a goal to meet as much of in-State demand for renewable fuels as feasible by 2030 ([Braccio and Finch 2011](#)). In September 2014, DOE and the State of Hawai‘i signed another MOU to reaffirm their commitment to the HCEI (<http://dbedt.hawaii.gov/blog/hawaii-and-u-s-department-of-energy-reaffirm-commitment-to-clean-energy-initiative/>).

Hawai'i's Renewable Portfolio Standard (RPS) is a policy that requires electricity retailers to provide a minimum percentage or quantity of their electricity supplies from designated or defined renewable energy sources.

Hawai'i's Energy Efficiency Portfolio Standard (EEPS) is a policy that sets usage levels as legally mandated targets for the reduction of electricity usage to be achieved through efficiency measures and technologies. Programs and technologies include improvements in energy efficiency of public buildings and creating incentives to achieve electricity use reductions.

In support of HCEI goals, the Hawai'i State Legislature passed and the Governor signed into law House Bill (HB) 1464 in 2009, establishing the current [Renewable Portfolio Standard](#) (RPS) and an [Energy Efficiency Portfolio Standard](#) (EEPS) in the State of Hawai'i. The RPS requires each electric utility that sells electricity for consumption in the State of Hawai'i to meet the following percentages from renewable sources:

- 10 percent of its net electricity sales by December 31, 2010;
- 15 percent of its net electricity sales by December 31, 2015;
- 25 percent of its net electricity sales by December 31, 2020; and
- 40 percent of its net electricity sales by December 31, 2030.

In the 2015 Legislative Session, the Hawai'i State Legislature further amended the State's RPS by passing [HB 623](#), which increases the RPS to 30 percent by December 31, 2020; 70 percent by December 31, 2040, and 100 percent by December 31, 2045. Governor David Ige signed the nation's first 100 percent RPS into law on June 8, 2015.

The Hawai'i EEPS calls for a reduction in electricity use of 4,300 gigawatt-hours via efficiency measures by 2030 compared with a business-as-usual scenario. The 4,300 gigawatt-hours represent 30 percent of the projected growth in Statewide demand for electricity by 2030 ([DBEDT 2011](#)). The EEPS also gives the Hawai'i Public Utilities Commission the authority to write interim 5-year goals for 2015, 2020, and 2025.

Targets for alternative transportation fuels and modes were also established in support of HCEI goals. The HCEI 2011 Road Map sets forth a goal of displacing the equivalent of 70 percent of ground transportation fuel demand with non-fossil fuels. It seeks to achieve this through a combination of fuel economy improvements, accelerated deployment of electric vehicles and supporting infrastructure, reduced vehicle miles traveled, and incorporation of renewable fuels into the transportation sector ([Braccio and Finch 2011](#)). However, unlike the electricity generation sector, the transportation sector does not currently have statute-mandated goals. With this in mind, the State of Hawai'i is reestablishing goals and timelines to reduce petroleum-based fuels for transportation as a priority of the next phase of the HCEI. The Hawai'i State Energy Office completed a series of stakeholder consultations in June 2015, culminating with a final report offering a set of actionable tactics (see <http://www.hawaiiicleanenergyinitiative.org/>). The State of Hawai'i intends to re-engage stakeholders to create a new energy-in-transportation road map, using the new report as a guide.

Already, Hawai'i is beginning to ramp up its energy efficiency measures and use of renewable energy resources. According to the Hawai'i State Energy Office, Statewide energy consumption in 2012 had already been reduced by 14.5 percent since the initiative was established ([DBEDT 2013a](#)). In addition, the percentage of electricity needs being met through energy efficiency and renewable energy measures has nearly doubled since 2007, with most of the gain occurring since 2009. In 2007, renewable generation and energy efficiency met 15.8 percent of Hawai'i's needs, in 2009 it was 18.8 percent, and in 2012 that figure was 28.2 percent ([DBEDT 2013b](#)). The *Energy Resources Coordinator's Annual Report* provides

an overview and summary of the State of Hawai‘i’s clean energy agenda and accomplishments achieved in 2013 ([DBEDT 2013c](#)).

The State of Hawai‘i has set forth the following five points as the core principles of its energy policy: (1) diversification of the State’s energy portfolio; (2) connection and modernization of the State’s grids; (3) balance of technical, economic, environmental, and cultural considerations; (4) leverage of the State’s position as an innovation test bed; and (5) creation of an efficient marketplace that benefits producers and consumers.

1.1.2 NOTICE OF INTENT AND AMENDED NOTICE OF INTENT

DOE has been active in helping to advance the State of Hawai‘i’s clean energy goals by providing technical research and analysis, direct staff involvement, competitive solicitations, and funding. In 2010, DOE announced its intent to prepare a programmatic environmental impact statement (EIS) for the wind phase of the Hawai‘i Interisland Renewable Energy Program (HIREP). The *Notice of Intent* (NOI) appeared on December 14, 2010, in the *Federal Register* ([75 FR 77859](#)), and it referred to the programmatic EIS as the HIREP: Wind PEIS (DOE/EIS-0459). The NOI identified the State of Hawai‘i as a joint lead agency.

The NOI invited comments from Federal, State, and local government agencies, Native Hawaiian and other organizations, and members of the public, and a subsequent *Federal Register* notice ([76 FR 2095](#), January 12, 2011) announced times and places of public scoping meetings. In February 2011, DOE held scoping meetings in Honolulu, Kahului, Kaunakakai, and Lāna‘i City. In meetings and submitted comments, commenters expressed concern that DOE and the State of Hawai‘i would not analyze energy efficiency measures, distributed renewable energy assets, or the full range of potential renewable energy technologies. Commenters also expressed concern about the construction of interisland electricity transmission connections and cables, the potential disparity of impacts on islands that could host wind development projects versus those that would use the electricity, and potential impacts to cultural resources, among other issues.

DOE and the State of Hawai‘i recognize the need for a broader range of activities and technologies to meet HCEI goals. Even though DOE was not required to alter the scope of its NEPA review to include renewable and non-transmission alternatives in addition to wind, in response to public scoping comments received on the HIREP: Wind PEIS, there was consensus between the DOE and State of Hawai‘i to broaden the range of energy efficiency and renewable energy activities and technologies to be analyzed as well as the number of islands to be evaluated consistent with the Statewide nature of the HCEI.

A new scoping process began with DOE’s publication of an Amended NOI in the *Federal Register* ([77 FR 47828](#), August 10, 2012), this time with the State of Hawai‘i as a cooperating agency instead of a joint lead agency. The Amended NOI identified the following five clean energy categories under the expanded range of energy efficiency activities and renewable energy technologies to be analyzed: (1) Energy Efficiency, (2) Distributed Renewables, (3) Utility-Scale Renewables, (4) Alternative Transportation Fuels and Modes, and (5) Electrical Transmission and Distribution. The Amended NOI further stated that the Hawai‘i Clean Energy PEIS would analyze potential environmental impacts of only those clean energy activities and technologies that were eligible under Hawai‘i’s RPS and EEPS, and that it would analyze such potential impacts on an island-by-island basis for the islands of Kaua‘i, O‘ahu, Molokai, Lāna‘i, Maui, and Hawai‘i. The definition of renewable energy for Hawai‘i’s RPS is presented in the Hawai‘i Revised Statutes, [Chapter 269-91](#). The technologies evaluated in this PEIS are not exclusive; they represent the most prominent examples of renewable energy technologies currently employed.

The Amended NOI identified a set of technologies or activities within the five clean energy categories (see [Section 1.2.2](#)) for which this PEIS evaluates environmental impacts relative to environmental resource areas (see [Section 1.2.3](#)).

The Amended NOI once again invited Federal, State, and local government agencies, Native Hawaiian and other organizations, and members of the public to submit comments and participate in public meetings on the proposed scope of the PEIS. This included the *proposed action*, the range of reasonable alternatives, potential environmental impacts, and other issues to be considered. DOE also invited, through the Amended NOI and direct email, government agencies with jurisdiction by law or special expertise to be cooperating agencies in the PEIS preparation. [Section 1.3](#) identifies those agencies that agreed to become cooperating agencies and discusses their roles in preparation of this PEIS.

DOE held eight public scoping meetings from September 11 through September 20, 2012, on six islands in the cities of Honolulu, Lihue, Kailua-Kona, Hilo, Kahului, Lāna‘i City, Kaunakakai, and Kāne‘ohe. [Section 1.4.4](#) presents a summary of the comments received at these scoping meetings and through other means during the scoping period.

1.2 Environmental Review Process

DOE prepared this PEIS pursuant to NEPA, as implemented by the [Council on Environmental Quality](#) (CEQ) NEPA regulations ([40 CFR Parts 1500 through 1508](#)) and DOE NEPA implementing procedures ([10 CFR Part 1021](#)). This PEIS considers, among other regulatory items, the requirements of the *Hawai‘i Environmental Policy Act* ([Chapter 343](#), Hawai‘i Revised Statutes).

This PEIS does not propose any specific project, activity, or technology. It merely analyzes the potential environmental impacts associated with a broad range of activities and technologies that could be implemented in the future to comply with the HCEI. This PEIS does not eliminate the need for project-specific environmental review of individual projects or activities that might be eligible for funding or other forms of support by DOE or other Federal agencies. Rather, to the extent that DOE proposes to fund or undertake particular projects or activities that may fall within the scope of this PEIS, project-specific NEPA reviews for such projects and activities are expected to build on, or tier from, this PEIS and to be more effective and efficient. Moreover, any such projects and activities would be subject to compliance with obligations under other environmental laws such as the *Endangered Species Act of 1973* ([16 U.S.C. §§ 1531–1544](#)) and the *National Historic Preservation Act of 1966* ([54 U.S.C. § 300101 et seq.](#)).

For those projects that do not have any connection to Federal actions, State-level environmental reviews would still have to occur as required under Hawai‘i Revised Statutes, such as the *Hawai‘i Environmental Policy Act* ([HRS 343](#)) and other statutes and administrative rules.

1.2.1 PURPOSE AND NEED FOR AGENCY ACTION

The purpose and need for DOE action is based on the 2008 MOU (reaffirmed in the 2014 MOU) with the State of Hawai‘i that established the long-term HCEI partnership. Consistent with this MOU, DOE’s purpose and need is to support the State of Hawai‘i in its efforts to meet 70 percent of the State’s energy needs by 2030 through clean energy.

DOE’s primary purpose in preparing this PEIS, which is not required under NEPA, is to provide information to the public, Federal and State agencies, Native Hawaiian and other organizations, and future energy developers on the potential environmental impacts of a wide range of energy efficiency activities and renewable energy technologies that could be used to support the HCEI. This environmental information could be used by decisionmakers, developers, and regulators in determining the best activities

and technologies to meet future energy needs. The public could use this PEIS to better understand the types of potential impacts associated with the various technologies.

The State of Hawai‘i’s intent regarding the Clean Energy PEIS is for the Federal, State, and county governments, the general public, and private developers to use the PEIS as a reference document when project-specific EISs are prepared. The PEIS can support the environmental review of future clean energy initiatives in Hawai‘i by identifying common impacts from a variety of clean energy technologies, local resources that potentially could be impacted, local entities that should be consulted, regulatory processes in place, and available best management practices to minimize foreseen environmental impacts. The PEIS does not serve to recommend or prioritize any specific clean energy technology or policy.

1.2.2 PROPOSED ACTION

DOE’s proposed action is to develop guidance that it can be used to support the State of Hawai‘i in achieving the goal established in the HCEI to meet 70 percent of the State’s energy needs by 2030 through energy efficiency measures and renewable energy resources.

For this PEIS, DOE and the State of Hawai‘i identified 31 clean energy technologies and activities associated with potential future actions that could require an environmental review and grouped them into the five clean energy categories DOE identified in its Amended NOI. This PEIS analyzes each of these technologies and activities at a programmatic level (rather than project/location-specific level) by considering the potential environmental impacts on the human environment. [Table 1-1](#) shows how each technology and activity is grouped within the five clean energy categories. The table also provides a roadmap for locating the PEIS section that provides a brief primer on a technology/activity, and the PEIS chapter that discusses the respective potential environmental impacts.

Table 1-1. Clean Energy Categories and Associated Technologies or Activities

Clean Energy Category	Technology or Activity	Primer Section	Impacts Chapter
Energy Efficiency	Energy Efficient Buildings	2.3.1.1	4
	Energy Conservation	2.3.1.2	
	Ground Source Heat Pumps	2.3.1.3	
	Initiatives and Programs	2.3.1.4	
	Sea Water Air Conditioning	2.3.1.5	
	Solar Water Heating	2.3.1.6	
Distributed Renewables	Biomass	2.3.2.1	5
	Hydroelectric	2.3.2.2	
	Hydrogen Fuel Cells	2.3.2.3	
	Photovoltaic	2.3.2.4	
	Wind	2.3.2.5	
Utility-Scale Renewables	Biomass	2.3.3.1	6
	Geothermal	2.3.3.2	
	Hydroelectric	2.3.3.3	
	Municipal Solid Waste	2.3.3.4	
	Marine Hydrokinetic Energy	2.3.3.5	
	Ocean Thermal Energy Conversion	2.3.3.6	
	Photovoltaic	2.3.3.7	
	Solar Thermal	2.3.3.8	
	Wind (Land-based)	2.3.3.9	
	Wind (Offshore)	2.3.3.10	

Table 1-1. Clean Energy Categories and Associated Technologies or Activities (continued)

Clean Energy Category	Technology or Activity	Primer Section	Impacts Chapter
Alternative Transportation Fuels and Modes	Biofuels	2.3.4.1	7
	Electric Vehicles	2.3.4.2	
	Hybrid Electric Vehicles	2.3.4.3	
	Hydrogen	2.3.4.4	
	Compressed and Liquefied Natural Gas and Liquefied Petroleum Gas	2.3.4.5	
	Multi-Modal Transportation	2.3.4.6	
Electrical Transmission and Distribution	On-Island Transmission	2.3.5.1	8
	Undersea Cables	2.3.5.2	
	Smart Grid	2.3.5.3	
	Energy Storage	2.3.5.4	

As mentioned previously, DOE is not proposing any specific project, activity, or technology. The Federal action that is being evaluated in this PEIS is the development of guidance that DOE could use in making future decisions about funding or other actions to support the State of Hawai‘i in achieving the HCEI goals.

1.2.3 ENVIRONMENTAL RESOURCE AREAS

DOE identified the following environmental resource areas that the technologies/activities could potentially affect. Chapter 3 of this PEIS provides a baseline assessment of these resource areas for the State of Hawai‘i and the six principal Hawaiian Islands.

- Geology and soils;
- Climate and air quality (including climate change and greenhouse gas emissions);
- Water resources (including floodplains and wetlands);
- Biological resources (including threatened and endangered species, special status species, and related sensitive resources);
- Land and submerged land use;
- Cultural and historic resources;
- Coastal zone management;
- Scenic and visual resources;
- Recreation resources;
- Land and marine transportation;
- Airspace management;
- Noise and vibration;
- Utilities and infrastructure;
- Hazardous materials and waste management;
- Socioeconomics;
- Environmental justice (background information to analyze the potential for disproportionately high and adverse impacts to minority and low-income populations); and
- Health and safety (including accidents and intentional destructive acts).

1.3 Agency Coordination

1.3.1 NEPA PROCESS

Under NEPA, a lead agency is strongly encouraged to prepare NEPA analyses and documentation in cooperation with State and local governments, other concerned public and private organizations, and other cooperating agencies.

CEQ regulations define a [lead agency](#) as the agency or agencies preparing or having taken primary responsibility for preparing the EIS ([40 CFR 1501.5](#) and [40 CFR 1508.16](#)) and a [cooperating agency](#) as any other Federal agency having jurisdiction by law or special expertise with respect to any environmental impact involved in a proposal (or a reasonable alternative) for legislation or other major Federal action significantly affecting the quality of the human environment ([40 CFR 1501.6](#) and [40 CFR 1508.5](#)). A State governmental agency may also become a cooperating agency. [Participating](#) (or consulting) agencies are agencies with an interest in defining the scope of an impact assessment and collaborating with lead and cooperating agencies in determining the methodologies and level of detail to be used in analyzing the alternatives.

1.3.2 COOPERATING AND PARTICIPATING AGENCIES

DOE sent invitations to various Federal agencies and the State of Hawai‘i Department of Business, Economic Development and Tourism (DBEDT), to be cooperating agencies for this PEIS. DBEDT agreed to represent the State of Hawai‘i as the sole cooperating agency for the State. [Table 1-2](#) lists the Federal and State agencies that have agreed to be a cooperating agency or participating agency for this PEIS.

Table 1-2. Cooperating and Participating Agencies

Agency	Department/Office
Cooperating Status	
U.S. Department of the Interior	National Park Service
	Bureau of Ocean Energy Management
U.S. Department of Agriculture	Natural Resources Conservation Service
U.S. Environmental Protection Agency	Region 9
U.S. Department of Defense	U.S. Marine Corps
	U.S. Navy
U.S. Department of Transportation	Federal Aviation Administration
State of Hawai‘i	DBEDT
Participating Status	
U.S. Department of the Interior	U.S. Geological Survey
	U.S. Fish and Wildlife Service
Advisory Council on Historic Preservation	N/A
U.S. Department of Agriculture	Farm Services Agency
U.S. Department of Commerce	National Marine Fisheries Service
	National Oceanic and Atmospheric Administration, National Ocean Service – Office of National Marine Sanctuaries
U.S. Department of Transportation	Federal Highway Administration
U.S. Department of Homeland Security	U.S. Coast Guard
U.S. Department of Defense	U.S. Army Corps of Engineers

The following sections describe each cooperating agency office's expertise, permitting authority, and responsibilities for any future clean energy project.

1.3.2.1 National Park Service (NPS)

The NPS has expertise in natural and cultural resources and is charged with protecting the U.S. National Park System including resources for future generations. In addition, the NPS monitors the condition of National Historic Trails and Landmarks and National Natural Landmarks outside of the park system, and it may provide technical preservation assistance to owners of landmarks. NPS also maintains the [National Register of Historic Places](#).

Specific to this PEIS, the NPS's primary environmental resource areas of interest include cultural and historic resources, scenic and visual resources, land and submerged land use, recreation resources, and biological resources.

1.3.2.2 Bureau of Ocean Energy Management (BOEM)

BOEM has expertise in and the responsibility for permitting leases and rights-of-way for renewable energy development activities on the Outer Continental Shelf and other offshore Federal waters. It also has expertise in coastal and marine biological and the physical sciences, as well as marine archaeological and cultural resources.

Under EPA Act 2005, BOEM was granted (through its predecessor agency) the authority for regulating the production, transportation, and transmission of renewable energy resources on the Outer Continental Shelf and other offshore Federal waters. Specific to this PEIS, BOEM's primary environmental resource areas of interest are water resources (ocean), submerged land use, and marine transportation. Technologies of interest include utility-scale renewables and transmission associated specifically with offshore wind, undersea cables, and marine hydrokinetic energy.

Pursuant to the *Outer Continental Shelf Lands Act* ([43 U.S.C. §§ 1331–1356, Public Law 113-212](#)), BOEM has been vested with jurisdictional authority for submerged lands greater than 3 miles seaward of the Hawaiian coastline; the area referred to as the Outer Continental Shelf. BOEM has no jurisdictional authority in Hawaiian waters from the coastline to the 3-mile State/Federal boundary. This authority does not apply to any area on the Outer Continental Shelf within the boundaries of any unit of the National Park System, National Wildlife Refuge System, National Marine Sanctuary System, or any National Monument.

1.3.2.3 Natural Resources Conservation Service (NRCS)

NRCS has expertise in conservation planning assistance to private landowners and in the soil sciences. NRCS derives its regulatory and permitting authority under the *Soil Conservation and Domestic Allotment Act* ([16 U.S.C. § 590](#)) and the *Food, Conservation, and Energy Act of 2008* ([Public Law 110-234](#); known as the "Farm Bill"), as well as subsequent Farm Bills, using programs such as the Conservation Stewardship Program ([7 CFR Part 1470](#)); Environmental Quality Incentives Program in the *Food, Conservation, and Energy Act of 2008* ([Public Law 110-246](#)); the Wildlife Habitat Incentive Program ([7 CFR Part 636](#)); and others.

Specific to this PEIS, NRCS's primary environmental resource areas of interest include geology and soils, land and submerged land use, water resources (surface water use and quality and groundwater), biological resources (invasive species), air quality (climate change), and socioeconomic issues. Technologies of

interest include distributed and utility-scale renewables and transmission issues, in particular, photovoltaic, geothermal, land use, and biomass and associated feedstock.

1.3.2.4 U.S. Environmental Protection Agency (EPA)

The EPA administers the programmatic and regulatory aspects of 11 pollution control statutes including the *Clean Air Act of 1990* ([42 U.S.C. § 7401 et seq.](#)) and *Clean Water Act of 1977* ([33 U.S.C. § 1251 et seq.](#)). EPA has interest in all environmental resource areas, activities, and technologies. As a cooperating agency, EPA assisted in the independent review of both the Draft and Final PEIS.

EPA's involvement as a cooperating agency does not constitute formal or informal approval of any part of this project under any statute administered by EPA, nor does it limit in any way EPA's independent review of the Draft or Final PEIS pursuant to [Section 309 of the Clean Air Act](#).

1.3.2.5 Federal Aviation Administration (FAA)

The FAA has expertise in airport land and airspace issues and permitting authority for matters related to hazards to air navigation. Specific to this PEIS, FAA's primary environmental resource areas of interest include airspace management and public health and safety. Technologies of interest include utility-scale renewables and transmission related to on- and offshore wind and land-based transmission lines.

1.3.2.6 U.S. Marine Corps and U.S. Navy

The U.S. Marine Corps and the Department of the Navy are cooperating agencies for this PEIS. Both have expertise related to U.S. military installations and training including radar, restricted areas, airspace, and training areas. All branches of the military are present on O'ahu. The branches of the military coordinate with the Department of Defense (DoD) on renewable energy project compatibility through the DoD Siting Clearinghouse in the Office of the Deputy Undersecretary of Defense for Installations and Environment. The Clearinghouse formal review process applies to projects filed with the U.S. Secretary of Transportation under [49 U.S.C. § 44718](#) as well as other projects proposed for construction within military training routes or special use airspace, whether on private, State, or Federal property.

HCEI goals are similar to the mandates required of Federal agencies (e.g., EPAct 2005, the [Energy Independence and Security Act of 2007](#), and [Executive Order 13514](#), "Federal Leadership in Environmental, Energy, and Economic Performance"). The U.S. Pacific Command (PACOM) is a Unified Combatant Command of the Armed Forces of the United States, headquartered in Honolulu and recognizes that the success of the HCEI depends on the cooperation of U.S. military forces stationed in Hawai'i. In 2009, the U.S. Army Chief of Staff signed the U.S. PACOM Energy Cooperation Strategy with the State of Hawai'i and has agreed to support the HCEI by matching or exceeding its goals.

Specific to this PEIS, the Marine Corps and Navy's primary environmental resource areas of interest include airspace management, accidents and intentional destructive acts, land use and submerged land use, and land and marine transportation. Technologies of interest are distributed and utility-scale renewables and transmission; particularly, anything on military lands, airspace, training areas, or restricted areas. These technologies could include wind (related to radar obstruction or navigation hazards), photovoltaic (related to reflectivity), and marine hydrokinetic energy and ocean thermal energy conservation such as may affect sea navigation.

Further, the Marine Corps is interested in matters related to the island of and waters around O'ahu, while the Navy is interested in matters related to the islands of and the waters around O'ahu and Kaua'i.

1.3.2.7 State of Hawai‘i

State of Hawai‘i agencies have expertise in all matters related to State energy policy, land use, Native Hawaiian culture, aquatic resources, ocean recreation, forestry and wildlife, land and coastal land management and conservation, historic preservation, and parklands. On behalf of all State of Hawai‘i agencies, DBEDT is serving as a cooperating agency for this PEIS. The State agencies have permitting authority and will serve as information sources for many entities, including but not limited to the public and developers of future projects in Hawai‘i.

The State of Hawai‘i has a vested interest in all environmental resource areas, clean energy categories, and activities and technologies evaluated in this PEIS.

1.4 Scope of the PEIS

This section discusses the scope of an EIS under NEPA and the scoping process that a lead agency must undertake as part of NEPA ([Sections 1.4.1](#) and [1.4.2](#)). [Section 1.4.3](#) discusses DOE’s scoping process with respect to the Hawai‘i Clean Energy PEIS. Finally, it provides a summary of the comments DOE received during the 2012 scoping period ([Section 1.4.4](#)).

1.4.1 DEFINING SCOPE

CEQ regulations define the scope in a NEPA process as a range of actions, reasonable alternatives, and impacts to be considered in an EIS ([40 CFR 1508.25](#)). A given scope may depend on its relationship to other EISs as described by the concept of [tiering](#) between a broader EIS and a subsequent EIS or [environmental assessment](#) (see [40 CFR 1508.28](#) for discussions on tiering).

Because this is a programmatic EIS and does not evaluate any specific project or proposal, DOE has prepared this document with the intent that future, project-specific NEPA evaluations could benefit from the information contained herein and build on, or tier from, this PEIS to streamline the future, project-specific environmental reviews. Additionally, because of its programmatic nature, the PEIS cannot present the same comparative analyses of each activity or technology that an evaluation of a specific project at a known location could present. The criteria used for such a specific analysis could include reliability, schedule-ability, economic feasibility, lifecycle analysis, potential for and scale of emergency/disaster impacts, and relative ease of integration onto each island’s grid. These criteria could be included in a future project-specific environmental review.

1.4.2 SCOPING PROCESS

The scoping process refers to an early and open process undertaken by a lead agency to determine the scope of issues to be addressed and to identify the significant issues related to the proposed action. The scoping process begins with publication of an NOI in the *Federal Register*.

Subsequent steps include the following:

- An invitation to all affected agencies and the public to participate;
- Determination of scope and significant issues to be analyzed in the NEPA document;
- Elimination of issues that are not significant or have already been covered by prior environmental reviews;

- Allocation of assignments among lead and cooperating agencies, with lead agency maintaining overall responsibility for the document;
- Indication of other NEPA documents being or that will be prepared related to but not part of the scope under discussion;
- Identification of other environmental review and consultation requirements to facilitate concurrent preparation of analyses and integration with the NEPA document;
- Indication of the relationship between timing of the preparation of environmental analyses and the agency's tentative planning and decision-making schedule.

1.4.3 HAWAI'I CLEAN ENERGY PEIS SCOPING PROCESS

As the lead agency, DOE undertook the scoping process for the Hawai'i Clean Energy PEIS and filed the Amended NOI ([77 FR 47828](#)) on August 10, 2012, announcing the 60-day public scoping period. As part of the Amended NOI, DOE invited all affected Federal, State, and local agencies and other interested parties to participate by submitting comments and/or attending one of eight public scoping meetings on six islands in September 2012.

In addition to the Amended NOI, DOE announced the scoping meetings to encourage public participation in the PEIS process through published notices in six different local newspapers, issuing a press release, sending postcards or emails to individuals and groups that had previously shown interest in the HIREP: Wind PEIS, and creating the Hawai'i Clean Energy PEIS website (www.hawaiicleanenergypeis.com). The website serves as a central online information location for PEIS announcements and documents throughout the PEIS process.

Prior to the public scoping meetings, a known expert in Hawaiian culture, on behalf of DOE, conducted small talk story sessions (informal, small group discussions) with local community groups and Native Hawaiian organizations. These sessions were designed to provide information on the status and scope of the PEIS and encourage participation in the formal public scoping process. The expert selected the groups based on their previous involvement and interest in the HIREP: Wind PEIS.

DOE held eight public scoping meetings between September 11 and September 20, 2012, on six islands in the cities of Honolulu, Lihue, Kailua-Kona, Hilo, Kahului, Lāna'i City, Kaunakakai, and Kāne'ohe. DOE representatives, representatives from DBEDT, a representative from BOEM, and DOE contractor staff attended every meeting. The known expert in Hawaiian culture facilitated the public scoping meetings. The facilitator's role was to ensure the meetings began on time and progressed in an orderly and fair fashion so that all members of the public were given the opportunity to make a formal comment. In some instances, and where the facility rules allowed, the meetings ran over the pre-established time so that all members of the public that had signed up to speak could provide their oral comments.

Each scoping meeting opened with a presentation given by the DOE NEPA Document Manager and included background information on the partnership between DOE and the State of Hawai'i, the history of the HCEI, the NEPA process, the planned scope of the Hawai'i Clean Energy PEIS, and ways to comment on the scope of the PEIS. Eight illustrative posters with photos and text were on display at these meetings presenting these same subjects. Project representatives were on hand for informal conversations about the topics the posters represented.

Meeting attendees were provided an opportunity to sign up to present a formal, transcribed comment for inclusion in the Administrative Record. In addition, and as needed, DOE made the court reporter available

to transcribe comments from individuals who wished to speak in a more private setting at the meeting location. These private comments also are included in the Administrative Record.

Other opportunities for submitting comments during the scoping period included submitting comments via the PEIS website; emailing comments to hawaiiicleanenergypeis@ee.doe.gov; faxing comments to DOE at (808) 541-2253, Attention: Hawai'i Clean Energy PEIS; and sending comments via U.S. mail to the DOE's Hawai'i office, 300 Ala Moana Blvd., P.O. Box 50247, Honolulu, HI 96850-0247.

1.4.4 SUMMARY OF HAWAI'I CLEAN ENERGY PEIS SCOPING COMMENTS

DOE received a total of 738 comment documents as part of the Hawai'i Clean Energy PEIS scoping process. These included:

- 44 public comment letters/faxes;
- 84 comment documents submitted at the PEIS public scoping meetings;
- 256 oral comments transcribed at the PEIS public scoping meetings; and
- 354 public comment documents received via email and the PEIS website.

DOE reviewed each scoping comment document, identified individual comments within each document, and grouped them into four broad subject areas: (1) PEIS process and structure, (2) environmental resource area, (3) island-specific concerns, and (4) clean energy category (energy efficiency, distributed renewables, utility-scale renewables, alternative transportation fuels and modes, and electrical transmission and distribution). DOE then categorized comments by detailed topic areas.

Topics cited most often in the public scoping comments for this PEIS relate to island energy independence and self-sufficiency, Native Hawaiian issues, cultural and historic resources, socioeconomics and communities, land use, biological resources, utility-scale wind (land-based) and geothermal renewables, and undersea cable corridors.

The *Scoping Summary Report for the Hawai'i Clean Energy Programmatic Environmental Impact Statement* contains a five-page summary of these comments (available online from <http://hawaiiicleanenergypeis.com/eis-documents/>).

1.5 Hawai'i Clean Energy Draft PEIS

On April 18, 2014, DOE published in the *Federal Register* its Notice of Availability for the *Hawai'i Clean Energy Draft Programmatic Environmental Impact Statement* (DOE/EIS-0407D) (79 FR 21909). DOE's Notice of Availability invited the public to comment on the Draft PEIS during a 90-day public comment period that ended on July 17, 2014, and described how the public could submit oral and written comments on the Draft PEIS. DOE's Notice also announced that eight public hearings would be held at the following locations:

- Lihue, Kaua'i Island – May 12, 2014
- Kailua-Kona Hawai'i Island – May 13, 2014
- Hilo, Hawai'i Island – May 14, 2014
- Kahului, Maui Island – May 15, 2014
- Kaunakakai, Molokai Island – May 19, 2014
- Lāna'i City, Lāna'i Island – May 20, 2014
- Honolulu, O'ahu Island – May 21, 2014
- Kāne'ohe, O'ahu Island – May 22, 2014

DOE posted advertisements soliciting comments on the Draft PEIS and announcing the public hearings in local newspapers both one week and then two days (as possible) prior to the hearing dates. DOE also sent email notification to individuals who had signed up on the PEIS website to receive email notifications related to the development of the PEIS as well as scoping meeting attendees who had signed up to receive such notification. Finally, DOE sent postcards through the U.S. postal service to those interested individuals who had not provided an email addresses.

Each public hearing opened with a presentation given by the DOE NEPA Document Manager and included background information on the partnership between DOE and the State of Hawai‘i, the history of the HCEI, the NEPA process, the scope of the Hawai‘i Clean Energy PEIS and any changes to the scope as a result of the scoping period, and ways to comment on the Draft PEIS. Three illustrative posters with photos and text were on display at these meetings presenting these same subjects. Representatives were on hand for informal conversations about the topics the posters represented.

As at the scoping meetings, public hearing attendees were provided an opportunity to sign up to present a formal, transcribed comment for inclusion in the Administrative Record. In addition, and as needed, DOE made the court reporter available to transcribe comments from individuals who wished to speak in a more private setting at the meeting location. These private comments also are included in the Administrative Record.

Other opportunities for commenting on the Draft PEIS included submitting a comment via the Internet at <http://hawaiiicleanenergypeis.com>; emailing comments to hawaiiicleanenergypeis@ee.doe.gov; and sending comments via U.S. mail to the DOE NEPA Document Manager in Albuquerque, New Mexico.

DOE made the Draft PEIS available on the Internet on two websites (<http://hawaiiicleanenergypeis.com> and <http://energy.gov/nepa/eis-0459-hawaii-clean-energy-programmatic-environmental-impact-statement>) and provided a CD or bound copy of the Draft PEIS upon request. The State of Hawai‘i DBEDT distributed bound copies of the Draft PEIS to numerous public libraries throughout the islands.

Chapter 9 of this Final PEIS is the Comment-Response Document that represents all comments received and DOE’s responses to the comments. All comments received have been saved in electronic form and are part of the project Administrative Record.

1.6 Structure of Hawai‘i Clean Energy PEIS

This PEIS is arranged into nine chapters as follows:

- Chapter 1, “Introduction,” provides background information and an overview of the NEPA process and the PEIS including its purpose and structure.
- Chapter 2, “Proposed Action,” describes each of the five clean energy categories and the associated 31 technologies and activities. The chapter discusses, from a programmatic perspective, the permitting and regulatory requirements needed to implement the technologies and activities associated with the different clean energy categories. It provides a brief primer of each activity/technology that includes a description of a representative project. The chapter includes a discussion of a no-action alternative and tables that summarize potential environmental impacts associated with the technologies and activities in each clean energy category. The chapter concludes with brief explanations of the PEIS’s treatment of cumulative impacts, irreversible and irretrievable commitment of resources, the relationship between short-term uses and long-term productivity, unavoidable adverse impacts, and DOE’s preferred alternative. This chapter also contains a glossary.

- Chapter 3, “Affected Environment,” provides the existing conditions for each of the potentially affected environmental resource areas. It considers these resource areas at the State (regional) level and on an island-by-island basis for six islands (Kaua‘i, O‘ahu, Molokai, Lāna‘i, Maui, and Hawai‘i). In order to avoid redundancy in later chapters focused on technology-specific impacts, this chapter also includes a discussion of the environmental impacts most often associated with construction and operation activities regardless of the clean energy activity or technology. The chapter organizes and discusses these impacts and associated best management practices in relation to the impacted resource, not the particular activity or technology.
- Chapters 4 through 8 present the environmental impact analyses of each activity/technology from and/or to each environmental resource area. The analyses are based on the potential programmatic-level impacts from the Chapter 2 representative projects on the Chapter 3 affected environment information to provide potential impact perspectives. Each section also presents best management practices and mitigation measures specific to an activity or technology.
 - Chapter 4, “Environmental Impacts from Energy Efficiency”
 - Chapter 5, “Environmental Impacts from Distributed Renewables”
 - Chapter 6, “Environmental Impacts from Utility-Scale Renewables”
 - Chapter 7, “Environmental Impacts from Alternative Transportation Fuels and Modes”
 - Chapter 8, “Environmental Impacts from Electrical Transmission and Distribution”
- Chapter 9, “Comment Response Document,” presents a description of the comment response process, the comments received during the public comment period, and DOE’s responses to those comments.
- The PEIS includes three appendixes:
 - Appendix A, “Public Notices”
 - Appendix B, “Distribution List”
 - Appendix C, “List of Preparers”

1.8 Glossary

Cooperating Agency: Any Federal agency other than the lead agency which has jurisdiction by law or special expertise with respect to any environmental impact involved in proposed legislation, a proposed action or reasonable alternative (40 CFR 1501.6 and 1508.5). A State, local, or tribal governmental agency may serve as a cooperating agency. *Related terms: Lead agency, participating agency.*

Council on Environmental Quality (CEQ): A division within the Executive Office of the President that coordinates Federal environmental efforts and works closely with agencies and other White House offices in the development of environmental policies and initiatives. Established under the National Environmental Policy Act (NEPA) of 1969, CEQ is tasked with ensuring that Federal agencies meet their obligations under NEPA by overseeing Federal agency implementation of the environmental impact assessment process and to act as a referee during agency disagreements.

Environmental Assessment (EA): A concise public document that an agency prepares under the National Environmental Policy Act (NEPA) or the Hawai‘i Environmental Policy Act (HEPA) to provide sufficient evidence and analysis to determine whether a proposed agency action would require preparation of an environmental impact statement (EIS) or a finding of no significant impact. A Federal agency may also prepare an EA to aid its compliance with NEPA when no EIS is necessary or to facilitate preparation of an EIS when one is necessary. The EA must include brief discussions of the need for the proposal, alternatives, environmental impacts of the proposed action and alternatives, and a list of agencies and persons consulted. *Related terms: Finding of No Significant Impact (FONSI), environmental impact statement (EIS).*

Environmental Impact Statement (EIS): The detailed written statement that is required by the National Environmental Policy Act (NEPA) or the Hawai‘i Environmental Policy Act (HEPA) for a proposed major agency action significantly affecting the quality of the natural or human environment. The EIS includes, among other information, discussions of the environmental impacts of the proposed action and all reasonable alternatives, adverse environmental effects that cannot be avoided should the proposal be implemented, the relationship between short-term uses of the human environment and enhancement of long-term productivity, and any irreversible and irretrievable commitments of resources. *Related terms: Finding of No Significant Impact (FONSI), environmental assessment (EA).*

Hawai‘i Clean Energy Initiative (HCEI): The partnership established through the 2008 Memorandum of Understanding (MOU) between the State of Hawai‘i and the U.S. Department of Energy in furtherance of the provisions of Section 355 of the Energy Policy Act of 2005 (EPAct 2005) in order to transform the way in which energy efficiency and renewable energy resources are planned and used in the Hawaiian Islands. The overarching goal of HCEI is to meet 70 percent of Hawai‘i’s energy needs by 2030 through energy efficiency and conservation measures and renewable energy generation, collectively referred to as clean energy. The 70 percent goal includes 30 percent from energy efficiency measures and 40 percent from locally-generated renewable sources. This commitment to the HCEI was reaffirmed in a 2014 MOU. *Related terms: Energy efficiency, energy efficiency portfolio standard, renewable energy, and Hawai‘i renewable portfolio standard.*

Hawai‘i Energy Efficiency Portfolio Standard (EEPS): A policy that sets usage levels as legally mandated targets for the reduction of electricity usage to be achieved through efficiency measures and technologies. Programs and technologies include improvements in energy efficiency of public buildings and creating incentives to achieve electricity use reductions. *Related terms: See energy efficiency, Hawai‘i Renewable Portfolio Standard.*

Hawai‘i Renewable Portfolio Standard (RPS): A policy that requires electricity retailers to provide a minimum percentage or quantity of their electricity supplies from designated or defined renewable energy sources. Related terms: See Renewable Energy, Hawai‘i Energy Efficiency Portfolio Standard.

Lead Agency: As defined by CEQ regulations, this is the agency or agencies preparing or having taken primary responsibility for preparing the environmental impact (40 CFR 1501.5 and 1508.16). *Related term: cooperating agency and participating agency.*

National Register of Historic Places (NRHP): The official list of the nation’s cultural resources that are worthy of preservation. The National Park Service maintains the list under direction of the Secretary of the Interior. Buildings, structures, objects, sites, and districts are included in the National Register for their importance in American history, architecture, archaeology, culture, or engineering. Properties included on the National Register range from large-scale, monumentally proportioned buildings to smaller scale, regionally distinctive buildings. The listed properties are not just of nationwide importance; most are significant primarily at the State or local level. Procedures for listing properties on the National Register are found at 36 CFR Part 60.

Notice of Intent (NOI): A notice that an EIS will be prepared and considered. The NOI is a document prepared as part of the NEPA/HEPA process.

Participating Agency: Participating (or consulting) agencies are agencies with an interest in defining the scope of an impact assessment and collaborating with lead and cooperating agencies in determining the methodologies and level of detail to be used in analyzing the alternatives. *Related terms: cooperating agency and lead agency.*

Programmatic Environmental Impact Statement (PEIS): A programmatic evaluation of the potential environmental consequences of implementing a proposed Federal program or policy on a regional scale. Subsequent site-specific environmental impact statements or environmental assessments may then be prepared on a proposed action included within the program or policy.

Proposed Action: Activity proposed to accomplish a Federal agency’s purpose and need. An EIS analyzes the environmental impacts of the proposed action. A plan that contains sufficient details about the intended actions to be taken, or that will result, to allow alternatives to be developed and its environmental impacts analyzed (40 CFR 1508.23). *Related term: affected environment.*

Renewable Energy: For the purposes of this PEIS, renewable energy includes energy derived from renewable sources such as the sun, wind, falling water, the ocean, geothermal, biomass, waste-to-energy, as well as hydrogen produced from renewable energy sources.

Scope: The range of actions, alternatives, and impacts to be considered in an EIS. *Related terms: scoping process, environmental impact statement.*

Scoping (or Scoping Process): The early and open process undertaken by a lead agency to determine the scope of issues to be addressed and for identifying the issues related to a proposed action while involving the public and other key stakeholders in developing alternatives and weighing the importance of issues to be analyzed in a NEPA/HEPA EIS.

Tiering: The coverage of general matters in broader EIS with a subsequent narrower EIS(s) or EA(s) incorporating the general discussion by reference and concentrating solely on the issues specific to the subsequent EIS(s) or EA(s).

2 PROPOSED ACTION

Chapter 2 describes the five clean energy categories and their associated technologies and activities to enable stakeholders (e.g., project developers, government reviewers, funding authorities, and the general public) to evaluate which projects would be deployable in support of [Hawai'i Clean Energy Initiative](#) (HCEI) goals. [Section 2.1](#) describes the proposed action in relation to the goals of [HCEI](#). [Section 2.2](#) discusses, from a programmatic perspective, the permitting and regulatory requirements needed to implement the technologies and activities associated with the different clean energy categories that DOE's proposed guidance would consider. [Section 2.3](#) provides a primer of the five clean energy categories, including characterizations of existing deployment across Hawai'i, feasibility and permitting requirements specific to certain technologies, and a "representative project" that generically characterizes a project that could be implemented in the State of Hawai'i. These representative projects are not based on a planned or proposed project; they form the basis against which environmental impacts can be evaluated. [Section 2.4](#) addresses the no-action alternative, and [Section 2.5](#) provides a summary of potential environmental impacts associated the technologies or activities of each clean energy category as evaluated across 17 environmental resource areas. The potential impacts are detailed in Chapters 4 through 8.

2.1 DOE's Proposed Programmatic Environmental Guidance

2.1.1 BACKGROUND

The State of Hawai'i historically has had the greatest dependence on imported oil of any state in the Nation to meet its energy needs (roughly 85 percent) with a disproportionate reliance on oil to generate electricity and electricity prices three times the U.S. average ([EIA 2012a](#)). This is in addition to heavy reliance on petroleum for transportation fuel. This reliance creates both environmental and economic risks for the State of Hawai'i.

The HCEI goals presented in Chapter 1 are based on a projected Statewide energy use of 14,300 gigawatt-hours for the year 2030 ([Braccio et al. 2012](#)). This is compared with the 10,500 gigawatt-hours of electricity produced within the State in 2013 ([DBEDT 2014a](#)) and the 9,500 gigawatt-hours of metered electricity sales in 2013 ([DBEDT 2014b](#)). Considering the projected electrical demand, the goal of reducing that energy need by 30 percent through energy efficiency and conservation measures equates to reducing the 2030 energy demand by 4,300 gigawatt-hours (which is the energy efficiency goal specifically identified in [HB 1464](#)). Conversely, the goal for meeting 40 percent of the 2030 energy demand through renewable energy sources is based on actual electricity sales, which may vary based on the success of energy efficiency and conservation measures and on the accuracy of the energy demand predictions. As an example, if an energy reduction of precisely 4,300 gigawatt-hours was achieved by 2030 and actual Statewide electricity sales for the year totaled 10,000 gigawatt-hours (meaning the projection of 14,300 gigawatt-hours was accurate), then the goal for renewable energy sources for the year would be 4,000 gigawatt-hours (40 percent of 10,000 = 4,000). If the actual electricity sales were higher or lower, the 40-percent goal for energy production from renewable sources would be higher or lower accordingly.

Forecasts and milestones have been developed on the energy measures that will have to be achieved over the interim in order to meet the HCEI goals for 2030. For example, HECO has published charts in its *Power Supply Improvement Plan* ([HECO 2014a](#), Figures 4-7 through 4-11) that depict the predicted HCEI-related energy levels from the present to 2030 for each of the islands it serves (i.e., Oah'u, Molokai, Lāna'i, Maui, and Hawai'i). According to the chart for Oah'u, which has the largest energy demand of any of the islands, electricity sales are anticipated to drop from just under 7,000 gigawatt-

hours in 2015 to 5,500 gigawatt-hours in 2030. But per the chart, the low value for electricity sales for 2030 is associated with achieving a reduction of about 3,000 gigawatt-hours from energy efficiency measures and producing about 1,000 gigawatt-hours from distributed photovoltaic (PV) systems that are not part of the utility's sales. The other charts provide similar types of information for the other HECO-served islands. At the State level, milestones have been established for meeting the HCEI goals and the status is tracked and made available by DBEDT. [Figure 2-1](#) provides the status of the HCEI renewable energy and energy efficiency (or energy savings) goals for the years 2007 through 2013. As can be seen in the figure, 18 percent of the electricity consumed in Hawai'i in 2013 was from renewables. This exceeds the statutory milestone of 15 percent set for 2015.

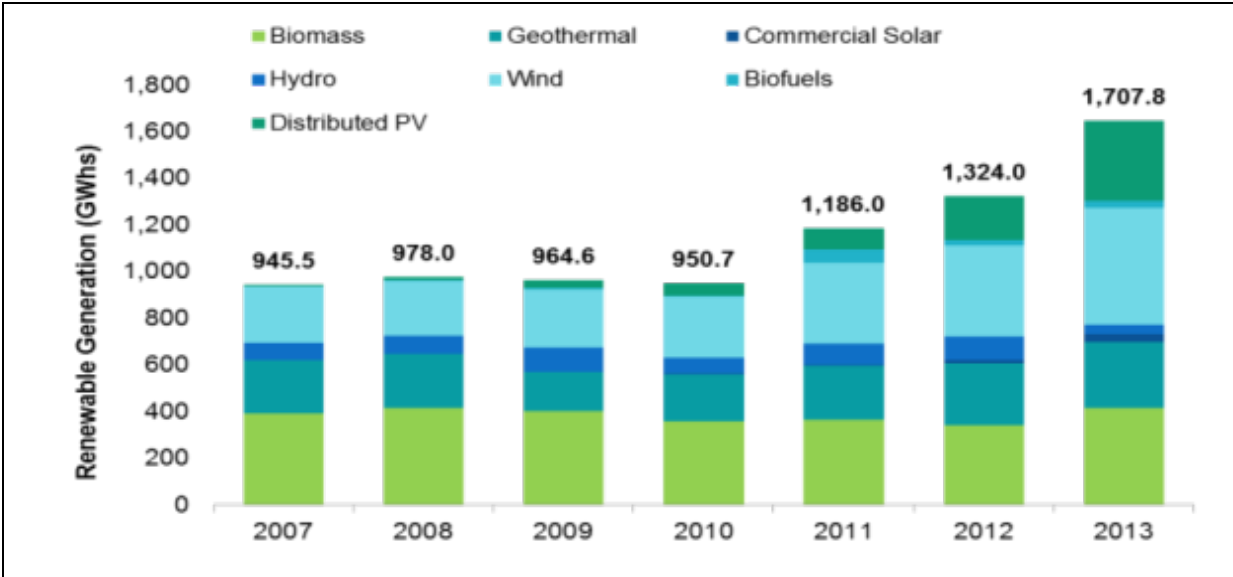

Figure 2-1. Status of HCEI Renewable Energy and Energy Efficiency Goals (Source: [DBEDT 2014a](#))

[Figure 2-2](#) provides the recent (2007 to 2013) status for Statewide renewable energy production by technology type. As can be seen in the figure, the Hawai'i State Energy Office tracks and publishes energy production status on a smaller list of renewable energy technologies than shown in Table 2-1 (and analyzed in this PEIS). The State's list is the result of combining some entries for simplification and the fact that some of the technologies have not been implemented in the state. At the bottom of the figure is a breakout of the technologies by island. [Figure 2-3](#) provides a summary of a previously developed estimate of the State's renewable energy potential. The information is presented by island and by general technology grouping. Because the graphic at the top of the figure contains very small markings that can be difficult to discern, the bottom of the figure provides a summary of the values used in generating the figure. The Hawai'i State Energy Office is currently working to refine its estimates of Statewide renewable energy potential, but the information in [Figure 2-3](#) provides a reasonable approximation. The analysis summarized in [Figure 2-3](#) concludes that the renewable energy potential would be high enough to provide all of the State's energy needs as long as the appropriate interconnections were available. Restated, the analysis shows there is potential to generate far more renewable energy than required by HCEI goals. The only island with electrical demand in excess of its estimated renewable energy potential is O'ahu. Each of the other islands could potentially generate more energy from renewable energy sources than they currently demand, although the demand and potential values for Kaua'i are quite close together.

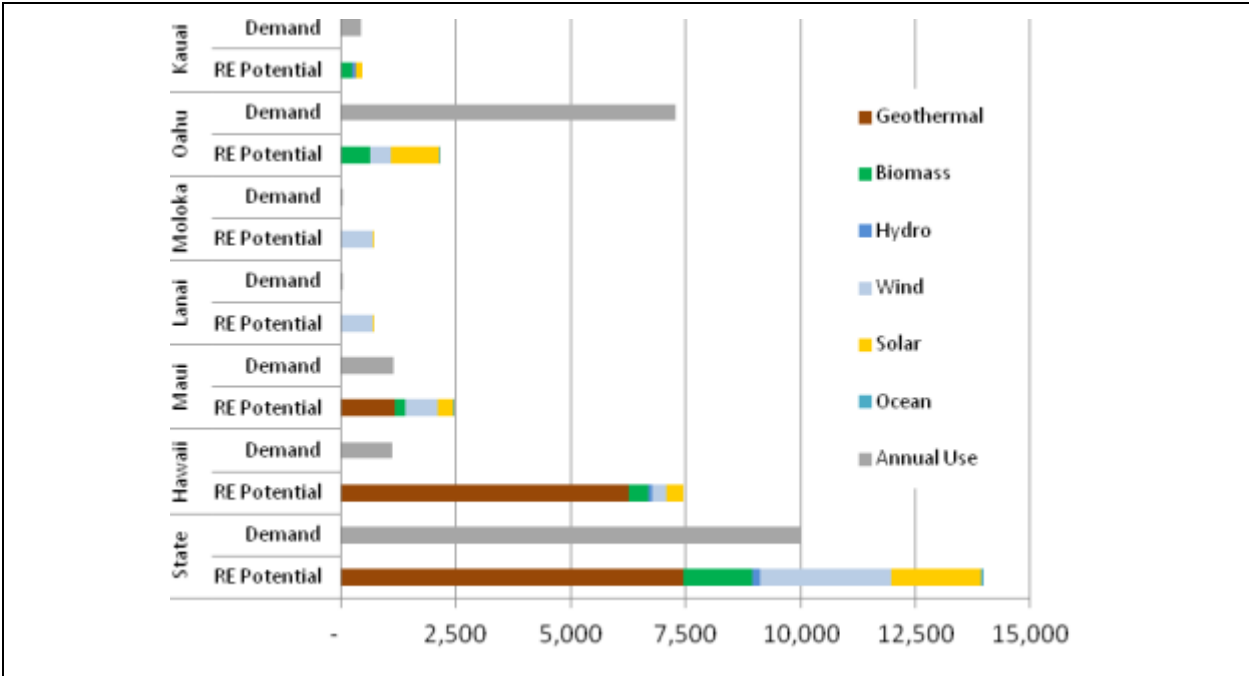

Technology	2013 Renewable Energy (gigawatt-hours) by Island or Island Group				Technology Totals ^a
	Kaua'i	O'ahu	Molokai, Lāna'i, and Maui	Hawai'i	
Biomass (including MSW)		374.6	41.1		415.7
Geothermal				281.4	281.4
Commercial Solar	14.3	27.3	5.1	1.5	48.2
Hydroelectric	33.4		4.8	35.4	73.5
Wind		121.7	230.3	151.6	503.6
Biofuels		28.5	1.3		29.8

Figure 2-3. Estimates of Renewable Energy Potential and Demand by Island

In Chapter 1, DOE presented its purpose and need for agency action in the form of the development of policy guidance that it could use in making decisions about future funding or other actions to support the State of Hawai‘i in achieving HCEI goals. The State of Hawai‘i intends that Federal, State, and county governments, the general public, and private developers use the PEIS as a reference document when preparing project-specific environmental impacts statements and environmental assessments. DOE’s action would assist residents and government decision-makers in Hawai‘i to understand the most viable options that are available to achieve the goals of the HCEI. For purposes of this PEIS, DOE has divided the potential future actions into five clean energy categories. This PEIS analyzes, at a programmatic level, the potential environmental impacts of future DOE actions that would fall within these categories and be subject to DOE’s proposed guidance.

As described in Section 1.2.2, DOE would develop programmatic environmental guidance, which it would use to further integrate environmental considerations into its analysis and support of proposed clean energy projects in Hawai‘i.

As with most human endeavors, most clean energy projects have the potential to cause environmental impacts—especially if not implemented properly. However, careful adherence to Federal, State, and

county laws, regulations, and permitting requirements; implementation of well-planned *best management practices* and *mitigation measures*; along with early consideration of local community concerns about the projects could alleviate many of the potential environmental impacts.

Early consideration of this guidance, especially in project planning and development, could substantially streamline future project-specific NEPA reviews, permitting processes, and community interactions, as well as lessen the potential for controversy over specific projects. DOE application of this guidance is limited to those actions where DOE has authority in a Federal decision-making role; however, the information in this PEIS and in any forthcoming guidance could be useful for any proposed project, whether Federal, State, or private.

2.1.2 CLEAN ENERGY CATEGORIES AND THEIR ASSOCIATED TECHNOLOGIES OR ACTIVITIES

HCEI identified four key energy sectors, each with specific goals. These sectors include end-use efficiency, electricity generation, transportation, and fuels. The clean energy categories selected for this PEIS were generally based on these key energy sectors. Ultimately, the goal of HCEI is to reduce reliance on fossil fuels in Hawai‘i, whether from the generation of electricity or from transportation. As mentioned previously, the five clean energy categories identified in this PEIS are energy efficiency, distributed renewables, utility-scale renewables, alternative transportation fuels and modes, and electrical transmission and distribution. Within each category DOE has identified a set of common technologies or activities that are currently or could reasonably be deployed in Hawai‘i. [Table 2-1](#) lists the clean energy categories and associated technologies and activities, along with the PEIS section where the technology or activity is described.

Table 2-1. Clean Energy Categories and Associated Technologies or Activities

Clean Energy Category	Technology or Activity	Section
Energy Efficiency	Energy Efficient Buildings (A)	2.3.1.1
	Energy Conservation (A)	2.3.1.2
	Ground Source Heat Pumps	2.3.1.3
	Initiatives and Programs (A)	2.3.1.4
	Sea Water Air Conditioning	2.3.1.5
	Solar Water Heating	2.3.1.6
Distributed Renewables	Biomass	2.3.2.1
	Hydroelectric	2.3.2.2
	Hydrogen Fuel Cells	2.3.2.3
	Photovoltaics	2.3.2.4
	Wind	2.3.2.5
Utility-Scale Renewables	Biomass	2.3.3.1
	Geothermal	2.3.3.2
	Hydroelectric	2.3.3.3
	Municipal Solid Waste	2.3.3.4
	Marine Hydrokinetic Energy	2.3.3.5
	Ocean Thermal Energy Conversion	2.3.3.6
	Photovoltaics	2.3.3.7
	Solar Thermal	2.3.3.8
	Wind (Land-based)	2.3.3.9
	Wind (Offshore)	2.3.3.10

Table 2-2. Clean Energy Categories and Associated Technologies or Activities (continued)

Clean Energy Category	Technology or Activity	Section
Alternative Transportation Fuels and Modes	Biofuels	2.3.4.1
	Electric Vehicles	2.3.4.2
	Hybrid-Electric Vehicles	2.3.4.3
	Hydrogen	2.3.4.4
	Compressed and Liquefied Natural Gas and Liquefied Petroleum Gas	2.3.4.5
	Multi-Modal Transportation (A)	2.3.4.6
Electrical Transmission and Distribution	On-Island Transmission	2.3.5.1
	Undersea Cables	2.3.5.2
	Smart Grid	2.3.5.3
	Energy Storage	2.3.5.4

Note: Entries designated with the letter “A” are considered activities rather than technologies.

2.1.3 ENVIRONMENTAL RESOURCE IMPACT AREAS

DOE identified the following 17 environmental resource areas for analysis on a programmatic (rather than project-specific) level. These resource areas encompass the physical, biotic, cultural, and social environments that could potentially be impacted by the activities or technologies identified in [Table 2-1](#).

- Geology and soils
- Climate and air quality
- Water resources
- Biological resources
- Land and submerged land
- Cultural and historic resources
- Coastal zone management
- Scenic and visual resources
- Recreation resources
- Land and marine transportation
- Airspace management
- Noise and vibration
- Utilities and infrastructure
- Hazardous materials and waste management
- Socioeconomics
- Environmental justice
- Health and safety (including intentional destructive acts)

Chapter 3 of this PEIS provides a discussion of the [affected environment](#) for each of these environmental resource areas. The discussion includes an overview of each resource for the State of Hawai‘i and more specific information for each of the six islands being addressed. This material provides a baseline understanding of each environmental resource area, from which the reader can get an appreciation of the potential for environmental impacts from each of the technologies being assessed.

2.2 Permitting and Regulatory Requirements

This PEIS does not identify any specific proposal or project for the development of an [energy efficiency](#) activity or [renewable energy](#) technology. Rather this PEIS analyzes and presents the typical environmental impacts that would be associated with these types of activities or technologies if they were to be implemented in the future (refer to Chapters 4 through 8). For this reason and in order to be beneficial to would-be developers of specific projects; Federal, State and county agencies; the general public; and other stakeholders, this section provides a programmatic overview of the types of permitting and regulatory requirements that would be applicable for such future projects. This includes Federal, State of Hawai‘i, and county ordinances.

Project-specific permitting and regulatory requirements are highly dependent on both technology type and project location. In addition, **this section is not intended to be exhaustive in its identification of these requirements** as not all requirements are listed; instead, it seeks to provide a perspective of the programs

and regulations that are presently in place to ensure that the proper environmental reviews occur before the implementation of proposed activities and technologies in the future.

The Hawai‘i State Energy Office strongly recommends that renewable energy applicants consult with the appropriate permitting agencies prior to submitting permit applications. The State of Hawai‘i has provided several guides to help projects comply with the appropriate regulations, which are provided in detail in [Sections 2.2.1](#) and [2.2.2](#) below. [Section 2.2.3](#) lists the types of permits that may be required. [Section 2.2.4](#) provides an overview of the roles and responsibilities of project proponents and the Federal, State, and county agencies in the permitting and regulatory review and approval process. General permitting and regulatory requirements for potential activities and technologies are described in [Section 2.2.5](#). Where permits or requirements are specific to a particular type of technology or activity, these are described individually within the detailed activity and technology descriptions in [Section 2.3](#).

2.2.1 PERMITTING INFORMATION WEB PAGE AND GUIDEBOOK

The Hawai‘i State Energy Office has developed and made available online a comprehensive list of Federal, State, and county-specific permits that are generally required for the activities that will accompany clean energy projects. These include permits related to siting, construction, operation, and other phases. This information is available at <http://energy.hawaii.gov> and includes a link to a single downloadable document that contains the same information. That document is called the *Guide to Renewable Energy Facility Permits in the State of Hawai‘i* (referred to herein as the “Guidebook” and cited as [DBEDT 2013a](#)), and it synthesizes and, where necessary, supersedes the previous county-specific guidebooks that were issued in 2010. Excerpts from this Guidebook have been included in this PEIS. Permit packets associated with each permit also are available for download at the above website. The Hawai‘i State Energy Office currently is updating the Guidebook, permitting website, and information on the large number of permits required for renewable energy development in Hawai‘i. In addition, many Federal, State, and county permitting agencies in Hawai‘i have developed their own guidance materials describing various permitting processes, procedures, and requirements. Where appropriate, this PEIS provides references to these other guidance materials.

2.2.2 ONLINE PERMITTING WIZARD

To supplement these tools, a free interactive online permitting tool, the Hawai‘i Renewable Energy Permitting Wizard, is also available from the Hawai‘i State Energy Office (<http://wizard.HawaiiCleanEnergyInitiative.org/>), which allows users (such as the public or a prospective renewable energy developer) to identify the Federal, State, and county permits that may be required for a specific renewable energy project in Hawai‘i, based on input provided by the user ([DBEDT 2013b](#)). Designed for renewable energy projects, the Wizard can create a permit plan for a proposed project based on the type of renewable energy technology proposed. The permit plan also includes the recommended sequence—with estimated timelines—in which the permits may be obtained.

2.2.3 TYPES OF PERMITS

Permits serve as safeguards to communities and the environment from potential adverse impacts and ensure better enforcement of environmental laws (Siah and [Zapka 2009a](#)). Permits and regulatory requirements for potential clean energy projects are categorized by the Guidebook into four general groups ([DBEDT 2013a](#)):

- Environmental permits and reviews
 - NEPA and *Hawai‘i Environmental Policy Act* (HEPA; [Chapter 343](#), Hawai‘i Revised Statutes) environmental impact reviews

- Endangered species reviews and habitat conservation
- Historic, archaeological, and cultural reviews
- Water, air, and soil protections and reviews
- Land use permits
 - Review for compatibility with existing zoning, special districts, land use waivers, and land use plan amendments (note that in Hawai‘i, each parcel is likely to be governed by two zones: the State land use district and the overlying county zoning district)
- Construction and operation permits
 - Site preparation and criteria for erecting a new building or structure, including electrical, plumbing, and drainage patterns
- Utility permits and approvals
 - Required for all utility construction, reconstruction, and maintenance activities

2.2.4 ROLES AND RESPONSIBILITIES

Clean energy projects in Hawai‘i are developed in a regulatory environment that is administered by Federal, State, and county agencies. The agencies review different aspects of proposed actions depending on their regulatory authority and issue required permits. Clean energy projects in Hawai‘i present new technological and permitting challenges that increase the need for coordination among applicants and the various Federal, State, and county agencies. The State of Hawai‘i has many protected cultural, historic, and ecological resources, as well as overlapping land use jurisdictions. It can typically take 1 to 5 years to permit a large clean energy project in Hawai‘i, and large energy projects in Hawai‘i average 15 Federal, State, and county permits (with some projects requiring more than 40 approvals). The Hawai‘i State Energy Office has developed both the Guidebook and the Permitting Wizard to encourage electronic permit processing, increase inter-agency communication, educate developers and agencies, and encourage early public involvement. Engaging impacted communities early in the process and addressing concerns raised prior to submitting permit applications can significantly shorten permitting timelines as agencies are typically more comfortable with permit approvals of specific projects that have community support. Future legislation to further streamline and prioritize the permitting processes could provide predictability to private companies and encourage their commitment of substantial amounts of capital, time, and effort necessary to develop renewable energy projects.

Obtaining the proper permits would be the responsibility of the engineering firm designing the project and the contractor performing the construction. Environmental permits and reviews are regulated at the Federal, State, and county levels. At the county level, the entire area of the State is encompassed by county government, except for Kalawao County and the City and County of Honolulu. The City and County of Honolulu is a consolidated city/county government on the island of O‘ahu and is considered a municipal government. The island of Kaua‘i is governed by the County of Kaua‘i; the island of Hawai‘i is governed by the County of Hawai‘i; and the islands of Maui, Lāna‘i, and Molokai are governed by the County of Maui. Kalawao County on Molokai is considered an adjunct of the State government and not counted as a separate county government. The role of Federal, State, and county permitting and regulatory agencies is described in [Table 2-2](#) including website links for more information. There are other State agencies with which project developers may want to confer when planning a clean energy project in Hawai‘i, depending on the site and nature of the project, including the Department of Taxation, the Office of Hawaiian Affairs, and the Department of Hawaiian Home Lands.

When detailed proposals are made to develop a specific clean technology project in Hawai‘i and elsewhere, project proposals are sent to government agencies with responsibility for managing resources

that may be affected by the project. The responsible agency can then review, comment, and provide recommendations to avoid, reduce, and mitigate any potential impacts to resources under their management authority. The coordination and exchange of information between responsible resource agencies and project proponents are an important part of the development process. It is essential that agencies be given sufficient time to review and evaluate specific proposed projects.

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles

Agency	Role
Federal	
Advisory Council on Historic Preservation (ACHP) ^a	<p>The ACHP operates under three standing committees:</p> <ol style="list-style-type: none"> (1) <u>Preservation Initiatives</u> – focus on partnerships and program initiatives such as heritage tourism to promote preservation with groups such as State and local governments, Indian tribes, and the private sector; (2) <u>Communications, Education, and Outreach</u> – conveys the ACHP’s vision and message to constituents and the general public through public information and education programs and a public recognition program for historic preservation achievement; and (3) <u>Federal Agency Programs</u> – administers the <i>National Historic Preservation Act (NHPA) Section 106 review process</i> and works with Federal agencies to help improve how they consider historic preservation values in their programs. State Historic Preservation Officers (SHPOs) administer the national historic preservation program and Section 106 compliance at the State level. <p>ACHP’s Policy Statement on the ACHP’s interaction with Native Hawaiian Organizations contains the commitments and principles that ACHP will implement when interacting with Native Hawaiian Organizations on matters relating to NHPA (ACHP 2008). The ACHP has also released a handbook, which identifies the significant role that Native Hawaiian Organizations play in consultation during the Section 106 process (ACHP 2011).</p> <p>http://www.achp.gov/renewable_energy.html</p>
Council on Environmental Quality (CEQ)	<p>The CEQ coordinates Federal environmental efforts and works closely with agencies and other White House offices in the development of environmental policies and initiatives. In addition, NEPA tasks the CEQ with ensuring that Federal agencies meet their obligations under the Act by overseeing Federal agency implementation of the environmental impact assessment process and to act as a referee during agency disagreements. However, the regulatory role remains with the Federal agency responsible for the proposed action.</p> <p>https://www.whitehouse.gov/administration/eop/ceq</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
U.S. Environmental Protection Agency (EPA) ^b	<p>The mission of the EPA is to protect human health and the environment. The EPA’s primary responsibilities include the regulation of air quality, water quality, and chemicals in commerce; the development of regulatory criteria for the management and disposal of solid and hazardous wastes; and the cleanup of environmental contamination. Most Federal environmental statutes envision a primary role for states, so EPA works closely with State, tribal, and local governments and other stakeholders to implement their environmental compliance and enforcement programs. EPA also provides financial assistance to States and local governments to aim them in administering pollution control programs and in complying with certain Federal environmental requirements. The EPA administers the programmatic and regulatory aspects of 11 Federal pollution control statutes including the Clean Air Act (CAA) and Clean Water Act (CWA).</p> <p>The EPA has a unique role in the NEPA process. Under Section 309 of the CAA, EPA is required to review and publicly comment on the environmental impacts of major Federal actions including actions which are the subject of EISs. In addition, EPA carries out certain procedural duties associated with filing and publishing EISs. EPA’s Office of Federal Activities has been designated the official recipient of all EISs prepared and filed by Federal agencies.</p> <p>http://www.epa.gov/compliance/nepa</p>
Federal Energy Regulatory Commission (FERC)	<p>FERC is an independent agency that regulates the interstate transmission of electricity, natural gas, and oil. FERC also reviews proposals to build liquefied natural gas terminals and interstate natural gas pipelines as well as licensing hydropower projects. Among other responsibilities, FERC is responsible for:</p> <ul style="list-style-type: none"> • Regulating the transmission and wholesale sales of electricity in interstate commerce; regulating the transmission and sale of natural gas for resale in interstate commerce; • Approving the siting and abandonment of interstate natural gas pipelines and storage facilities; • Reviewing the siting application for electric transmission projects under limited circumstances; ensuring the safe operation and reliability of proposed and operating liquefied natural gas terminals; • Licensing and inspecting private, municipal, and state hydroelectric projects; • Protecting the reliability of the high voltage interstate transmission system through mandatory reliability standards; enforcing FERC regulatory requirements through imposition of civil penalties and other means; and • Overseeing environmental matters related to natural gas and hydroelectricity projects and other matters. <p>FERC’s Office of Energy Projects fosters economic and environmental benefits for the Nation through the approval and oversight of hydroelectric and natural gas pipeline energy projects. That office has the engineering and environmental expertise to certify new gas pipeline projects and to authorize and monitor hydroelectric projects and focuses on project siting and development, balancing environmental and other concerns, ensuring compliance, and safeguarding the public.</p> <p>http://www.ferc.gov/about/offices/oep.asp</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
U.S. Department of Agriculture (USDA)	<p>USDA's mission is provide leadership on food, agriculture, natural resources, rural development, nutrition, and related issues based on sound public policy, the best available science, and efficient management. http://www.usda.gov</p> <p>Farm Service Agency (FSA)^a administers farm commodity, crop insurance, credit, environmental, conservation, and emergency assistance programs for farmers and ranchers. The FSA implements the Conservation Reserve Program that sets aside private lands for the conservation of natural resources. FSA published a Programmatic EA in 2006 for implementation of the Hawai'i Conservation Reserve Enhancement Program Agreement to enroll 30,000 acres of cropland and marginal pastureland (USDA 2006). The FSA also operates the Biomass Crop Assistance Program to provide financial assistance to owners and operators of agricultural and non-industrial private forest land who wish to establish, produce, and deliver biomass feedstocks. http://www.fsa.usda.gov/FSA/webapp?area=home&subject=ecrc&topic=landing</p> <p>Natural Resources Conservation Service (NRCS)^b is the USDA's principal agency for providing conservation technical assistance to private landowners, conservation districts, tribes, and other organizations. Energy is a key resource for which NRCS provides conservation planning assistance to private landowners, so NRCS will use the PEIS when conducting environmental compliance in the planning process. NRCS authorities regarding conservation planning are from the <i>Soil Conservation and Domestic Allotment Act</i>, found in 16 U.S.C. § 590a(2). NRCS is also authorized under the Food, Conservation, and Energy Act of 2008 (and subsequent Farm Bills) using various programs such as the Conservation Stewardship Program (7 CFR 1470.3); Environmental Quality Incentive Program (Public Law 110-246); Wildlife Habitat Incentive Program (7 CFR Part 636) and others. http://www.nrcs.usda.gov/wps/portal/nrcs/main/national/programs/technical</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
U.S. Department of the Interior (DOI)	<p>DOI's mission is to protect America's natural resources and heritage, honor cultures and Tribal communities, and supply energy to power the Nation's future.</p> <p>DOI's Office of Native Hawaiian Relations is responsible for matters related to Native Hawaiians and serves as a conduit for the DOI's field activities in Hawai'i. http://www.doi.gov/ohr/index.cfm</p> <p>Bureau of Ocean Energy Management (BOEM)^b: BOEM is an agency within DOI that was granted the authority for regulating the production, transportation and transmission of renewable energy sources on the Outer Continental Shelf through EPA Act 2005. BOEM has specific subject matter expertise in coastal and marine biological and physical sciences in addition to marine archaeological and cultural resources. http://www.boem.gov/OEP/; http://www.boem.gov/Renewable-Energy-Program/Regulatory-Information/Index.aspx</p> <p>National Park Service (NPS)^b: The NPS, another DOI agency, has special expertise on the unique natural and cultural resources within and surrounding units of the National Park System within Hawai'i. The NPS is charged with protecting park resources unimpaired for the enjoyment of future generations, including activities inside and near park units. In accordance with 36 CFR 65.7, NPS monitors the condition of National Historic Landmarks and National Natural Landmarks and may offer preservation assistance. NPS also maintains the National Register of Historic Places in accordance with the NHPA. http://www.nature.nps.gov/environmentalquality/external.cfm</p> <p>U.S. Fish and Wildlife Service (USFWS)^a: The USFWS, also part of DOI, manages all designated National Wildlife Refuges and is the regulatory and management authority for all Federally listed plant and animal species under the Endangered Species Act (ESA). In addition, USFWS has regulatory authority for the protection of migratory birds under the Migratory Bird Treaty Act and bald and golden eagles under the Bald and Golden Eagle Protection Act. To ensure fish and wildlife resources receive equal consideration to other features of water resource development projects, the Fish and Wildlife Coordination Act requires Federal agencies involved with such projects to first consult with the USFWS and the respective state fish and wildlife agencies regarding the potential impacts of the project on fish and wildlife resources. http://www.fws.gov/permits/</p> <p>The Pacific Islands Fish and Wildlife Office within the USFWS is an ecological services office headquartered in Honolulu. It carries out the USFWS mission in the Hawaiian Islands. http://www.fws.gov/pacificislands/</p> <p>U.S. Geological Survey (USGS)^b: As a Federal agency with special expertise in the earth sciences, the USGS may elect to evaluate, review, and prepare technical comments on EISs and associated documents prepared by other Federal agencies. In addition, through its Environmental Affairs Program, the USGS has established policies to implement NEPA. http://water.usgs.gov/eap</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
<p>U.S. Department of Commerce (DOC)</p>	<p>The DOC mission is to promote job creation, economic growth, sustainable development, and improved standards of living for all Americans by working in partnership with businesses, universities, communities, and the Nation’s workers. DOC also provides effective management and monitoring of the Nation’s resources and assets to support both environmental and economic health. http://www.commerce.gov/</p> <p>National Oceanic and Atmospheric Administration (NOAA) is an agency within the DOC that provides environmental information such as weather forecasts and climate monitoring and scientific research to help manage U.S. coastal ecosystems, fisheries, and the marine environment and related commerce. http://www.noaa.gov</p> <p>NOAA’s National Ocean Service Office of National Marine Sanctuaries^a has permitting authority for all activities that are prohibited (15 CFR Part 922) in marine sanctuaries. If a proposed activity includes any prohibited action, a permit is likely required. Section 304(d) of the National Marine Sanctuaries Act (16 U.S.C. 1431-1445) requires interagency consultation between NOAA and Federal agencies taking actions, including authorization of private activities, “likely to destroy, cause the loss of, or injure a sanctuary resource.” http://sanctuaries.noaa.gov/</p> <p>NOAA’s National Marine Fisheries Service (NMFS)^a has regulatory authority for the protection of marine mammals under the Marine Mammal Protection Act, management and protection of marine threatened and endangered species. This includes implementation of ESA including cooperating with States, interagency consultation, enforcement, and permitting for conservation plans. It also includes protection and management of essential fish habitat (EFH) under the Magnuson-Stevens Fishery Conservation and Management Act.</p> <p>The NMFS Office of Protected Resources works to conserve, protect, and recover species under the ESA and the Marine Mammal Protection Act in conjunction with its regional offices, science centers, and various partners. http://www.nmfs.noaa.gov/pr/permits/</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
U.S. Department of Transportation (USDOT)	<p>The mission of the USDOT is to ensure a fast, safe, efficient, accessible, and convenient transportation system that meets vital national interests and enhances the quality of life of the American people, today and into the future. http://www.transportation.gov/</p> <p>The Federal Highway Administration (FHWA)^a is an agency within the USDOT that supports State and local governments in the design, construction, and maintenance of the Nation's highway system (Federal Aid Highway Program) and various Federally and tribal owned lands (Federal Lands Highway Program). FHWA's Office of Planning, Environment, and Realty serves as FHWA's advocate and national leader for environment protection and enhancement, comprehensive intermodal and multi-modal transportation planning, and for fair and prudent acquisition and management of real property. http://www.fhwa.dot.gov/hep</p> <p>The Federal Aviation Administration (FAA)^b has the mission to provide an efficient aerospace system. The FAA's Environmental Policy Team falls under the Airspace Policy and Air Traffic Control Procedures Group, handling environmental matters for Mission Support Services for Air Traffic Organization. The team develops environmental policy, standards, and guidance and provides technical advice to FAA headquarters, service areas, and field offices. The team also represents Mission Support Services at meetings and conferences on environmental activities that affect air traffic operations and the National Airspace System. https://oeaaa.faa.gov/oeaaa/external/portal.jsp</p>
U.S. Department of Homeland Security (DHS)	<p>The U.S. Coast Guard (USCG)^a within the DHS has a primary role in marine navigational safety through its Aids To Navigation Program and vessel traffic management responsibilities. Any offshore renewable energy development that requires marking for navigational safety would fall under the authority of the USCG. http://www.uscg.mil/top/missions</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
U.S. Department of Defense (DoD)	<p>The U.S. Marine Corps (USMC)^b and U.S. Navy (Navy)^b protect DoD mission capabilities from incompatible development by collaborating with DoD components and external stakeholders to prevent, minimize, or mitigate adverse impacts on military operations, readiness, and testing. USMC and Navy are committed to maintaining an effective, consistent, transparent, and timely process for evaluating the impact of energy projects on military test, training, and operational missions.</p> <p>The DoD Siting Clearinghouse is a “one-stop-shop” for comprehensive, expedited evaluation of energy projects and their potential effect on DoD operations. The Clearinghouse’s formal review process applies to projects filed with the Secretary of Transportation, under 49 U.S.C. § 44718 (FAA’s obstruction evaluation process), as well as other projects proposed for construction within military training routes or special use airspace, whether on private, State, or Federal properties. FAA’s airspace jurisdiction for obstruction evaluation extends 12 nautical miles from the U.S. shoreline. Offshore renewable energy projects beyond 12 nautical miles would have to contact the DoD Clearinghouse directly to request a formal review. http://www.acq.osd.mil/dodsc</p> <p>The U.S. Army Corps of Engineers (USACE)^a restores degraded ecosystems; constructs sustainable facilities; regulates waterways; manages natural resources; and cleans up contaminated sites from past military activities. USACE works in partnership with Federal and State agencies, non-governmental organizations, and academic institutions to find innovative solutions to challenges that affect everyone—sustainability, climate change, endangered species, environmental cleanup, ecosystem restoration and more. USACE also manages, designs, and executes a full range of cleanup and protection activities that focus on reducing risk and protecting human health and the environment. http://www.usace.army.mil/Missions/Environmental.aspx</p> <p>The Pacific Ocean Division is one of nine divisions worldwide that make up the USACE. The Pacific Ocean Division is responsible for carrying out the USACE mission in the Pacific region, including in the Hawaiian Islands. http://www.pod.usace.army.mil</p>
State of Hawai‘i	
Department of Agriculture	<p>The Hawai‘i Department of Agriculture supports, enhances, and promotes Hawai‘i’s agriculture and aquaculture industries. http://hdoa.hawaii.gov/</p>
Department of Business, Economic Development and Tourism (DBEDT) ^b	<p>The Department of Business, Economic Development and Tourism (DBEDT) is Hawai‘i’s resource center for economic and statistical data, business development opportunities, energy and conservation information, and foreign trade advantages. Within DBEDT are multiple offices and commissions that help carry out this mission. http://dbedt.hawaii.gov/</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
Hawai'i State Energy Office (HSEO)	<p>The Hawai'i State Energy Office (HSEO) provides a catalyst through investment, policy, and regulatory frameworks that enables the development of clean energy businesses, projects, and the growth of new jobs for Hawai'i. The HSEO is tasked with implementing Hawai'i's State Energy Policy, which is rooted in one principle: a commitment to maximize the deployment of cost-effective investments in clean energy production and management for the purpose of promoting Hawai'i's energy security. The policy is implemented following a 5-point energy strategy that includes: (1) diversification of the State's energy portfolio; (2) connection and modernization of the State's grids; (3) balance of technical, economic, environmental, and cultural considerations; (4) leverage of the State's position as an innovation test bed; and (5) creation of an efficient marketplace that benefits producers and consumers.</p> <p>http://energy.hawaii.gov/energypolicy/</p>
State Land Use Commission (LUC)	<p>The State <i>Land Use Law</i> (HRS Chapter 205) was adopted in 1961, establishing a framework of land use management and regulation in which all lands in the State of Hawai'i are classified into one of four land use districts. To administer the Land Use Law, the State Legislature established the Land Use Commission, composed of nine members appointed by the Governor and confirmed by the State Senate. One member is appointed from each of the four counties; five members are appointed at-large. The Commissioners are <u>non-paid</u> volunteers who represent a cross-section of the community.</p> <p>http://luc.hawaii.gov</p>
Office of Planning	<p>The Office of Planning guides the development of the State through a continuous process of comprehensive, long-range, and strategic planning to meet the physical, economic, and social needs of Hawai'i's people, and provide for the wise use of Hawai'i's resources in a coordinated, efficient, and economical manner – including the conservation of natural, environmental, recreational, scenic, historic, and other limited and irreplaceable resources required for future generations. The Office of Planning's three main objectives are: (1) fix responsibility and accountability to successfully carry out Statewide programs, policies, and priorities; (2) improve the efficiency and effectiveness of the operations of the executive branch; and (3) ensure comprehensive planning and coordination to enhance the quality of life of the people of Hawai'i. A significant element of the Office of Planning is the implementation of the Coastal Zone Management Program through which Federal projects and activities are reviewed and coordinated with other State agencies to ensure consistency with approved State coastal programs.</p> <p>http://planning.hawaii.gov</p>
Hawai'i Community Development Authority	<p>The Hawai'i Community Development Authority works to stimulate the economic development of specific community districts by planning and implementing community development programs and facilitating capital investments. The Authority's main objectives are: (1) plan and implement capital improvement projects to upgrade infrastructure and develop public facilities to meet Hawai'i's economic and recreational needs, and (2) implement long-term planning initiatives to support residential development in a mixed-use community.</p> <p>http://www.hcdaweb.org</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
Department of Health (DOH)	<p>The Environmental Management Division implements and maintains Statewide programs for controlling air and water pollution, assuring safe drinking water, and the proper management of solid and hazardous waste. The division also regulates the State's wastewater. http://health.hawaii.gov</p> <p>The Clean Air Branch is responsible for the implementation of a Statewide air pollution control program through services that include engineering analysis and permitting, monitoring and investigations, and enforcement of the Federal and State air pollution control laws and regulations. http://health.hawaii.gov/cab</p> <p>The Clean Water Branch administers and enforces Statewide water pollution laws and rules. This is achieved through permitting of point sources, compliance monitoring, inspections, investigations of complaints, and ambient water quality monitoring. http://health.hawaii.gov/cwb</p> <p>The Solid and Hazardous Waste Branch oversees management of all solid waste generated within the State through the promotion of pollution prevention and waste minimization activities, and the development of partnerships with both generators and the regulated community. This office also works to prevent releases, or threats of releases, of petroleum, hazardous substances, pollutants or contaminants into the environment through aggressive enforcement of environmental laws and regulations. http://health.hawaii.gov/shwb/</p> <p>The Hazard Evaluation and Emergency Response Office provides risk assessments, responds to the release of hazardous substances, and oversees the cleanup of contaminated sites. The office responds to at least 150 incidents a year. Office activities include evaluating health effects of air and water pollutants when no standards exist. http://eha-web.doh.hawaii.gov/eha-cma/Org/HEER</p> <p>The Office of Environmental Quality Control (OEQC) was established to help stimulate, expand, and coordinate efforts to maintain the optimum quality of the State's environment. OEQC's main duty is implementing HRS Chapter 343, "Environmental Impact Statements." Office planners review and comment on hundreds of environmental disclosure documents each year. Twice a month, OEQC publishes <i>The Environmental Notice</i>, which announces the availability of environmental assessments and environmental impact statements under public review. http://health.hawaii.gov/oeqc/</p>
Department of Labor & Industrial Relations	<p>The Department of Labor and Industrial Relations administers programs designed to increase the economic security, physical and economic well-being, and productivity of workers, and to achieve good labor-management relations, including the administration of workers' compensation, employment security, apprenticeship training, wage and hour, and industrial relations laws. http://labor.hawaii.gov</p> <p>The Hawai'i Occupational, Safety & Health Division administers the Occupational Safety and Health Program through several activities, including safety and health standards, inspections, and consultation. http://labor.hawaii.gov/hiosh/</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
Department of Land and Natural Resources (DLNR)	<p>The commissions, divisions, and offices that make up the DLNR are responsible for managing, administering, and exercising control over public lands, natural resources, ocean waters, navigable streams, coastal areas (except commercial harbors), minerals, and oversee development being proposed for State-owned lands, as well as on private and public lands that lie within the State LUC District. These organizations must be consulted during the development and permitting process of any clean energy project. Those relevant to this PEIS are discussed in more detail below. http://dlnr.hawaii.gov</p> <p>The Commission on Water Resource Management of DLNR sets overall water conservation, quality, and use policies; defines beneficial and reasonable uses; protects ground and surface water resources, watersheds, and natural stream environments; establishes criteria for water use priorities while assuring appurtenant rights and existing correlative and riparian uses; and establishes procedures for regulating all uses of Hawai‘i's water resources. http://dlnr.hawaii.gov/cwrm/</p> <p>The Division of Forestry and Wildlife of DLNR manages and protects watersheds, native ecosystems, and cultural resources and provides outdoor recreation and sustainable forest products opportunities, while facilitating partnerships, community involvement, and education. http://dlnr.hawaii.gov/dofaw/</p> <p>The Engineering Division of DLNR provides engineering services and technical assistance to other Departmental divisions and State agencies to implement capital improvement or repair and maintenance projects and administer programs for water and land development, mineral resources development, and prevention of natural disasters. https://dlnr.hawaii.gov/eng</p> <p>The Land Division of DLNR is responsible for managing State-owned lands in ways that will promote the social, environmental, and economic well-being of Hawai‘i's people and for ensuring that these lands are used in accordance with the goals, policies, and plans of the State. Lands that are not set aside for use by other government agencies come within the direct purview of the division. These lands are made available to the public through fee sales, leases, licenses, grants of easement, rights-of-entry, month-to-month tenancies, or kept as open space area. http://dlnr.hawaii.gov/ld/</p> <p>The Office of Conservation and Coastal Lands of DLNR is responsible for overseeing approximately 2 million acres of private and public lands that lie within the State Land Use Conservation District. In addition to privately and publicly zoned Conservation District lands, the office is responsible for overseeing beach and marine lands out to the seaward extent of the State's jurisdiction. http://dlnr.hawaii.gov/occl/</p> <p>The State Historic Preservation Division (SHPD) of DLNR works to preserve and sustain reminders of earlier times that link the past to the present. SHPD's three branches, History and Culture, Archaeology, and Architecture, strive to accomplish this goal through a number of different activities. The division's Statewide Inventory of Historic Properties contains information on more than 38,000 historic sites in Hawai‘i. Reviews of development projects are the primary means of lessening the effects of change on the historic and cultural assets. http://dlnr.hawaii.gov/shpd/</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
Department of Land and Natural Resources (DLNR) (continued)	The Division of Aquatic Resources manages the State's aquatic resources and ecosystems through programs in commercial fisheries and resource enhancement; aquatic resources protection, habitat enhancement, and education; and recreational fisheries. Major program areas include projects to manage or enhance fisheries for long-term sustainability of the resources, protect and restore the aquatic environment, protect native and resident aquatic species and their habitat, and provide facilities and opportunities for recreational fishing. http://dlnr.hawaii.gov/dar/
Department of Transportation (HDOT)	<p>The Hawai'i Department of Transportation (HDOT) is responsible for planning, designing, constructing, operating, and maintaining State facilities in all modes of transportation, including air, water, and land. Coordination with other Federal, State, and county programs is maintained in order to achieve these objectives. Within HDOT are various divisions that help the agency in carrying out its mission. These are discussed in more detail below. http://hidot.hawaii.gov</p> <p>The Highways Division provides a safe, efficient, and accessible highway system through the utilization of available resources in the maintenance, enhancement, and support of land transportation facilities. http://hidot.hawaii.gov/highways/home/doing-business/guide-to-permits</p> <p>The Harbors Division maintains, repairs, and operates the ten commercial harbors that comprise the Statewide harbors system; plans, designs, and constructs harbor facilities; provides program planning and administrative support; manages vessel traffic into, within, and out of harbor facilities; provides for and manages the efficient utilization of harbor facilities and lands; and maintains offices and facilities for the conduct of maritime business with the public. http://hidot.hawaii.gov/harbors/doing-business</p> <p>The Airports Division develops, manages, and maintains a safe and efficient global air transportation organization. http://hidot.hawaii.gov/airports/</p>
Public Utilities Commission (PUC)	The Public Utilities Commission (PUC) regulates all franchised or certificated public service companies operating in the State; prescribes rates, tariffs, charges, and fees; determines the allowable rate of earnings in establishing rates; issues guidelines concerning the general management of franchised or certificated utility businesses; and acts on requests for the acquisition, sale, disposition, or other exchange of utility properties, including mergers and consolidations. http://puc.hawaii.gov
County	
City and County of Honolulu	The City and County of Honolulu Department of Planning and Permitting provides services and information on building permits, development projects, and planning activities for the City and County of Honolulu. http://www.honolulu.gov/dpp/
County of Kaua'i	<p>Project permits required in the County of Kaua'i are issued by the Planning Department and the Department of Public Works. http://www.kauai.gov</p> <p>The Planning Department is responsible for the administration and enforcement of the Zoning and Subdivision Ordinances, as well as the County's planning program, which includes long-range and regulatory policy documents like the General Plan and Comprehensive Zoning Ordinances. http://www.kauai.gov/Government/Departments/PlanningDepartment/ZoningandLandUsePermits/tabid/649/Default.aspx</p>

Table 2-2. Federal, State, and County Permitting and Regulatory Agencies and Their Roles (continued)

Agency	Role
	<p>The Department of Public Works is responsible for the planning, design, and construction of all new improvements to County-owned facilities, excluding Department of Water projects. The maintenance, repair, and upkeep of all County facilities, the collection and disposal of garbage and refuse, the collection and treatment of sewage, the review and enforcement of the various codes, and other regulations pertaining to public and private construction work are also responsibilities of this Department.</p> <p>http://www.Kauai.gov/Government/Departments/PublicWorks/Engineering/DesignandPermitting/tabid/133/Default.aspx</p>
County of Maui	<p>Project permits required in the County of Maui are issued by the Department of Planning and the Department of Public Works.</p> <p>http://www.co.maui.hi.us/index.aspx?nid=121; http://www.co.maui.hi.us/index.aspx?nid=124</p>
County of Hawai‘i	<p>Project permits required in the County of Hawai‘i are issued by the Department of Planning and the Department of Public Works.</p> <p>http://www.HawaiiCounty.gov</p> <p>The Department of Planning provides oversight on all planning and land use matters, and administers subdivision and zoning codes.</p> <p>http://www.cohplanningdept.com</p> <p>The Department of Public Works administers regulatory and code enforcements for building, engineering, and transportation.</p> <p>http://www.HawaiiCounty.gov/public-works</p>

- a. Participating agency.
b. Cooperating agency.

2.2.5 GENERAL PERMITTING AND REGULATORY REQUIREMENTS

This section describes the typical permitting and regulatory requirements applicable to most proposed clean energy projects in Hawai‘i. Potential requirements applicable to proposed land-based and marine-based projects are discussed, followed by a description of typical Federal, State, and county requirements. Depending on the proposed project, not all of the typical Federal, State, and county permits would be applicable. Permitting and regulatory requirements specific to certain activities and technologies are discussed in [Section 2.3](#).

The potential Federal, State, and county permitting and regulatory requirements vary widely by technology and activity, even when grouped by energy category, and depend on the specific project location and design. In general, more permits would be required for a utility-scale project than for a distributed-scale project. According to a National Renewable Energy Laboratory (NREL) report ([NREL 2013a](#)), renewable energy project developers should be aware that there are a number of particularly complex permits that must be obtained, which can be time-consuming. These include Conservation District Use Permits, State Land Use Boundary Amendment, HDOH air permits, and Special Management Area permits. For proposed clean energy projects that would integrate into existing facilities or industrial operations, permitting may be accomplished through modification of existing permits.

In March 2012, BOEM kicked off a renewable energy task force with the State of Hawai‘i in order to coordinate ocean renewable energy deployment in the outer continental shelf, which begins 3 miles off

the coast of Hawai‘i. The task force includes officials from State and local agencies with relevant regulatory jurisdiction, as well as relevant Federal agency representatives. Any marine-based projects beyond the 3-mile area around Hawai‘i must consult with the BOEM to address all relevant permitting requirements for mooring, cabling, and transmission connections. For marine-based projects within the 3-mile buffer, the project developers need to seek a variety of permits from Federal, State, and county regulatory agencies addressing the various issues related to coastal zone management, environmental and cultural sensitivities, and a State environmental review, among other possible permits for construction and rights-of-way. The Hawai‘i DLNR controls all submerged lands within the 3-mile State buffer, other than those lands controlled by the Federal government (e.g., military installations and Federal parks). Additionally, FAA airspace jurisdiction for Obstruction Evaluation extends to 12 nautical miles from shore, while U.S. territorial seas extend to 24 nautical miles. Offshore renewable energy projects beyond 12 nautical miles would have to contact the DoD Clearinghouse directly to request a formal review. Therefore, any “in-water” renewable energy project, such as marine hydrokinetic, offshore wind, ocean thermal energy conversion, and an undersea cable, would require considerable effort for permitting and regulatory review.

2.2.5.1 General Federal Requirements

Typical Federal agency permitting and regulatory considerations include regulation of discharges into *navigable waters of the United States*, species review and protection approvals, archaeological and cultural review and protection approvals, and clean water approvals. Examples of Federal clean energy reviews and approvals that may be required for clean energy projects, in general, are listed below:

- [CWA Section 404](#) approval
- Endangered Species Act Incidental Take Statement [Section 7\(a\)\(2\)](#) and Incidental Take Permit [Section 10\(a\)\(1\)\(B\)](#)
- Groundwater and Drinking Water Permit
- Historic and Archeological Resource Protection, [Section 106 process](#)
- [Land and Water Conservation Fund Act Section 6\(f\)](#)
- [Marine Protection, Research, and Sanctuaries Act Section 103](#) approval
- [Magnuson-Stevens Fishery Conservation and Management Act, Section 305\(b\)](#) [EFH](#) consultation
- [National Ambient Air Quality Standards](#)
- [National Pollutant Discharge Elimination System](#) (NPDES) permits
- [NEPA compliance](#)
- [New Source Performance Standards](#)
- [Notice of Proposed Construction or Alteration in Airspace](#)
- [Outer Continental Shelf Renewable Energy Project Leases, Rights-of-Use and Easement, and Rights-of-Way](#)
- [Prevention of Significant Air Quality Deterioration Determination](#)
- [Rivers and Harbors Act Section 9](#) and [10](#) approvals

NMFS and USFWS share responsibility for implementing ESA. Generally, the USFWS regulates activities that may impact *threatened* and *endangered* terrestrial and freshwater species, while the NMFS regulates activities that may impact marine and anadromous species. Federal agencies must consult with NMFS and USFWS, under Section 7(a)(2) of the ESA on Federal activities, including Federally funded activities, that might affect a *listed species*. These interagency consultations, or Section 7 consultations, are designed to assist Federal agencies in fulfilling their duty to ensure Federal actions do not jeopardize the continued existence of a species or destroy or adversely modify *critical habitat*. Section 7 consultations may conclude with the issuance of Incidental Take Statements, under which the Federal agency is authorized *to incidentally take* certain members of a *listed species* but only under certain

conditions. Federal agencies that may adversely affect [EFH](#) must consult with the NMFS under Section 305(b) of the [Magnuson-Stevens Fishery Conservation and Management Act](#).

[NPDES](#) or other run-off and/or clean water permits are required during construction and potentially throughout facility operation to regulate facility discharges.

The FAA would be involved in reviewing potential airspace conflicts for any proposed site in proximity to civilian airports or navigational aids (navaids). The Obstruction to Navigation Federal Regulation ([14 CFR Part 77](#)) requires FAA approval of any project higher than 200 feet above ground level. An FAA Finding of No Hazard to Air Navigation does not address all military airspace and other issues; coordination with the military command responsible for management of the training space (military operating areas, military training areas, and special use airspace) also would be required.

Additionally, developers should consult with NPS on projects that could have direct or indirect impacts on sensitive, cultural, natural, scenic, visual, and recreation resources of the National Park System and other protected resources.

2.2.5.2 General State of Hawai‘i Requirements

Typical State agency permitting and regulatory considerations include approvals to use the seafloor within 3 miles of the coastline; Conservation District Use Permits (for shoreline construction activities); coastal zone management review and approvals; species review and protection approvals; archaeological and cultural review and protection approvals; clean water approvals; approvals to impact local transportation activities; clean air approvals; and solid waste approvals. Examples of State of Hawai‘i clean energy reviews and approvals that may be required for clean energy projects, in general, are listed below. Since these are examples, some of these permits may not be applicable to all potential projects. Further, this list is not an exhaustive list of potential permits that may be required.

- Air Pollution Control Permit (Covered and Non-covered Source)
- Agricultural Burning
- Closed Watershed Entry
- Conservation District Use Permit
- Coastal Zone Management Federal Consistency Review
- Groundwater Control Area
- HEPA compliance
- Historic Preservation Review ([HRS Chapter 6E](#))
- Incidental Take License and Habitat Conservation Plan
- Individual Wastewater System Permit
- Noise Permits
- Oversize and Overweight Vehicles
- Special Management Area Use Permit and Shoreline Setback Approval
- Special Use Permit (over 15 acres)
- State Land Use Boundary Amendment
- Transmission Line Approvals
- Underground Injection Control
- Underground Storage Tank
- Use and Occupancy Agreement (Lane Use Permit for Construction Work)
- Variance from Pollution Control
- Water Quality Certification Permit
- Well Construction and Modification Permit

- Wildlife Sanctuary Entry
- Zone of Mixing permit

Hawai‘i’s relatively small electrical grids impact permitting, and the appropriate utility must be contacted early in the planning stages to discuss project interconnection to the electrical grid ([DBEDT 2013a](#)). Contracts such as Power Purchase Agreements (PPAs) with local utility companies may be required to either provide backup power or to sell any excess energy produced. For proposed clean energy projects that would support existing agricultural, industrial, or commercial businesses, the businesses would likely be connected to the local power grid. However, agreements would be required to sell electricity to the utility. Transmission line approvals are required to interconnect a proposed renewable energy project to the existing grid when new transmission lines are required (this approval is in addition to necessary easements or authorizations from property owners).

The project proponent must prepare an EIS under HEPA for certain proposed actions enumerated under [HRS Chapter 343-5](#) that would use State or county lands, State or county funds, or have the potential to significantly affect Hawai‘i’s environment. As part of this process, a cultural impact assessment must be conducted and included in the EIS or EA. Such an assessment considers all the project’s impacts to the cultural resources of Hawai‘i.

An Incidental Take License and Habitat Conservation Plan would be required to allow incidental *take of endangered or threatened species* while carrying out an otherwise lawful activity. The proponent of a project with the potential to adversely impact threatened or endangered species must develop a State Habitat Conservation Plan in consultation with the State Division of Forest and Wildlife and the USFWS (this process is intertwined with the Federal process described above). The Plan and its supporting information must include sufficient scientific and other information to determine estimated take levels and, if applicable, the project proponent must begin the process of obtaining a State Incidental Take License. This often requires the project proponent to develop and maintain a separate area to support the proliferation of species impacted by the primary project. These management areas generally require their own permits and approvals.

The State of Hawai‘i regulates historic preservation matters per [HRS Chapter 6E](#) and has a role in implementing Section 106 of NHPA. SHPO approval from the State Historic Preservation Division within the Hawai‘i DLNR may be required. Historic places or structures listed (or eligible for listing) on the [National Register of Historic Places](#) require special consideration.

Proposed sites on presently or previously contaminated sites would need to engage with the Hazardous Evaluation and Emergency Response Office within the Hawai‘i Department of Health. The Hawai‘i State Energy Office strongly recommends that renewable energy applicants consult with that office prior to submitting permit applications. The language used in certain applications can trigger other permits or approvals not otherwise required ([DBEDT 2013a](#)).

The State of Hawai‘i established a “Call Before You Dig” program with mandatory participation for excavators (such as installation contractors) and operators (including public utilities). As established under a 2004 State law, the Hawai‘i PUC created the Hawai‘i One Call Center (HOCC). The HOCC maintains a single phone number for excavators to call anytime 24 hours a day, 7 days a week for information in locating and marking underground lines, including lines for electric, gas, telecommunications, cable, water, and sewer facilities. The HOCC number is 1-866-423-7287 or 811. Additional information is available at <http://www.callbeforeyoudig.org/Hawai'i/index.asp>.

2.2.5.3 General County Requirements in Hawai'i

County permitting and consultation requirements vary by county. Typical county agency permitting and regulatory considerations include building permit approvals, approvals for many construction and operation activities (e.g., grubbing, grading, electrical and water/sewage connections), as well as ensuring county-level land use compatibility reviews. Examples of reviews and approvals common to one or more of the counties and applicable to clean energy projects, in general, are listed below:

- Building permits
- Certified shoreline/shoreline setback variance
- Flood zone variances and approvals
- Grading permits
- Grubbing permits
- Sewer, plumbing, and/or water service connection or tank installation permits
- Special Management Area Use Permit and Shoreline Setback Approval
- Special use permits
- Zoning permits

County-level departments with permitting and regulatory jurisdiction in these areas would include the Department of Planning and Permitting for the City and County of Honolulu and the Departments of Public Works and the Planning for Kaua'i, Maui, and Hawai'i counties (descriptions of the county-level departments and web links for each are provided in [Table 2-2](#) above). The Planning Department plays the major role in permitting larger projects. Once submitted, the process for permits varies by county (e.g., Maui County has building, electrical, and plumbing permits, whereas the City and County of Honolulu issues only building permits).

Potential project developers should view each county's development plans to ensure the proposed project is sited appropriately and consistent with county zoning purposes and ordinances. For new construction, a series of county-level agency project reviews and approvals may be necessary. In addition to county Planning and Public Works approvals, new construction activities could require approval by other county departments, such as the Departments of Water, Health, Engineering, Wastewater Management, and the Fire Department.

2.3 Activities/Technologies

This section contains a detailed discussion of various aspects of the technologies and activities identified in this PEIS. There are 31 distinct technologies or activities that have been grouped into 5 general clean energy categories: energy efficiency, distributed renewables, utility-scale renewables, alternative transportation fuels and modes, and electricity transmission and distribution. [Table 2-1](#) above presents these technologies and activities along with the broader clean energy groupings. Activities and technologies were selected for these clean energy categories based on their ability to make a timely contribution to the reduction on Hawai'i's reliance on fossil fuels and the specific *HCEI* goals and their stage of technical development, which makes it more likely to advance to the implementation or commercialization stage. For purposes of this PEIS, the clean energy categories are defined below along with footnotes citing sources.

Energy efficiency refers to reducing the energy needed for a given purpose or service or the act of going without a service in order to save energy. Energy efficiency technologies or activities include technologies that reduce the need for energy (such as ground source heat pumps, sea water air conditioning, and solar water heating) and sets of activities (such as energy efficient buildings, energy

conservation, and initiatives and programs) that require less energy or save energy. The activities and technologies in the energy efficiency category were selected to represent those actions that could be taken to achieve improvements in end-use efficiency; one of the key sectors of the energy economy identified in HCEI.

Distributed renewables refer to the use of *renewable energy* resources in *distributed generation*, which in turn refers to any electricity generation by a generator that is located close to the particular load that it is intended to serve. The generating capacity of a distributed generation source is significantly smaller than those of centrally located utility-scale plants and can range from generation at a single residence to larger installations for commercial or multi-unit housing applications. Distributed renewable technologies are those distributed generation projects that use renewable energy resources, including biomass, hydroelectric, hydrogen *fuel cells*, photovoltaic, and (small) land-based wind energy systems. Taken in concert with the utility-scale renewables (below), the technologies in these two categories represent “electricity generation,” one of the key sectors of the energy economy identified in the HCEI.

Utility-scale renewables refer to the use of renewable energy resources at the utility scale, meaning at the scale of a centrally located power plant. Utility-scale renewable technologies include the same kinds of renewable energy resources as in the distributed renewables category (biomass, hydroelectric, PV, and land-based wind) but also include others whose use at the distributed scale is presently impractical (*geothermal systems*, *municipal solid waste*, *marine hydrokinetic energy*, ocean thermal energy conversion, solar thermal, and offshore large-scale wind energy systems). The generating capacities for utility-scale technologies are typically at least an order of magnitude larger than for distributed applications.

Alternative transportation fuels and modes encompass those kinds of fuel and types and methods of transportation that are different than the conventional gasoline-powered private automobile. The technologies associated with this category include the production and use of biofuels; compressed and liquefied natural gas and liquefied petroleum gas; and hydrogen. It also includes electric vehicles and hybrid-electric vehicles. Finally, it also encompasses multi-modal transportation activities such as using public transportation (bus, rail, and marine), ridesharing, car sharing, biking, walking, and telecommuting. The inclusion of alternative transportation fuels and modes as a clean energy category in this PEIS is in direct response to the “transportation” key sector of the energy economy identified in HCEI.

Electrical transmission and distribution refers to the transmission of power from a point of generation and the means by which it is stored and distributed to electricity users. Electricity transmission and distribution systems form an electrical grid or network that is used to manage and distribute electricity. Electricity transmission and distribution technologies evaluated in this PEIS include on-island transmission, undersea cables (including land-sea cable transition sites), smart grid, and energy storage. While electrical transmission and distribution is not specifically addressed as a key energy sector in HCEI, these actions would be a direct result of implementing new renewable energy technologies or improving the existing electrical network in Hawai‘i and are therefore included as an integral element of the Hawai‘i Clean Energy PEIS.

The remainder of [Section 2.3](#) considers the technologies or activities associated with these five clean energy categories. For each technology and activity, this section contains an in-depth description; a characterization of the feasibility and deployment; activity-specific or technology-specific permitting and consultation requirements (not including general permitting requirements discussed in [Section 2.2](#)); and a description of a representative project. Where available, the individual sections also provide a characterization of cost savings potential for the evaluated technologies.

DOE defined representative projects for each activity and technology to serve as analytical tools to allow the PEIS to evaluate and present the typical impacts (beneficial and adverse) associated with the respective activity or technology. The representative projects for each activity and technology characterize typical proposed projects that could be implemented in Hawai‘i by 2030 based on realistic capacity factors and feasibility. The representative projects are hypothetical and not intended to represent any real or proposed project and are provided for analytical purposes only. As stated previously, DOE is not proposing any specific projects as part of this PEIS. An overview of the approach to the representative projects for each energy category is presented in [Sections 2.3.1](#) through [2.3.5](#), followed by detailed descriptions of activities and technologies for each energy category.

2.3.1 ENERGY EFFICIENCY

Among the HCEI goals is a Statewide reduction in electricity usage of 30 percent through energy efficiency and conservation measures by 2030. The implementing legislation for HCEI ([HB 1464](#)) establishes an [Energy Efficiency Portfolio Standard](#) (EEPS) for the State of Hawai‘i that is designed to achieve this goal. Specifically, it calls for a demand reduction of 4,300 gigawatt-hours by 2030 – a figure that corresponds to a 30 percent reduction ([Braccio and Finch 2011](#)). To meet this requirement, the State of Hawai‘i is seeking to align efficiency regulatory policy framework with clean energy goals, support the retrofitting of existing residential and commercial buildings, strengthen new construction policies and building codes, and identify non-building related energy efficiency measures. The energy efficiency category focuses on activities and technology options that reduce energy use from residential and commercial buildings as well as what agencies and consumers can do to reduce and conserve energy use and increase cost savings. The energy efficiency technologies and activities discussed in this section include the following:

- Energy Efficient Buildings (Activity)
- Energy Conservation (Activity)
- Ground Source Heat Pumps
- Initiatives and Programs (Activity)
- Sea Water Air Conditioning
- Solar Water Heating

For energy efficiency activities, representative projects are based on Hawai‘i’s energy efficiency goals. Representative projects for energy efficiency technologies are based on what is considered a typical project in Hawai‘i. A representative project is not evaluated for Energy Conservation activities since there would be no potential for adverse environmental impacts from those activities. Additionally, there is no representative project evaluated for Initiatives and Programs because environmental impacts from these initiative would also be unlikely. No representative project is defined for Ground Source Heat Pumps because they are unlikely to be deployed in Hawai‘i by 2030.

2.3.1.1 Energy Efficient Buildings

Residential and commercial buildings use energy for cooling, lighting, water heating, and appliances and electronics. Today’s buildings consume more energy than any other sector of the U.S. economy, including the transportation industry ([DOE 2008a](#)). In an effort to decrease energy consumption of residential and commercial buildings, energy efficiency measures are incorporated into building construction and retrofits ([Figure 2-4](#)). Much of the information in this section can be found online at the State of Hawai‘i’s Department of Business, Economic Development and Tourism Energy Programs website: <http://energy.hawaii.gov/programs>.

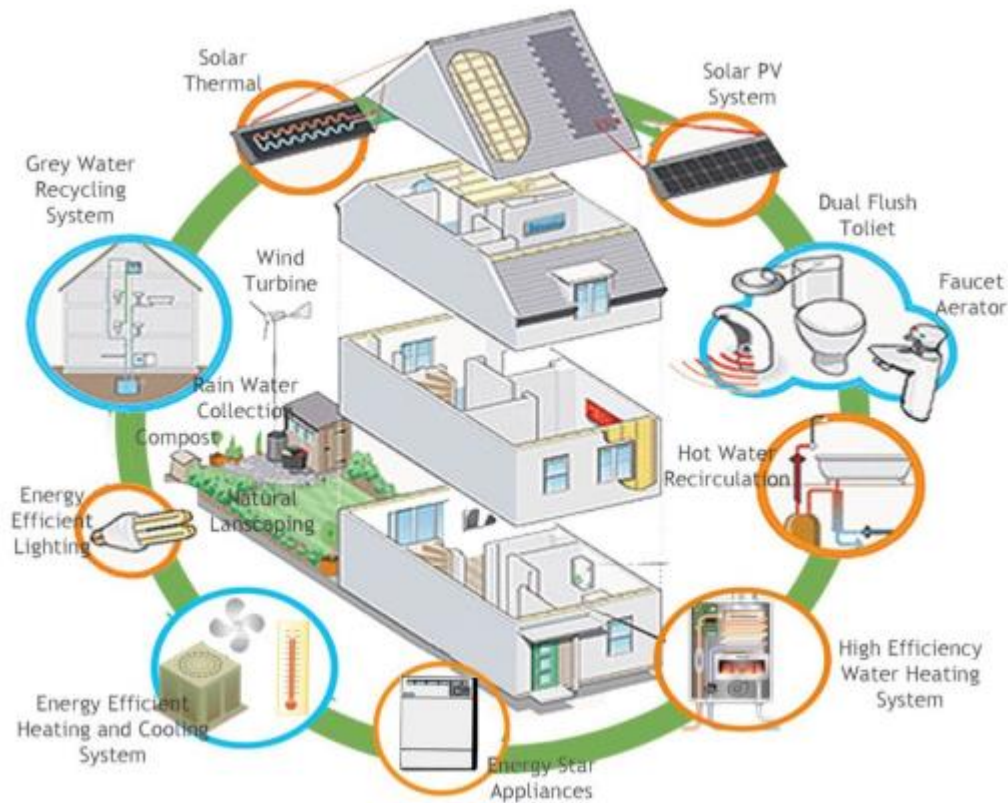

Figure 2-4. Illustration of an Energy Efficient Home

2.3.1.1.1 Activity Description

The State of Hawai‘i is characterized by its mild tropical climate, which experiences very little seasonal variation in day length. The islands are exposed to high sun angles throughout the year, resulting in a relatively constant amount of incoming solar energy annually with very small temperature fluctuations. This presents a unique challenge to designers as incoming solar radiation significantly affects the heat load and increases energy demand on air conditioning systems in buildings. As such, energy efficiency measures in the State focus on balancing the amount of heat gained from the sun and the heat generated internally from lights, people, and equipment, with the demand for air conditioning and electric lighting in buildings (Royle and Terry 1990). To help decrease energy usage from buildings, energy efficiency measures are incorporated into building construction and retrofits in the State. [Table 2-3](#) provides a descriptive list of common energy efficient measures applicable to building construction and retrofits in the State.

Table 2-3. Energy Efficiency Measures

Measure	Description
Integrated Building Design	A well-integrated building system design ensures that all of the building's components are designed to work together. This includes solar control strategies, daylighting/visual comfort strategies, thermal comfort strategies, special indoor requirements, indoor air quality strategies, specific building type issues, and commissioning. For example, in the State, this can mean limiting heat build-up in a building by minimizing the area of east- and west-facing walls and windows; providing generous areas of planting and ground cover to help reduce site temperatures; increased use of porous paving materials to reduce thermal mass, heat gain, and glare; shading roofs to prevent heat build-up or integrating cool roofs; and orienting buildings to maximize the cooling potential of prevailing winds. When performing at optimum levels, these components can save money in the long run and provide a durable and comfortable system that can help avoid future maintenance and repair costs.
Daylighting	Daylighting controls the amount of light entering a building by diffusing sunlight across a room through proper window sizing, light colored interiors, higher ceilings, and the use of shutters and skylights/lightwells. In Hawai'i, the key to daylighting is finding a way to get light into a building while minimizing the amount of heat a building receives (e.g., minimizing the difficult-to-shade east- and west-facing windows and preventing heat gain and glare when installing skylights).
Shading	Shading keeps the sun's heat from entering buildings. This can be achieved via overhangs, awnings, and trees. Overhangs and awnings provide shade and direct water away from buildings; overhangs, specifically, have been used extensively in Hawaiian architectural design. Where possible, energy efficient landscaping can also provide shading.
Natural Ventilation	In the State, gentle trade winds can make air conditioning unnecessary. Summer is the windiest time of the year in Hawai'i, and capturing cooling breezes can help keep buildings comfortable. As such, outlet vents or exhaust fans that are placed strategically remove moisture and pollutants. A controlled, filtered air intake ensures plenty of fresh air. ^a
Energy Efficient Lighting & Controls	Replacing existing lighting systems or the installation energy efficient lighting systems including ENERGY STAR®-qualified light bulbs and light fixtures (i.e., compact fluorescent light bulbs or light-emitting diode) in homes, buildings, street lights, and park lights can result in energy and cost savings. Proper installation and placement (for effective light delivery) of energy efficient lighting technologies (including controls such as timers, occupancy sensors, and photo sensors) can reduce lighting energy use in buildings by 50 to 75 percent.
Energy Efficient Windows	Windows can have a significant impact on energy consumption in a building's perimeter spaces. Energy efficient windows help to control and reduce ultraviolet light that can keep window areas cooler and improve the comfort of homes or buildings. In the State, it is important to shade windows and other openings and to use high-performance glazing or window film on windows exposed to the sun.
Dehumidification	Ensures that indoor humidity levels are kept at a comfortable level. Dehumidification is an important component of air conditioning loads.
Right-Sized & High-Efficiency Heating, Ventilation, and Air Conditioning System	The installation of a properly sized, high-efficiency heating, ventilation, and air conditioning system costs less than bigger equipment, saves energy, and is designed to comfortably handle heating and cooling loads.

Table 2-3. Energy Efficiency Measures (continued)

Measure	Description
High-Performance Heating & Cooling and Power Systems	The installation, tune-up or upgrade to energy efficient heating and cooling systems results in less energy for operations, decreased indoor humidity, less noise, and improves overall building comfort. When combined with proper equipment maintenance and appropriate insulation, air sealing, and adjusted thermostat settings, a 20 to 50 percent energy savings can result. For maximum energy savings and to prolong the life of these systems, use only when necessary or when natural ventilation is inadequate.
Cool Roof Systems	A cool roof emits the sun's heat back to the sky instead of transferring it to the building below. This can be achieved via ventilating attics, installation of fiberglass or foam board insulation or radiant barriers, the installation of white roofs to keep roof surfaces up to 70°F cooler. These measures can help reduce cooling load, thereby reducing air conditioning needs.
Appliances	When upgrading, replacing, or buying new appliances, ENERGY STAR®-certified appliances or ENERGY STAR® Most Efficient appliances such as air conditioners, ceiling fans, refrigerators, dishwashers, clothes washers, as well as digital video disc (DVD) and videocassette recorder (VCR) players, televisions, home office electronic equipment and control panels (to completely shut off entertainment centers) can help reduce energy usage in both residential and non-residential buildings.
Tight Construction/Air Sealing and Sealed Ducts	Advanced techniques for sealing holes and cracks in a building's "envelope" (i.e., floors, walls, ceilings, windows, doors, and fireplaces) and in heating and cooling ducts help reduce drafts and moisture, as well as dust, pollen, pests, and noise. A tightly sealed building improves comfort and indoor air quality while lowering utility and maintenance costs.
Effective Insulation	Properly installed and inspected insulation in floors, walls, crawl spaces, and attics in conjunction with air sealing ensures consistent temperatures with less energy use, resulting in lower utility costs and a quieter, more comfortable building. Insulation is measured by "R-value." The higher the R-value, the thicker and more effective the insulation. For Hawai'i, an R-value of R 30 (about 10 inches thick) is recommended for roofs and a rating of R 13 (13 inches thick) is recommended for walls by DBEDT.
Well-Designed Moisture Barriers	A well-designed moisture barrier in tropical climates helps avoid expensive structural damage and helps stop humidity, mold, and mildew.
Solar Water Heating/ High Efficiency Water Heating	Solar water heating systems use energy from the sun to heat water and are composed of solar collectors and storage tanks. This can replace conventional water heating, which is a big expense and accounts for approximately 40 percent of a house's utility bill in the State (see Section 2.3.1.6). As of January, 2010 any newly constructed single-family home must have a solar water heating system, unless granted a variance. ^b Alternatively, the installation of an energy-efficient hot water heater tank, or an on-demand tankless water heater can result in energy savings. For added savings homes can use less hot water, turn down the thermostat on water heaters, or insulate existing water heaters and use timers.
Energy Efficient Landscaping	Energy efficient landscaping involves careful planning to keep buildings and the air surrounding the buildings cool. Landscaping can involve the use of trellises or trees to shade structures and paved areas; the use of light-colored exterior surfaces such as cream colored concrete to keep exterior areas cool; limiting unplanted and paved surfaces; and/or the use of porous paving materials that allow grass to grow in gaps.

Table 2-3. Energy Efficiency Measures (continued)

Measure	Description
Commissioning/Retro-commissioning	Commissioning is the process of verifying that a building's heating, ventilation, air conditioning, and lighting systems perform correctly and efficiently and in accordance with the design intent and owner's project requirements.
	The commissioning process for new construction integrates the traditionally separate functions of design, construction, and operation by bringing the project team together during each phase of the project. Existing building commissioning (retro-commissioning) investigates, analyzes, and optimizes the performance of existing building systems by identifying and implementing measures to improve their performance. Without commissioning, system and equipment problems can result in higher than necessary utility bills and unexpected and costly equipment repairs.

Source: [DOE 2004a](#).

- a. At this time, the Hawai'i Natural Energy Institute (HNEI) is proposing to partner with the University of Hawai'i School of Architecture's Environmental Research and Design Lab (ERDL) and Loisos + Ubbelohde (an architecture and engineering firm) to leverage current research at the Lawrence Livermore National Laboratory to develop ceiling fan controls, hardware, and the prototype to test the controls in facilities HNEI currently monitors. The technology developed will be directly applicable to schools and other State facilities that need to improve comfort and reduce energy costs, and will allow more buildings to be naturally ventilated, thus advancing HCEI goals ([HSEO 2013a](#)).
- b. A PUC-approved replacement solar water heater is required to qualify for a rebate.

New Construction

Energy efficiency measures can be incorporated during both preconstruction and construction of new buildings, including through scoping and design, procurement, codes and standards compliance, building development, and commissioning. For example, proper site selection and building placement can optimize the use of the existing environment while creating opportunities for energy efficiency. This takes advantage of solar access, natural areas, prevailing wind resources, water resources, and existing landscaping. During the design phase, high-performance building design takes into consideration the entire building—from the building materials used for the foundation and structure, to design elements that include high levels of insulation or reflective surfaces, high-performance windows with solar controls, daylighting, indoor air quality, and high-performance mechanical systems (e.g., direct digital controls, building monitoring systems, and building automation). High-performance mechanical systems can include, ground source heat pumps (see [Section 2.3.1.3](#)), sea water air conditioning (see [Section 2.3.1.5](#)), solar water heaters (see [Section 2.3.1.6](#)) energy efficient lighting, occupancy sensors, low-flow water fixtures, and cogeneration. Where applicable, buildings can also incorporate energy efficient landscaping (for shading/wind protection). Additional research and piloting of new building construction projects are integrating renewable energy resources (e.g., solar panels and small-scale wind turbines) into buildings to achieve *net zero energy* demand (see below and [Section 2.3.2](#) of this PEIS).

Retrofits

Energy efficiency retrofits help ensure that existing buildings meet or exceed their optimal operational needs. Oftentimes, historic buildings and other older structures contain inherent energy conserving features such as construction materials that provide good insulation and design features that maximize ventilation and cooling characteristics in certain locations. Rather than demolishing these types of older buildings, additional retrofits can further maximize energy efficiency parameters. Energy efficiency retrofits encompass general energy saving projects and range from energy efficient equipment to controls. These include replacing incandescent light bulbs with compact fluorescent and light-emitting diode light bulbs, installing insulation and duct sealing, and replacing water heaters, air conditioning units, roofs, floors, windows, boilers, heat pumps, and other appliances and features with energy efficient models and material. Historically, replacement of aging and outdated equipment has been cost-prohibitive. Today, however, energy efficient retrofits in a building can result in a 15 to 30 percent energy savings through

improved operations and maintenance. So while the initial investment to retrofit buildings may be high, given Hawai'i's high electricity prices, payback times are often less than three years.

Net Zero Building

Net zero-capable building, or zero energy-capable building, is the term of art for highly efficient new building construction or retrofits where energy efficiency is supplemented by renewable energy, resulting in zero fossil fuel energy consumption. The Building Industry Association of Hawai'i, the Hawai'i State Energy Office, the Department of Hawaiian Home Lands, and residential military community developers in Hawai'i have built and monitor zero energy-capable homes and communities. Private home owners also have designed and built their own net zero homes. Regardless of their energy efficiency, net zero homes can only achieve zero energy consumption if the occupant maintains and operates the home in an efficient and optimal level. Therefore, continued public education and outreach are key to the success of this concept.

Heat Pump Water Heaters

A heat pump is a device that uses a small amount of energy to efficiently move heat from one location to another. These devices are designed to pull heat out of the air, ground, or water. Heat pump water heaters can be used to extract the waste heat from a facility's operations and use it as energy for water heating purposes. These heat pumps use electricity to move the heat from the cooling towers to the water heater, rather than generating heat directly with the electricity. There are two main types of heat pump water heater systems: air-to-water and water-to-water.

Air-to-water heat pumps are similar to self-contained air conditioners with water-cooled condensers, in that their evaporator coils extract energy from the ambient air and use a conventional refrigeration cycle to deliver this energy to the water heating system. The water heater pulls heat from the surrounding air and discharges it into a tank to heat water. Because they remove heat from the air, air-to-water heat pump systems work more efficiently in a warmer climate. This can be two to three times more energy efficient than conventional, electric-resistance water heaters ([DOE 2012n](#)).

Water-to-water heat pumps are more appropriate for larger-scale buildings that have high hot water heating loads and central air conditioning. Water-to-water heat pumps extract heat from the cooling tower or the return chilled water circulating in the building air conditioning system. Heat contained in the chilled water can be used as a heat source for a water-to-water heat pump. In this design, the heat pump acts to pre-cool the return chilled water and reduces the workload on the chiller, which lowers the energy consumption. Because the system provides both cooling and water heating benefits, water-to-water heat pumps are highly energy efficient and provide significant energy savings ([HECO 2003](#)).

2.3.1.1.2 Feasibility and Deployment

Existing Buildings

Buildings in the State have been developed in compliance with the State's building energy code requirements, which vary by county. The basis for the code was set by the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) and the Illuminating Engineering Society Standard 90.1 (the first standard in the nation to set requirements for energy efficiency in buildings in the early 1980s). Since its initial adoption, the code has been amended and changed several times to incorporate measures that help the State meet its energy efficiency goals. The current code was approved in February 2012, with the State Building Code Council (SBCC) approving the 2009 International Energy Conservation Code (IECC) with State-specific amendments. The SBCC is charged with adopting the International Code Council (ICC) suite of codes and follows the ICC cycle which is updated every three years. The new Hawai'i Model Energy Code applies to new and renovated buildings, and requires that all equipment and products be commissioned by a third party. The counties in the State are free to modify the

code, as long as the codes that are adopted are at least as stringent. At the time of the Draft PEIS, the 2009 IECC had only been locally adopted by Kaua‘i. Adoption in Honolulu, Maui, and Hawai‘i was still in progress. The SBCC is also currently proposing amendments to the 2012 IECC.

DBEDT is in the process of developing a “Tropical Energy Code” to address conditions unique to the tropical climate. This new code will draw substantially from the Guam Energy Code (available from <http://www.guamenergy.com>), and is being shared with the Pacific and Caribbean islands. A proposal to add a Tropical Climate Zone to the existing eight climate zones was approved at the October 2013, International Codes Council final hearings.

LEADERSHIP IN ENERGY AND ENVIRONMENTAL DESIGN (LEED)

LEED is a national voluntary program developed by the U.S. Green Building Council that promotes a whole-building approach to sustainability by recognizing performance in five key areas of human and environmental health: sustainable site development, water savings, materials selection, indoor environmental quality, and overall energy efficiency. The program provides performance ratings that range from the lowest, LEED certified, to the highest, LEED Platinum.

Refer to <http://www.usgbc.org/leed> for more information and to get the latest certification requirements.

[HRS Chapter 196-9](#) (a and b) requires that all State buildings (including facilities receiving State funds) achieve Silver certification under the *Leadership in Energy and Environmental Design (LEED)* program to the extent practicable. The statute allows for alternative certification under other nationally recognized standards that meet State approval, if necessary. The Statute further requires that counties also meet Silver certification for both new construction and retrofits unless deemed not feasible, inappropriate, or the resulting system would interfere or conflict with the use of the building or facility as an emergency shelter.^{1,2} Pursuant to [HRS Chapter 46-19.6](#), the State has the authority to prioritize construction and development permits for those project that achieve LEED Silver certification. Further, each county is allowed to prioritize permit applications submitted by private parties in the same manner.

LEED version 4 was adopted in the fall of 2013 and includes a prerequisite that buildings must be designed to meet ASHRAE 90.1-2010. Other energy-related pre-requisites are that fundamental Commissioning and Measurement and Verification, along with an Operations and Maintenance Plan will be required. In 2010, the State mandated that solar water heating systems be installed on all State facilities and newly constructed single-family homes, with some exceptions ([DBEDT 2013c](#); [HSEO 2013a](#)).³

¹ HB 2175, which was codified in [HRS Chapter 196-9](#), applies to all new State-owned or -funded construction of 5,000 square feet or greater, including K-12 public schools.

² HB 1464, also codified in [HRS Chapter 196-9](#), addresses energy efficiency requirements for existing public buildings. By the end of 2010, State agencies had to evaluate the energy efficiency of all existing public buildings larger than 5,000 square feet or that use more than 8,000 kilowatt-hours annually. Furthermore, the bill required that opportunities for increased energy efficiency be identified by setting energy benchmarks for these buildings using ENERGY STAR Portfolio Management. The bill also requires buildings to be retro-commissioned every five years.

³ This is a requirement for State facilities and single-family homes as long as life-cycle cost-benefit analyses determine it to be cost-effective; the State exempts single-family residential clients of the Department of Hawaiian Home Lands or any agency that can take advantage of utility rebates from this requirement.

Hawai‘i Clean Energy Initiative

As part of the HCEI, HSEO created a 30-percent EEPS to reduce electricity consumption by 4,300 gigawatt-hours in the State by 2030 by the use of clean, renewable energy.

In an effort to meet this goal, the State initiated and supports several programs, including the following:

- Energy savings performance contracts for government buildings. These contracts use guaranteed future energy and water utility bill savings to pay for the upfront capital costs of facility improvements;
- A public benefits fund to help finance retrofitting of building energy technologies;
- Lead by Example initiative, a retrofitting program for State-owned facilities, fleets, and personnel practices;
- Adoption of new, highly efficient building codes [such as the 2009 (and forthcoming 2012) International Energy Conservation Code 06 and higher]; and
- Funding of net zero-capable building pilot projects that incorporate renewable energy technologies, such as PVs, to achieve a goal of zero energy consumption.

The State also supports the Green Sun Hawai‘i Loan Program, a public-private partnership with the potential to save energy via energy efficiency and renewable energy equipment installation Statewide (see <https://hcrc-hawaii.org/community-development/financing-programs2.html>). These loans help fund ENERGY STAR refrigerators to lighting retrofits and upgrades, energy efficient windows, cool roofs, and many other projects. DOE has also provided *low-income* households with assistance through its Weatherization Assistance Program, and the State has a homestead program ([HSEO 2013a](#)). [Section 2.3.1.4](#) of this PEIS provides additional information about the State’s energy efficiency initiatives and programs.

Net Zero Buildings

Several pilot projects involving net zero-capable buildings have been conducted in the State ([Braccio and Finch 2011](#)), as listed below.

- [The Hawai‘i Gateway Energy Center in Kailua-Kona on Hawai‘i island](#) – Completed in 2005, this new construction visitor complex was designed to house research, development, and demonstration facilities for energy and technological fields ([DOE 2013a](#)). The building incorporates aggressive energy efficiency design including extensive daylighting, a passive thermal chimney (which captures heat and creates air movement), a cooling system that uses seawater to reduce energy consumption, and a 20-kilowatt PV system on its copper rooftop. The PV system produces all the energy required by the building, including the power needed for the cooling pumps. For more information about this pilot project. <http://zeb.buildinggreen.com/overview.cfm?projectid=592>.
- [The Kaupuni Net-Zero Energy Village](#) – a LEED-Platinum net zero community comprising 19 homes and a community center for low-income Hawaiian families. The village integrates cultural sustainability concepts of an ahupua‘a with solar water heating and solar modules for electricity. Energy efficiency measures incorporated into the project include dual-pane windows, composite roofing, fully insulated walls and ceilings, ENERGY STAR appliances and lighting packages, and a porous concrete driveway for drainage. The village is also equipped with outlets for

charging electric vehicles. Based on actual measured average consumption in a study conducted thereafter, the village came within 1 percent of its net zero energy goal, which proves the pilot a success in that the community performed near-net zero during its first year of use ([Norton et al. 2013](#)).

- [The Energy Lab at Hawai‘i Preparatory Academy](#) – the first of its kind in the world—a facility for students, by students, that will connect young people and their schools, allowing them to collaborate and develop sustainable living. The lab is located in Kamuela, on the island of Hawai‘i where a variety of renewable resources are readily available and accessible. The design team and head of the Hawai‘i Preparatory’s Science Department have furthered these goals; expanding the mission to include a great number of building systems that employ sun, water and wind. The project has achieved LEED Platinum and Living Building Challenge certification. <http://www.hpa.edu/academics/energy-lab/about-lab> and <http://living-future.org/case-study/hpaenergylab>
- [Kuykendall Hall](#) – The University of Hawai‘i at Manoa is currently retrofitting this building to reduce energy consumption by at least 30 percent and achieve net zero energy use. The retrofit design uses the prevailing winds to aid ventilation and cooling and incorporates lighting elements that reduce the need for cooling. Planned for completion during 2014, this project is on track to use about 50 percent less energy than the current building, exceeding the 30 percent savings goal. With the addition of building-mounted solar modules, the retrofitted building is projected to achieve net zero annual energy use. Altogether, the project is expected to result in a 49-percent energy savings ([DOE-EERE 2013a](#)).

Heat Pump Water Heaters

Heat pump water heaters do not generate heat directly, causing them to be two to three times more energy efficient than conventional electric-resistance or fuel-fired water heaters. Heat pump water heater systems typically have higher initial costs than conventional systems; however, their lower operating costs also typically offset the higher purchase and installation prices. Further information on the benefits and requirements for heat pump water heaters can be found online at:

- HECO has posted [Guide to Heat Pump Water Heating For Condominiums and Industrial Facilities](#), which has a description of the different types of heat pump water heaters, requirements and benefits (HECO 2003).
- DOE provides an overview of installation requirements and energy efficiency benefits of the heat pump water heaters on its website (<http://energy.gov/energysaver/articles/heat-pump-water-heaters>).

Existing Energy Demand

Few studies and energy audits have been conducted of existing buildings in the State and their respective energy footprints. Therefore, the baseline energy demand from buildings discussed herein is based on the most current study available, the *State of Hawai‘i Energy Efficiency Potential Study*, which was prepared for the Hawai‘i PUC. The study provides quantitative estimates regarding baseline energy usage across residential, commercial, water/wastewater, military, and street lighting sectors. This PEIS limits its analysis to those sectors mainly affecting buildings in the State, such as building energy demand from the residential and commercial sectors.⁴ According to the study, total electricity use for residential and commercial buildings in the State of Hawai‘i in 2012 was 8,119 gigawatt-hours. This continues the trend

⁴ Due to the challenging nature of data collection and sensitivity of information of the military sector, existing and projected energy demand and savings for the military sector were omitted from this discussion.

in reduced energy usage in the State since it peaked in 2004, which was likely due to a combination of factors, including the recession, the State’s ongoing energy efficiency goals and programs, and increasing use of renewable energy ([Evergreen Economics 2013](#)).

According to the PUC study, electricity usage in 2012 was largest in the commercial sector at 52 percent, or 4,983 gigawatt-hours, followed by the residential sector at 32 percent, or 3,136 gigawatt-hours. The highest amount of energy intensity among the building usage categories in the commercial sector included retail/services, offices, and miscellaneous or various building types including manufacturing facilities. Primary end uses for the commercial sector included lighting and cooling. In the residential sector, energy intensity was mostly concentrated in single-family homes. This was due to larger sized single-family homes when compared to multi-family homes, and includes higher air conditioning saturation and more appliances and electronics. The largest end-uses identified in the residential sector were appliances, water heating, and lighting ([EnerNOC 2014](#)).

Projected Energy Demand

As noted above, there are a limited number of studies and audits of existing buildings in the State and their respective energy footprints. Therefore, projected energy demand was modeled using projections from 2012 energy usage demand estimates.⁵ Also, as noted above, actual energy usage rates have decreased since 2004. Whether or not future economic factors affect these demand estimates is still unknown.

According to the *State Energy Efficiency Potential Study* ([EnerNOC 2014](#)), the projected baseline energy demand for residential and commercial buildings in 2030 is estimated at 10,907 gigawatt-hours, or an increase of 2,788 gigawatt-hours from 2012 energy demand. This estimate includes an increase in energy usage from 3,136 gigawatt-hours in 2012 to 4,463 gigawatt-hours in 2030 (a 42 percent increase) for the residential sector, and an increase in energy usage from 4,983 gigawatt-hours in 2012 to 6,444 gigawatt-hours (a 29 percent increase) for the commercial sector. These estimates do not take into consideration potential energy efficiency savings from appliance standards or building codes since 2008, market-driven conservation measures, and other energy efficiency programs. Therefore, increased demand resulting from increased building activity may be partially offset by energy code compliance and aggressive retrofits. [Table 2-4](#) shows the projected baseline energy usage for buildings until 2030 below.

Table 2-4. Energy Usage Baseline Projection Summary for Buildings, Statewide (gigawatt-hours)

Sector	2012	2015	2020	2025	2030
Residential	3,136	3,398	3,698	4,047	4,463
Commercial	4,983	5,373	5,765	6,123	6,444
Total	8,119	8,771	9,463	10,170	10,907

Source: [EnerNOC 2014](#).

The PUC projects that there is substantial potential to reduce energy usage in the State including via adoption of a “best-in-class” energy efficiency program to achieve the majority of potential energy savings. In order to achieve these savings, current programs would need to continue to increase awareness of the value of energy efficiency and accelerate energy savings ([Hawai‘i PUC 2013](#)) including for both new construction and retrofits.

⁵ Baseline projections were utilized from the *State Energy Efficiency Potential Study* which used EnerNOC’s Load Management Analysis and Planning tool (LOADMap) and data gathered from the HECO residential appliance saturation survey (RASS), Kaua‘i Island Utility Cooperative (KIUC) RASS survey, the non-residential baseline study for HECO companies, the non-residential billing analysis by KEMA for KIUC, and various secondary data, as well as electricity sales information.

New Construction

It is forecast that new construction would occur as a result of increased housing and commercial demand and as a result of replacing existing buildings with newer (more efficient ones). The energy consumption of new buildings is projected to increase with the adoption of more extensive air conditioning units and more energy-intensive appliances. According to a report released by the Energy Information Administration, while new homes and buildings have become more energy-efficient, new homes and buildings actually use slightly more energy than older ones as most buildings today are bigger and are used differently, i.e., use more electronic gadgets ([EIA 2013a](#)). However, as noted above, the State's overall goal for energy efficiency is to attain a 30-percent reduction of electricity demands by 2030. In order to meet this goal, the State plans on strengthening new construction policies and building codes. As such, new building construction will be code-compliant and designed and constructed in accordance with LEED Silver certification requirements. This would include incorporation of the energy efficiency measures listed above ([Section 2.3.1.2.1](#)). Building owners and managers should evaluate the most cost-effective efficiency improvements and develop a priority list of retrofits to meet their specific circumstances.

Based on the *State Energy Efficiency Potential Study* ([EnerNOC 2014](#)), assuming the adoption of future equipment standards and building codes (known as of September 2013), an energy savings of 17 percent or 761 gigawatt-hours could be achieved in the residential sector, and a savings of 11 percent or 714 gigawatt-hours could be achieved in the commercial sector over 2030 baseline projections. These energy savings would primarily result from lighting, as a result of Federal lighting standards, increasingly stringent energy codes, rebate programs, and the falling cost of energy efficient lamps. However, these savings are not absolute as additional codes and standards could be adopted in the future.

Finally, the State goals for future new building construction are poised to shift toward the development of more zero energy-capable buildings to eliminate the State's reliance on imported energy. As such, new building construction (where feasible) is anticipated to incorporate renewable energy to supplement energy code requirements and energy efficiency measures to meet a building's energy demand. With additional research and development of zero energy-capable buildings, it is anticipated that the State will continue to progress toward its end goal of zero net energy consumption for new construction. Furthermore, with DOE's ongoing support to help the State achieve its HCEI goals, including NREL's continued feasibility studies and assessments of zero energy-capable buildings, it is anticipated that zero energy-capable buildings will be deployed to the extent feasible in the future. Altogether, these policies will help provide flexibility and permit innovation to further increase energy savings for new building construction.

Retrofits

Energy efficiency retrofits provide more potential energy savings when compared with the energy savings from new building construction because new construction requires, among other things, new building material and land disturbance (such as clearing and grading), which consumes energy. Therefore, from an energy footprint standpoint, building retrofits provide greater energy savings.

In order to maximize the amount of electricity savings from building retrofits, the least viable candidates for retrofit must first be identified and confined to low-cost retrofits with short payback times. Retrofits, on the other hand, should be targeted at the buildings that are capable of being cost-effectively retrofitted. This is due to the fact that most buildings that operate in the lower 20 percent of the energy efficiency curve may be slated for demolition in the not-distant future. If the buildings are not replaced, they would continue to act as a drag on the State's energy load reduction efforts. Therefore, those buildings that can be retrofitted in a cost-effective manner should be upgraded, while those that would not be cost-effective to retrofit should be replaced entirely. This would generate the maximum efficiency savings from both

existing buildings (more retrofits will happen) and from new construction (highly efficient new construction replaces the worst of the energy users) ([Finch and Potes 2010](#)).

Assuming all feasible cost-effective energy savings measures for buildings are adopted in the State, it is projected that a potential energy savings of 5,462 gigawatt-hours of “economic potential” (or cost-effective) savings could be achieved ([EnerNOC 2014](#)). This would exceed the HCEI goal of 4,300 gigawatt-hours of electricity demand reduction with new construction. Specifically, this would include an energy savings of 2,115 gigawatt-hours from the residential sector and an energy savings of 3,347 gigawatt-hours from the commercial sector ([EnerNOC 2014](#)).

Lighting retrofits in the State would provide the greatest energy savings potential for both residential and commercial sectors.⁶ Specifically, energy savings from lighting in the residential sector would result from the conversion of interior and exterior lamps to LED lamps, the installation of solar water heaters or heat pump water heaters, the installation of low-flow showerheads and faucet aerators, and the use of ENERGY STAR electronics and appliances. In the commercial sector, the majority of energy savings could come from the use of LED lamps and the installation of heat pump water heaters ([EnerNOC 2014](#)).

In addition to retrofits, proper building retro-commissioning, operation, and maintenance are anticipated to achieve the full savings potential of building retrofits, as building operators may be unfamiliar with new technologies. In particular, focus should be on the proper operation of building controls, as properly installed and operating equipment can have a large impact on building energy use for minimal cost. As such, energy retrofits are encouraged to help residents and businesses save energy, as well as save money, support job growth, and reduce pollution.

While building energy retrofits may provide ample energy savings reduction, consumer behavior should also be taken into account. Most energy use can simply be reduced via small behavioral changes to avoid wasted energy. This PEIS addresses such issues in [Section 2.3.1.2](#).

Furthermore, it is anticipated that continued research and development of zero energy-capable buildings can help existing building retrofits achieve the State’s HCEI goals of increased energy savings. With existing buildings, this can be done via efficiency and the installation of PV systems or other renewable energy systems to help offset energy demand. This presents a feasible scenario for buildings but would require extensive investment, including private funding.

2.3.1.1.3 Permitting and Consultation Requirements

Permitting and consultation requirements for new building construction and building retrofits across the State of Hawai‘i are likely to be more general in nature (see [Section 2.2.5 above](#)). In an effort to accelerate energy efficiency implementation, the Hawai‘i State Legislature passed a bill to promote a priority permitting process for construction projects that are certified LEED Silver, two Green Globes, or other comparable program. As mentioned in [Section 2.3.1.1.2](#), counties are in the process of implementing their respective priority permitting programs. Certain projects (such as re-roofing) may not require a permit.

Careful consideration should be given when retrofitting historic buildings since not all energy efficient retrofits are appropriate for historic buildings (e.g., replacing historic windows may be inappropriate to retain the building's historic integrity). Specifically, consultation with the State Historic Preservation

⁶ For example, ENERGY STAR LED lamps are rated to remain in service for at least 25,000 hours (approximately 23 years in residences), which is longer than typical incandescent lamps (1,000 hours) or compact fluorescent light bulbs (6,000 to 10,000 hours) ([DOE 2012a](#)).

Division would be required if a retrofit were to involve a residential or commercial building listed in the [National Register of Historic Places](#). Retrofits of historic buildings should follow the *Secretary of the Interior's Standards for Illustrated Guidelines on Sustainability for Rehabilitating Historic Buildings* (see <http://www.nps.gov/tps/standards/rehabilitation/sustainability-guidelines.pdf>).

2.3.1.1.4 Representative Project

The representative project focuses on energy retrofits as opposed to new construction to allow for specific impact analysis of retrofit projects. As such, this representative project is for all existing single- and multi-family residential homes in the City and County of Honolulu beginning in 2015. This includes the retrofit of homes to bring them into compliance with the 2009 International Energy Conservation Code (which is expected to result in a greater than 15-percent energy savings when compared with the 2006 Code) and replacement of the remaining 50 percent of incandescent light bulbs inside a home with LED lamps to reduce energy loads in a typical single-family residential home.⁷ Based on incorporation of these energy efficiency measures, the estimated energy savings from these retrofits would result in a total energy savings of approximately 1,550 kilowatt-hours per home, per year, as shown in [Table 2-5](#). This total energy savings of approximately 129 kilowatt-hours per month of the estimated 561 kilowatt-hours per month (6,700 kilowatt-hours per year)⁸ represents an approximately 23-percent energy savings for a residential home in the City and County of Honolulu. Assuming energy usage remained constant, when multiplied by the projected 402,321 residential units in Honolulu County in 2030, this would result in a total countywide energy savings of about 620,000 megawatt-hours per year (620 gigawatt-hours per year). This would represent approximately 14 percent of HCEI's goal of 4,300 gigawatt-hours per year for 2030. With adoption of future updates to the IECC, it is anticipated that energy savings would be greater in the future when compared with existing energy savings. However, as energy demand from more energy-efficient homes decreases in the future, so would potential energy savings.

Table 2-5. Projected Energy Savings with the Representative Project

Energy Efficiency Measure	Estimated Energy Savings (kWh/yr)
Update State Building Code to IECC 2009	Equal to or greater than 15% of 7,827 kWh/yr = ~1,175 kWh/yr
Replace 50% of 50-watt incandescent light bulbs with 12-watt LED light bulbs = 38 W/hr (0.038 kWh)	0.038 kWh × 17 sockets × 1.6 hours a day × 365 days a year = ~377 kWh/yr ^a
Total Energy Savings per Home	~ 1,552 kWh/yr

a. Estimate based on the assumption that half of the light sockets utilize high-efficacy lamps to be compliant with IECC 2009, and based on half of the average number of light sockets inside a home in Hawai'i (based on an average of 34 lamps per household) ([Evergreen Economics 2013](#)). Estimate assumes light bulb is on for 1.6 hours a day ([DNV KEMA and PNNL 2012](#)).

IECC = International Energy Conservation Code; kWh/yr = kilowatt-hours per year; LED = light-emitting diode; W/hr = watts per hour.

Investment in the energy efficiency measures for the representative project likely would result in decreased loads on the grid and subsequently decreased [air pollution](#) and [greenhouse gas](#) emissions. However, adoption of such measures would require extensive investment from homeowners, as these retrofits are costly. Investments may further be hampered by recent economic conditions. As such, subsidies and/or State incentives would be required to increase the success of the representative project. In addition, waste materials may increase as a result of building retrofits, which should be recycled to the extent feasible and disposed of appropriately if containing [hazardous materials](#) (e.g., asbestos insulation).

⁷ The 2009 IECC requires that 50 percent of bulbs inside a home be replaced with energy efficient bulbs. Therefore, the representative project requires that the remaining bulbs inside a home be replaced.

⁸ Recent figures for the City and County of Honolulu show a decrease in average residential electricity use to 561 kilowatt-hours per month. This is based on Hawai'i Facts & Figures: Electric Utilities, Residential Electricity Use, Rates, and Average Bill, 2012.

As noted above, consultation with the State Historic Preservation Division would be required if the retrofit involved a residential or commercial building listed in the [National Register of Historic Places](#).

2.3.1.2 Energy Conservation

Energy efficiency is using less energy to perform the same service or task. Energy conservation is the act of reducing or going without a service or task in order to save energy. For example, turning off a light is energy conservation; replacing an incandescent light bulb with a different type of light bulb that uses less energy to produce the same amount of light is energy efficiency. However, both conservation and efficiency can reduce the amount of energy used. Using less energy generally has positive potential [environmental consequences](#).

2.3.1.2.1 Characterization of Activity Feasibility and Implementation

There are numerous initiatives and programs in place and funded that support energy conservation and efficiency in Hawai‘i. Many of these programs were established and have evolved over more than two decades. Others are new to the State and in the pilot stage. They all support Hawai‘i’s current and evolving energy initiatives and include relevant updates to the State Building and Energy Code, the GreenSun Hawai‘i Loan Loss Reserve Program, Hawai‘i Green Business Program, Lead By Example Initiative, Energy Savings Performance Contracts, Department of Hawaiian Homelands Energy Policy, net-zero energy homes, and the many DBEDT energy efficiency programs. [Section 2.3.1.1](#) of this PEIS discusses these initiatives and energy efficiency programs.

[Table 2-6](#) contains energy conservation measures from HECO, also available online at <http://www.heco.com/portal/site/heco/menuitem.508576f78baa14340b4c0610c510b1ca/?vnextoid=7c4e5e658e0fc010VgnVCM1000008119fea9RCRD&vnextfmt=default>. [Table 2-7](#) lists energy saving measures that Hawaii Energy’s rebate program supports for residents on O‘ahu, Maui, and Hawai‘i when they purchase energy efficient equipment and appliances for their home. Information on this program is available at <http://hawaiienergy.com/tips-to-save-energy>. On Kaua‘i, Kaua‘i Island Utility Cooperative (KIUC) supports Energy Wise Programs with solar rebates and loans, lighting and energy efficient appliance replacement and rebates for more energy efficient appliances and equipment. Information on this program is available at <http://website.kiuc.coop/content/energy-wise-programs-0>.

Various agencies and industry groups have developed many programs to train students, faculty, and residents in energy efficiency, auditing, and assessments. Cumulatively, all of these efforts are providing positive contributions to educating and increasing the awareness of residents and businesses in energy conservation and energy efficiency; helping toward achieving the HCEI goals.

[Hawai‘i Energy’s Educational and Training](#) – Programs drive capabilities for the Building Operators and decision-makers such as Building Operator Certification training, International Facility Management Association local technical training seminars, Association of Energy Engineers certification classes and testing for Certified Energy Managers and Certified Energy Auditor, Energy Efficiency Funding Group Selling Energy Efficiency seminars.

Table 2-6. Energy Conservation Measures

Measure	Results / Savings ^a
Light with Compact Fluorescents (new programs include light-emitting diodes)	Changing just one regular 100-watt bulb to an energy-saving 26-watt compact fluorescent light bulb can save 81 kWh and more than \$24 per year per bulb, when used 3 hours a day.
Use Fans instead of Air Conditioners ^b	Use fans instead of air conditioners, a savings of \$71 per month. A ceiling fan on for eight hours per day uses 24 kWh per month, or \$7. An air conditioner (12,000 Btu/H, EER 10.8) running eight hours per day uses 26 kWh or \$78 per month.
Shorten Showers	Cutting just 2 minutes per shower could save up to 463 kWh and \$139 a year.
Repair Leaky Faucets	One drop each second can waste about 1,661 gallons of water a year. A leaking hot water faucet wastes water and up to \$79 in energy costs a year.
Wash Clothes in Cold Water	Switching from hot wash/warm rinse to the cold/cold cycle on a standard, top-loading washing machine for just two loads a week can save 225 kWh and \$68 per year.
Eliminate Energy Sneakers (Phantom Load)	Use a power strip to eliminate energy sneakers (phantom loads) by turning off devices not in use, such as cell phone chargers, camera battery chargers, and computers. Such devices use standby power when not in use. Using a power strip to turn off your computer can save 50 kWh and \$15 per year.
Air Dry Dishes	Letting dishes air dry instead of using a dishwasher's heated drying cycle saves 110 kWh and \$33 per year.
No Peeking	Limiting how often and how long you open the refrigerator will save electricity and protect the appliance. Also limit opening the oven while cooking or baking to save electricity, protect the appliance, and speed up cooking times, too.
Install Motion/Occupancy Detectors Indoors and Out	Cutting use of a 150-watt, outdoor flood light from six hours to one hour per night with a motion sensor saves up to 270 kWh and \$81 per year. Switching off a 100-watt light for just one, eight-hour day per week, can save 41 kWh and over \$12 per year.
Use ENERGY STAR Appliances	When it is time to replace or add appliances, look for the ENERGY STAR symbol on refrigerators, ovens, dishwashers, DVD and VCR players, televisions, and home office equipment.

a. All savings are based on industry averages and 30 cents per kilowatt-hour.

b. Use natural ventilation and open your windows to take advantage of the trade winds first and foremost.

kWh = kilowatt-hour; Btu/H = British thermal units per hour.

Table 2-7. Hawaii Energy’s Residential Rebate Program – Measures, Savings, Cost, and Payback

Measure	Annual Savings	Install Cost	Payback
Put in a solar water heater	\$500 to \$1,600 after credits and rebates	\$1,000 - 2,000	4 years
Energy savings, rebates, and tax credits will pay for a solar water heater for a family of four on O‘ahu in as little as four years.			
Switch to compact fluorescent light (CFL) bulbs	\$240	\$1 - 100	1 year
CFLs use up to 75 percent less energy and last up to 10 times longer than incandescent light bulbs. Switch 10 incandescent bulbs to CFLs and save \$240. Each CFL could save about \$24 a year.			
Use fans and not air conditioning	\$560	\$1 - 100	1 year
Use fans along with air conditioners to circulate cold air and save energy and money. Savings based on O‘ahu electric rates for an 8,000 Btu/H; air conditioner replaced by an oscillating ceiling fan, both running for 8 hours a day.			
Replace your 10-year-old or older refrigerator	\$300	\$501 - 1,000	3 years
Replace old, less-efficient refrigerator with a new ENERGY STAR model and pay back within two to three years (depending on the model) with electric bill savings. Average savings for a 19- to 21-foot refrigerator/freezer built before 2001 when replaced by an ENERGY STAR model.			
Take shorter showers and install low-flow showerheads	\$38 - 57	FREE	
Save money for every minute deducted from a hot shower – electricity and water.			

CFL = compact fluorescent light bulb; Btu/H = British thermal units per hour.

It is important that the State’s population understand energy usage in their daily lives. In working toward the goals of the HCEI, the ignorance of energy consumption or energy illiteracy presents a significant impediment to progress, especially in the context of personal behavior and its impact on energy efficiency and conservation. In order to affect behavior, the State’s population must improve its [energy literacy](#).

Behavior modification will be built upon the foundation of energy literacy. The program will be developing an offering that will not only serve to develop future green employees through great internships, but will do so through an in-home mentoring program. This offer is envisioned to provide an educational experience to families while conducting a simple home energy assessment. See <http://www.Hawaiienergy.com/media/assets/2013Hawai‘iEnergy2013AnnualPlan.pdf>.

[The UH Community College and Department of Labor and Industrial Relations Training: Home Energy Survey Professional](#) – The Home Energy Survey Professional provides participants with training in small business and residential energy auditing. Participants received hands-on experience using state-of-the-art building performance equipment and will leave with an understanding of appropriate technologies and strategies for improved energy performance in Hawai‘i. Topics include building envelope features and performance, mechanical equipment types, renewable energy uses, and appliance and lighting characteristics. This course is appropriate for contractors, architects, inspectors, or anyone looking to pursue a career in an emerging industry in Hawai‘i.

[The E²U Program and KUPU](#) (formerly the YEAH Program) – The E²U Program is centered on energy conservation and vocational training in the sustainability field. E²U is designed for young adults who are interested in learning how to conserve energy and want to help others learn how to conserve energy too. The E²U Program provides members the latest training in how to conserve energy while providing members hands-on experience, conducting energy assessments of O‘ahu residences. E²U members also learn about conservation and health issues related homes.

[KANU](#) – Completed an energy assessment for a home in Manoa Valley. From the Rewarding Internships for Sustainable Employment (RISE) Program, interns and crew went through HECO’s “Power To Save: An Energy Conservation Guide for Your Home” curriculum to assess the home’s energy use. The goal from this was to take a look at overall energy usage and behavior. Throughout the assessment they focused on different areas of energy consumption, including lighting, water heating, cooling, electronics, clothes washer and dryer, refrigerator and freezer, and kitchen appliances such as microwave ovens and toasters.

Based on what KANU learned working with hundreds of families to save energy, the organization is developing a free energy efficiency course. The course is designed to help anyone better manage modern devices including video game systems, Digital Video Recorders (DVRs), and other devices that lack energy efficiency information. KANU will be testing a new energy savings concept centered on a KANU lending library in partnership with HECO.

[Rewarding Internships for Sustainable Employment](#) – This program is centered on sustainability and the development of Hawai‘i’s green-collar workforce. It is designed for college students and recent college graduates interested in gaining entry-level experience in areas such as clean energy, pollution, sustainable development, and greenhouse gas reduction. This internship experience allows individuals to work on projects addressing various sustainability issues.

[HECO’s Home Energy Challenge](#) – HECO and the Hawai‘i State Department of Education team for this annual event. Students learn about conserving energy while helping the environment and their families. All homes participating in the Home Energy Challenge who reduce their energy use during the Challenge period of October to March are automatically included in the drawing to win a free 2-kilowatt Kumu Kit PV system, courtesy of Hawai‘i Energy Connection. All of the families who participated last year saved almost \$100,000.

[Teacher’s Energy Resource Center](#) – Hawaiian Electric’s Teachers Energy Resource Center provides school teachers on O‘ahu with free and effective educational videos, literature, hands-on material, and school presentations to make learning about electricity-related topics such as renewable energy, the environment, energy conservation, and electrical safety, engaging and fun.

[Hawai‘i Student Energy Ambassador Development](#) – The mission of the Hawai‘i Student Energy Ambassador Development Program is to empower students to create a bright energy future for Hawai‘i through sustainability education and energy audit training.

[U.S. Green Building Council Hawai‘i Chapter’s Green Schools Committee](#) – The committee’s goal is to develop and support green school champions by creating a resource clearinghouse in support of Hawai‘i Green Schools, collaborating and partnering with organizations that promote and advocate for green schools, and reaching out to the public on the benefits of Green Schools.

2.3.1.2.2 Permitting and Consultation Requirements

Non-substantive energy conservation measures may not be subject to permitting and consultation requirements. However, the appropriate county and State agencies should be consulted prior to commencement of work to ensure all installations are done properly and as required by law.

2.3.1.2.3 Representative Project

Because of the speculative nature of this activity and that adverse environmental impacts would be unlikely, this PEIS is not analyzing associated impacts (that is, Chapter 4 will not include an impacts

analysis for energy conservation). However, the following examples and tips are provided to characterize the types of environmental consequences that could occur as a result of conservation and efficiency activities.

Typically, lighting accounts for about 11 percent of a home's and 38 percent of a business's total electric bill. If the total watts of light used in the home or business were reduced by 50 percent by either reducing the wattage of the bulbs used, reducing the amount of time the lights were turned on, or replacing the types of bulbs used with more efficient types of bulbs, the total energy reduction would be about 5.5 and 19 percent, respectively ([NEED 2012a](#)).

Other similar examples include the following:

- Walking, riding a bicycle, or driving a more efficient vehicle to work or for other travel needs;
- Raising the thermostat setting for the air conditioner;
- Installing a more energy-efficient cooling system in a home; and
- Buying a smaller or more energy-efficient refrigerator for a home or office.

As another reference point, buying a larger home, appliance, or other item that is more energy efficient might not result in a reduction in energy use if the increased efficiency is offset by the larger size.

2.3.1.3 Ground Source Heat Pumps

Underground temperatures are more stable than air temperatures, with temperatures 10 feet below the ground holding nearly constant between 50° and 60°F regardless of seasonal temperature extremes. A ground source heat pump, also known as a geothermal heat pump or geoexchange, is an electrical-powered heating and cooling system that takes advantage of the relatively constant ground or [groundwater](#) temperature to transfer energy for space heating/cooling and water heating. Ground source heat pumps provide heating, cooling, and domestic hot water for homes, schools, and government and commercial buildings.

There are many benefits to installing a ground source heat pump. They can be installed in homes and buildings of any size. They can be installed under lawns, landscaped areas, driveways, or the structure itself. Ground source heat pumps are energy efficient; they use 25 to 50 percent less electricity than conventional heating or cooling systems and up to 72 percent less compared with electric resistance heating with standard air-conditioning equipment ([DOE 2012b](#)). Compared to conventional heating and cooling systems, ground source heat pumps cost more initially but provide long-term cost savings. Ground source heat pumps can be used to preheat water tanks, thereby reducing water-heating costs. Installing a ground source heat pump in a residence or building can be particularly cost-effective for newly constructed homes or building or if replacing an existing heating and cooling system. Ground source heat pumps maintain about 50 percent relative indoor humidity, and are more efficient and use less electricity than conventional heat pumps. Relative to air source heat pumps, ground source heat pumps are quieter, last longer, require less maintenance, and do not depend on the variable temperature of outside air.

Barriers to using ground source heat pumps include the costs and difficulty of evaluating the suitability of individual installation sites, the need for installation-specific design and engineering of the ground loop, and space requirements for ground coupling in densely built areas ([Navigant 2009](#)). Technical knowledge and equipment expertise is necessary to properly design and size a ground source heat pump system. Although ground source heat pumps offer long-term energy cost savings, they initially cost more than conventional heating and cooling systems.

2.3.1.3.1 Technology Description

Ground source heat pumps use the earth as a heat source and transfer heat from the ground source to a building when in the heating mode (typically in the winter). In the cooling mode, ground source heat pumps use the earth as a heat sink and heat is transferred from a building to the ground source (typically in the summer). [Figure 2-5](#) illustrates this heat exchange process. Some systems are designed to operate in one mode only (that is, heating or cooling). Space-heating typically is not used in Hawai‘i; whereas, space-cooling is widely used in commercial and government buildings and in residences, albeit less often. Hence, the single-mode operation is the only one likely to be used in Hawai‘i.

Figure 2-5. Ground Source Heat Pump Heat Exchange (Source: [EnergyBible.com 2013](#))

Since first developed in the 1940s, the ground source heat pump technology’s efficiency has considerably improved. Ground source heat pumps are one of the fastest growing applications of renewable energy in the world, with an annual growth rate in the United States of 12 percent between 1999 and 2009 ([Lund et al. 2009](#)). The regions of the United States that have the largest implementation of ground source heat pumps are the Midwest and South. Ground source heat pump system warranties, similar to conventional heating and cooling system, are usually offered. Most ground source heat pumps can be added to existing home insurance policies ([DOE 2012b](#)).

Components

Ground source heat pumps consist of three main components: an earth connection loop; a heat pump; and the heating, ventilation, and air conditioning distribution system. The components are maintained through routine inspections and cleaning. Ground source heat pumps are expected to last about 25 years for the indoor components and more than 50 years for the earth connection loop ([DOE 2012c](#)). Hybrid systems combine ground source heat pump technology with geothermal, solar, or air source technologies.

Earth Connection Loop

The earth connection loop is a series of connected pipes buried in the ground that circulate a fluid (water or a mixture of water and antifreeze) that absorbs heat from, or relinquishes heat to, the surrounding soil, depending on whether the *ambient air* is colder or warmer than the soil ([DOE 2013b](#)). The loop is buried either vertically or horizontally in the ground near the building to receive the air conditioning/heat. Vertical systems are the most common because they have the smallest area of disturbance.

There are four types of earth connection loops (see [Figure 2-6](#)). Earth connection loops can be either closed-loop or open-loop. Closed-loop configurations typically circulate heat exchange fluid, usually water or a water-antifreeze solution, through a closed loop of pipes buried underground or submerged in a

body of water. As shown in the figure, the closed-loop system can be horizontal or vertical in the ground or in a nearby body of water. Open-loop systems use ground or surface water as the heat exchange fluid that circulates directly through the system and then returns to the ground through a well or surface discharge ([DOE 2012c](#)). All types work for residential and commercial buildings; the type selected is based on site-specific climate, soil conditions, available land, and installation costs.

Figure 2-6. Types of Earth Connection Loops (Source: [DOE 2012c](#))

Heat Pump

A heat pump removes heat from a fluid and transfers it to a building for heating; the process is reversed for cooling. The heat pump operates in a similar fashion as a refrigerator or air conditioning unit. A heat exchanger transfers heat between the refrigerant in the heat pump and the fluid in the earth connection loop. Alternatively, a direct exchange system can pump the refrigerant through copper tubing buried in a horizontal or vertical configuration instead of using a heat exchanger, which is better in areas with moist soils that are not corrosive to copper tubing. Most residences can sufficiently use a heat pump as small as a typical washing machine ([IGSHPA 2010](#)). Heat pumps require a small amount of electricity to run the heat pump compressor; however, the energy output is 4 times the input ([Lund et al. 2009](#)).

Heating, Ventilation, and Air Conditioning Distribution System

The heating, ventilation, and air conditioning distribution system uses conventional ductwork to distribute the heated or cooled air throughout a building. An air handler contains the indoor coil and fan and moves

the building air through the heat pump for heating or cooling, and contains a blower and a filter exactly like conventional air conditioners. Heating, ventilation, and air conditioning distribution systems can be used in existing houses by retrofitting the existing ductwork. No external venting is required (hybrid systems excluded) and there is no associated noise.

2.3.1.3.2 Characterization of Technology Feasibility and Deployment

Ground source heat pumps have not been used in Hawai‘i, likely because of Hawai‘i’s moderate climate. The benefits of ground source heat pumps may not be as substantial as they would be in areas where climate variation is more extreme ([HREDV 2009a](#)). However, there is no technical reason that ground source heat pumps could not be used in the future. Hybrid systems, where PVs provide power for ground source heat pump operation, have deployment potential in Hawai‘i. Regardless of hybrid or standard, the high upfront costs likely would prohibit wide-scale use of ground source heat pumps in Hawai‘i by 2030.

Heat pump water heaters and their feasibility and deployment in Hawai‘i are discussed under energy efficient buildings (see Sections [2.3.1.1.1](#) and [2.3.1.1.2](#)).

2.3.1.3.3 Permitting and Consultation Requirements

Permitting and consultation requirements for ground source heat pumps in Hawai‘i are likely to be more general in nature (see [Section 2.2.5](#)).

Ground source heat pump installations require the services of a trained professional. Installation of ground source heat pumps also run the risk of damaging or otherwise interfering with existing subsurface utility infrastructure. All projects must use the area HOCC (see [Section 2.2.5](#)).

2.3.1.3.4 Representative Project

Ground source heat pumps currently are not deployed in Hawai‘i and unlikely to be in any notable amount by 2030; therefore, this PEIS does not present a representative project against which to evaluate impacts for this technology.

2.3.1.4 Initiatives and Programs

Utility- and government-sponsored clean energy initiatives and programs can help to make renewable energy, efficiency, and conservation practices attractive to communities. The State of Hawai‘i’s energy efficiency and renewable energy objectives are intended to reduce Hawai‘i’s high reliance on imported fossil (primarily petroleum) fuels.

There are several ways to provide incentives to individuals, businesses, and communities that will result in a reduced overall demand for imported fossil fuels, ranging from education and training to financial incentives for using energy efficient appliances and equipment at home and in commercial operations. Examples include energy savings compensation from street-lighting retrofits and underwriting the cost of compact fluorescent bulbs or providing interest subsidies for the purchase of highly efficient, but more expensive, household appliances (e.g., energy efficient refrigerators) and equipment for industry. The State of Hawai‘i, island utilities, counties, and the Federal Government have employed several energy efficiency and renewable energy (i.e., clean energy) initiatives and programs for specific State-, island-, and community-level projects.

A combination of Federal, State, and county (including utility) initiatives and programs can influence the use of energy efficiency and renewable energy technologies in general, or of certain technologies in particular.

2.3.1.4.1 Activity Description

There are many clean energy initiatives and programs throughout the United States. The DOE and North Carolina State University maintain the Database of State Incentives for Renewables and Efficiency found online at <http://www.dsireusa.org/>. The database is a comprehensive source of information on incentives and policies that support renewables and energy efficiency in the United States.⁹ A large majority of this section summarizes information from the database and associated websites, references, and other related information sources.

2.3.1.4.2 Characterization of Activity Implementation and Deployment

Financial Incentives

Federal financial incentives and implementing policies and regulations are applicable and available to all residents of the United States, and provide a component for achieving *renewable energy* and *energy efficiency* goals in Hawai'i. This PEIS focuses on State energy programs and initiatives and, therefore, discusses only those programs sponsored by the State of Hawai'i and counties therein. Financial incentives administered by the State of Hawai'i and local jurisdictions are varied and can be grouped in the following incentive categories: taxes, loans, rebates, green building, and performance-based.

Tax Incentives

State corporate tax incentives include tax credits, deductions, and exemptions. These incentives are available in Hawai'i to corporations that purchase and install eligible renewable energy or energy efficiency equipment, or construct green buildings. In a few cases, the incentive is based on the amount of energy produced by an eligible facility. Tax credit may only be allowed for a corporation that has invested a minimum amount in an eligible project. Typically, there is a maximum limit on the dollar amount of the credit or deduction. There is a corporate solar and wind energy credit available in Hawai'i.

Personal tax incentives include income tax credits, deductions, and exemptions. The percentage of the credit or deduction varies by state, and in most cases, there is a maximum limit on the dollar amount of the credit or deduction. The same solar and wind energy credit that is available to the corporate sector is available to the personal and residential sector.

Property tax incentives include exemptions, exclusions, abatements and credits. Most property tax incentives provide that the added value of a renewable energy system be excluded from the valuation of the property for taxation purposes. There is one property tax exemption program in the State of Hawai'i that is applicable to corporate and residential sectors and consists of a real property tax exemption for a period of 25 years for alternative energy improvements associated with a variety of renewable energy technologies (excluding geothermal) that are installed in the City and County of Honolulu.

Loan Incentives

Loan incentives provide financing for the purchase of renewable energy or energy efficiency systems or equipment. Low-interest or zero-interest loans for energy efficiency projects are a common *demand-side*

⁹ The North Carolina Solar Center at the North Carolina State University operates the Database of State Incentives for Renewable and Efficiency with support from the Interstate Renewable Energy Council, Inc. DOE provides partial funding. The Database of State Incentives for Renewables and Efficiency does not include incentives and policies that promote alternative transportation fuels and vehicles.

management practice for electric utilities. At the Hawai‘i State level, loans are available for farm and aquaculture alternative energy applications and other eligible efficiency and renewable technologies. From a local standpoint, the City and County of Honolulu and Maui County offer solar loan programs to eligible residents. On the island of Kaua‘i, KIUC administers a solar water heating loan program.

Enabling legislation for an innovative financing program passed the 2013 Hawai‘i State Legislature and is expected to be implemented in 2014, once enacted into law. This program aims to bring together a more traditionally industrial financing mechanism to issue low-interest bonds to acquire a pool of low-cost money to fund a clean energy financing program such as on-bill financing. While each specifically designed loan program will have to file a Green Infrastructure Program Order with the Hawai‘i PUC for approved use of funds, the legislation enables the use of funds for clean energy technology, demand response technology, and energy use reduction and demand side management infrastructure, programs, and services. Electric utility customers will be able to finance these approved installations and the repayment obligation will be tied to the meter and repaid via the participating customers’ electric bills.

The GreenSun Hawai‘i program works with various lenders throughout Hawai‘i to offer financing for renewable energy and energy efficiency upgrades. Through the program, and using Federal funds (via the *American Recovery and Reinvestment Act of 2009* (ARRA; [Public Law 111-5, 123 Stat. 115](#)), homeowners may be eligible to finance ENERGY STAR refrigerators and air conditioners, solar water heating systems or heat pumps, insulation installed with an ENERGY STAR air conditioner, and PV (solar module) systems. Multi-family residential/commercial property owners may be eligible to finance lighting retrofits or upgrades, air conditioning, solar water heating systems, solar PV systems, and windows. An energy assessment is required for multi-family residential/commercial property owners.

Green Energy Market Securitization (GEMS) is a financing model designed to make clean energy improvements, such as PV systems, affordable and accessible to underserved community members, including low- and moderate-income homeowners, renters, and nonprofit organizations. GEMS will take a proven rate-reduction bond structure and use it to provide low-cost financing to utility customers. Payment for the devices would be made over time through the customer’s electric utility bill and paid for with energy savings. As of early 2014, the GEMS program, which will be facilitated by DBEDT, was awaiting approval from the PUC. For more information, see <http://energy.hawaii.gov/testbeds-initiatives/gems>.

Rebate Incentives

Rebate programs for the islands of Hawai‘i, Lāna‘i, Maui, Molokai, and O‘ahu are administered by Hawai‘i Energy, which is a ratepayer-funded conservation and efficiency program under contract with the Hawai‘i PUC. Utilizing electricity ratepayer funds, Hawai‘i Energy offers cash rebates and other incentives to residents and businesses to help offset the cost of installing energy efficient equipment. In addition to rebates, the program conducts education and training to residents, businesses, and contractors to encourage the adoption of energy conservation behaviors and efficiency measures ([Hawai‘i Energy 2013](#)). Hawai‘i Energy offers rebates for three programs: (1) commercial energy efficiency, (2) residential energy efficiency, and (3) solar water heating. As part of the commercial energy efficiency incentive, Hawai‘i Energy offers a Whole Building Assistance program that includes energy audits, energy study assistance, energy study project implementation, and design assistance.

KIUC offers two rebates for the island of Kaua‘i: the Energy Wise Commercial Energy Efficiency program and the Solar Water Heating program.

Green Building Incentives

Green buildings are designed and constructed using practices and materials that minimize the impacts of the building on the environment and human health. Several organizations issue certification for green

buildings, including the U.S. Green Building Council's Leadership in Energy and Environmental Design (LEED certifications) program, the Green Building Initiative (Green Globes certification), and the National Association of Home Builders Research Center (National Green Building Certification). [HRS Chapter 46-19.6](#) requires each county agency in Hawai'i that issues building, construction, or development-related permits to establish a procedure to give priority to permit applications for construction projects that incorporate green building designs.

Many cities and counties offer financial incentives to promote green building. The most common form of incentive is a reduction or waiver of a building permit fee. This had been in place in Honolulu until the PV installation permits grew to over 25 percent of total construction activity, and the lack of fees interfered with the permitting agency's ability to hire the staff necessary to process the permits in a timely manner ([Honolulu 2013](#)).

Performance-Based Incentives

Performance-based incentives, also known as production incentives, provide cash payments based on the number of kilowatt-hours or British thermal units a renewable energy system generates. A feed-in tariff is an example of a performance-based incentive. To ensure project quality, payments based on a system's actual performance are generally more effective than payments based on a system's rated capacity. In September 2009, the Hawai'i PUC issued a decision that established a feed-in tariff in Hawai'i. The feed-in tariff is offered by the three investor-owned utilities providing service on O'ahu, Maui, Molokai, Lāna'i, and Hawai'i. The rates for the feed-in tariff, schedule, and standard interconnection agreements were approved on October 13, 2010 ([Hawai'i PUC 2010](#)). Several renewable energy technologies are eligible for the feed-in tariff, including PV, concentrating solar power, land-based wind, and in-line hydropower ([Hawai'i PUC 2009](#)). However, the feed-in tariff queue was closed pursuant to Docket No. 2013-0194, Order No. 32499. Future modifications to the feed-in tariff program will be addressed in Docket No. 2014-0192 or 2014-0183.

A State facility incentive with a performance-based requirement is provided for ethanol production facilities. In accordance with [HRS Chapter 235-110.3](#), in order to receive the income tax credit/payment, the facility must produce at least 75 percent of its nameplate capacity. As part of the 2015 Legislative Session, the Hawai'i State Legislature passed Senate Bill 349, which would establish a five-year renewable fuels production tax credit and repeal the ethanol facility tax credit. This bill was vetoed by the Governor.

Rules, Regulations, and Policies

In addition to financial incentives, several rules, regulations, and policies in Hawai'i further enhance the State's ability to achieve renewable energy and energy efficiency goals.

Building Energy Codes

Building energy codes adopted by states (and some local governments) require commercial and/or residential construction to adhere to certain energy standards. While some government entities have developed their own building energy codes, many use existing codes (sometimes with State-specific amendments), such as the International Energy Conservation Code. A few local building energy codes in Hawai'i require certain commercial facilities to meet green building standards. The State has adopted its Hawai'i Model Energy Code, and in February 2012, the Hawai'i State Building Code Council approved Hawai'i's adoption of the [2009 International Energy Conservation Code](#). The counties of Hawai'i are free to modify the Statewide code as long as the codes they adopt are at least as stringent. Hawai'i County adopted the 2006 version of the International Code in October 2010, Maui County adopted the 2006 Code in October 2009, Honolulu County adopted the 2006 Code in November 2009, and Kaua'i County adopted the 2009 Code in May 2010. The 2009 Code gives options for roof insulation including cool roofs, advanced ventilation, and low-emitting roofs by testing or specification.

A second building energy code program consists of legislation enacted in June 2008 ([HRS Chapter 196-6.5](#)) with the intent to require solar water heating systems to be installed on all single-family new home construction, with a few exceptions. [Section 2.3.1.2](#) of this PEIS presents a more detailed discussion of energy efficient new building construction and building retrofits.

Energy-Efficiency Portfolio Standards

Hawai‘i’s EEPS sets a goal of reducing electricity use by 4,300 gigawatt-hours by 2030 through the use of energy efficiency and renewable displacement and offset technologies.

Energy efficiency resource standards are State of Hawai‘i policies that require utilities to meet specific targets for energy savings according to a set schedule. These standards set policies that establish separate reduction targets for electricity sales, peak electric demand and/or natural gas consumption. In most cases, utilities must achieve energy savings by developing demand-side management programs, which typically provide financial incentives to customers to install energy efficient equipment. An energy efficiency resource standard policy is sometimes coupled with a state’s renewables portfolio standard. In these cases, energy efficiency typically is included as a lower-tier resource.

Energy Standards for Public Buildings

Many states and local governments, as well as the Federal Government, have chosen to lead by example by requiring new government buildings to meet strict energy standards. In May 2006, the State of Hawai‘i established a standard that requires renewable energy, energy efficiency, and alternative fuels in State facilities and operations. Enacted in June 2009, [HB 1464](#) addressed energy efficiency requirements for existing public buildings. By the end of 2010, State agencies had to evaluate the energy efficiency of all existing public buildings larger than 5,000 square feet or that use more than 8,000 kilowatt-hours annually. Agencies must identify opportunities for increased energy efficiency by setting benchmarks for these buildings using ENERGY STAR Portfolio Management or another similar tool. Buildings must be retro-commissioned every five years.

The Database of State Incentives for Renewables and Efficiency includes green building standards, energy-reduction goals, equipment-procurement requirements, and the use of onsite renewable energy in other locations. Many of these policies require that new government buildings (and renovated buildings, in some cases) attain a certain level of certification under the LEED program. Equipment procurement policies often mandate the use of the most efficient equipment, including equipment that meets ENERGY STAR criteria. Policies designed to encourage the use of onsite renewables generally establish conditional requirements tied to life-cycle cost analyses.

Interconnection Standards

Interconnection standards specify the technical and procedural process by which a customer connects an electricity-generating system to the electrical grid. Such standards include the technical and contractual terms by which system owners and utilities must abide. State PUCs typically establish standards for interconnection to the local distribution grid, while the Federal Energy Regulatory Commission has adopted standards for interconnection to the transmission-level grid. While many states have adopted interconnection standards, some state standards apply only to investor-owned utilities (i.e., not to municipal utilities or electricity cooperatives). Hawai‘i has established interconnection rules for small renewable resources and other [distributed generation](#). In May 2010, a Hawai‘i PUC decision and order created a standard three-party interconnection agreement.

The State’s largest electric utility, HECO, which owns Hawai‘i Electric Light Company (HELCO) and Maui Electric Company (MECO), uses a set of interconnection guidelines ([HECO 2013a](#)). The State’s only other utility, KIUC, has a similar set of rules for interconnection. The current interconnection tariff ([Rule 14H](#)) utilizes a screening process to evaluate a project’s potential impact to the utility grid including

screens for percentage of peak circuit load and minimum daytime circuit load. Projects which exceed certain percentages may trigger the need for an interconnection requirements study which involves a more comprehensive technical evaluation of a project's impacts and potential solutions to mitigate identified impacts. Although such a requirement does not mean a project will not go forward, it can add time to the interconnection review process and in some cases may cause a developer to reconsider a project if the developer does not wish to pay for the interconnection requirements study, or the identified mitigation measures. The Hawaiian Electric Companies are continuously working to improve the distributed generation process including through efforts to more precisely identify and target system constraints through more accurate understanding of specific conditions on measured and observed conditions on the specific feeder system, rather than the use of proxy figures; allow project developers to check online for current feeder capability to accept the system's output; enable better understanding of the need and scope of any interconnection requirements study; and direct utility actions to foresee potential circuit and system issues through comprehensive analysis, data, modeling, and mitigation. This process includes performing planning studies (i.e. representative studies) rather than formal interconnection requirements studies for individual customers where prudent. More recently, the Companies, together with stakeholders in the Hawaii Commission's Reliability Standards Working Group proceeding (Docket No. 2011-0206), submitted two stipulations proposing modifications to improve the Rule 14H interconnection process in response to Commission Order No. 32053. Currently, the Companies are engaged in discussions with stakeholders in the Commission's Distributed Energy Resources proceeding (Docket No. 2014-0192) to develop additional technical revisions to the Rule 14H interconnection process and to develop among other things, both self-supply and grid supply options for customers. ([IREC 2013](#)).

Net Metering

For electricity customers who generate their own electricity, net metering allows for the flow of electricity both to and from the customer—typically through a single, bi-directional meter. When a customer's generation exceeds the customer's use, electricity from the customer flows to the grid, offsetting electricity consumed by the customer at a different time during the same billing cycle. In Hawai'i, net metering is available on a first-come, first-served basis to residential and small commercial customers (including government entities) that generate electricity using solar, wind, biomass or hydroelectric systems. Third-party owned and operated systems (leased systems and systems with a third-party power purchase agreement) can participate in net metering. Hawai'i's three investor-owned utilities (HECO, HELCO, and MECO) and sole electric cooperative (KIUC) have slightly different programs but achieve similar results.

Public Benefits Fund

Most public benefits funds were developed by states during the electric utility restructuring era (the late 1990s) to ensure continued support for renewable energy, energy efficiency and low-income energy programs. These funds are commonly supported through a very small surcharge on electricity consumption (e.g., less than \$0.01 per kilowatt-hour). This charge is sometimes referred to as a "system benefits charge." Public benefits funds commonly support rebate programs, loan programs, research and development, and energy education programs. In June 2006, the Hawai'i State Legislature enacted legislation to create a public benefits fund for energy efficiency and demand-side management. This legislation granted authority to the Hawai'i PUC to develop the details of the third-party administered public benefits fund. In July 2009, Hawai'i Energy was created, and administration of the public benefits funds programs transitioned from the utilities to Hawai'i Energy, a third-party administrator. The public benefits fund is available through Hawai'i Energy for energy efficiency programs and technologies on the islands of Hawai'i, Maui, Molokai, Lāna'i, and O'ahu.

Renewable Portfolio Standards

[Hawai‘i’s Renewable Portfolio Standard](#) (RPS) law ([HRS Chapter 269-91](#)) requires each electric utility company that sells electricity for consumption in Hawai‘i to establish the following percentages of renewable electrical energy sales:

- 10 percent by the end of calendar year 2010 (standard achieved);
- 15 percent by the end of 2015;
- 25 percent by the end of 2020; and
- 40 percent by the end of 2030.

Generation from existing renewable energy facilities may be counted in the total. In addition, an electric utility company and its electric utility affiliates may aggregate their renewable portfolios in order to achieve the Hawai‘i RPS (i.e., HECO and affiliated utilities may add together their renewable energy numbers to meet the goal). Before December 31, 2014, energy efficiency and renewable energy displacement can be counted toward meeting the RPS. Beginning in January 2, 2015, only renewable generation (including customer-sited PVs) will count toward the meeting the Standards; efficiency (including domestic solar water heating and sea water air conditioning) will count toward the EEPS (see [HRS 269-92](#)).

In the 2015 Legislative Session, the Hawai‘i State Legislature further amended the State’s RPS by passing [HB 623](#), which increases the RPS to 30 percent by December 31, 2020; 70 percent by December 31, 2040, and 100 percent by December 31, 2045. Governor David Ige signed the nation’s first 100 percent RPS into law on June 8, 2015.

According to the Hawai‘i RPS law, “renewable energy” is energy from:

- Sun (i.e., solar);
- Wind;
- Falling water (i.e., hydropower);
- Bioenergy, including biomass (e.g. crops, agricultural and animal residues, municipal and other solid waste), biofuels, and biogas;
- Geothermal;
- Ocean water, including ocean thermal energy conversion and wave energy; and
- Hydrogen produced from renewable energy sources

Most states have established an RPS law. Some laws in other states require utilities to use or procure renewable energy or renewable energy credits to account for a certain percentage of their retail electricity sales—or a certain amount of generating capacity—according to a specified schedule. The term set-aside, or carve-out, in this context refers to a provision within an RPS that requires utilities to use a specific renewable resource (usually solar energy) to account for a certain percentage of their retail electricity sales (or a certain amount of generating capacity) according to a set schedule. Hawai‘i’s RPS does not have credits or carve-outs.

Solar and Wind Access Policy

Solar and wind access policies are designed to establish a right to install and operate a solar or wind energy system at a home or other facility. [HRS Chapter 196-7](#) prohibits the creation of any covenant or restriction contained in any document restricting the installation or use of a solar energy system on a residential dwelling or townhouse. Furthermore, Hawai‘i requires homeowners associations to adopt rules that provide for the placement of solar energy systems and do not unreasonably restrict the placement.

Some solar access laws also ensure a system's access to sunlight. In some states, access rights prohibit homeowners associations, neighborhood covenants, and local ordinances from restricting a homeowner's right to use solar energy. At the local level, communities use several policies to protect solar access, including solar access ordinances, development guidelines requiring proper street orientation, zoning ordinances that contain building height restrictions, and solar permits.

Solar and Wind Contractor Licensing

Some states have established a licensing process for solar energy and/or wind energy contractors. These requirements are designed to ensure that contractors have the necessary knowledge and experience to install systems properly. Solar licenses typically take the form of either a separate, specialized solar contractor's license, or a specialty classification under a general electrical or plumbing license. Hawai'i offers several specialty licenses for solar contractors through Hawai'i's Department of Commerce and Consumer Affairs; Hawai'i does not require specialty licenses for wind power contractors at present.

2.3.1.4.3 Permitting and Consultation Requirements

The financial incentives and rules, regulations, and policies in the State of Hawai'i associated with renewable energy and energy efficiency do not require typical environmental permits or consultations (see [Section 2.2.5](#)). They do, however, require research and understanding of the requirements for the application and approval process for initiatives and programs. The DOE Database of State Incentives for Renewables and Efficiency provides links to specific websites and other documents that outline additional detail, eligibility criteria, requirements, and forms for participating in each program (see <http://www.dsireusa.org>).

2.3.1.4.4 Representative Project

The Initiatives and Programs discussion presents government- and utility-sponsored efforts to provide incentives to individuals, communities, municipalities, and businesses to make it easier or financially beneficial to support renewable energy technologies and energy conservation and efficiency in Hawai'i. As such, the incentives presented are not typically viewed as technologies or programs that could have the potential to cause adverse impacts to an environmental resource, and therefore, this PEIS does not present a representative project against which to evaluate impacts for this activity. The information is provided to the reader for general knowledge and a more complete understanding of the available incentives.

2.3.1.5 Sea Water Air Conditioning

2.3.1.5.1 Technology Description

District cooling systems provide cooling from a centralized location to a large number of end users—typically a group of buildings. In district systems, the heating or cooling can come from any source, such as coal- or gas-generated electricity, combined heat and power, nuclear power, or renewable energy sources. Sea water air conditioning, or deep water cooling, uses the temperature gradients between deep and surface water to chill water for individual buildings or district cooling air conditioning systems. This energy efficiency technology replaces the conventional electric chiller component of a cooling system with a significantly less energy-intensive deep, cold sea water cooling station or heat exchanger to cool a closed-loop air conditioning system ([DBEDT 2002a](#); [Konan 2012](#)). The heat exchanger transfers heat from the closed-loop fresh water to the cold sea water. Pumps circulate the warmed sea water (effluent) back into the ocean at higher depths than where retrieved to ensure the effluent is introduced into an environment of similar temperature to minimize impacts. Sea water and fresh water never mix because of the closed-loop system. The newly chilled water in the closed-loop air conditioning system cools the facility in the same manner as a standard district cooling system, whereby the chilled water is distributed

via insulated pipes to the various buildings connected to the chilling station ([Figure 2-7](#)). Sea water used for this process is generally below 45°F, and found at depths that vary based on location. It does not require any working fluids other than sea and fresh water, as opposed to conventional cooling which may employ refrigerants. To maximize economic benefits, sea water air conditioning systems generally operate at a “district” level, with one system cooling a specified geographical district or grouping of buildings. Depending on the availability of cold water, and the length of the intake pipe, sea water air conditioning can meet or exceed the cooling capacity of a standard district cooling system. Sea water air conditioning systems could replace an existing conventional district cooling system used to supply electrically chilled air to a population center or facilities that require significant cooling requirements. Alternatively, a sea water air conditioning system can be developed for end-users with no existing conventional district cooling or centralize cooling systems in place.

From an operations and maintenance perspective, the intake pipes can be designed for maintenance “recovery” thus eliminating the need for deep-water diving for repairs ([Makai 2013](#)). [Figure 2-7](#) represents a typical system configuration, but specific elements, such as the closed-loop lines and heat exchanger processes, could reasonably be at different positions within the overall system. Comparing operations and maintenance costs, a study conducted by the State University of New York found that chilled deep water facilities are comparatively less expensive to operate and maintain than conventional electric chiller systems ([State of New York 2011](#)).

Figure 2-7. Illustration of a Deep Water Cooling Facility ([Source: Makai 2013](#))

2.3.1.5.2 Characterization of Technology Feasibility and Deployment

The potential economic benefit of energy efficient sea water air conditioning is directly related to two main factors: access to deep sea water and the distance the cold sea water must be pumped from the ocean to the cooling station. In general, the deeper the intake pipe depth, the higher the initial costs (due to installation materials); the shallower the intake pipe, the higher the eventual operating cost (due to warmer water). Owing to their volcanic geology, the Hawaiian Islands generally present an ideal environment for easily accessible, cold, deep sea water. As is standard in district cooling systems, local water resources, or treated waste/grey water can supply the fresh water used in the closed-loop system, which carries the heat from buildings and transfers it to the sea water through the heat exchanger. Because it is a closed loop, the utility does not need to continuously supply the fresh water.

Industry sources indicate that financially feasible sea water air conditioning operations require ocean temperatures between 40° and 68°F ([Makai 2013](#); [Konan 2012](#)). In the Hawaiian Islands, the Pacific Ocean averages 46°F at a depth of 1,650 feet ([NREL 2013b](#)). Water at 46°F can be found at depths ranging from 330 to 1,315 feet off the northwestern shore of Hawai‘i island. Similarly, offshore waters near Maui, Lāna‘i, Molokai, and O‘ahu are at a depth and temperature to facilitate a sea water air conditioning operation. With such abundant thermal resources available, deployment of such an operation in Hawai‘i is feasible. The basic considerations would be the distance of the cooling facility (heat exchanger) from the shore and the required cooling capacity (size of district).

The cost of sea water air conditioning is typically cheaper than conventional cooling systems because it replaces electricity costs associated with conventional chillers ([Makai 2013](#); [DBEDT 2002a](#)). Previous case studies on O‘ahu have shown that a district sea water air conditioning system can save more than 75 percent (77.5 million kwh/year) of the yearly energy cost of operating a conventional cooling system ([Konan 2012](#); [DBEDT 2002a](#)). In March 2015, Honolulu Seawater Air Conditioning, LLC announced that a Record of Decision had been issued by the USACE for its proposed water cooling facility, marking completion of the Federal NEPA process ([Honoluluswac 2015](#)). Although all approvals have not yet been obtained, Honolulu Seawater Air Conditioning, LLC hopes to have its proposed 25,000-ton seawater cooling facility online early in 2017 ([Honoluluswac 2015](#)). In Hawai‘i’s warm climate, this capacity can provide cooling for about 10 million cubic feet, sufficient for a number of high rise buildings, office spaces, and other commercial air conditioning applications.

On Hawai‘i island, temperature conditions in Kona require roughly 12,000 British thermal units per hour (3.5 kilowatts) to cool an average hotel room ([Josey 2008](#)); most of the island’s resorts are on the Kona and Kohala coasts. While Hilo, on the opposite side of the island, is the second largest city in the State, its population is only 20 percent of Honolulu’s, with considerably fewer large buildings that would benefit from such a system ([Grant 2012](#)). Smaller-scale systems could be designed for more localized cooling needs, such as the small-scale system the Natural Energy Laboratory of Hawai‘i Authority (NELHA) deployed in 1986, which supplements the Authority’s use of deep water for other research interests including agriculture and irrigation ([Makai 2013](#)). Additionally, the Kahala Resort on O‘ahu makes use of a small sea water air conditioning system saving 380,000 kilowatt-hours and 4.5 million gallons of water annually ([UH Manoa 2015](#)). The Kahala Resort pumps from deep wells that tap seawater and, after passing through the heat exchanger process, the warmed seawater flows through resort features including a decorative water fall (dissipating heat and absorbing oxygen) and dolphin and tropical fish-stocked lagoons ([UH Manoa 2015](#)).

The use of sea water air conditioning systems replaces the need for conventional chillers that use refrigerants that have chemicals known to damage the ozone layer ([Cornell University 2013](#)). In addition, using a renewable energy source, such as wind or offshore wave energy, to power a sea water air conditioning system’s pumps can reduce the system’s energy consumption to effectively zero. As such,

this technology has the potential to address many of HCEI's energy-savings goals. Furthermore, these systems can be designed to last up to 100 years ([Cornell University 2013](#)).

Despite the benefits of sea water air conditioning, one potential issue is a lack of information on how ocean microbes would respond to the return of nutrient-dense deep water at, or closer to, the surface of the ocean ([Konan 2012](#)). Based on the findings of preliminary field experiments conducted by the Center for Microbial Oceanography Research and Education (C-MORE), the deeper and more diffuse the effluent the better. However, placing the outflow pipe beneath the euphotic zone (the depth that receives enough sunlight for photosynthesis to occur) increases the cost of a sea water air conditioning system.

The immediate feasibility of sea water air conditioning technology can be facilitated by the presence of chilled-water air conditioning systems in commercial buildings, which typically produce their own chilled water through onsite electric chillers ([HonoluluSwac 2013](#)). A building or complex can easily connect to a planned or existing district system by removing its chillers and retrofitting its existing cooling system (i.e., closed-loop system) to connect to the district cooling system. By connecting to an existing cooling system, the building or complex would avoid the capital investment of installing a new cooling system by tapping into the sea water system. However, if no existing system is in place, building developers would have the flexibility of installing a bigger (or smaller) cooling system depending on their current and future needs, considering future development in the area that could tap into the same cooling system.

The Honolulu Seawater Air Conditioning project represents what may be possible on other islands at a similar scale. Several feasibility and environmental impact studies have been done on the site. The *Honolulu Seawater Air Conditioning Final Environmental Impact Statement* included an analysis of four components of the project's operation and installation ([DBEDT 2009](#)):

- Seawater intake and return pipes would be deployed offshore of Honolulu,
- A cooling station would be built on a site in Kakaako,
- Freshwater distribution pipes would be installed beneath streets in the downtown area, and
- A shoreline site in Keehi Lagoon would be used for staging and pipeline assembly.

Other locations could use this project as a model for a similar system, but would only be economically feasible in locations with larger building cooling needs ([Konan 2012](#)). Densely populated areas with many district cooling subscribers, particularly commercial buildings such as hotels and large apartment residences, are desirable in order to mitigate startup costs. While the system operation would be similar, the physical aspects would be different; primarily, the depths at which seawater is at optimal temperature would determine the depth of the intake and discharge components. However, as was noted above ([Section 2.3.1.5.1](#)), water temperatures around the Hawaiian Islands do not vary widely.

For a direct comparison, readers are directed to a study prepared about a sea water air conditioning project in Waikiki that potentially would employ similar parameters as the Honolulu Project ([Lilley 2012](#)). This study also gauged public opinion on use of the technology in O'ahu, showing that 62 percent of the island's residents support its use.

2.3.1.5.3 Permitting and Consultation Requirements

In addition to general permitting and regulatory requirements described in [Section 2.2.5](#), technology-specific requirements for installing a sea water air conditioning system (land-based with off-shore piping) would include complying with environmental regulations involving water quality and marine habitats. These facilities generate large volumes of effluent (in other words, heated water) and "Zone of Mixing" considerations are especially important. Sea water cooling systems might also require a lease for

submerged State lands from the Hawai'i DLNR; a process that may be subject to public auction or competitive bidding.

Water quality impairment and cooling water intake for ocean thermal energy conversion facilities is regulated by the [CWA](#) Sections 316(b), 402, and 403. Under CWA Section 402, any discharge of a pollutant or combination of pollutants into a waterway requires a valid NPDES permit, and Section 403 provides for the promulgation of guidelines applicable to NPDES permits for discharge of pollutants into oceans and territorial seas. Clean energy projects would have to apply to HDOH at least 180 days prior to commencement of operations to receive an NPDES permit. The project would then have to meet all conditions set forth in its NPDES permit, including numeric effluent limitations established to protect water quality in the receiving water. Applicants for clean energy projects within Federal waters would have to apply to the EPA for this permit.

Section 316(b) provides a means to demonstrate to EPA that the location, design, construction, and capacity of cooling water intake structures for facilities reflect the best technology available for minimizing adverse environmental impacts ([33 U.S.C. §§ 1326\(b\), 1342, and 1343](#)). Clean energy projects would have to demonstrate to the satisfaction of HDOH and EPA that the intakes for their facilities would meet 316(b) requirements prior to receiving their NPDES permits. Compliance with Section 316(b) likely would require an entrainment analysis and monitoring plan to assess any impacts resulting from kills of small organisms that could pass through intake screens and into pumping equipment.

In order to meet the State's water quality standards, a zone of mixing (per [HAR 11-54-9](#)) may need to be approved under the permitting process. The zone of mixing is a limited area around the discharge outfall where dilution would be allowed. The permittee would be required to conduct a dilution study to determine the dilution factor representative of the zone of mixing. The permit would then include conditions or limitations with consideration of the dilution factor. If an acceptable zone of mixing could not be established, alternatives such as treating the water (for example, nutrient removal or temperature adjustment) before discharge may need to be considered.

Were components of a sea water air conditioning system to be installed in a commercial harbor, the action would be subject to approval by the Hawai'i Department of Transportation's Harbors Division before any improvement could begin. In addition, water-based facilities, whether within or outside commercial harbors, are subject to the U.S. Department of the Army permit to conduct work in navigable waters. Other possible permits may include a Conservation District Use Permit and a Special Management Area/Coastal Zone Management Permit.

Compensatory mitigation under CWA Section 404 could be required if projects involve unavoidable impacts to species and their habitat, including coral reefs. Best management practices such as those presented in Section 3.4.6.2 should be incorporated into project-level analyses to minimize damage from moorings, anchors, anchor lines, and pipelines during construction, particularly in areas near coral reefs. Areas should be designated for moorings and anchors that specifically avoid impacts to corals, and areas of high coral value should be marked with buoys to ensure avoidance of those areas during construction.

2.3.1.5.4 Representative Project

The representative project would replace an existing conventional district cooling system with an energy efficient district sea water air conditioning system. The intake pipe and cooling station would be located close to a population center and would supply electricity chilled air to facilities that require significant cooling requirements. Cooling towers used in conventional cooling towers would be removed and conventional chiller machinery would be substituted with heat exchangers.

The system would use a screened pipe, 63 inches in diameter, 4 to 5 miles long, with intake at a depth of 1,770 feet to access water at 44° to 45°F. The pipe would be made of high-density polyethylene for its strength, impact resistance, corrosion resistance, and biofouling resistance. In order to minimize wear on the pipe and impacts to shoreline ecosystems, installation crews would bury the pipe on land a certain distance from the shoreline, using one of several available trenchless technologies: (1) horizontal directional drilling, which involves drilling underneath obstructions and pulling the pipe through the tunnel; (2) microtunneling, which uses a remote-control boring machine to drill tunnels and generally is used for smaller-diameter pipes; or (3) conventional tunneling, which involves personnel entering the tunnel on a boring machine. The project developer will determine the drilling method based on local geotechnical conditions and the proposed pipe route.

Using bathymetric analysis, it is possible to determine the shortest distance to the desired depth, while avoiding sensitive habitats such as coral reefs. Analysis must be done to mitigate impacts on all ocean-floor benthic zones along the shore and into the ocean depths. Additional care would need to be taken to ensure the pipe did not interfere with recreational or fishing activities in the area.

For the representative project, the effluent pipe would be constructed with the same material as the intake pipe and placed where the average water temperature at depth is closest to the temperature of the effluent exiting the cooling station, approximately 53°F. This depth could be fairly close to the surface, possibly as high as about 150 feet below the surface, or as deep as 650 feet, depending on location ([NREL 2013b](#)). A sea water air conditioning developer would need to conduct site specific studies to determine the depth that would be most appropriate to most effectively minimize localized temperature gradient impacts. In other words, the effluent sea water would be pumped back into the ocean at a depth that provides temperatures closest to the discharging sea water to avoid altering the local temperature gradient ([Makai 2013](#)). The main concern is related to the impacts on offshore water quality. Maintenance of the pipe and screen would be performed regularly to prevent excessive biofouling and clogging. Automated systems are available for the pipe itself, thus eliminating the need for deep-water diving for repairs.

The cooling station would be built close enough to the shoreline to ensure minimal change in the incoming seawater's temperature. The representative project would take into account exposure to waves and tsunamis, soil conditions, and availability of tunneling to connect to both the seawater and freshwater loops. Potential sites can include parking lots and unused buildings. Two sets of pumps located in the cooling station would be connected to the electrical grid; each would require between 300 and 450 kilowatts of power. For comparison, the Honolulu Sea Water Air Conditioning project proposes a 25,000-square-foot station, two stories tall. Finally, the representative project may also spur the construction of more distribution lines, which would be installed beneath the city's streets.

2.3.1.6 Solar Water Heating

Solar water heating is an energy efficiency technology that uses the sun to heat water. It is generally considered for use in residential rooftop applications. This section focuses on its use in single-family homes; however, it is scalable to multi-family residences. Solar water heating technology has the potential to reduce household energy consumption by up to 40 percent ([NREL 2011a](#)).

2.3.1.6.1 Technology

Residential solar water heating systems consist of two main parts: a solar collector and a storage tank ([NREL 2013c](#)). The solar collector is usually a flat, black plate made of metal, which absorbs the sunlight, enclosed in a weatherproof insulated metal box with a transparent cover. The collector is located on the rooftop, and angled for maximum exposure to sunlight. Water flows from the storage tank into small metal tubes, coated black for maximum heat absorption located in the collector and is warmed by

the absorber plates (DOE 2012d). The heated water then flows back to the storage tank for use. The tank is similar to, or may even be a modified version of, a standard home water heater and is well insulated to maintain the water's temperature (Figure 2-8). Solar water heating systems can scale to provide hot water to bigger, commercial facilities, such as convention centers or even small communities. These larger systems generally consist of an array of smaller heating units, connected in parallel, to provide the desired amount of hot water

Solar water heating technology can be an active or passive system. Active systems, which are more efficient (ANL 2013), utilize pumps to move the water between the collector and storage tank. Passive systems rely on natural convection to circulate the warm water. Active systems rely on fluid circulated by pumps to provide a building's hot water (DOE 2012d). Direct circulation systems of the type used in Hawai'i pump water throughout the system, directly heating it for use in the home. Solar water heating systems typically require a backup system, such as a gas or electric water heater, for use during times of minimal sunlight. A solar heating system can replace an existing gas or electric system to provide an efficient means of maintaining a hot water supply. In some cases, solar modules are installed behind the collectors to provide electrical power for the pumps and (DBEDT 2002b).

2.3.1.6.2 Characterization of Feasibility and Deployment

Solar water heating systems are commonly used on houses in Hawai'i; there are more than 100,000 systems installed Statewide (InSynergy 2012). The systems range in size depending on the family's needs and resources. Over the life of the solar water heating system, the initial cost of the system is returned to

Figure 2-8. Basic Solar Water Heater (Source: DOE 2012d)

the homeowner by the savings in energy, and it will continue to provide monetary savings while the home uses less energy to heat water.

As much as 40 percent of home energy use in Hawai'i is directly related to the water heater (DBEDT 2002b). The success of solar water heating is proportional to the amount of solar radiation received in a given area. That is, the more direct sunlight that strikes a rooftop, the more water a system can heat, and for longer periods of time. Because many parts of Hawai'i receive direct, year-round sunlight for long durations of the day, solar water heating is a feasible, if not ideal, energy-efficiency solution.

The productivity of solar water heating systems depends on the amount of sunlight. Most places in Hawai'i receive ample sun to heat a household's water. For example, a home near Ala Manoa in Honolulu might receive approximately 570 watt-hours per square foot of solar energy (sunlight) every day (DOE 2012e), equivalent to 6.1 hours of peak sunlight [defined as 1 kilowatt per square meter (0.09 kilowatt per square foot)]. Therefore, even a small system with a south-facing, 40-square-foot collector in Honolulu would receive 22.8 kilowatt-hours per day of solar energy, or 683 kilowatt-hours per month. For comparison, a conventional electric water heater for a typical household of four people consumes 8.7 kilowatt-hours per day, or 260 kilowatt-hours per month (DBEDT 2013e). Under this scenario, a solar water heating system provides a sufficient amount of energy required to heat the home's water. If properly sized and oriented, the percentage energy provided by the solar heating system, the

solar savings fraction, can be as high as 90 percent ([DBEDT 2013e](#)). The remaining heat is provided by a backup system, usually electric resistance heating.

Solar radiation levels vary widely across the State, depending on localized weather patterns; however, according to solar radiation maps produced by the State of Hawai‘i ([Hawai‘i 2013](#)) and DOE ([DOE 2012e](#)), most locations in Hawai‘i receive between 3.5 to 6 hours of peak sunlight every day, enough to supply sufficient solar heat for domestic uses. Other factors can affect a system’s efficiency, including whether or not the home currently uses conventional heating and the amount of hot water it consumes. All things remaining equal, an average four-person home would require around 4 hours of peak sunlight to make a solar water heating system an economic replacement for a gas or electric water heater, lower levels of solar radiation would require larger collectors ([DBEDT 2013f](#)).

Most major cities and towns on the islands receive sufficient sun. On the sparsely populated islands of Lāna‘i, Molokai, and Kaua‘i, the areas of greatest peak sunlight roughly align with population centers. The windward slopes of the eastern half of Molokai is mostly high forest and receives large amounts of rain. The western half of the island is more low-lying and drier; the town of Kaunakakai receives approximately 6 hours of peak sunlight a day ([Hawai‘i 2013](#)). Lāna‘i’s main town, Lāna‘i City, also is located in an area that receives large amounts of sunlight; that is, approximately 6 hours of sunlight a day ([DOE 2012e](#)). Coastal cities on Kaua‘i receive a smaller, but still considerable, amount of peak sunlight: Hanapepe and Poipu each receive about 5.8 hours and Lihue and Kapaa each receive 5 hours of peak sunlight.

The island of Hawai‘i receives a significant amount of peak sunlight. However, its largest city, Hilo, is located on the coast at a lower elevation and receives only 4.6 hours of direct sunlight.

On Maui, the areas with the highest amounts of solar radiation occur along the coast (all but its northeastern coast), including Kahului and Wailuku, both of which receive between 5 and 6 hours of peak sunlight ([Hawai‘i 2013](#)).

On O‘ahu, coastal parts of Honolulu receive more than 6 hours of peak sunlight, as do other cities along the southern coast, all of which are heavily populated areas. For Honolulu, most homes could completely replace conventional heating systems. Because of the amount of direct sunlight, some homes even need to use temperature control schemes to prevent their water from becoming too hot ([Hawai‘i 2013](#)).

Hawai‘i has significant market penetration of solar water heating compared with other states; between 1977 and 2011, over 103,000 solar water heating systems were installed in Hawai‘i, resulting in a current savings of 152,800 megawatt-hours per year for the State ([InSynergy 2012](#)). In 2010, the State of Hawai‘i instituted a mandate requiring that all new single-family homes be built with solar water heaters ([DBEDT 2013c](#)). The Hawai‘i PUC, through the Public Benefits Fee Administrator, provides rebates for qualified retrofit solar water heating systems on homes built before the mandate was enacted.

Because of the abundance of sunlight, the new State mandate, and its ease of use, solar water heating is on track to becoming a significant part of the HCEI’s goals of meeting 30 percent of Hawai‘i’s energy goals through energy efficiency and conservation. Solar water heating is appealing to many homeowners and is seen as a substantial “first step” in energy efficiency and saving money in the near future.

2.3.1.6.3 Permitting and Consultation Requirements

Although a residential solar water heating system is fairly non-invasive, some general permitting and consultation may still be required (see [Section 2.2.5](#)). Residential rooftop projects, such as solar heat,

generally only require county-level permits for electrical and plumbing work. Federal or State permits generally are not required for a residential-scale rooftop renewable energy project ([DBEDT 2013a](#)).

2.3.1.6.4 Representative Project

For purposes of this PEIS, the representative project is an active solar water heater system with a 40-square-foot collector and 120-gallon storage tank for a single-family residence. The water would circulate between the collector and the 120-gallon storage tank located in the home, in place of the conventional water tank. Since freezing is not a concern, the system utilizes direct circulation, where the water itself is heated, rather than indirect circulation, which uses a heat-transfer fluid and a heat exchanger. Because the system itself would require electricity to run its pumps and control system, the collector would use a PV cell to power the pumps. The components for the representative project would be on the roof and interior of the house. Pipes would run from the rooftop collector to the tank through existing crawlspaces or under the eaves of the roof, and the tank would connect with existing plumbing. Residential systems can typically be installed in one day with limited onsite construction by a small team of several contractors and without any disruptions to the property.

2.3.2 DISTRIBUTED RENEWABLES

Renewable energy technologies produce sustainable, clean energy that can be incorporated via a range of uses including residential, commercial, and industrial uses. Although similar to utility-scale technologies, distributed energy is designed primarily for local use as opposed to providing electricity to an electrical grid for distribution to multiple electricity users (utility-scale). Additionally, distributed energy sources are often connected to the electrical grid and can provide a financial incentive for local electricity producers. Distributed technologies discussed in this section harness energy from renewable energy sources such as the sun, wind, falling water, and biomass, as well as hydrogen produced from renewable energy sources:

- Biomass
- Hydroelectric
- Hydrogen Fuel Cells
- Photovoltaic
- Wind (land-based)

As mentioned previously, distributed scale projects could range from single family residences to larger commercial uses. Representative projects were defined based on technology-specific capacity factors, uses, and feasibility in Hawai'i. The description of each technology within Section 2.3.2 includes a discussion of the differences between nameplate capacity and actual capacity based on efficiency and the range of typical capacity factors for that technology. Chapter 5 discusses how the impacts would scale (for example, linearly, exponentially, or not at all) for the range of potential technology applications to explain the effects of smaller or larger projects and how impacts could change based on the size of the technology implemented.

2.3.2.1 Small-Scale Biomass

Biomass energy encompasses multiple energy production technologies that use organic matter from trees, agricultural crops, and animal waste as well as biogenic material in urban waste streams to produce a variety of potential energy end products ([EPA 2007](#); [Bain et al. 2012](#); [HNEI 2012a](#)). Because biomass resources (i.e., *feedstock*) represent a wide variety of biochemical material such as sugars, starch, fiber, and oils, different conversion technologies can be used to produce electricity and heat or used as alternative transportation fuel (i.e., biofuels such as ethanol and biodiesel). For the purposes of analysis,

this PEIS discusses biofuels as alternative transportation fuel in [Section 2.3.4.1](#). Biomass energy products produce electricity and heat are discussed under both distributed renewable and utility-scale renewable energy.

2.3.2.1.1 Description of Technology

A biomass energy system is composed of several interdependent components including: (1) biomass or feedstock production, (2) feedstock logistics or handling of the biomass source, (3) energy technology conversion system, (4) distribution, and (5) end use ([HNEI 2009a](#), [2012a](#)). For example, to produce electricity from sugar cane bagasse (milling waste), a supply of bagasse must be produced and then delivered to an operating generating station. The electrical power is then generated and delivered to an existing market of users. The pathway analysis of each component is important for understanding potential environmental impacts from developing a biomass energy industry ([HNEI 2012a](#)).

Feedstock Production

Production of biomass feedstock in Hawai‘i occurs through three primary sources: agriculture, forestry, and urban waste streams. Agriculture could potentially produce feedstock through three processes: (1) crop residues, (2) dedicated energy crops, and (3) animal waste ([Bain et al. 2012](#); [Turn et al. 2002a](#), [2002b](#); [Khanal et al. 2009](#)). The forest industry produces potential feedstock in wood residues from timber harvest and processing and possibly through dedicated timber stands planted to produce wood biomass. Urban waste streams represent a diversity of feedstock as byproducts of human activity. These include municipal solid waste, sewage sludge, food wastes, and fat/oil/grease.

Agriculture Biomass

Crop Residues

Crop residues are unused plant parts left in the field after harvesting or leftover material after crop processing. In Hawai‘i, sugar and pineapple historically have been two of the largest agricultural industries, but have greatly declined over the past two decades because of the production and market economy ([DBEDT 2012a](#)). Sugar cane has been grown commercially in Hawai‘i for more than 170 years and the technology for producing and processing sugar cane is well established in the State ([Khanal et al. 2009](#)). Sugar cane has high fertilizer requirements and optimally requires about 70 inches of water annually ([Khanal et al. 2009](#)). Irrigation, in addition to natural precipitation, is normally required to meet sugar cane’s annual water needs.

The commercial milling of sugar cane produces two byproducts, bagasse and molasses ([Turn et al. 2002a](#)). Bagasse is a fibrous residue left after the milling and extraction of sugar from the sugar cane stalks, and molasses is the liquid stream remaining after normal sugar extraction. Sugar cane production and processing also produces sugar cane trash fiber (i.e., leaves, plant tops, and ground trash) ([Turn et al. 2002b](#)). There is only one operating sugar mill in Hawai‘i, the Puunene factory operated by Hawaiian Commercial & Sugar Co. (HC&S) at Puunene on Maui. The Gay and Robinson (G&R) factory located at Kaunakani on Kaua‘i closed in 2009. As reported in [Turn et al. \(2002a\)](#), in 2002, HC&S produced about 550,000 tons of bagasse at 50 percent moisture (about 275,000 tons of fiber) and 80,000 tons of molasses. Also in [Turn et al. \(2002a\)](#), during the same year, G&R produced about 147,000 tons of bagasse at 50 percent moisture (about 74,000 tons of fiber) and 15,000 tons of molasses. In addition, HC&S and G&R produced 137,000 and 37,000 tons of cane trash fiber, respectively. Both mills at the time produced electricity using conventional steam boiler technology with bagasse as fuel. Currently, HC&S fires coal and Bunker C fuel oil to satisfy the terms of its power contract with Maui Electric Company. HC&S operates three boilers in total with an installed generating capacity of 44 megawatts. G&R operated one boiler with an installed capacity of 4 megawatts. A decrease in sugar cane production has potentially made land available for the production of biomass crops.

Pineapples were once a major industry in Hawai‘i ([Turn et al. 2002a](#)). However, major pineapple growers have ceased operation. The pineapple industry did not produce biomass that was used for biomass energy production. Pineapple residues left in the field (about 10 dry tons per acre) were typically turned into the soil or burned before replanting. Pineapple processing produced a residue byproduct (dewatered skins) that was used by cattle producers as feed. The decrease in pineapple production has potentially made land available for the production of biomass crops.

Nutshells are a byproduct of Hawai‘i’s macadamia nut industry. From 2011 through 2012, growers harvested 15,000 acres of macadamia nut trees, producing 49 million pounds on a wet-in-shell basis ([NASS 2012](#)). (No estimate of nut shell production was provided.) [Turn et al. \(2002a\)](#) estimated that about 19,000 tons of nutshells, industry-wide, were produced during this same time period. Macadamia nut shells have a [heating value](#) of 21.1 mega-[Joules](#) per kilogram, a value higher than sugar cane bagasse. Macadamia nut shells also are lower in nitrogen content than other biomass sources, which lowers the potential for the formation of nitrogen oxides (an [air pollutant](#)) during combustion ([Turn et al. 2002b](#)). Nut shells are used as boiler fuel to generate steam for drying processes (nuts and coffee) and to generate electricity ([Turn et al. 2002a](#)).

Crop residues are ideally suited for distributed generation of renewable energy because the crop production technology and harvesting and handling infrastructure are already established and the energy production from the residue can be integrated into existing agricultural or processing facilities or marketed as an energy commodity. Crop residue availability is a function of the economic viability of the industry. For example, as the sugar industry in Hawai‘i has decreased, the amount of bagasse feedstock also has decreased. This effect is often mitigated in distributed renewable energy applications because the energy requirement also decreases with the industry. It should be recognized that agricultural residues have other uses including animal feed, soil amendments, industrial feedstock, and other commercial products that also have economic value; therefore, not all residues are available for use in energy generation.

Energy Crops

Although not commercially developed in Hawai‘i, dedicated energy crops are a potential source of feedstock for biomass energy. Research has been conducted for many years on potential energy crop plant species that are adapted to Hawai‘i’s soils and climate ([Khanal et al. 2009](#); [Turn et al. 2002a](#); [Poteet 2006](#)). Energy crops are grown specifically for use in biomass energy production. With the significant decline in both the sugar and pineapple industries, land formerly used for sugar cane and pineapples could

HEATING VALUE

The [heating value](#) of a biomass fuel is a measure of the amount of heat energy released during combustion of a unit mass of material. The [heating value](#) is often expressed as energy per unit mass such as mega-[Joules](#) per kilogram.

potentially support energy crops and improve the agricultural industry and local economies.

Approximately 136,000 acres suitable for growing biomass are estimated to be available in the State without displacing any current farming ([DBEDT 2013h](#)).

Sugar cane could be grown as an energy crop because of significant amounts of fiber and sugar that are

produced. The agronomic practices for growing, harvesting, and milling cane are well established although some changes in agronomic procedures (e.g., frequency of harvest, burning) may be changed when growing for energy opposed to sugar production. Banagrass is a tropical grass that has been studied for fiber production. Because of the similarities between sugar cane and banagrass, production strategies and harvest techniques have been based on experience with sugar cane. However, work remains on developing superior banagrass cultivars with characteristics adapted to Hawai‘i’s growing conditions, establishing management practices specific to banagrass, and improving harvest and transportation systems. Other potential energy crops that industry has considered but not extensively tested are sweet

sorghum, guinea grass and industrial hemp. A major concern with any plant species (herbaceous or woody) tested for use as biomass crops is their potential to be an invasive species ([HNEI 2012b](#); [Buddenhagen et al. 2009](#); [Daehler et al. 2012](#)). Banagrass is considered a potential risk as an invasive species; however, based on field evidence from recent plantings (less than 10 years old), green banagrass has not yet become invasive or shown signs of becoming a serious invader ([HNEI 2012b](#)). Guinea grass is a weedy grass established in Hawai‘i ([HNEI 2012b](#)).

Another group of potential energy crops are oil crops ([Poteet 2006](#)). These crops are primarily grown for their oil-producing seeds and fruits. The plant oils are extracted and processed to produce a biodiesel fuel that can be used as a fuel to generate electricity in a steam boiler and combustion engine power plant. [Poteet \(2006\)](#) identified a variety of plant species that have potential as oil crops. Although some of these species have been used in other countries to produce biodiesel, oil crops have not been widely developed in Hawai‘i but are being studied.

Dedicated energy crops face a dilemma described in the 2009 *Hawai‘i Bioenergy Master Plan* as the “chicken and egg problem” ([HNEI 2009a](#)). Without an established market for biomass crops, biomass producers are reluctant to invest in production. Conversely, without a reliable supply of energy biomass, energy producers are reluctant to invest in biomass conversion facilities. This issue is less of a concern for distributed biomass energy systems that are typically integrated into existing commercial operations, which often produce their own biomass. Distributed biomass energy systems may be the way to develop the market for commercial energy crops, which could eventually supply utility-scale biomass energy production. Establishing production contracts between biomass producers and electrical power producers is another means by which to establish a market for biomass fuels.

A concern in developing biomass energy crops in Hawai‘i is the availability of land and water resources necessary to produce the crops. Because of both spatial and seasonal variation in precipitation, biomass energy crops in Hawai‘i may require significant amounts of irrigation water in addition to natural precipitation. Questions remain regarding allocation of water resources to competing needs. Hawai‘i also has limited lands suitable for the production of agricultural crops. Extensive development of energy crops could compete with other agricultural crops or grazing lands. However, recent decreases in sugar cane and pineapple production has opened land area that could be used for biomass crops without using lands dedicated to other agricultural products ([DBEDT 2013d](#)). Energy crops may be a means to offset the economic impacts associated with declines in the pineapple and sugar industries and provide an alternative agricultural industry. As part of the 2009 Hawai‘i Bioenergy Master Plan, the University of Hawai‘i at Manoa (College of Tropical Agriculture and Human Resources) evaluated the land and water resources issues associated with the potential development of bioenergy crops in Hawai‘i ([CTAHR 2009](#)).

The potential development of energy crops in Hawai‘i also introduces the possibility of using genetically modified organisms (GMO) for the production of biomass. Genetic engineering could be used to enhance plant characteristics such as productivity and oil content of seeds. The use of genetic engineering in Hawai‘i agriculture is an active area of research. GMO crops (e.g., corn and papaya) are currently grown on the islands. For additional information on GMO in Hawai‘i, the reader is referred to the biotechnology website of the University of Hawai‘i College of Tropical Agriculture and Human Resources (<http://www.ctahr.hawaii.edu/biotech/>).

Animal Waste

Livestock production produces animal waste (i.e., manure), which is a potential biomass feedstock. Animal waste, with its high moisture content, is amenable to anaerobic digestion to produce a biogas that is largely methane gas. The main domesticated livestock populations in the State are dairy and beef cattle, hogs, and chickens. However, animals must be raised at high density to produce sufficient manure accumulation with low collection costs to serve as a biomass resource. The beef industry in Hawai‘i

largely uses dispersed pasture and rangeland grazing and therefore does not produce a concentrated supply of animal waste. Several large livestock production operations exist in Hawai‘i that would have sufficient numbers and concentrations of cows, hogs, and chickens to produce large accumulations of manure ([Turn et al. 2002a](#)). However, animal waste has competing uses. Manure from dairy operations currently is either spread on fields as fertilizer or disposed of as waste. Chicken manure is high in nitrogen and is often mixed with mulch and composted and sold as fertilizer. O‘ahu has the largest concentration of large livestock producers. In the past, two anaerobic digesters operated at swine production facilities and one at the University of Hawai‘i Waialeale Livestock Experiment Station on O‘ahu ([Turn et al. 2002a](#)) but all have been decommissioned. Additional labor for maintenance and operation of the digester system is the primary reason this technology has not been adopted.

Forest Residues and Energy Forests

Hawai‘i’s forest industry is a potential source of biomass feedstock. The forestry industry produces biomass either through wood residues generated as a byproduct of timber harvesting and wood processing or potentially through the development and production of dedicated forest biomass crops. The island of Hawai‘i has the largest inventory of timber resources in the State, while Maui and Kaua‘i have smaller acreages. Hawai‘i’s timber resource comprises native and nonnative species. Eucalyptus trees were brought to Hawai‘i as a potential commercial timber species and are commonly grown in Hawai‘i. There are many species of eucalyptus trees and different species have adapted to the variety of growing conditions found on the islands ([Khanal et al. 2009](#)). Research continues to evaluate a variety of woody species as potential dedicated wood biomass feedstock, including eucalyptus species adapted to different microclimates and soils, leucaena, and albizia ([Khanal et al. 2009](#)). Wood residues include slash (waste timber after harvesting), bark, sawdust, and mill residues (slab wood and trimmings). In dedicated energy forests, the entire timber harvest would be processed into wood residues or chips. Wood residues are used to generate electricity or produce steam heat for lumber drying, typically in steam boiler generator systems. Similar to herbaceous crops, there are concerns about invasive characteristics for some of these species, such as jatropa and leucaena ([HNEI 2012b](#); [Buddenhagen et al. 2009](#)).

Urban Waste Streams

The third primary source of biomass is urban waste streams, which include municipal solid waste, sewage sludge, food wastes, and fat/oil/grease (urban grease). Similar to animal waste, urban waste streams need to be sufficiently large and concentrated, such as at landfills, to provide an adequate biomass source.

Municipal Solid Waste

Municipal solid waste includes biogenic waste materials that are intended for disposal in landfills but can be burned in a steam-cycle power plant ([Turn et al. 2002a](#)). Landfills can provide a secondary source of biomass through the decomposition of waste following landfill closure. Anaerobic mesophilic bacteria in the landfill produce a biogas that is about 50 percent methane, which can be collected and extracted from wells bored into the landfill. This PEIS discusses municipal solid waste in [Section 2.3.3.4](#).

Sewage Sludge

Sewage sludge or biosolids are a byproduct of wastewater treatment facilities and are generated at primary and secondary stages of treatment. Sludge is often further stabilized prior to disposal, typically by digestion, to reduce the volume, dewater the sludge, reduce the organic content, and reduce odor ([Turn et al. 2002a](#)). Smaller treatment facilities often do not have this capability, in which case the sludge is often transported to public facilities thus consolidating the sludge from several locations.

Food Waste

Food waste is produced by restaurants, food courts, hotels, markets, food manufacturers and processors, caterers, and hospitals. Food waste has multiple uses including mixing with other biogenic municipal

solid waste, hog feed, and anaerobic digestion (methane production). Hog feed is the current primary use of food waste in Hawai'i ([Turn et al. 2002a](#)). Food waste generation is largely a function of the concentration of people.

Urban Grease Waste

Urban grease waste is generated as byproducts from food preparation activities. Urban grease can be classified into two categories, yellow grease and grease trap waste. Yellow grease is derived from used cooking oil and waste greases that are separated and collected at the point of use by the food preparation facility. Yellow grease is normally picked up by a company that consolidates it and either uses it or sells it for manufacturing into tallow, animal feed supplements, fuels, or other products. Grease traps are located in the drain lines from restaurant and food service facility sinks and dishwashers and serve to accumulate grease, thereby preventing it from entering the sewage system. Grease trap waste is collected and treated and used similar to yellow grease.

Biomass Logistics

Biomass logistics includes two primary components: the transportation and delivery of the biomass from the point of origin to the point of use and the preparation of the biomass material for use in an energy conversion technology. Transporting biomass differs from transporting fossil fuels in two ways ([Jorgenson et al. 2011](#)). First, biomass has a significantly lower energy density and higher fuel moisture content compared with fossil fuels, such as coal. Therefore, the cost per unit of energy to transport biomass is higher. Second, biomass resources are more spatially distributed than fossil fuels, which are typically extracted from a mine or well. Increasing the biomass collection radius may increase the available biomass but also may increase the related transportation costs. Availability of a biomass resource within a reasonable distance is an important consideration in determining the feasibility of a distributed biomass energy application ([EPA 2007](#); [Jorgenson et al. 2011](#)). However, each of the islands in Hawai'i is relatively small, and transportation costs for distributed biomass projects likely would not be prohibitive. Commercial industries that produce biomass waste as part of their operation are ideally suited for distributed biomass energy production because transportation costs are minimal and energy production can be scaled to match their energy requirements and the available biomass. The sugar and macadamia nut industries in Hawai'i are two examples that have used self-produced crop wastes to produce their own electricity.

The preparation of the biomass material for use in an energy conversion technology typically includes receiving, processing, storing, and then feeding the biomass into the energy production facility (i.e., furnace/boiler or gasifier) ([EPA 2007](#); [Jorgenson et al. 2011](#)). There are three primary considerations in biomass preparation: moisture content, particle size, and storage. Moisture content varies with the type of biomass material and season. Higher moisture content decreases boiler efficiency because of energy required to evaporate the water ([Jorgenson et al. 2011](#)). However, drying biomass either requires additional costs or longer storage times for biomass to dry to equilibrium moisture content (i.e., moisture content in balance with surrounding air temperature and relative humidity).

Particle size and particle size distribution are important for efficient use of the biomass material and the application of different conversion technologies. Biomass materials of more uniform particle size burn more efficiently (i.e., combust more completely per unit time). Different energy conversion technologies may require particles of a different size.

Biomass energy systems will require some amount of storage to ensure an available biomass supply. Biomass materials will eventually decay (i.e., compost), are a potential fire risk, and are a possible source of stormwater contamination. Proper storage and management of the biomass material will minimize loss. Dryers, grinders, conveyors, separators, and storage bins may be necessary depending on the feedstock and the energy conversion technology being used. Biomass preparation does not necessarily have to be

part of the energy production system. For a distributed biomass energy system, a fully processed and prepared biomass material could be procured from a biomass producer. However, securing a reliable source of cost-competitive biomass fuel is essential for implementing a biomass energy system. Commercial industries that produce biomass material as a byproduct of their operations have a distinct advantage and are prime candidates for implementing distributed biomass energy production systems.

2.3.2.1.2 Characterization of Activity Implementation and Deployment

Biomass energy generation is a valuable distributed renewable energy source in areas where it can fulfill the power supply needs of local agricultural and industrial operations and other residents. Because of the lower energy content of biomass materials compared with fossil fuels, it is important to locate the energy production facility near the biomass source to offset the transportation costs (see above discussion). The economic value of agricultural and forest waste residues and crops as fuel sources makes biomass conversion a potential benefit to agricultural and forest product producers, enhances energy security, and reduces strain on the electrical grid. Use of urban waste streams minimizes waste disposal.

Because biomass energy sources include a variety of materials with different chemical constituents (e.g., fiber, oils, sugars, starch), a number of different technologies are being used to convert biomass energy into a useable product that can then be used to produce electricity and heat. Biomass energy conversion technologies can be broadly grouped into two categories; thermochemical processing, and biochemical processing ([HNEI 2012a](#)). Thermochemical processing is accomplished in different steps by altering the amount of air or oxygen available. The most common and familiar thermochemical process is direct combustion or burning of biomass with excess air in a boiler furnace to produce steam to drive a steam turbine or supply steam heat (e.g., drying and facility heating). Other forms of thermochemical processing involve heating but not burning (i.e., restricted air) biomass to convert it into an intermediate gas or liquid (i.e., biofuel) that is then used to produce heat and electricity ([Bain et al. 2012](#)). Intermediate conversion technologies include thermal gasification (gaseous products) and thermal pyrolysis (liquid products). Another process is transesterification of plant oils that is mostly a chemical process performed at much lower temperatures (~50°C) to produce biodiesel. The liquid and gaseous energy products are then used in steam turbine (i.e., furnace/boilers), gas turbine, or internal combustion engine generators ([Bain et al. 2012](#)).

Biochemical processing involves the use of bacteria, yeasts, and enzymes to ferment or digest biomass (e.g., anaerobic digestion) to produce a methane-rich gas. The analysis in this PEIS includes combustion (direct fire, co-fire), pyrolysis, gasification, and anaerobic digestion technologies. The following sections briefly describe these technologies and potential uses in Hawai‘i. [Section 2.3.4.1](#) of this PEIS discusses the production of transportation biofuels such as ethanol and biodiesel.

Combustion (direct fire and co-fire)

Combustion technology uses biomass fuel, typically those high in fiber such as bagasse, wood products (sawdust, chips, mill residues), and municipal solid waste, in conventional steam boilers and turbines to produce electrical power ([EPA 2007](#)). Depending on the supply, both the amount and seasonality, biomass fuel may be co-fired with other energy sources such as coal or fuel oil to replace part of the fossil fuel. The impact of biomass co-firing on capacity and heat rate is facility-specific and a function of co-firing rate and boiler control characteristics ([Bain et al. 2012](#)). Direct fire, steam-based biomass power plants are a proven, simple, and mature technology ([EPA 2007](#); [Peterson and Haase 2009](#); [Bain et al. 2012](#); [Khanal et al. 2009](#)). The oxidation of biomass with excess air produces hot flue gas to generate steam in boilers. The steam is then used in a standard steam generator to produce electricity. The conversion efficiency typically is 15 to 35 percent depending on the system being used ([Peterson and Haase 2009](#)). The overall conversion efficiency can be increased to as much as 85 percent if operated as a combined heat and power system, where a portion of the steam is used as process heat for industrial

applications such as drying (e.g., nut processing or lumber drying). Because heating requirements are limited in Hawai‘i, use of a combined heat and power system most likely would be limited to distributed industrial heating applications.

Biomass combustion technology is particularly suited for distributed energy production where biomass energy can be integrated into existing facilities near the biomass source. The sugar industry in Hawai‘i has long produced electricity using biomass combustion technology primarily to meet internal energy needs and also for export to utility companies. Direct combustion biomass technology is scalable by using different sized boilers and generators and is adaptable to various distributed energy applications as long as a reliable biomass source exists that can be economically acquired ([Khanal et al. 2009](#); [Jorgenson et al. 2011](#)). Construction of conventional combustion steam-cycle generating stations involves land disturbance and building of structures to house the boilers and turbines, an emission stack, and electrical distribution lines. However, for distributed applications, the generating stations are often co-located near the biomass source (e.g., agricultural production or processing plant, landfill, or lumber mill) adjacent to or in existing disturbed sites.

Transesterification

Transesterification is a chemical process in which plant oils and animal fats are reacted with an alcohol (typically methanol) to yield a fuel (methyl esters) with properties (e.g., density, flash point, viscosity, and pour point) similar to diesel fuel ([Berchmans and Hirata 2008](#); [Raja et al. 2011](#)). The processing of oil crops begins with an extraction process that separates the plant oils from the oil-producing plant part (i.e., seeds, fruit). In addition to the plant oils, the processing of oil crops produces several byproducts that have potential value. Following the transesterification process, approximately 10 to 15 percent of the final product is glycerin or glycerol, a sugar alcohol that is used in soap-making and other cosmetics ([Poteet 2006](#)). The seedcake that remains after oils are extracted has potential uses as an organic fertilizer, animal feed, or even combusted for energy. However, some plant species contain natural botanical toxins (e.g., *Jatropha* and castor bean), and the seedcake cannot be used as animal feed unless it is detoxified ([Poteet 2006](#)).

Pyrolysis

Pyrolysis and gasification are thermochemical conversion processes that use a controlled destruction of the biomass material to produce solids, liquids, and gases ([Overend 2004](#); [Verma 2012](#)). Differences in the two processes (temperature, rate of heating, amount of air) will favor the production of more or less solids, liquids, and gases. The reader is directed to [Overend \(2004\)](#) and [Verma \(2012\)](#) for a more detailed technical discussion about thermochemical processes.

Pyrolysis is a process in which biomass material is heated to about 450 to 500°C in the absence of oxygen ([Khanal et al. 2009](#)). Pyrolysis is actually an old process that is used to produce charcoal and cooking coal. However, for biomass energy production, fast pyrolysis (rate of heating is increased) is designed to maximize the production of pyrolysis oils, or bio-oils ([Overend 2004](#); [Verma 2012](#)). Bio-oil, as a liquid fuel, has a heating value similar to most solid biomass fuels and about 55 percent of fuel oil ([Khanal et al. 2009](#)). With additional processing, bio-oil can be used in combustion turbines, but bio-oils have seen limited application as a boiler fuel for either power or heat production. In boilers, bio-oils provide no energy advantage over direct firing of biomass except in situations where it is necessary to transport fuel from the point of production to point of use because bio-oil has a higher energy density and therefore a lower transportation cost. Bio-oils also might be advantageous and the preferred option when existing fuel-oil-fired boilers are being converted to biomass fuels. Although research, testing, and development continues on combustion turbines that burn bio-oils and on portable pyrolysis units, the use of pyrolysis-produced bio-oils for distributed renewable energy has potential but currently limited application ([Khanal et al. 2009](#)).

Gasification

Gasification is an extension of the pyrolysis process designed to give the highest yields of carbon and energy in the gas phase. This is achieved by reacting the biomass material at high temperatures (greater than 700°C) with a controlled amount of oxygen and possibly steam (partial oxidation). The resulting gas mixture is called synthetic gas (syngas) or producer gas, which is processed (i.e., cleaned and upgraded) into a variety of fuels that can be combusted at a higher temperature than the original biomass material to produce electricity (i.e., having a higher heating value) ([EPA 2007](#); [Jorgenson et al. 2011](#)). Different types of gas reactors are available for performing the gasification process including fixed bed, atmospheric and pressurized bubbling-fluidized bed, and circulating fluidized-bed technologies ([Kinoshita et al. 1997](#); [Khanal et al. 2009](#)).

Several approaches exist for using the gases produced ([Khanal et al. 2009](#)). Smaller-scale gasification using internal combustion systems are at the commercial stage ([EPA 2007](#); [Bain et al. 2012](#); [Khanal et al. 2009](#)). Another approach is the more complex biomass integrated gasifier, combined-cycle application where the product gas from the biomass conversion is fired in a combustion gas turbine to generate electricity (topping cycle) ([Khanal et al. 2009](#)). The hot exhaust products then pass through a heat recovery steam generator and the steam produced is used in a steam turbine to generate additional electricity (bottoming cycle). The combined cycle system is at the demonstration stage ([Bain et al. 2012](#)). A third approach is removal of the combustion turbine from the combined cycle system and directly fire the product gas in a steam cycle boiler system ([Peterson and Haase 2009](#)). This approach has commercial application. Gasification technology has potential application for distributed renewable energy production. However, the technology is not yet widely applied, although available in different forms. One of the disadvantages of gasification for distributed energy is the larger scale required to capture cost and efficiency benefits ([Bain et al. 2012](#)). Gasification also requires fuel of uniform size and with low moisture content ([Peterson and Haase 2009](#)).

Anaerobic Digestion

Anaerobic digestion is a biological process in which microorganisms degrade biomass material into a methane and carbon dioxide gas mixture in an oxygen-free environment. Anaerobic digestion, or decomposition, is a complex process and occurs in three basic stages from the activity of a variety of microorganisms. Initially, a group of microorganisms converts organic material to a form that a second group of organisms utilizes to form organic acids. Methane-producing (methanogenic) anaerobic bacteria use these acids and complete the decomposition process. Generally, 1 kilogram (2.2 pounds) of organic matter generates about 0.35 cubic meter (0.46 cubic yard) of methane gas ([Khanal et al. 2009](#)).

Anaerobic digestion typically is used to produce biogas in two ways. One is the natural anaerobic fermentation that occurs in closed landfills, which produces methane as a byproduct of the breakdown of municipal solid waste. The second approach is the use of constructed anaerobic digesters—also known as biodigesters—which typically consist of an air-tight tank into which the biomass material is placed. The advantage of an anaerobic digester is environmental conditions can be managed to optimize the gas production. Optimal digestion occurs around 98°F. Efficient operation requires maintaining the appropriate pH and proper ratios of water to solids and carbon to nitrogen, mixing the digesting material, selecting the best particle size of the material being digested, and identifying the optimal retention time. Although many types of biomass materials can be used in a biodigester, livestock manures are a common feedstock as well as sludge from water treatment facilities. Anaerobic digesters are constructed with concrete, steel, brick, or plastic. They are shaped like silos, troughs, basins, or ponds, and may be placed underground or on the surface. All anaerobic digestion system designs incorporate the same basic components: a pre-mixing area or tank, digester vessel(s), system for using the biogas, and a system for distributing or spreading the effluent (the remaining digested material).

Gas collected from an anaerobic digester or landfill can be used as fuel gas or in a power plant to generate electricity. Biogas produced in anaerobic digesters consists of methane (50 to 80 percent), carbon dioxide (20 to 50 percent), and trace levels of other gases such as hydrogen, carbon monoxide, nitrogen, oxygen, and hydrogen sulfide. The relative percentage of these gases in biogas depends on the feed material and management of the process ([Khanal et al. 2009](#)). Impurities must be removed prior to use as fuel. Carbon dioxide is not an impurity but does reduce the heating value of the fuel. Hydrogen sulfide is an extremely reactive corrosive gas that must be removed. Biogas has traditionally been used as a boiler fuel for steam generation for electricity production or process heat production ([Khanal et al. 2009](#)). However, it also could be used in internal combustion engine generators, gas turbine generators, [fuel cells](#), and as vehicle fuel.

Anaerobic digestion is a mature technology and could easily be implemented in Hawai'i's tropical climate. The 85-acre Kapaa landfill operated a successful landfill gas recovery system. In 1998, the landfill produced 2.3 million cubic feet of gas per day that was used in a gas turbine generator system ([Khanal et al. 2009](#)). The turbine exhaust also was used to dry rock aggregate. The operation terminated in 2002 because of operating difficulties with the combustion turbine. No landfill gas recovery systems are currently operating in Hawai'i. Constructed anaerobic digesters have been used in Hawai'i but none is currently operating. Two digesters operated at swine production facilities. A third digester was operated at the University of Hawai'i Waialeale Livestock Experiment Station on O'ahu but was subsequently decommissioned ([Turn et al. 2002a](#)). The primary reason for abandoning this technology was the lack of maintenance and operations personnel. Anaerobic digestion is suitable for distributed energy development. However, adoption and development of the technology by private industry will depend on the economic benefits. Landfill gas is less likely to be used as a distributed energy source because of the gas recovery infrastructure required. However, the CAA requires many landfills to manage landfill gas either by collecting and flaring it or using it (<http://www.epa.gov/lmop/faq/lfg.html#07>).

2.3.2.1.3 Permitting and Consultation Requirements

As discussed in [Section 2.2.5](#), the number of permits required for a biomass energy project can vary depending on the scope of the project, the anticipated environmental and social impacts, and location within certain zoning districts or special management areas ([Siah and Zapka 2009a](#)). The number of required permits, uncertainty regarding approval or denial of important permits, and potential lengthy appeal processes may impact the implementation of biomass energy projects. The Hawai'i Bioenergy Master Plan provide a review of potentially applicable laws, permits, and permitting issues with respect to the biomass energy industry in Hawai'i ([Siah and Zapka 2009a](#)).

Technology-specific permitting and consultation requirements for a biomass energy project need to consider not only the construction and operation of an energy conversion facility such as a power plant or gasification facility, but also the feedstock production component and bioenergy distribution system. Permits required for the production and collection of common biomass feedstock such as agricultural residues, crops, forest and mill residues, and municipal waste should be in place as part of existing production operations. However, additional permitting may be required for the handling and transportation of feedstock such as municipal solid waste or animal waste. The development of new feedstock production operations or the expansion of existing operations may require new permits or modification of existing permits.

2.3.2.1.4 Representative Project

A representative biomass energy project would involve the direct combustion of biomass in a steam boiler to produce steam for electricity generation and industrial steam. This is a proven technology and has been used on the Hawaiian Islands for many years. For example, the sugar industry has long used bagasse as a

fuel source to generate electricity to operate its mills, irrigation pumps, wells, and facilities (<http://hcsugar.com/keeping-maui-green/energy-through-agriculture/>). Similarly, a high-producing nut processing plant uses nut shells in a steam boiler to generate electricity for the nut processing plant and steam heat for the nut drying tanks (<http://www.maunaloa.com/about/sustainability.asp>).

The representative project would produce about 50 kilowatts (0.05 megawatt) of electricity. The boiler unit(s) would use a fibrous residue biomass material from either an agricultural or forest source. Biomass feedstock would be supplied by nearby sources either produced as part of the commercial or industrial operation for which the power is being produced or procured from local biomass producers. In either case, transportation of the biomass feedstock would be local and for relatively short distances (up to 5 miles).

The biomass steam generator would provide baseload electricity with a capacity factor of 80 percent, or 350,400 kilowatt-hours of electricity per year ([Aabakken 2006](#)). Biomass fuels such as bagasse, wood, straws, and nut shells all have essentially the same gross heating value on a moisture and ash free basis, about 20 mega Joules per kilogram ([Kaupp 2013](#); [Turn et al. 2005](#)). Higher moisture and ash content reduce the heating value. For purposes of calculating the amount of biomass required to operate a representative 50-kilowatt biomass steam generator and the land area needed to produce the biomass, bagasse would be fired at 50 percent moisture with 3 percent ash content. Therefore, 1.53 kilograms of bagasse would need to be fired to produce each kilowatt-hour of electricity. This translates into an annual requirement of about 590 tons of bagasse to operate a 50-kilowatt plant at 80 percent capacity.

The average sugar cane production from 2010 to 2012 (24-month harvest cycle) was about 82 tons per acre ([NASS 2013](#)). The general ratio of bagasse to cane production is about 0.3, or about 12.3 tons of bagasse per 1 acre of sugar cane. Production of 590 tons of bagasse biomass would require about 48 acres of sugar cane. For the representative project, the sugar cane bagasse would be a byproduct of an existing agricultural operation; therefore, this PEIS does not consider existing agricultural conditions, related to water, fertilizer runoff, pesticide and herbicide use, or air emissions from burning cane fields.

Construction of the representative project would require clearing, grading, and leveling an area of about 2 to 4 acres for the boiler and turbine building, biomass handling and feed system, and temporary construction space. Construction would require approximately 30 workers for about 9 months. Operations would require 2 employees per shift. The energy facility would be adjacent to the commercial or industrial facility where the electrical power would be used. Therefore, road access and utility services such as water and sewer would exist nearby. Approximately 1 to 2 acres of land would be disturbed for the extension of water and sewer lines and also possibly new road access. Depending on the configuration of the power plant, electrical distribution lines could be either above or below ground but would be relatively short (less than 200 feet) because the power would be used close to the point of generation. The electrical steam generator would be connected to the local power grid to deliver excess power to the local electrical utility. This connection would be made through existing electrical utility services and would allow purchases of power when the steam generator is not operating.

The buildings would be about 20 feet tall with an emission stack height of approximately 60 feet. The steam boilers would produce carbon dioxide, nitrogen oxide, particulate matter, carbon monoxide, and sulfur dioxide emissions. Biomass combustion would produce ash waste, and ash-handling facilities would be integrated into the generating station. The representative project would produce about 18 tons of ash per year based on 590 tons of biomass fuel burned per year with 3 percent ash content. It is assumed that ash waste would be used on nearby agricultural fields as fertilizer, with some disposal in a landfill. Industrial noise would be produced from operation of the biomass handling facilities and removal of ash waste. Noise from the steam boilers and turbines mostly would be contained within the buildings.

[Table 2-8](#) summarizes the specifications and capacities for the representative project.

Table 2-8. Steam Boiler Electricity Generation

Power Plant Specifications	Value
Production Capacity	50 kilowatt
Capacity Factor	80%
Energy Efficiency	25%
Kilowatt-hours per year	350,400
Construction Area (acres)	3 – 6
Construction Crew (9 months)	30
Operations Crew/shift	1 – 2
Biomass (50% moisture, 3% ash)	
Annual Requirement (tons)	590
Land Production Area (acres)	48
Ash Produced (tons)	18

2.3.2.2 Small-Scale Hydroelectric Systems

Hydroelectric power, or hydropower, utilizes the energy in flowing water to spin a turbine attached to a generator to produce electricity. The potential extractable energy in the water is determined by the product of the *head* and *flow* characteristics of a given hydro system. Head, measured in feet or units of pressure, is the vertical distance that water drops and, in the case of a conduit system, is a characteristic of the channel or pipe that water flows through before it interacts with the turbine. Flow measures the quantity of water, in cubic feet per second, flowing in a system ([DOE 2001](#)). Together, these factors determine the type of hydropower plant suitable for a given location.

Hydropower plants require a water source in a geographic area generally characterized by uneven terrain, such as hills or mountains, to have sufficient power-generation potential. There are three common types of hydropower plant designs: impoundment, diversion, and pumped storage hydropower. Ultimately, regardless of design, hydropower plants can be scaled to meet the size of a given hydro system, but the type of hydropower turbine technology used to generate electricity is dependent on the head and flow characteristics of the hydro system in question.

An impoundment hydropower plant captures water, via dam or other means, to store water in a reservoir and generate head. The annual downstream flow characteristics of rivers with impoundment plants are very stable compared to water availability upstream of the power plant, which can fluctuate greatly across seasons due to rainfall variations. The flow function of an impoundment is determined by the amount of water flowing into the reservoir. Diversion hydropower plants utilize the water flowing in a river to generate electricity without significantly impounding water, and are, therefore, subject to annual variations in rainfall. The flow, and thus the power-generating potential, is determined by the water available in the river. Any system where the water flowing into a hydropower plant is equal to water flowing out of the hydropower plant is known as run-of-the-river.

In general, impoundments utilize dams that control outflow to stabilize variations in inflow, while diversions are run-of-the-river. While there are exceptions, for the purposes of analysis, this PEIS approaches the technology from this general understanding.

2.3.2.2.1 Technology Description

The technical description for this section focuses on diversionary hydropower and hydropower from conduit systems made up of the pipes used to transport water in and around cities or towns. Typically, a diversion system falls into the DOE's small hydropower category, with a capacity between 0.1 to 30 megawatts ([DOE 2011a](#)). While these power plants are not designed to store or regulate water flow like a dam, they typically have a component, known as a forebay tank ([DOE 2001](#)), for stabilizing short-term

water availability, filtering sediments, and ensuring that only water enters the power plant, as air and debris can damage the turbine through cavitation, a phenomenon where bubbles formed by pressure in a liquid implode, damaging the turbine blades over time ([BOR 2009](#)).

In simplified terms, a diversion system works by redirecting a small portion of water from a river into a holding tank, forcing it through a pipeline, and then using the water to move turbines to generate power. The technical components of most diversion systems include an upstream intake, a forebay tank, a penstock for transporting the water to the powerhouse, the powerhouse itself (which includes all the necessary power generation and conversion equipment), and an outlet (or tailrace), where the water returns to the river ([Figure 2-9](#)). Distance from the water intake to the powerhouse can vary depending on the site and the desired head. Some sites may require the use of a penstock (pipeline for transporting water directly into the powerhouse) that is a mile or longer to optimize head, while some penstocks may be shorter when natural head created by a high waterfall is available. Typically, however, the powerhouse for a diversion system is close (i.e., using a short penstock) to the intake.

Figure 2-9. A Microhydropower System with Water Diverted into a Penstock (Source: [DOE 2001](#))

There are two main types of turbines used to generate electricity in any size hydropower plant: impulse and reaction turbines. Impulse turbines rely on a high-velocity water jet striking the turbine, or runner blades, to spin the generator. Common types of impulse turbines include the pelton wheel and the turgo wheel. Ideal for low-flow, high-head application, pelton and turgo wheel designs have narrow nozzles that direct high-pressure (high-head) jets of water at a wheel with scooped-bucket-shaped blades.

Reaction turbines resemble propeller blades and, essentially, are submerged in a sealed housing filled with water. The runner speed is controlled by the pressure of the water on the runner within the housing. Typically, due to complexity and cost, reaction turbines are used in large hydropower applications, but can be scaled for smaller projects ([DOE 2001](#)).

As noted above, hydropower plants can be scaled to the size of the river and desired application; the footprint of the intake, forebay, penstock, powerhouse, and tailrace likewise can scale with the size and site requirements. As a point of reference, a powerhouse for a 4-megawatt generator and associated equipment would be roughly the size of a 1-room cabin (16 × 28 feet). In addition to the plant footprint, a hydropower facility may require the construction of transmission or distribution to connect to the power grid. For remote locations, new access roads may be required to transport equipment and power plant workers. Development of small, non-grid connected systems used for local power generation would not require extensive transmission lines; however, access roads and cabling may be required to connect electricity from the powerhouse to the house, farm, or small business using the power.

Separate from diversion systems, conduit hydropower systems can be installed in existing systems used for water transportation. Such systems use turbine technology that generates power based on flow of water, rather than requiring an impoundment for creating *potential energy* in the form of stored head ([DOE 2004b](#)). In conduit hydropower systems, power-generating equipment is installed within the water system, utilizing the existing flow. Such systems are cost- and time-effective by making use of an existing municipal or irrigation system that delivers water in and around cities.

2.3.2.2 Characterization of Technology Feasibility and Deployment

Hawai‘i’s geography is characterized by variations in elevation, high levels of rainfall, numerous waterways, and uneven terrain. While not conducive to utility-scale hydropower ([Section 2.3.3.3](#)), such conditions can be suitable for diversion hydropower generation. To that point, the islands of Hawai‘i and Maui currently operate systems ranging from 0.1 megawatt to 12.1 megawatts ([DBEDT 2015](#)). Furthermore, there are eight small hydroelectric plants in operation on the island of Kaua‘i, ranging from 0.13 megawatt to 4 megawatts. Developers have also conducted additional feasibility assessments on sites that can generate between 4 megawatts and 8 megawatts, if constructed. Due to availability of hydroelectric resources, future development interest has primarily been directed at the islands of Hawai‘i and Kaua‘i. Along with Maui, these islands have an extensive irrigation system that is no longer used for agriculture, but has been highlighted as upgradeable for use with diversion hydropower and pumped storage ([USACE 2011](#)). Furthermore, many plantations currently use hydropower systems for irrigation. While many have fallen into disrepair, they could be revitalized and used to support new hydropower facilities.

Constructing and successfully operating new power plants depends on a number of technical and political factors. A 2011 assessment by USACE investigated the various elements that could affect the feasibility of a diversion hydropower system in the Hawaiian Islands ([USACE 2011](#)). Finding:

- A site is considered potentially economically feasible if it can produce energy comparable with the prevailing O‘ahu HECO rate for electricity.
- The degree of feasibility for hydropower is largely determined by the available locations.
- Ideally, hydropower would be installed in an area with adequate transmission line connectivity and proper land use rights.

Additional feasibility issues related to environmental and social concerns over land use may present large socio-political factors to consider. Along with the State's contentious water rights, issues regarding protected lands and tourism considerations may block access to otherwise ideal water resource sites.

The USACE's report identified the Waimea Canyon ditch system on Kaua'i as a viable location for a diversionary hydropower plant. It is the site of two small hydropower plants and has an extensive network of irrigation and reservoirs. Like many potential projects, it can be combined with additional existing or planned public works projects such as flood control and sediment management. A renewal of hydropower, especially on the small scale, could contribute much to HCEI's goals. Small hydropower can boost production in isolated areas.

2.3.2.2.3 Permitting and Consultation Requirements

Permitting and consultation requirements for distributed hydroelectric in Hawai'i are likely to be more general in nature (see [Section 2.2.5](#)). In-stream flow is heavily regulated and monitored by the State of Hawai'i Department of Land and Natural Resources, Commission on Water Resource Management, when multiple users are accessing the same waterway. To minimize conflict, it is recommended developers consult all potential waterway users and regulators prior to any type of use or diversion for hydropower, including those using waterways for indigenous or cultural practices. In addition, various State agencies now control or maintain old water ditches, which can further impact the siting and permitting of in-stream hydropower as use of State facilities triggers other processes (e.g., public auction) and permits (e.g., environmental assessment or environmental impact statement). Impacts to protected marine and terrestrial species must also be considered.

2.3.2.2.4 Representative Project

Diversion

A representative project would be located at a site identified with sufficient head and flow characteristics to sustain regular power generation, ideally on a steep slope or close to a waterfall. Typically, this would be a rural area, on a farm, park, or similar site. The hydropower plant would be designed to generate up to 10 megawatts of electricity, utilizing either pelton wheel or turgo wheel technology, and require a shorter penstock due to the relative slope of the ideal deployment location. System configuration sizes may vary, depending on the river resource as well. Depending on the location, these power plants may also require construction of transmission or distribution lines to ensure grid connectivity.

Conduit Hydro

A conduit hydropower system would be composed of a kinetic turbine and generator system rated from small kilowatt sizes up to 6 megawatts to meet the municipal water flow of the chosen site. This technology would be installed at a water distribution/pressure control facility. The representative project would be located in an existing site; therefore, no new transmission or distribution lines would be needed.

2.3.2.3 Hydrogen Fuel Cells

A [fuel cell](#) is a device that converts the chemical energy from a fuel into electricity through a chemical reaction with oxygen or another oxidizing agent. A hydrogen fuel cell uses the chemical energy of hydrogen to react with oxygen to produce electricity. Fuel cells can be used for almost any application typically powered by batteries or internal combustion engines, and can scale to provide energy to a laptop computer or to a utility power station. Fuel cells produce no criteria [air pollutants](#) or [greenhouse gas](#) emissions at the point of operation. While there are associated byproducts from manufacturing and decommission fuel cells, the scope of this PEIS is construction and operation of renewable energy projects and, therefore, it does not address this topic. Readers are directed to the many available Internet

resources on fuel cell byproducts (e.g., <http://www1.eere.energy.gov/hydrogenandfuelcells/fuelcells/systems.html>).

The following sections focus on hydrogen fuel cell use as a potential replacement for traditional electricity generation. This PEIS discusses hydrogen-powered vehicles in [Section 2.3.4.4](#).

2.3.2.3.1 Technology Description

A single fuel cell consists of an electrolyte and two catalyst-coated electrodes. Electricity is generated when hydrogen feeds to the negative electrode (anode) where a catalyst, often platinum, separates hydrogen's negatively charged electrons from positively charged protons ([Figure 2-10](#)). The electrons from the anode cannot pass through the electrolyte to the cathode and must travel around it via an electrical circuit to reach the other side of the cell. The movement of electrons is an electric current ([DOE 2010a](#)). At the positively charged electrode (cathode), the positively charged protons and the negatively charged electrons combine with oxygen to form water and heat. The amount of power produced by a fuel cell depends on the fuel cell type, cell size, temperature at which it operates, and pressure at which the gases are supplied. Combining individual fuel cells into fuel cell stacks increases the amount of electricity generated. The scalability of a fuel cell stack enables fuel cells to operate a wide variety of applications, including laptop computers (20 to 50 watts), homes (1 to 5 kilowatts), vehicles (50 to 125 kilowatts), and central power generation (1 to 200 megawatts) ([DOE 2010b](#)).

Figure 2-10. Illustration showing Chemical Reaction of a Fuel Cell

Fuel cells can provide stationary power for buildings and power for transportation applications. Stationary fuel cells provide backup power, power for remote locations, distributed power generation, and cogeneration. This section focuses on fuel cell use for stationary application.

In general, all fuel cells have the same basic configuration, an electrolyte, an anode, and a cathode; the difference is the type of electrolyte used. The electrolyte determines the kind of chemical reactions that take place within the fuel cell, the temperature range of operation, and other factors that determine its most suitable applications. Each fuel cell type has its own advantages, limitations, and potential applications ([DOE 2011b](#)), as the following addresses:

- **Polymer Electrolyte Membrane Fuel Cells** – Also called proton exchange membrane fuel cells, these fuel cells have a high power density (amount of power delivered by volume) due to their low weight and volume. They use a solid polymer as an electrolyte and porous carbon electrodes containing a platinum catalyst. They need only hydrogen, oxygen from the air, and water to operate. They are typically fueled by pure hydrogen supplied from storage tanks or on-board reformers, devices that extract hydrogen from hydrocarbon or alcohol fuels.

Polymer electrolyte membrane fuel cells operate at relatively low temperatures (around 176°F), which allows them to start quickly and results in less wear on system components. However, the low temperature requires a noble-metal catalyst, such as platinum, to separate the hydrogen's electrons and protons. Not only is platinum expensive, it is extremely sensitive to carbon

monoxide in the fuel gas. However, the platinum can be recovered at the end of the fuel cell's operating life.

Polymer electrolyte membrane fuel cells are used primarily for transportation applications and some stationary applications. However, due to their fast startup time and high power density, they are particularly suitable for use in passenger vehicles such as buses and cars.

- Alkaline Fuel Cells – This type of fuel cell was one of the first fuel cell technologies to be developed and was widely used in the U.S. space program to produce electricity and water on spacecrafts. They use a solution of potassium hydroxide in water as the electrolyte and can use non-precious metals as a catalyst. These older, high-temperature alkaline fuel cells operate between 212° and 482°F, while newer designs operate at lower temperatures of 74° to 158°F.

Alkaline fuel cells are easily poisoned by carbon dioxide, even that occurring in the air, and thus need to purify the oxygen in the atmosphere before use. The susceptibility to carbon dioxide also reduces the cell's lifetime. As a result, this type of fuel cell would not be competitive in commercial applications.

- Phosphoric Acid Fuel Cells – Phosphoric acid fuel cells use liquid phosphoric acid as an electrolyte and porous carbon electrodes containing a platinum catalyst. Considered the first-generation modern fuel cells and the first to be used commercially, the phosphoric acid fuel cell typically generates stationary power, but has been used to power large vehicles such as city buses.

Phosphoric acid fuel cells are more tolerant of impurities in fossil fuels that have been converted into hydrogen than polymer electrolyte membrane cells. They are 85 percent efficient when used for the cogeneration of electricity and heat, but only about 40 percent efficient when generating electricity alone. This is only slightly more efficient than combustion-based power plants. They are less powerful than other fuel cells of the same weight and volume, and the expensive platinum catalyst raises the cost of the fuel cell.

- Molten Carbonate Fuel Cells – Currently being developed for use in natural gas and coal-based power plants, molten carbonate fuel cells are high-temperature fuel cells that use an electrolyte composed of a molten carbonate salt mixture suspended in a porous, chemically inert ceramic lithium aluminum oxide matrix.

Molten carbonate fuel cells can operate at very high temperatures, about 1,200°F, which is advantageous because non-precious metals can be used as a catalyst and the fuel cell can convert hydrogen to fuel without an external reformer. When coupled with a turbine, these fuel cells can reach efficiencies of about 65 percent. Further, molten carbonate fuel cells are not susceptible to carbon monoxide or carbon dioxide poisoning and can thus be fueled with gases made from coal.

The primary disadvantage of these fuel cells is durability. The high temperatures and corrosive electrolyte cause increased component breakdown and corrosion, which decreases cell life compared to other types of fuel cells.

- Solid Oxide Fuel Cells – Solid oxide fuel cells use a hard, non-porous ceramic compound as the electrolyte and are expected to be about 50 to 60 percent efficient. Similar to the molten carbonate fuel cells, these fuel cells operate at very high temperatures of about 1,830°F and can use a non-precious metal catalyst and reform fuels internally.

The high operating temperatures results in a slow startup and requires significant thermal shielding. Durability of components is also an issue.

- Direct Methanol Fuel Cells – Unlike most fuel cells that are powered by hydrogen fed into the system directly or generated within the fuel cell system, as the name implies, direct methane fuel cells are powered by pure methanol, which is mixed with steam and fed directly to the fuel cell anode.

This technology is relatively new compared with that of pure hydrogen-powered fuel cells, and its research and development is about four years behind that of other fuel cell types, which means it is not yet suitable for commercial development.

Hydrogen Production

The development of processes that can produce clean and cost-competitive hydrogen is one of the keys to the successful implementation of the hydrogen fuel cell. The following are some basic facts about hydrogen that affect its usability for energy production ([DOE 2011d](#)):

- Hydrogen combines readily with other elements and is almost always found as part of another substance, such as water, biomass, or hydrocarbons. Therefore, it must be separated from compounds that contain it.
- Hydrogen can be produced using domestic resources, including fossil fuels (such as natural gas and coal) and biomass, or by using nuclear energy and renewable technologies such as geothermal, wind, and solar to split water. This diversity of supply is an important reason why hydrogen has a large potential as an energy carrier.
- Hydrogen can be produced at either large central plants or in small distributed units located at or very near the point of use.

Hydrogen can be produced via a range of different technologies, each with its own advantages, disadvantages, and environmental impacts.

- Renewable Electrolysis – Electrolysis uses an electric current to split water into hydrogen and oxygen. Although the electricity can be generated from any source, as its name implies, renewable technologies that utilize wind, solar, geothermal, and hydroelectric power are preferred. Because of the variable nature of wind and solar electricity production, excess electricity produced during times of high wind or sunshine can generate hydrogen that can be stored and used to produce electricity during times of low wind or low sun.
- Natural Gas Reforming – Natural gas can produce hydrogen by using high-temperature steam in a process called “steam methane reforming.” This process accounts for about 95 percent of the hydrogen used today in the United States ([DOE 2010c](#)). Another method, called “partial oxidation,” produces hydrogen by burning methane in air. Both steam reforming and partial oxidation produce a “synthesis gas,” which reacts with additional steam to produce a gas with higher hydrogen content.

Solid oxide fuel cells and carbonate fuel cells often use an internal reformation process due to their high operating temperatures. As a result, fuels convert to hydrogen within the fuel cell itself and do not require an external reformer. Larger commercial operations often use this technology so they can use natural gas as a fuel. Although the conversion of natural gas to hydrogen within

the fuel cell would result in some greenhouse gas emissions, the amount of greenhouse gas released would be less than that from the combustion of natural gas in a conventional engine.

- Gasification – Gasification is a thermal process in which coal or biomass is converted into gaseous components by applying heat under pressure in the presence of oxygen and steam. The biomass is broken apart to produce a synthesis gas, which then reacts with steam to produce a gas stream with an increased hydrogen concentration that can be separated and purified. With carbon capture and storage, hydrogen can be produced from coal with only minor greenhouse gas emissions. Because growing biomass consumes carbon dioxide in the atmosphere as part of the natural growth process, biomass can produce hydrogen with near-zero net release of greenhouse gas emissions.
- Renewable Liquid Reforming – Biomass resources can be converted to ethanol, bio-oil, or other liquid fuels that can be relatively easily transported to the point of use and then reformed with steam at high temperatures to produce hydrogen.
- High-Temperature Thermochemical Water-Splitting – High temperatures generated by solar concentrators (mirrors that focus and intensify sunlight) or nuclear reactors can drive a series of chemical reactions that split water into hydrogen and oxygen.
- Biological Processes – Certain microbes, such as green algae and cyanobacteria, produce hydrogen as a byproduct of their natural metabolic processes by splitting water in the presence of sunlight. Other microbes can produce hydrogen directly from biomass.
- Photoelectrochemical Processes – Sunlight and a special type of semiconductor material can produce hydrogen from water. The highly specialized semiconductors absorb sunlight and use the light energy to separate water into hydrogen and oxygen.

Hydrogen Delivery

Hydrogen produced at centralized locations requires infrastructure to move the hydrogen to where it is used in a fuel cell. This infrastructure can include pipelines, trucks, ships, and barges to carry the fuel and the facilities and equipment to load and unload the hydrogen. Producing the hydrogen at the site of the fuel cell rather than at a centralized location (known as distributed production) can reduce the potentially high costs of transportation.

Readers are directed to the DOE website on hydrogen fuel cells for more detailed information about the above topics: <http://www1.eere.energy.gov/hydrogenandfuelcells/>.

2.3.2.3.2 Characterization of Technology Feasibility and Deployment

The major challenges facing the commercialization of fuel cell technology include a reduction in production costs, improved durability ([DOE 2011c](#)), and creation of a distribution infrastructure. In order to be a viable alternative, fuel cell systems must be cost-competitive with, and perform as well or better than, traditional power technologies over the life of the system. Ongoing research is focused on identifying and developing new materials that will reduce the cost and extend the life of the systems without decreasing performance.

In 2001, the State of Hawai‘i commissioned the Hawai‘i Natural Energy Institute (HNEI) to prepare a hydrogen and fuel cell feasibility study, with a revision in 2004. The study, as revised, concluded that geothermal-electricity-produced hydrogen on the Island of Hawai‘i and biomass-produced hydrogen on

Hawai'i, Maui, and Kaua'i could eventually compete with the price of gasoline and that liquefied natural gas-produced hydrogen on O'ahu could also be cost competitive, but that the lack of infrastructure for liquefied natural gas could prohibit development ([HNEI and Sentech 2004](#)). Although the study concluded that hydrogen produced from wind electricity on Hawai'i, Maui, and Kaua'i would not be cost effective due to the intermittency of the wind resource, curtailed wind might be a source for producing hydrogen economically. An island-by-island technical feasibility for producing hydrogen, as determined by that study, follows ([HNEI and Sentech 2004](#)):

- Hawai'i – Possesses the greatest diversity of renewable resources, including solar, wind, biomass, and geothermal. It is the only island with a geothermal power plant, and off-peak electricity is often available from which to produce hydrogen. The island contains airports, commercial resorts, commercial agriculture, and a tourist industry that potentially could use electricity made by fuel cells. Although the study concluded that the limited population and large size of the island would limit the application of hydrogen, there is potential to convert the island's bus system to hydrogen. The hydrogen could be produced from electricity generated from geothermal or curtailed wind.
- O'ahu – Contains the greatest population, including the urban center of Honolulu. The large population represents the greatest opportunity to use hydrogen and fuel cells. Urban issues such as electricity transmission limitations, power quality, and commercial peak power create a potential market for fuel cells, but electricity demand patterns and limited availability of renewable resources decrease the ability to produce hydrogen. Sources of hydrogen from imported oil are available from the existing refinery and synthetic natural gas capability, but this source of hydrogen still requires the importation of fossil fuel products and is not considered a renewable resource.
- Maui and Kaua'i – Both islands have biomass, solar, and wind resources. Maui also has geothermal resources that are being developed. The large biomass availability makes hydrogen gasification an option.

No large-scale use of stationary hydrogen fuel cells exists within the State of Hawai'i. This is due, in part, to the high cost of producing hydrogen as a fuel source. Although natural gas is used as a primary fuel for fuel cells in the continental United States and other countries, natural gas is not readily available in Hawai'i and synthetic natural gas derived from fossil fuels is not a renewable resource ([HCEI 2010](#)). Consequently, HNEI has been conducting hydrogen research since 1983 and is making advances in hydrogen production using biological techniques, gasification of biomass, and the solar splitting of water into hydrogen and oxygen using photoelectrochemical devices ([HNEI 2013a](#)). In addition, private companies are working to develop processes and procedures to produce gaseous products from renewable feedstock such as plant oils and animal fats that could be used to produce hydrogen ([HREDV 2013](#)).

Hawai'i's emphasis in hydrogen fuel cell use has been with transportation vehicles rather than in stationary power plants. A modular hydrogen production and fueling station for hydrogen vehicles has been in operation at Hickam Air Force Base since 2006. ([Section 2.3.4.4](#) of this PEIS discusses hydrogen vehicles and their hydrogen production and fueling systems.) The United States military recently began developing and deploying stationary hydrogen fuel cells. In 2012, Joint Base Pearl Harbor-Hickam announced that it will build a 100-kilowatt power system using polymer electrolyte membrane fuel cells. Although the energy system will not account for the base's entire energy needs, it will provide the base with additional stationary power flexibility and energy security capabilities ([Hydrogen Fuel News 2012](#)).

Hydrogen produced by electrolysis of water from geothermal, solar or wind electricity, biological techniques, and gasification of biomass could contribute to HCEI goals of meeting 40 percent of the

State's energy needs through renewable energy by 2030. Electrolysis technologies are commercially viable today, but biological technologies are still mainly in the research phase and are not yet commercially available at a scale that would greatly impact the State's renewable energy needs. Gasification of biomass is still in the research phase, but getting close to commercial availability ([DOE 2012f](#)). Using natural gas, including renewable natural gas produced from renewable feedstock, to fuel the fuel cells could be a bridge to a renewable hydrogen future and could thus help meet HCEI's goals of using renewable energy.

The potential to reform fuel cell grade hydrogen from natural gas in Hawai'i is currently limited to areas that can be supported by infrastructure for natural gas in urban O'ahu. As natural gas infrastructure expands, so would the technical feasibility of hydrogen production for use in fuel cells.

Outside of Hawai'i, hydrogen fuel cells are being installed as part of commercial and public policy. The world-wide developments include:

- Within the continental United States, a growing number of Fortune 500 and other companies are purchasing fuel cells for backup electrical power and for distributed electricity generation. Depending on the company that is building and selling the fuel cell, the fuel cell systems are usually sold in modules of 200 or 300 kilowatts, 1.4 megawatts, or 2.8 megawatts. The technology is usually either solid oxide fuel cells or molten carbonate fuel cells and utilizes natural gas, wastewater treatment gas, propane, coal gas, and biogas as the fuel source. Existing commercial fuel cells do not normally use purified hydrogen gas as their fuel source, but rather generate the hydrogen within the fuel cell from the other fuel sources. Fuel cell systems totaling greater than 32 megawatts were purchased in the year 2012 ([Curtin et al. 2012](#)). Some of the top fuel cell power users in the continental United States include AT&T (17.1 megawatts at 28 sites), Wal-Mart (10.4 megawatts at 26 sites), eBay (6.5 megawatts at 2 sites), and Apple (5.3 megawatts at 2 sites) ([Curtin et al. 2012](#)). The fuel cell systems are compatible with, and complement, other energy technologies such as natural gas, biogas, solar, wind, and batteries.
- Other countries, most notably Japan, Germany, and South Korea, have policies in place to promote fuel cell technology. Japan is focusing primarily on small, 1-kilowatt fuel cell units primarily for single-family homes. The fuel cells run on either liquefied petroleum gas or natural gas, but the majority uses natural gas as fuel ([ORNL 2011](#)). Germany is still largely in the research and development phase due to limited funds. South Korea, which is 97 percent dependent on imported energy, has committed to a low-carbon energy future and selected hydrogen and fuel cells as one of the new energy sources. South Korea is implementing 1-kilowatt fuel cells for both home systems and larger systems for power generation ([ORNL 2011](#)). Construction on a 58.8-megawatt stationary fuel cell plant using molten carbonate fuel cell technology and natural gas for fuel was scheduled to begin in late 2012 ([Fuel Cell Today 2012](#)).

In an effort to increase the feasibility of hydrogen fuel cell technology in Hawai'i, DOE awarded DBEDT a contract to develop a hydrogen power park project in the State of Hawai'i in October 2002. DBEDT in turn contracted with HNEI to implement the project ([HNEI 2013b](#)). The power park provides an opportunity for operating integrated hydrogen energy systems (including providing stationary power and dispensing hydrogen for hydrogen-fueled vehicles), measuring operational results, and evaluating technical and economic performances. The project has completed initial testing of various full-scale components and installed and tested an integrated wind-solar hydrogen production and fuel cell power system at Kahua Ranch, which is near the north end of the Island of Hawai'i. The State chose this location because it has excellent wind and solar resources and has been used to test wind-to-hydrogen and solar-to-hydrogen hydrogen generation systems ([HNEI 2013b](#)).

The Hawai‘i power park project expanded to include the building of a hydrogen production and fueling station ([HNEI 2013b](#)). Under this expansion, DOE and the State of Hawai‘i provided additional funding to HNEI to build a hydrogen production and dispensing station that was originally intended to be installed at Hawai‘i Volcanoes National Park to support its Hydrogen Shuttle Bus project. However, delays in the acquisition of shuttle buses, the arrival of a fleet of General Motors Equinox fuel cell electric vehicles on O‘ahu, and the start of a new project to produce hydrogen at the Puna Geothermal Venture power plant on Hawai‘i island resulted in relocating the hydrogen production and dispensing station to the Marine Corps base Hawai‘i on O‘ahu. Originally built as a 350 bar (5,000 psi) system, the hydrogen dispensing system on the Marine Corps base is being upgraded to 700 bar to support the General Motors Equinox fuel cell electric vehicles deployed on O‘ahu. The Puna Geothermal plant will produce the hydrogen for the Hawai‘i Volcanoes National Park hydrogen dispensing system and deliver the hydrogen by road to the Park, providing the hydrogen requirements for the Hydrogen Shuttle Bus project ([HNEI 2013b](#)).

Centralized hydrogen production using electricity generated by geothermal, wind, or solar would need to be located near those geothermal, wind, and solar sources for hydrogen production to be economical. Hydrogen could be produced during times of low electricity demand, stored, and delivered to distributed fuel cells when needed. The hydrogen generated from centralized production would require an infrastructure to transport the hydrogen from the point of production to the point of use. Depending on scale, this could include pipelines or truck transportation. HNEI anticipates installing a hydrogen production facility at the Puna Geothermal plant. The electrolyzer is being tested as a grid management tool to help regulate grid frequency while at the same time producing hydrogen as a value-added product to support transportation ([HNEI 2012c](#)). Trucks will transport the hydrogen produced at the plant via road to support fuel cell electric buses the County of Hawai‘i Transit Agency and the Hawai‘i Volcanoes National Park are operating. The hydrogen could also be used to provide peak power support to the grid utilizing stationary fuel cells.

Distributed hydrogen production could use smaller wind or solar resources at the site of the fuel cell to generate electricity to produce hydrogen from water via electrolysis.

2.3.2.3.3 Permitting and Consultation Requirements

Even as a distributed energy source, most hydrogen fuel cells likely would be constructed in areas that already contain buildings and an existing electrical grid. Construction within existing developed areas likely would not need environmental permits such as protected species, sensitive environments, and cultural and archaeological impacts (see [Section 2.2.5](#)). Permits for, and impacts from, the associated plants used for hydrogen production (e.g., Puna Geothermal) are discussed in the respective technology sections of the PEIS.

2.3.2.3.4 Representative Project

This PEIS analyzes a representative project to provide a perspective of the potential environmental impacts that could be expected from a distributed-scale fuel cell project. The representative project is hypothetical and is not intended to reflect actual or planned proposals at any specific location. In general, fuel cells have a small footprint, produce little noise or hazardous waste, and produce fewer criteria air emissions than a comparable generator.

A representative hydrogen fuel cell project in Hawai‘i would possibly be different than a representative fuel cell project in the continental United States. Whereas fuel cell projects on the mainland tend to be fueled by natural gas, near-term hydrogen fuel cell projects in Hawai‘i likely would be powered directly by hydrogen produced from electrolysis processes using geothermal, solar, or wind electricity; from biomass; or from biological production methods if existing research proves to be commercially viable.

5-kilowatt Fuel Cell Power System

The representative project is a 5-kilowatt fuel cell power system designed for use by a single-family residence. The power system would be housed in a container either inside or outside the residence and would use stacks of fuel cells in a modular system to produce the power output specified. The hydrogen would be produced onsite as part of the modular system using water and electricity for the electrolysis process or be purchased from a centralized hydrogen production facility. Electricity for the electrolysis process could be supplied either via the existing electrical grid or via renewable resources at the site such as solar or wind.

Different manufacturers have different specifications for their fuel cells and hydrogen generators. The specifications this PEIS uses represent approximate consumptions and fuel uses and are not intended to reflect any actual project or product.

Individual hydrogen fuel cells are stacked together in racks as part of a modular system. According to various product specifications, the rack for a hydrogen fuel cell system that produces 5 kilowatts of electricity would be about $5 \times 2.5 \times 7$ feet in size and weigh about 2,300 pounds. Assuming that a fuel cell produces 15 kilowatt-hours of electricity per kilogram of hydrogen consumed, about 0.33 kilogram (0.73 pound) of hydrogen would be required per hour for a 5-kilowatt fuel cell system.

Enough hydrogen would need to be produced at the site of the fuel cell power system to meet the consumption requirements of the fuel cells if the hydrogen is produced onsite by electrolysis. The electrolyzer would have to be $6 \times 3 \times 6$ for the fuel cell to produce sufficient kilowatt-hours for the project. The unit would require about 28 kilowatt-hours of electricity and about 1 gallon of deionized water per hour. [Table 2-9](#) provides a brief description of operational parameters for a 5-kilowatt fuel cell power system.

Scaling of the Representative Project

The representative project could be scaled up to a larger fuel cell power system designed for use in the average commercial system. Existing hydrogen fuel cell systems and hydrogen-production systems are modular and stack individual fuel cells and hydrogen-production units together to produce the desired power output. Consequently, the operational parameters for fuel cell systems of increasing size tend to be linear with respect to size. For example, each individual 5-kilowatt fuel cell system would produce the same amount of electricity, consume the same amount of hydrogen, and have the same emissions, whether a single fuel cell system is used or 10 fuel cell systems are grouped for a 50-kilowatt system. Likewise, the space required for the fuel cell stacks of a 5-kilowatt system would increase linearly for larger systems (even though the required space may vary slightly due to specific system layouts).

Table 2-9. Operational Parameters for a 5-kilowatt Fuel Cell Power System

Project Parameters (associated with resource areas)	Operational Parameter
Site disruptions (cultural, biological)	None. Built in developed areas next to (or inside of) existing buildings
Air emissions	None
Noise generated	Depending on the technology, less than 60 dBA at 3 feet for fuel cell, 80 dBA at 3 feet for hydrogen electrolyzer system
Waste generated	None
Infrastructure	Hydrogen production uses electricity and water
Size of facility	Small indoor or outdoor containers (fuel cells grouped in racks)
Visual aesthetics	Small indoor or outdoor containers
Location	Next to existing facilities

2.3.2.4 Photovoltaics

PV cells convert sunlight to electricity. PV cells are assembled into a solar module, or group of PV cells. Solar modules are placed in an area or added to a larger system to generate and supply electricity for homes and businesses. A system typically includes one or more solar modules (sometimes referred to as an array), equipment to convert direct current (DC) electricity to alternating current (AC) electricity (i.e., inverters), and connecting wiring. Some systems are designed with batteries to store the generated electricity for later use and/or sun tracking devices to increase the amount of solar energy collected.

PV systems can be located on rooftops or mounted on racks on the ground. The systems can connect to the local electrical transmission grid or can operate as stand-alone systems. Stand-alone systems can be used with or without batteries. Solar modules have a typical life span of 20 to 30 years. The National Renewable Energy Laboratory determined that life-cycle greenhouse gas emissions from solar modules were significantly less than fossil and nuclear electricity generation, as well as many other renewable energy technologies ([NREL 2012a](#)).

2.3.2.4.1 Technology Description

All PV cells operate by absorbing a portion of the sunlight that shines on the cell. The energy of the absorbed light transfers to some of the electrons in the atoms of the PV cell's semiconducting material and those electrons escape from their normal positions in the atoms and become part of the electric flow, or electricity ([Harman 2000](#)). However, there are multiple PV cell technologies that use different types of semiconducting materials. PV cells made of crystalline silicon (single crystalline or multi-crystalline silicon) represent 85 to 90 percent of the global market ([IEA 2010](#)). Single crystalline silicon is more expensive to manufacture than multi-crystalline silicon but has a higher conversion efficiency (produced electrical power per amount of incident solar energy; 14 to 20 percent versus 13 to 15 percent).

Thin-film PV cells is another technology that, as the name implies, consists of a thin film (about 1 micron thick) of semiconducting material ([Harman 2000](#)). Because of the lower material volume, material costs are lower. However, conversion efficiencies also are lower (6 to 11 percent) so an additional area of collectors would be required to achieve the same amount of electric power production from silicon PV cells. Thin-film PV cells represent about 10 percent of the global market ([IEA 2014](#)). Materials used in thin-film PV cells can be divided into three main groups: (1) amorphous silicon, (2) cadmium-telluride, and (3) copper-indium-gallium-diselenide ([IEA 2014](#)).

A third type of PV cell technology is concentrating PVs, which use optical concentrators to focus solar radiation on a PV cell to increase conversion efficiency (approximately 25 percent) ([IEA 2010, 2014](#)). Concentrating PV technologies represent less than 1 percent of the global market.

The amount of energy from the sunlight that converts to electricity depends on a number of factors, including the wavelength of the light, the amount of light absorbed, the temperature of the PV cell, and the resistance of the materials to the electrons' flow. Capacity factors among the different PV cell materials and designs range from about 6 to 40 percent. Typical commercially available modules used in distributed, or small-scale, installations range from 15 to 20 percent.

The generated electricity (DC) must be converted with one or more inverters to AC before use. The electricity can either be used onsite or transmitted to the local utility grid and used in nearby homes and businesses. Stand-alone systems without batteries produce electricity only when there is a light source. Stand-alone systems with batteries produce electricity when there is light and will store the excess electricity in the battery for later use. Users can draw electricity from the batteries with or without a light source.

Distributed PV systems connected to the grid will produce electricity during the day, and send excess electricity to the local utility distribution grid. During periods when the PV system is not operating (i.e., no light source), the PV customer’s electricity needs can be met from the local utility distribution grid. Depending on the local regulations, the utility either buys the excess electricity or provides offset credits that can be used when a customer draws energy from the local grid. [Figure 2-11](#) is a diagram of the major items of a distributed PV system connected to a local utility distribution grid, and [Figure 2-12](#) is a diagram of a stand-alone system with battery storage.

A less-common but possible configuration is a grid-tied distributed PV system that includes batteries and the ability to disconnect from the grid during outages. This allows the customer to power the residence using stored electricity when the grid is down, without endangering utility personnel.

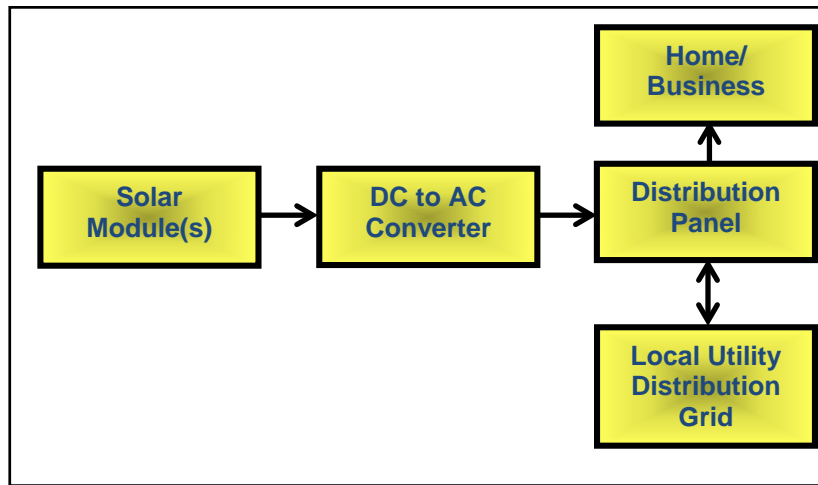

Figure 2-11. Diagram of the Major Items of a Distributed PV System Connected to a Local Utility Distribution Grid

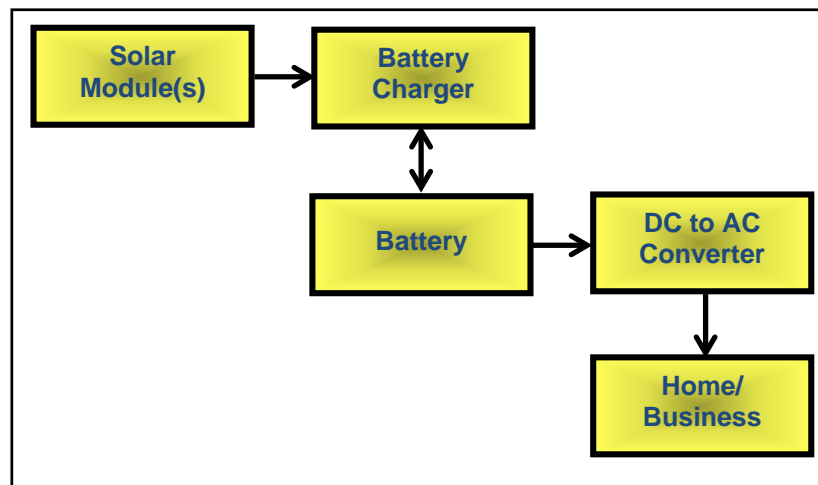

Figure 2-12. Diagram of the Major Items of a Stand-Alone Distributed PV System with Battery Storage

There are a multitude of distributed PV system designs derived from the basic systems to meet individual customers’ needs. Additional information and resources on solar can be found online at the following sites: <http://energy.hawaii.gov> and <http://energy.gov>.

2.3.2.4.2 Characterization of Technology Feasibility and Installation

Distributed PV systems are a mature and reliable renewable energy technology. The DOE SunShot Initiative is a national collaborative effort to make solar energy cost-competitive with other forms of electricity by the end of this decade (DOE 2013c). The State of Hawai‘i has ideal sun conditions for distributed PV systems. The HECO website provides additional information on site considerations for solar systems:

<http://www.Hawaiianelectric.com/portal/site/heco/menuitem.8e4610c1e23714340b4c0610c510b1ca/?vgnextoid=3b0ac44a75709310VgnVCM10000005041aacRCRD>.

The number of PV systems in Hawai‘i has increased exponentially over the last five years. As of 2013, the State of Hawai‘i is third in the Nation for the amount of installed PV capacity per capita; most of which is distributed solar (DBEDT 2014a). Homes and businesses have roofs that are large enough for installation of these systems.

Interconnection standards specify the technical and procedural process by which a customer connects an electricity-generating system to the electrical grid. Such standards can include the technical and contractual terms by which system owners and utilities must abide. State PUCs typically establish standards for interconnection to the local distribution grid, while FERC has adopted standards for interconnection to the transmission-level grid. While many states have adopted interconnection standards, some state standards apply only to investor-owned utilities (i.e., not to municipal utilities or electricity cooperatives). Hawai‘i has established interconnection rules for small renewable resources and other distributed generation, and in May 2010, a Hawai‘i PUC decision and order created a standard three-party interconnection agreement.

The State’s largest electric utility, HECO, which has as subsidiaries HELCO and MECO, utilizes a set of interconnection guidelines. The State’s only other utility, KIUC has a similar set of rules for interconnection. The companies’ current interconnection tariff (Rule 14H) utilizes a screening process to evaluate a project’s potential impact to the utility grid including screens for percentage of peak circuit load and minimum daytime circuit load. Projects that exceed certain percentages may trigger the need for an interconnection requirements study, which involves a more comprehensive, technical evaluation of a project’s impacts and potential solutions to mitigate identified impacts. Although such a requirement does not mean a project will not go forward, it can add time to the interconnection review process and, in some cases, may cause a developer to reconsider a project if the developer does not wish to pay for the interconnection requirements study or the identified mitigation measures. HECO and its subsidiaries are continuously working to improve the distributed generation process, including efforts to more precisely identify and target system constraints through more accurate understanding of specific conditions on measured and observed conditions on the specific feeder system rather than the use of proxy figures; allow project developers to check online for current feeder capability to accept the system’s output; enable better understanding of the need and scope of any interconnection requirements study; and direct utility actions to foresee potential circuit and system issues through comprehensive analysis, data, modeling, and mitigation. This process includes performing planning studies (i.e., representative studies) rather than formal interconnection requirements studies for individual customers where prudent. More recently, HECO, together with stakeholders in the Hawaii Commission’s Reliability Standards Working Group proceeding (Docket No. 2011-0206), submitted two stipulations proposing modifications to improve the Rule 14H interconnection process in response to Commission Order No. 32053. Currently, the HECO and its subsidiaries are engaged in discussions with stakeholders in the Commission’s Distributed Energy Resources proceeding (Docket No. 2014-0192) to develop additional technical revisions to the Rule 14H interconnection process and to develop, among other things, both self-supply and grid-supply options for customers.

HECO follows a PUC-approved process for reviewing and approving rooftop PV applications. As of December 31, 2014, more than 12 percent of O‘ahu customers have rooftop PV systems ([HEI 2015](#)). With that said, changes in utility interconnection requirements in recent years have caused solar generation growth to slow down. For example, total PV generation doubled between 2012 and 2013, from 201 gigawatt-hours to 404 gigawatt-hours, respectively. However, the pace of growth did not continue in 2014, with a total PV generation of 559 gigawatt-hours.

2.3.2.4.3 Permitting Requirements

General permits requirements are discussed in [Section 2.2.5](#). Distributed PV systems are permitted primarily by the respective county authorities. Many solar modules contain substances that could pose a risk to the environment and potentially to public health if not properly disposed of or recycled. There are industry initiatives to develop recycling guidelines and processes for solar modules. Currently some discarded solar modules may need to be managed and disposed of as hazardous waste. Batteries and electrical equipment also may need to be managed and disposed of as hazardous waste. State law requires that battery sellers accept and recycle used batteries. More information on the management of used batteries and electrical/electronic equipment can be found at http://www.opala.org/solid_waste/eWaste.html.

There have been issues with delays and costs associated with installations in areas that are near their distribution percentage maximum (see previous discussion).

2.3.2.4.4 Representative Project

The representative project involves a typical distributed PV project for a home or business installation. Regardless of home or business, the system would be mounted on the rooftop. The representative project assumes a typical home 5-kilowatt installation would cover about 350 square feet, and a typical business 50-kilowatt installation would cover about 3,500 square feet or about one-tenth of an acre. The number of solar modules depends on the wattage of the modules selected, their efficiency, the desired load, the solar resource, and the orientation of the array. Depending on the type of system there may also be batteries for storage or the system may be tied into the local utility distribution grid.

WIND CURTAILMENT

Occurs when wind plants are required to reduce their electric generation output. Typically occurs when there is excess electric production in an area and there is insufficient transmission capacity to move that electricity to where it is needed.

2.3.2.5 Small-Scale Wind Power

2.3.2.5.1 Technology Description

Wind turbines convert the *kinetic energy* of the wind to mechanical power. The wind turbine blades are designed to act like an airplane wing; the wind causes a pocket of low-pressure air on one side of the blade, which generates “lift” and pulls the blade toward it, causing the blade to move and the rotor to turn. The rotor turns a shaft and, through a gearbox, spins a generator to make electricity. Small wind turbines generally are those with capacities ranging from 20 watts to 100 kilowatts. At the low end of this range, units with capacities of 20 to 500 watts are often referred to as micro-turbines ([DOE 2007](#)). At the high end of the range, small wind turbines can have a similar configuration and appearance to utility-sized wind turbines. [Figure 2-13](#) provides a group of drawings showing several views of a typical small wind turbine, its primary components, and the component names.

Figure 2-13. Illustrations of Typical Small Wind Turbines (Sources: DOE 2007; NEED 2012b)

Small wind turbines manufactured today generally are horizontal-axis, upwind machines, such as depicted in [Figure 2-13](#). Upwind refers to the direction of the rotor; specifically, during operation, the rotor faces into the wind and the nacelle and tail are positioned behind (downwind). The other primary type of wind turbine is the vertical-axis machine in which the axis or shaft that spins is in a vertical orientation and the blades, which can be of several different configurations, are basically arranged in a horizontal plane. The vertical-axis wind turbine has the advantage of intercepting wind from any direction without changing its own orientation. However, the vertical-axis wind turbine is not yet as cost-effective as the conventional horizontal-axis turbine ([Boyd 2013](#)). [Figure 2-14](#) provides examples of several vertical-axis wind turbine and blade configurations. While not as cost effective, there are still numerous manufacturers that promote and sell vertical-axis wind turbines, and research to find and develop different configuration continues ([DOE 2010d](#)).

Figure 2-14. Illustrations of Various Vertical-Axis Wind Turbines and Blade Configurations

In simple terms, the primary components of a horizontal wind turbine can be described as follows:

- Rotor and Blades** (where the rotor is formed by two or three blades mounted on a shaft) – The rotor, attached to a shaft and being turned by the wind, converts the energy to rotational shaft energy. The power that can be produced by the wind turbine is a direct function of the swept area of the blades ([Figure 2-13](#)), so if the swept area increases by a factor of two, the power generating capacity basically doubles (all other factors staying equal). This also means the power generating capacity increases by the power of two with increases in blade length. For example, increasing the blade length by a factor of about 1.4 results in roughly doubling the wind turbine’s power capacity ([DOE 2007](#)), because 1.4 squared is approximately 2. For comparisons, a 2-kilowatt wind turbine requires a rotor diameter of about 12 feet, while 5- and 10-kilowatt machines require 18- and 25-foot diameter rotors, respectively ([AWEA 2013](#)). As the machines increase in size, particularly at the higher end of the small wind turbine category, they have slightly shorter blades than would be assumed from the above discussion. This is because manufacturers generally rate the turbines at increasing wind speeds as the size of the turbine increases, which is consistent with larger systems being able to take advantage of the fact that wind speeds increase with elevation above the ground. As an example of a rating being based on a higher wind speed, 100-kilowatt wind turbines generally have rotor diameters of about 60 feet ([AWEA 2013](#)) (whereas, following the discussion above, the required diameter would be almost 80 feet).
- Drive Train** – The drive train, which includes the gearbox and generator, as well as the low- and high-speed shafts ([Figure 2-13](#)), carries the rotational energy through gears to control and change the revolution speed that is put to the generator for production of electricity. Small wind turbines generally generate DC electricity ([DOE 2007](#)), although in the upper range of the category, wind turbines can produce AC. In small, stand-alone system applications, such as recharging batteries or for some home uses, there may be direct uses of DC electricity, but in most instances balance-

of-system components (see below) need to include equipment to convert to AC. The conversion is required for any wind turbine connected to the electrical power grid. An alternate drive train approach, the direct-drive is also worthy of note. This approach eliminates the gear box and links the rotor shaft directly to the generator. Direct-drive wind turbine technology is advancing in the larger, utility-scale category, particularly with regard to off-shore wind power and, accordingly, is described further in [Section 2.3.3.10](#).

- **Housing and Tail** – The housing, or nacelle in larger wind turbines, provides protection for the gearbox and generator, as well as a more streamlined structure. The tail is designed to keep the turbine facing into the wind. Wind turbines in the upper range of the small category generally have no tails, but rather have internal motors and electronic controls that turn and maintain the turbine into the wind just like the larger utility-scale wind turbines.
- **Tower** – The tower supports the rotor and drive train with the objective of putting the rotor blades into a zone of higher wind velocity and lower wind turbulence than occurs near the ground. The average height of small wind turbines is about 80 feet, which is twice the height of a standard telephone pole, and the range of heights is from 30 to 140 feet. As a general rule, the bottom of the wind turbine blade should be at least 30 feet above any obstacle within 300 feet of the tower ([DOE 2007](#)). Therefore, the bigger the rotor diameter, the higher the tower must be. Otherwise, there is no required relationship between the height of the tower and the size of the wind turbine. The higher the tower, however, the greater the wind speed and the more power produced from the same turbine. As an example, raising a 10-kilowatt turbine from 60 feet to 100 feet is estimated to add about 10 percent to the overall cost of the system, but results in a 25-percent increase in power production ([DOE 2012g](#)). As described above, the power that can be produced by a wind turbine is a direct function of the swept area of the blades, but the power production also varies exponentially, by the power of three, with increases in wind velocity. So if the wind speed is doubled, or increased by a factor of 2, the potential power production increases by a factor of 8 [or 2 to the power of 3 (2^3)].

There are two basic types of towers: self-supporting and guyed. The towers can be either of monopole or lattice design. Guyed towers are the least expensive, but because of the guy wires, they require more area. Various configurations of tilt towers, either guyed or self-supporting also are available, but generally only for the lighter and smaller wind turbines of 10 kilowatts or less ([DOE 2012g](#)). The tilt towers allow the wind turbines to be easily brought down to ground level for maintenance or during hazardous weather conditions.

- **Balance-of-System Equipment** – Balance-of-system refers to additional equipment needed to condition the electricity produced by the wind turbine, to safely transmit it to the load, and, if desired, to store it for future use. The type of additional equipment needed primarily depends on whether the wind turbine is a stand-alone system or to be connected to the electrical grid.
 - **Stand-Alone System.** The simplest system would be one connected directly to the equipment using the power, and if a battery was needed for times the system was not operating, the balance-of-system equipment could be as simple as batteries and associated charge controller. If the wind turbine system was intended to power equipment or appliances in a home or other building, the balance-of-system equipment would be more complicated and likely would consist of batteries (or accumulators), charge controller, power conditioning equipment (including a converter), safety equipment, and meters and instrumentation ([DOE 2012h](#)) ([Figure 2-15](#)).

- Connected to the Grid. If the wind turbine system connected to the electrical grid, the balance-of-system equipment would include that necessary to safely accommodate the local loads and whatever was needed to comply with area power provider's grid requirements. The equipment would be similar to that described above for a home or building, and likely would involve equipment meeting certain manufacturing and installation specifications and codes to give the power provider assurance that neither the grid nor other clients would suffer any harm. Inclusion of batteries with a charge controller would be appropriate if that fit with the local needs ([DOE 2012h](#)).

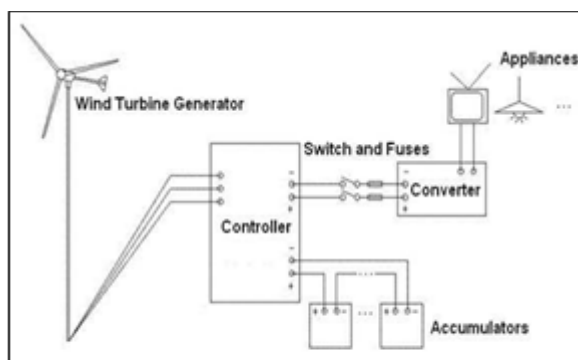

Figure 2-15. Stand-alone System Providing Power to a Home or Other Building

Vertical-axis wind turbines have many of the same components as described above for the horizontal axis variety with the following exceptions: The rotor and blades would be different, there would be no tail, and a vertical-axis turbine likely would have nothing resembling a housing positioned up in the air, but the necessary functions would still be there.

It should also be noted that entrepreneurs are pursuing alternative approaches to harnessing wind energy. For example, it is relatively easy to find websites describing various means of using tethered devices similar to kites, wind sails, or even rigid wing-like items to generate power from wind. Some of these devices may hold great promise as future distributed or even utility-scale energy producers; however, these devices are too early in development for this PEIS to address in any detail.

Small Wind Turbine Uses

Micro-turbines (20- to 500-watt machines) are often used for charging batteries for recreational vehicles or sailboats. Wind turbines in the range of 1 to 10 kilowatts are often used for dedicated uses such as pumping water. The average U.S. home uses about 10,000 kilowatt-hours of electricity per year, so a wind turbine capacity in the range of 5 to 15 kilowatts, depending on the average wind speed, would be needed to make a significant contribution to powering an average home ([DOE 2007](#)); smaller units would support some of the electrical demands. Wind turbines in the upper range of the small wind turbine category, such as 50- to 100-kilowatt machines, are considered too large for a single home, but could be used to support multiple homes or larger facilities such as public buildings, businesses, or industries. Such larger wind turbines, as well as any of the other sizes, can be connected to the area's electrical grid as long as the wind turbine system includes the appropriate power conditioning and safety equipment as part of its balance-of-system equipment and otherwise meets the local utility's connection requirements.

Provided the small wind turbine is located in proximity to the electrical grid and the utility's requirements for connection are not prohibitively expensive, connection to the grid presents an almost ideal situation for the small wind turbine owner. If the wind turbine does not generate enough energy to meet the owner's needs, the utility would provide the remainder; if the wind turbine generates more energy than the owner can use, the utility would buy the excess. Utilities are required to connect with and purchase power from small wind energy systems in accordance with the *Public Utility Regulatory Policies Act of 1978* ([16 U.S.C. § 2601](#)) ([DOE 2007](#)). If the utility allows net metering as the means to satisfy this requirement, the owner's electricity meter basically turns backwards when producing more energy than the owner uses. This means the wind system owner receives credit for electricity at the full retail rate for the energy generated; that is, the same price the owner pays when the wind turbine is not operating. In

Hawai‘i, the PUC has established a slightly different approach, termed feed-in tariffs. Under this program, standardized pricing, terms and conditions, and procedures are established that allow small renewable energy producers to easily enter into simple contracts with the utility that includes a pre-set level of compensation ([Hawai‘i PUC 2010](#)).

Utilities implement net metering programs differently, often with specific limits on the size of the power system that can be connected to the grid and limits on the amount of net metering allowed over a certain period of time. DOE tracks the various net metering programs across the United States as part of the Database of State Incentives for Renewables and Efficiency program, which can be found online at <http://www.dsireusa.org/>. Information in this database shows that all utilities in Hawai‘i offer net metering to wind systems, albeit the three investor-owned utilities (HECO, HELCO, and MECO) as well as the sole electric cooperative (KIUC) have slightly different programs ([NCSU 2012](#)).

Wind turbines considered “distributed renewables” often are deployed as small single units to produce energy for individual homes, farms, and small businesses. Although the category of small wind turbines is generally associated with this type of application, there would be no reason that a larger wind turbine, even into the megawatt range, could not be deployed in a manner consistent with a distributed energy source.

Locations for Small Wind Turbine Systems

Guidelines suggest wind turbines large enough to provide a significant portion of a single home’s energy demand require about 1 acre of property ([DOE 2007](#)) and, as indicated previously, the blade should have a 30-foot clearance above any obstacle within 300 feet of the tower. Local, county requirements specify that turbines be set back from the property line by a distance at least as great as the tower height. Manufactures and installers of small wind turbines generally recommend that a site have average wind speeds of at least 12 or 13 miles per hour at the hub height to be feasible ([AWEA 2013](#); [NEED 2012b](#)). According to the American Wind Energy Association, less than 1 percent of existing small wind turbines are located in urban settings. This is attributed to zoning issues and also to the poor wind quality associated with heavily built-up areas ([AWEA 2013](#)).

2.3.2.5.2 Characterization of Technology Feasibility and Deployment

Feasibility of Small Wind Resources Deployment by Island

[Figure 2-16](#) shows areas within Hawai‘i where small wind turbines may be appropriate based on average wind speeds at 30 meters, or about 100 feet, above the ground. It can be seen that the wind speed categories shown in the map are in units of meters per second. As a point of reference, 12 miles per hour, the minimum average wind speed for most small wind turbines, equates to 5.4 meters per second. Based on this conversion, the areas of the islands shown in green or yellow likely would not be appropriate for locating small wind turbines.

Characterization of Existing Deployment

[Table 2-10](#) shows existing small wind turbine projects identified by the Hawai‘i State Energy Office. As can be seen in the table, the wind turbine size planned for the Lalamilo Wind Farm Project, at 2 megawatts, is well over the size considered for the small wind turbine category. It is listed in the table because the intended use for this system is consistent with that of a distributed renewable project.

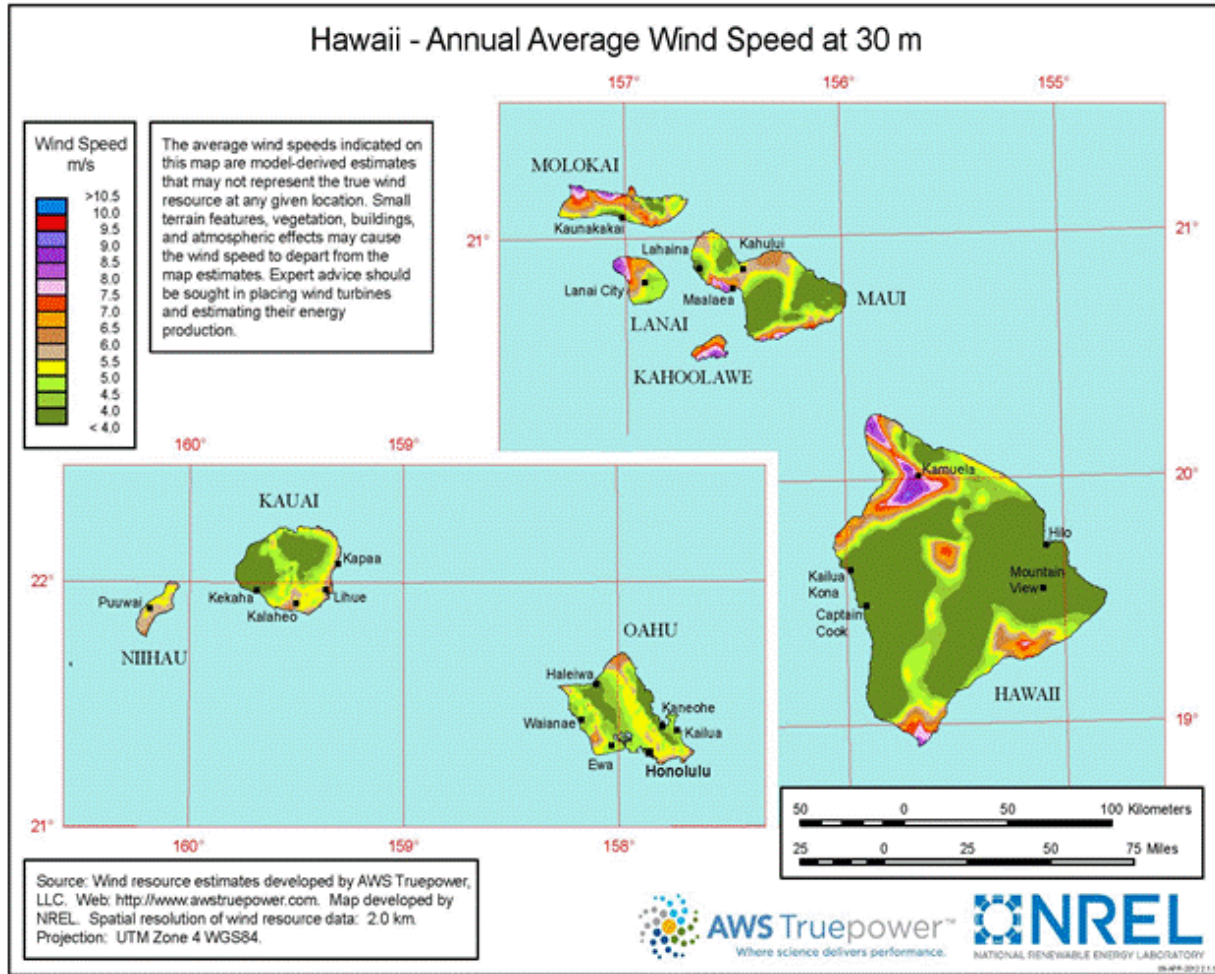

Figure 2-16. Average Wind Speeds at 30 Meters, or about 100 Feet, Above the Ground (wind speed in meters per second multiplied by 2.24 equals miles per hour) (Source: DOE 2012i)

2.3.2.5.3 Permitting and Consultation Requirements

In addition to the general permitting requirements discussed in [Section 2.2.5](#), there are several noteworthy requirements specific to wind projects. Those requirements associated with bird and bat species are included here since wind projects generally have a higher-than-average likelihood of impacting flying species compared with other renewable energy technologies.

- A USFWS Incidental Take Permit is required to conduct any activity that might incidentally *take* a terrestrial or freshwater aquatic species *listed* as a *threatened* or *endangered species* pursuant to ESA. With limited exceptions, USFWS will require the applicant for an Incidental Take Permit to submit a Habitat Conservation Plan to the USFWS.
- USFWS also implements the *Migratory Bird Treaty Act* (16 U.S.C. §§ 703-712) and the *Bald and Golden Eagle Protection Act* (16 U.S.C. §§ 668-668c). The unauthorized take of species protected under these statutes is prohibited. As such, the project proponent may need to discuss with USFWS necessary mitigation, minimization, or avoidance measures that would limit the risk of the project proponent violating the statutes. The project proponent may also need to obtain a permit under the applicable statute.

Table 2-10. Small Wind Turbine Projects

Project Name	Location	Wind Turbine Size	Status	Purpose/Description
Big Island Beef Community Wind Project	Paauilo, Hawai'i island	100 kW	Planning	Power the Big Island Beef facility.
Lalamilo Wind Farm Repowering Project	South Kohala, Hawai'i island	2 MW	Planning	County Department of Water Supply is seeking bids for a wind energy system large enough to supply power to four existing water wells.
Off-Grid Powered Agricultural Operation	Hawi, Hawai'i island	100 kW	Active	Power for a water pumping system for diversified agricultural operation. Partially funded by the DOE.
Waikoloa Water Community Wind Project	Waikoloa, Hawai'i island	100 kW	Active	Power for the Waikoloa water treatment facility.

kW = kilowatt; MW = megawatt.

a. Source: [Hawai'i 2013b](#).

- The State may require a Habitat Conservation Plan (HCP) and Incidental Take License (ITL). These permits are issued by the Hawai'i DNLR and are required in order to allow the incidental take of endangered or threatened species while carrying out an otherwise lawful activity.
- The project may require a "Notice of Proposed Construction or Alteration of Airspace" from the FAA for structures taller than 200 feet above the ground (this is higher than would be expected for small wind turbine systems) and within 20,000 feet of the nearest point of the nearest runway.
- It is worth noting that county zoning designations often carry height restrictions that would be applicable to wind turbines and, as identified previously, counties have established setback requirements for wind turbines.

Some unique challenges to permitting a distributed wind facility in Hawai'i include:

- ESA compliance and consultation for smaller wind facilities can be a significant portion of overall costs and may be too burdensome financially to pursue the project.
- Hawai'i's limited land areas often result in increased project visibility, particularly for wind projects. Thorough community outreach is needed in constructing a structure that can be seen from a distance at day and night (via red lights).
- Hawai'i's strong military presence warrants DoD consultation to determine if the wind project would be in or near military fly zones.
- Proximity to cultural, historic, and scenic resources, including National Parks; any NPS park units within the viewshed of the proposed wind resource development (and associated facilities and transmission corridors) should be consulted early in the planning process.

2.3.2.5.4 Representative Project

A representative small wind project for purposes of evaluation in this PEIS is assumed to consist of the construction and operation of a single 100-kilowatt wind turbine. It is further assumed that the turbine is a

horizontal-axis unit, with a 60-foot rotor diameter (that is, it has blade lengths of about 30 feet), and is mounted on a 120-foot monopole. Noise produced by the wind turbine is 55 dBA at a distance of 130 feet. Connection to the grid is a distance of 300 feet from the wind turbine.

A 100-kilowatt wind turbine is at the top of the range generally considered for the category of small wind turbines. Potential environmental impacts would be expected to decrease in a linear manner in some resource areas as the size of the wind turbine decreased. For example, noise production would be expected to decrease steadily with decreases in its rated power capacity. The tower height, however, can be independent of generator size, often being determined by such factors as zoning, wind characteristics, or surrounding terrain and obstacles. Other resource areas such as biological resources could have decreasing impacts with decreasing wind turbine size, but this would depend on the location and the types of wildlife involved. Impacts associated with land disturbance would likely decrease with wind turbine size, but not linearly because things like new access roads and power line installation would involve land disturbance amounts largely independent of the wind turbine size, and if the tower height did not change, there might be little, if any, change in land disturbance. Access roads and power line construction associated with wind turbines also would impact viewsheds.

2.3.3 UTILITY-SCALE RENEWABLES

Utility-scale renewable energy technologies are similar to distributed energy technologies but involve medium-to-large scale installations designed to generate larger amounts of electricity for distribution to an electrical grid for eventual distribution to multiple end users. The utility-scale technologies discussed in this section harness energy from renewable energy sources such as the sun, wind, falling water, the ocean, geothermal, and biomass, as well as waste-to-energy:

- Biomass
- Geothermal
- Hydroelectric
- Municipal Solid Waste
- Marine Hydrokinetic Energy
- Ocean Thermal Energy Conversion
- PV systems
- Solar Thermal
- Wind (land-based)
- Wind (offshore)

Representative projects were defined based on technology-specific capacity factors, uses, and feasibility in Hawai‘i. The description of each technology within Section 2.3.3 includes a discussion of the differences between nameplate capacity and actual capacity based on efficiency and the range of typical capacity factors for that technology. [Table 2-11](#) presents acre per megawatt estimates for surface disturbance using nameplate values for energy output associated with each technology. These estimates are based on the listed capacity factors, which are an important element. Higher capacity factors result in

Table 2-11. Estimated Acreage of Permanent Surface Disturbance for Utility-Scale Renewable Technologies for the Representative Project by Nameplate Capacity, Total Acreage, and per Megawatt

Utility-Scale Renewable Energy Technology	Nameplate Capacity (megawatts)	Total Permanent Surface Disturbance (acres)	Acreage of permanent surface disturbance per MW (ratio)	Notes
2.3.3.1 Biomass	10	5,100	510	<p>Type: Direct combustion steam boiler project Permanently disturbed land area: 12 to 16 acres including:</p> <ul style="list-style-type: none"> • 6 to 8 acres for boiler and turbine building; biomass handling and feed system, and any electrical transformer station; • 2 to 3 acres for landscaping acres and parking lots; • 2 to 5 acres for road access and utility services such as water and sewer. <p>Total permanently disturbed land: 10 to 16 acres. Land production area: 5,100 acres. Typical capacity factors range from 75 to 85 percent.</p>
	10	14,000 – 27,000	1,400 – 2,700	<p>Type: Biodiesel project Total permanently disturbed land: 10 to 16 acres in the same manner as for the direct combustion steam boiler facility. Land production area: 14,000 to 27,000 acres. Typical capacity factors range from 75 to 85 percent.</p>
2.3.3.2 Geothermal	25	58	2.3	<p>Exploration including slim holes or coring wells: 5 acres Drilling operations and utilization Total: 53 acres Total permanently disturbed land: 53 acres (excludes exploration phase) Typical capacity factors range from 75 to 95 percent.</p>
2.3.3.3 Hydroelectric	-	-	-	<i>No representative project</i>
2.3.3.4 Municipal Solid Waste (MSW)	5	10	2	<p>Permanently disturbed land for an MSW-to-energy direct combustion facility designed to produce 5 megawatts: 10 acres (Facility requires 165 tons of solid waste per day.) Typical capacity factors range from 75 to 85 percent.</p>
2.3.3.5 Marine Hydrokinetic Energy (MHK)	Various	-	-	<p>Representative project assumes no surface disturbance. Different generation capacities were given in Section 2.3.3.5 based on the type of MHK technology including 5 to 10 megawatts for facilities using overtopping devices and 0.5 megawatt for a shore-based facility using an oscillating water column. Typical capacity factors are uncertain due to developing nature of the technology but are estimated at about 25 percent.</p>

Table 2-11. Estimated Acreage of Permanent Surface Disturbance for Utility-Scale Renewable Technologies for the Representative Project by Nameplate Capacity, Total Acreage, and per Megawatt (continued)

Utility-Scale Renewable Energy Technology	Nameplate Capacity (megawatts)	Total Permanent Surface Disturbance (acres)	Acreage of permanent surface disturbance per (ratio)	Notes
2.3.3.6 Ocean Thermal Energy Conversion	50	-	-	Representative project assumes no surface disturbance. However, based on the platform size in the representative project, its surface area would be 83,200 square feet, or 1.9 acres. This would yield a permanent on-water “surface disturbance” ratio of: 1.9/50 = 0.04 . This figure does not include any other components associated with the technology. Typical capacity factors are uncertain due to developing nature of the technology but are estimated at about 25 percent.
2.3.3.7 Photovoltaic	50	250	5	Ratio refers to aerial extent of a 200,000-module array; General rule: 5 acres per megawatt Typical capacity factors range from 18 to 26 percent.
2.3.3.8 Solar Thermal	5	20 to 45	4 – 9	Ratio refers to aerial extent of the solar mirror array. According to NREL, a typical land parabolic trough plant would require between 6 and 10 acres of land per megawatt generation capacity (NREL 2013d). Typical capacity factor (without thermal storage) is about 25 percent.
2.3.3.9 Land-Based Wind	25	17.5	0.7	Ratio is based on the permanently disturbed land acreage figure of 17.5 acres stated in the description of the representative project. <ul style="list-style-type: none"> • Array size: Ten 2.5-megawatt turbines with 42.5 acres of temporarily disturbed land; • Land required for the entire project: 250 acres or 10 acres per megawatt. Typical capacity factors range from 19 to 50 percent.
2.3.3.10 Offshore Wind	50	-	-	Representative project assumes no surface disturbance. As described in the text, an array of ten 5-megawatt turbines, meaning the total affected surface area of the sea would be 3.9 square miles, or about 2,500 acres. This would yield a ratio of 2,500/50 = ~50. Typical capacity factors range from 26 to 55 percent.

Note: Capacity factors obtained from NREL website http://www.nrel.gov/analysis/tech_cap_factor.html.

a smaller potential footprint. As an example, if a land-based wind turbine installation had a 50 percent capacity factor instead of 25 percent, the number of turbines and affected land area would be cut in half. Chapter 6 discusses how the impacts would scale (for example, linearly, exponentially, or not at all) for the range of potential technology applications to allow the reader to understand the effects of smaller or larger projects and how impacts could change based on the size of the technology implemented.

2.3.3.1 Utility-Scale Biomass

2.3.3.1.1 Activity Description

Biomass energy sources for utility-scale projects are the same as those for distributed renewable energy projects (see [Section 2.3.2.1](#) of this PEIS). Some types of biomass resources are more or less suited for utility-scale projects and those limitations are discussed in this section. The cost-effective acquisition (i.e., collecting, processing, and transportation) of biomass resources is a key component to implementing a utility-scale biomass energy system. The *Hawaii Bioenergy Master Plan* provides a description of the policies, procedures, actions, and issues associated with developing a bioenergy program in the State of Hawaii ([HNEI 2009a](#)).

Biomass Production

Agricultural and forestry residues and dedicated energy crops and forests are well suited to utility-scale biomass electrical power and heat production. These biomass resources are distributed across the Hawaiian Islands. The islands of Kaua‘i, O‘ahu, Maui, and Hawai‘i all have established agricultural and forestry resources that could be used. Biomass resources on the islands of Molokai and Lāna‘i are less developed. Dedicated energy crops have not been developed extensively in Hawai‘i, although considerable research has been done. Development of utility-scale biomass energy projects would provide an opportunity to the bioenergy sector of the Hawai‘i agriculture and forestry industries. Recent estimates indicate about 136,000 acres of land could be available for developing biomass resources without competing with existing agricultural food production ([DBEDT 2013d](#)). Another potential source of biomass is from efforts to eradicate invasive plant species, such as albizia. Utility-scale biomass power production requires a reliable biomass resource to produce constant electricity. Energy crops have the potential to provide the long-term reliable biomass resource that agricultural and forestry residues may not be able to provide. One of the concerns with developing dedicated energy crops is the potential use of plant species that could escape cultivation and become invasive in undisturbed areas ([Buddenhagen et. al 2009](#); [Daehler et al. 2012](#)). The native flora and fauna of Hawai‘i have been greatly impacted by the introduction of invasive species. Hawai‘i has established a weed risk assessment system to screen and evaluate potential risks of particular species (<https://sites.google.com/site/weedriskassessment/home>). Nonnative energy crops should be thoroughly screened and evaluated prior to commercial production.

Animal waste has less potential as a biomass resource for utility-scale production of electricity. The cost-effective availability of animal waste (i.e., transportation cost) and competing uses (e.g., fertilizer and composted mulch) limits its potential. Components of urban waste streams such as grease waste, food waste, and sewage sludge have potential as biomass resources for utility-scale energy production but are limited to areas that have sufficient concentration of waste streams to make it cost effective. Municipal solid waste, because of its concentration in landfills, offers potential use as biomass fuel (either [solid waste](#) material or landfill gas production) for utility-scale projects (see [Section 2.3.3.4](#)).

Biomass Logistics

Biomass logistics includes two primary components: the transportation and delivery of the biomass from the point of origin to the point of use and the preparation of the biomass material for use in an energy conversion technology. As discussed in [Section 2.3.2.1](#), transportation of biomass material is more costly because the energy density is lower than fossil fuels, bio-oils, and biodiesel. However, each of the islands

in Hawai‘i is relatively small, and the transportation distances for biomass resources are even smaller when considering those island areas suitable for producing biomass material and locating potential power generation facilities. Intra-island transportation costs likely would not be prohibitive. Utility-scale biomass power generation projects, by virtue of their larger scale, would require a larger biomass resource produced over a larger area. As with distributed biomass production, the location of power production in relation to the biomass resource is an important consideration. Initial study of interisland marine transportation of liquid and bulk biofuels feedstock (pyrolysis oil versus bagasse) indicate that transportation of liquid feedstock is considerably cheaper. It should be noted that cost estimates for potentially cheaper open dry bulk barge transport of bagasse were not available ([HNEI 2012d](#)). In the near term, use of bulk biomass (agriculture and forestry products) for generation of electrical power most likely would be developed on an island-by-island basis using locally produced biomass.

The preparation of the biomass material includes receiving, processing, storing, and then feeding the biomass into the energy production facility (i.e., furnace/boiler or gasifier) ([EPA 2007](#); [Jorgenson et al. 2011](#)). Biomass handling and preparation for utility-scale power production is similar to that discussed for distributed biomass energy. The mass and volume of biomass handled and processed for utility-scale power production would be significantly larger. However, in many cases, the biomass could be prepared (e.g., ground, chipped, dried, and sorted) offsite as part of the biomass production process and delivered to the power plant as a finished product. Onsite handling of biomass would then be limited to storage and furnace/boiler feeding systems.

2.3.3.1.2 Characterization of Technology Feasibility and Deployment

The energy conversion technologies available to utility-scale production of biomass energy are the same as those for distributed energy applications: combustion, pyrolysis, gasification, and anaerobic digestion. A description of these technologies is given in [Section 2.3.2.1](#). The following sections discuss application of each of these technologies to utility-scale biomass energy production. One primary difference between utility-scale and distributed renewable energy with respect to biomass is distributed applications typically are installed in close proximity to where the electrical power or heat is being used. Because energy from utility-scale facilities is distributed through power grids, energy production facilities may face a tradeoff between locating near a biomass resource or a power distribution grid.

Combustion (direct- or co-fired)

Combustion technology (burning of biomass material) to produce steam to generate electricity or industrial and commercial heat is a well-developed technology and has a long history in Hawai‘i ([Khanal et al. 2009](#)). The technology is well suited to utility-scale production of energy and is similar to steam turbine generators that use coal, natural gas, and diesel fuel technology. Combustion technology is scalable by using different sized steam boilers and turbines and can be sized to match the available biomass. Because of the island geography of Hawai‘i, utility-scale implementation of biomass combustion technology is most feasible on an island-by-island basis because of the interisland transportation cost of unprocessed biomass material ([HNEI 2012d](#)). Agricultural and forest residues, energy crops, and municipal solid waste are potential biomass sources that could support utility-scale production of electricity and heat. The technology has been deployed on the islands using crop residues from the sugar industry. Increased production of dedicated energy crops could support increased development of utility-scale projects. Currently, several utility-scale biomass power projects are in different stages of planning and development ([HECO 2013c](#); [KIUC 2013](#)).

Pyrolysis

Pyrolysis is a thermochemical process that converts biomass material such as crop and forest products into bio-oils which can then be used in combustion turbines or steam-cycle generators to produce electricity and heat. In boiler systems, bio-oils do not provide significant energy advantages over direct

combustion of the biomass material because any increased efficiency is offset by the energy to produce the bio-oil ([Khanal et al. 2009](#)). The potential advantage of bio-oils in utility-scale steam boilers lies in the greater energy density (energy/unit volume) compared with the unprocessed biomass material. Bio-oils may create a means to more cheaply transport biomass energy between islands or to a centrally located power plant by first converting the less energy dense biomass material and then transporting the more energy dense bio-oil ([HNEI 2012d](#); [Khanal et al. 2009](#)). While technically feasible, production of bio-oils by pyrolysis and use as fuel for utility-scale generation of electricity has not been widely implemented.

Gasification

Gasification is a thermochemical conversion process for biomass materials that produces gas products rather than the liquid bio-oils produced by pyrolysis. The gases produced can then be combusted in a combustion gas turbine or traditional gas-fired steam boiler to produce electricity and heat. This technology is suited to utility-scale power production, probably more than for distributed energy applications because of investment in technology. While still an emerging technology for commercial energy production, one integrated biomass gasification and steam-cycle turbine project to produce electricity is planned on O‘ahu ([HECO 2013d](#)).

Transesterification

Transesterification is a chemical conversion process that is used to convert plant oils and animal fats into a biodiesel fuel (methyl esters) that have properties similar to petroleum diesel fuel. The chemical process reacts the oils with methanol using a catalyst (e.g., sodium hydroxide) at temperatures (~50°C) much lower than those used in the pyrolysis or gasification processes ([Berchmans and Hirata 2008](#)). The biodiesel produced can be used as a partial (blended mix) or complete substitute for petroleum diesel fuel in steam boiler systems or combustion engines to generate electricity.

Anaerobic Digestion

Anaerobic digestion is a biological process in which microorganisms degrade biomass materials into gaseous fuel (i.e., biogas), especially methane gas, in an oxygen-free environment. As discussed in [Section 2.3.2.1.2](#), biogas can be produced either through specially designed anaerobic digesters or under natural anaerobic conditions in closed landfills. Biogas has been traditionally used in steam boilers to produce electricity but also can be used in combustion gas turbines and engine generators ([Khanal et al. 2009](#)). Biogas is a suitable utility-scale technology that was been implemented at the Kapaa landfill on O‘ahu. However, that project was shut down in 2002 because of problems with the combustion turbine. See [Section 2.3.3.4](#) for a discussion of municipal solid waste and landfill gas. Anaerobic digesters have been used in the past for distributed renewable energy but all have been decommissioned. Future use of digesters for utility-scale energy production may depend on the cost-effective acquisition of sufficient waste streams such as animal waste, food waste, sewage sludge, and possibly green silage produced from crops. However, these waste streams have competing uses such as fertilizer, animal feed, and other biomass energy technologies and may not be economically viable for production of biogas, at least for utility-scale power production.

2.3.3.1.3 Permitting and Consultation Requirements

As discussed in [Section 2.2.5](#), the number of permits required for a biomass energy project can vary depending on the scope of the project, the anticipated environmental and social impacts, and location within certain zoning districts or special management areas ([Siah and Zapka 2009a](#)). The number of required permits, uncertainty regarding approval or denial of important permits, and potential lengthy appeal processes may impact the implementation of biomass energy projects. The *Hawaii Bioenergy Master Plan* provides a review of potentially applicable laws, permits, and permitting issues with respect to the biomass energy industry in Hawai‘i ([Siah and Zapka 2009a](#)).

Technology-specific permitting and consultation requirements for a biomass energy project need to consider not only the construction and operation of an energy conversion facility such as a power plant or gasification facility, but also the feedstock production component and bioenergy distribution system. Permits required for the production and collection of common biomass feedstock such as agricultural residues, crops, forest and mill residues, and municipal waste should be in place as part of existing production operations. However, additional permitting may be required for the handling and transportation of feedstock such as municipal solid waste or animal waste. The development of new feedstock production operations or the expansion of existing operations may require new permits or modification of existing permits.

2.3.3.1.4 Representative Projects

To illustrate potential utility-scale renewable biomass projects that could be developed in Hawai‘i for the generation of electricity and heat, two representative biomass energy projects are described in the following sections. These representative projects were selected to provide a perspective of the potential environmental impacts that could be expected from utility-scale biomass projects. Because of the diversity of biomass resources and potential energy conversion technologies, a variety of different types of biomass projects are possible but generally involve using the biomass as a solid (direct combustion), converting it to a liquid (bio-oils and biodiesel), or producing a gas fuel (gasification and anaerobic digestion). For the purposes of evaluating potential environmental impacts, it was assumed that the biomass was produced specifically for the electrical energy project. Therefore, potential impacts from the biomass production process are explicitly considered part of the project. These representative projects are hypothetical and are not intended to reflect actual or planned proposals at any specific location but include a range of project types that are similar to biomass energy projects being planned or could be developed on the islands. The potential environmental impacts of these types of utility-scale renewable biomass energy projects are discussed in Chapter 6.

Direct Combustion Biomass Fueled Steam Turbine Generator

The direct combustion of biomass in a steam boiler to produce steam for electricity generation and industrial process steam is a proven technology and one that has been used on the islands for many years. Although designed as a distributed renewable application, the HC&S Company on Maui generates electrical power to operate its mills, irrigation pumps, wells, and facilities using bagasse in a steam generator system. HC&S sells excess power to the Maui Electric Company. Similar technology could be implemented in utility-scale projects using a variety of biomass resources that are locally available as crop or forestry residues or from dedicated energy crops.

Table 2-12. Biomass Steam Boiler Electricity Generation

Power Plant Specifications	
Production Capacity	10 megawatts
Capacity Factor	80%
Energy Efficiency	25%
Megawatt-hours per year	70,080
Construction Area (acres)	6 – 8
Construction Crew (18 months)	250
Operations Crew	25
Biomass	
Biomass Supply Chain jobs	30 – 40
Sugar cane (50% moisture, 3% ash)	
Annual Requirement (tons)	118,200
Land Production Area (acres)	3,340
Ash Produced (tons)	3,540
Wood (25% moisture, 1% ash)	
Annual Requirement (tons)	74,940
Land Production Area (acres)	5,100
Ash Produced (tons)	740

The representative project would use a typical direct combustion biomass steam generating station built for utility-scale applications to produce 10 megawatts of electricity ([Table 2-12](#)). The steam boiler unit(s) would use a fibrous biomass source such as sugar cane, banagrass, or wood from dedicated crops or

forests. The representative project assumes local sources (i.e., less than 10 miles from the generating site) would supply the biomass feedstock to minimize transportation costs.

Biomass fuels such as bagasse, wood, straws, and nut shells all have essentially the same gross calorific value on a moisture- and ash-free basis, about 20 mega Joules per kilogram ([Kaupp 2013](#); [Turn et al. 2005](#)). On an energy basis, 1 kilowatt-hour is equivalent to 3.6 mega Joules. However, biomass steam generator systems are only 20 to 35 percent efficient ([Aabakken 2006](#); [McHale & Associates 2010](#)). Therefore, generating 1 kilowatt-hour of electricity at 25 percent efficiency would require 14.4 mega Joules of moisture- and ash-free biomass (i.e., 3.6 mega Joules divided by 25-percent efficiency equals 14.4 mega Joules, the equivalent of 1 kilowatt-hour). Although biomass materials have similar calorific values on a moisture- and ash-free basis, the moisture and ash content varies among different types of biomass. Higher moisture and ash content reduce the heating value. Therefore, the representative project looks at two cases when calculating the amount of biomass needed to operate a 10-megawatt biomass steam generator project and the land area needed to produce the biomass: sugar cane and wood chips. Estimating the amount of land required for either the sugar cane or wood chips requires dividing the weight of biomass fuel required by the average biomass produced per acre (see below).

The first case assumes use of energy cane (sugar cane grown for biomass), which would be fired at 50 percent moisture with 3 percent ash content. Thus, approximately 1,500 kilograms (1.7 tons) of processed sugar cane would need to be fired to produce each megawatt-hour of electricity. The biomass steam generator would provide baseload electricity with a capacity factor of 80 percent, or about 70,000 megawatt-hours of electricity per year ([Aabakken 2006](#)). This translates to an annual requirement of about 120,000 tons per year of processed cane material to operate the 10-megawatt plant.

Land required for sugar production is based on cane production at about 82 tons per acre (average for years 2010-2012) per 2 years (24-month harvest cycle), or 41 tons per acre per year ([NASS 2013](#)). The representative project assumes that energy cane would be harvested annually with some loss during processing but with fuel characteristics of bagasse. The project further assumed a production value of 35 tons per acre. Production of the 120,000 tons of processed cane biomass for the 10-megawatt plant would require about 3,300 acres of sugar cane.

The second case assumes that wood chips from dedicated eucalyptus forest plantations would fire the biomass steam generator at 25 percent moisture and 1 percent ash. Approximately 970 kilograms (1.1 tons) of wood chips would need to be fired to produce each megawatt-hour of electricity. At 80-percent capacity, or about 70,000 megawatt-hours, operation of the 10-megawatt plant would require about 75,000 tons of wood chips per year.

Wood production from dedicated biomass forests varies based on harvest rotation length, species mix, planting density, and fertilization rate ([Whitesell et al. 1992](#)). The representative project assumes a single-species (*Eucalyptus saligna*) forest with a 6-year harvest rotation and a production rate of 66 tons of dry biomass per acre ([Whitesell et al. 1992](#), Table 11). Because the wood chips are fired at 25 percent moisture, the production per acre would be 88 tons per acre including the moisture. Production of the required 75,000 tons of wood chips would require harvesting approximately 850 acres of forestland each year. However, because of the 6-year harvest rotation (i.e., 850 acres multiplied by 6 years), maintaining a sustainable annual harvest would require about 5,100 acres of dedicated forestland. The estimated acreage assumes all harvested wood biomass is used for biomass fuel. In a forest production system, some logs could be marketed for timber rather than used for biomass fuel; this would require an increase in the acreage required for biomass production. Approximately 50,000 acres of forest land has been planted for the management and natural regeneration of tree species for the purpose of possible harvest (<http://www.Hawai'iForestInstitute.org/Hawai'i-forests/healthy-and-productive-forests-campaign/healthy-and-productive-forests-campaign-fact-sheet/>).

Biomass energy crops differ from the use of agriculture or forest residues in that the biomass production is part of the biomass energy production system. Potential environmental impacts of producing the dedicated energy crops should be considered along with other potential impacts of biomass energy production. In addition to acres of arable land, biomass crops may require varying amounts of irrigation water, fertilizers, herbicides, and pesticides. Sugar cane requires about 50 to 70 inches of annual precipitation for optimal growth and typically requires supplemental irrigation because either total annual precipitation or seasonal precipitation is insufficient (http://www.sugarcancrops.com/agronomic_practices/irrigation_water_management/) (Khanal et al. 2009). Annual water requirements are about 180,000 to 250,000 cubic feet per acre, part of which is met with naturally occurring precipitation. The amount of irrigation water needed varies across the islands by location (i.e., windward versus leeward) and season (summer versus winter) (Fares 2008). Sugar cane is drip irrigated in Hawai‘i, allowing more efficient control over the amount of water that needs to be applied. The representative project assumes no irrigation for the production of the wood chips.

Sugar cane has relatively high fertilizer requirements for nitrogen (about 200 pounds per acre) and potassium (about 200 pounds per acre) and significant requirements for phosphorus (about 50 to 250 pounds per acre). Weeds are controlled through applications of pre-emergent herbicides and inter-row herbicides prior to canopy closure. Fertilizer for improving forest production is primarily nitrogen. Studies indicate that approximately 300 to 400 pounds of nitrogen per acre should be applied over a 4 to 5 year growing period for pure stands of eucalyptus (Whitesell et al. 1992). Nitrogen fertilizer requirements can be reduced by inter-planting nitrogen-fixing trees, such as albizia, with eucalyptus (Whitesell et al. 1992; Binkley et al. 1992). However, albizia is considered an invasive species in Hawai‘i and out-competes native ‘ohi‘a trees.

Construction of a utility-scale biomass-fueled steam turbine generating plant would require clearing, grading and leveling an area of about 6 to 8 acres for the boiler and turbine building, biomass handling and feed system, possibly an electrical transformer station, and construction space. On final grading, approximately 2 to 3 acres maybe landscaped or used for worker parking lots. Construction would require approximately 250 workers for about 18 months. Operations would require about 25 employees. The energy facility would be near existing biomass sources (0 to 10 miles) such as agricultural fields or forests. Biomass production operations would require an additional 35 workers in agriculture or forestry type jobs. Road access and utility services such as water and sewer would require extension into the power plant and require disturbance of approximately 2 to 5 acres of land. Aboveground electrical distribution lines would be constructed to connect the power plant to the local electrical grid. Approximately one mile of high voltage distribution would be required.

The buildings would be 30 feet tall with an emission stack height of approximately 80 feet. The steam boilers would produce air emissions with nitrogen oxides, particulate matter, carbon monoxide, and sulfur dioxide. Ash waste would be produced from biomass combustion, and ash handling facilities would be integrated into the generating station. It is assumed that ash waste would be used on nearby agricultural fields or forest plantations as fertilizer with small quantities disposed of in a landfill. Industrial noise would be produced from truck deliveries of biomass, operation of the biomass handling facilities, and removal of ash waste. Noise from the steam boilers and turbines would be mostly contained within the buildings.

Biodiesel Plant and Electric Power Plant

Another approach to generating electricity would be to produce biodiesel from oil crops, which is then used as fuel in a power plant. A representative biodiesel energy system would comprise an oil crop production system, a facility to extract and process the plant oils into biodiesel, and an electrical power plant. The power plant would be a 10-megawatt-capacity facility that could use either diesel combustion engines or biodiesel-fired steam boilers to generate electricity (Table 2-13).

Table 2-13. Biodiesel Production Plant and Electrical Power Plant

Biodiesel Production Facility	
Production Capacity (gallons/day)	30,000
Construction Area (acres)	6 – 8
Construction Crew (12 to 18 months)	150 to 200
Operations Crew	20
Power Plant Specifications	
Production Capacity	10 megawatt
Capacity Factor	80%
Energy Efficiency	25%
Megawatt-hours per year	70,080
Construction Area (acres)	6 – 8
Construction Crew (18 months)	200
Operations Crew	20
Biodiesel Fuel (125 MJ/gallon)	
Biomass Supply Chain jobs	25 – 30
Annual Requirement (gallons/year)	8 million
Land Production Area (acres)	14,000 – 27,000

A variety of plant species have been identified as potential crops for oil production in Hawai‘i such as soybean, flax, rapeseed, African oil palm, and Jatropha tree ([Poteet 2006](#)). Most of the species identified as potential oil crops are species not native to Hawai‘i. Because Hawai‘i’s native flora has been greatly impacted by the introduction of invasive nonnative species, the use of any introduced plant for oil crop production would have to be carefully evaluated prior to cultivation. This PEIS assumes an oil crop production system with Jatropha trees. The Jatropha tree is a small tree with a shrubby growth form that produces an oil-rich seed (43 to 59 percent) ([Poteet 2006](#)). The Jatropha tree grows under a variety of conditions, being tolerant of high temperatures, drought, poor soils, and varied pH levels. Growing Jatropha trees under moist conditions (natural or irrigation) could allow more than one seed crop per year. The selection of Jatropha tree as an example of an oil crop in this PEIS is only for illustrative purposes. A specific plant species was selected to allow estimation of the amount of land area that may be needed to produce biodiesel and the potential environmental impacts that could occur.

On an energy basis, 1 kilowatt-hour is equivalent to 3.6 mega Joules. However, biomass conversion systems are only 20 to 35 percent efficient ([Aabakken 2006](#); [McHale & Associates 2010](#)). Therefore, generating 1 kilowatt-hour of electricity at 25 percent efficiency would require 14.4 mega Joules or 14,400 mega Joules per 1 megawatt-hour of electricity production. A 10-megawatt electrical power plant operating at 80 percent of annual capacity would produce approximately 70,000 megawatt-hours of electricity per year. Biodiesel produced from Jatropha seed oil has an energy value of approximately 125 mega Joules per gallon ([Prueksakorn and Gheewala 2006](#)). Therefore, the 10-megawatt power plant would need approximately 8 million gallons of biodiesel per year.

The production of oil per acre from the Jatropha tree varies based on the growing conditions. Jatropha trees are capable of growing in low rainfall areas and would be adaptable to the leeward side of the islands and in lower-quality soils. However, production increases (through multiple seed crops per year) with higher amounts of precipitation or supplemental irrigation. [Poteet \(2006\)](#) used a production value of 300 gallons of oil per acre from one Jatropha seed crop per year. To produce the 8 million gallons of biodiesel, approximately 27,000 acres of land would be needed assuming one seed crop but could be reduced to about 14,000 acres if the production location had higher annual precipitation or agronomic practices were adopted that would increase production to two seed crops per year. Some inputs of fertilizers and supplemental irrigation would be anticipated but the amounts are uncertain based on the

site conditions. *Jatropha* grows well with 35 to 50 inches of annual precipitation ([Prueksakorn and Gheewala 2006](#)). Because some arable lands in Hawai‘i receive about 20 inches of precipitation, it was assumed that on average about 20 inches of supplemental irrigation would be applied. The oil extraction process produces a seedcake that could be returned to the fields as a fertilizer and reduce the input of inorganic fertilizers. However, water and fertilizer inputs are likely to be less for other energy crops such as sugar cane or banagrass. Some inputs of herbicides and pesticides are possible depending on the agronomic conditions.

The development of a biodiesel production system would require an industrial facility for extraction of the seed oil and processing of the oil (transesterification) into biodiesel. Storage tanks and bulk liquid handling facilities would be included. Construction of the biodiesel production facility would require approximately 6 to 8 acres. Construction would require 150 to 200 workers for approximately 12 to 18 months. The facility would require road access, electrical, sewer, water, and communications utilities. If the biodiesel production facility and the power plant were not co-located, tanker truck transportation would be required to transport the biodiesel from the production facility to the power plant. Assuming the use of 7,500-gallon tanker trucks, approximately 1,066 deliveries would be required to transfer the biodiesel from production plant to power plant.

Construction of a 10-megawatt generating plant would require clearing, grading, and leveling an area of about 6 to 8 acres. On final grading, approximately 2 to 3 acres may be landscaped or used for worker parking lots. Construction would require approximately 250 workers for about 18 months. Operations would require about 25 employees. Road access and utility services such as water and sewer would require extension into the power plant and require disturbance of approximately 2 to 5 acres of land. Aboveground electrical distribution lines would be constructed to connect the power plant to the local electrical grid. Approximately one mile of high voltage distribution line would be required. The power plant would produce air emissions with nitrogen oxides, particulate matter, carbon monoxide, and sulfur dioxide.

2.3.3.2 Geothermal

2.3.3.2.1 Technology Description

[Geothermal energy](#) recovery systems use heat from the earth. Heat radiates from the center of the earth where temperatures are greater than 7,200°F (greater than 4,000°C) ([Green and Nix 2006](#)) and often compared to temperatures on the sun’s surface ([GEA 2012](#)), which is about 10,000°F. This radiating heat, which is maintained by the constant decay of radioactive particles ([EIA 2012b](#)), equates to an estimated 42 million megawatts of power flowing from the earth’s interior ([GEA 2012](#)). It results in a gradient of increasing temperature with depth that is often referred to as the geothermal gradient, which averages about 13.7° to 16.5°F per 1,000 feet in the upper 30,000 feet of the earth’s crust ([Dickson and Fanelli 2004](#)). In some areas, geothermal gradients are lower and in some instances, such as Hawai‘i, gradients are controlled by unique and localized conditions. In Hawai‘i, it is common for geothermal resources to be constrained by igneous (volcanic) dikes and cooling water from infiltrating precipitation and the nearby ocean. As a result, shallow geothermal gradients are often not present despite the geothermal resource. In general, however, the geothermal gradient can be more than 10 times the average value over large areas of the earth’s surface. This is particularly the case in areas along the margins of the earth’s tectonic plates where the crust is constantly (on a geologic timescale) shifting and characterized by densely fractured zones, a large number of volcanoes, the ascent of very hot magmatic materials toward the surface, such as in Hawai‘i, and high heat flow. In general, these are areas of important geothermal resources and often the location of natural geothermal systems, which consist of a heat source, a reservoir of hot, permeable rocks, and a fluid to transfer the heat.

Natural geothermal systems can be in the form of hot water or steam reservoirs that are deep in the earth and accessed by drilling, or they can be in geothermal reservoirs located near the earth's surface. In the United States, geothermal reservoirs near the earth's surface are limited to the western states, including Alaska and Hawai'i. Geothermal systems are often characterized by their temperature. For example, the U.S. Geological Survey classifies geothermal systems as follows: low temperature [less than 90°C (194°F)], moderate temperature [90° to 150°C (194° to 302°F)], or high temperature [greater than 150°C (302°F)] ([USGS 2008](#)). Often, systems are simply classified as high temperature [above 150°C (302°F)] or low temperature [below 150°C (302°F)] ([NREL 2012b](#)). On a large scale, these geothermal systems can be used directly for heating buildings or in industrial processes, or they can be used to generate electricity. Because it is difficult to transport heat over any large distance, both direct use and electricity production must take place at, or very near, the geothermal system. Once converted to electricity, the energy can be transported great distances over transmission lines.

Geothermal energy projects generally begin with exploration to find the areas with high potential for geothermal resource development. This is followed by drilling into the reservoir and performing tests to determine if the reservoir has the appropriate characteristics to support development. The success or failure of each step determines the nature of the next step or if the next step is even taken. Exploration includes analyzing existing data (for example, aerial and satellite imagery, geologic surveys, and geologic mapping); conducting geophysical, geochemical, and seismic surveys; drilling temperature gradient wells; and using other means to determine where the higher-temperature gradients may occur. The specific exploration actions vary by site. For example, in Hawai'i where temperature gradients are often not present at shallow depths, slim-hole drilling is used to reach greater depths and collect subsurface materials, such as cores, and data from down-hole instrument surveys. Drilling performed during exploration is usually done with relatively small truck-mounted rigs that can go to depths of more than 4,000 feet. These drill holes are not intended to reach the geothermal reservoir, are not large enough for use in producing geothermal fluids if a developable resource is identified, and the rigs do not require construction of a drill pad. The rigs and other equipment, however, do require road access in most instances and, depending on the areas to be drilled or surveyed, may require construction of temporary access roads and the drill sites may require clearing and leveling. Drilling muds and additives are used in drilling temperature gradient wells and slim holes, and sumps and tanker trucks are generally used to capture the fluids ([BLM and USFS 2008](#)).

Drilling to the geothermal reservoir is a more significant undertaking and requires larger drill rigs that need constructed pads for operations. Once the reservoir is reached, operations include flow testing, producing and evaluating geothermal fluids, and possibly injecting fluids into the reservoir. These activities require construction of sumps and pits to hold fluids and sludges as well as development of the necessary infrastructure to support the testing. If a viable geothermal reservoir is determined through this testing, then the site is further developed for commercial operations. This includes construction of more permanent access roads and infrastructure; drilling and developing well fields; and building power production facilities, substations, and transmission lines ([BLM and USFS 2008](#)).

More detail on the general actions involved in developing a geothermal resource can be found in the Bureau of Land Management's and the U.S. Forest Service's *Final Programmatic Environmental Impact Statement for Geothermal Leasing in the Western United States* ([BLM and USFS 2008](#)). [Table 2-14](#), taken from this same document, provides estimates of the typical amount of land disturbance associated with development of a geothermal resource. As indicated in the table and as would be expected, the amount of disturbance can vary greatly depending on site conditions and the nature and size of the development. Much of the land disturbed during exploration and even some of that disturbed during large-scale drilling and facility construction would be reclaimed after those initial actions, so the amount of land dedicated to the facility during long-term operations would be less than that shown in the table ([BLM and USFS 2008](#)). For example, the Puna Geothermal Venture on Hawai'i island is a well-

established geothermal power production facility, and the total amount of property not revegetated is less than 50 acres.

Table 2-14. Typical Land Disturbances Associated with Geothermal Resource Development
(Source: BLM and USFS 2008)

Development Phase and Activity	Disturbance Estimate per Plant
Exploration	2 – 7 acres
Geologic mapping	Negligible
Geophysical surveys	30 square feet ^a
Gravity and magnetic surveys	Negligible
Seismic surveys	Negligible
Resistivity surveys	Negligible
Shallow temperature measurements	Negligible
Road/access construction	1 – 6 acres
Temperature gradient wells	1 acre ^b
Drilling Operations and Utilization	51 – 350 acres
Drilling and well field development	5 – 50 acres ^c
Road improvement/construction	4 – 32 acres ^d
Power plant construction	15 – 25 acres ^e
Installing well-field equipment including pipelines	5 – 20 acres ^f
Installing transmission lines	24 – 240 acres ^g
Well work-overs, repairs, and maintenance	Negligible ^h
TOTAL	53 – 367 acres

- Calculated assuming 10 soil gas samples, at a disturbance of less than 3 square feet each.
- Calculated assuming area of disturbance of 0.05 to 0.25 acre per well and six wells. Estimate is representative average disturbance of all well sites. Some wells may require a small footprint (for example, 30×30 feet), while others may require larger rigs and pads (for example, 150×150 feet).
- Size of the well pad varies greatly based on the site-specific conditions. Based on a literature review, well pads range from 0.7 acres up to 5 acres. Generally a 30 to 50 megawatt power plant requires about five to 10 well pads to support 10 to 25 production wells and five to 10 injection wells. Multiple wells may be located on a single well pad.
- One-half (½) mile to 9 miles; assumes about one-quarter mile of road per well. Estimates 30-foot wide surface disturbance for an 18- to 20-foot road surface, including cut and fill slopes and ditches.
- 30-megawatt plant disturbs approximately 15 acres; 50 megawatt plant disturbs approximately 25 acres.
- Pipelines between well pad to plant assumed to be one-quarter mile or less; for a total of 1½ to 7 miles of pipeline in length, with a 25-foot corridor.
- Five to 50 miles long, 40-foot-wide corridor.
- Disturbance would be limited to previously disturbed areas around the well(s).

For purposes of this PEIS, DOE assumes that any sizeable, future geothermal resource development in Hawai‘i would be for the purpose of generating electricity or hydrogen (see [Section 2.3.4.4](#)). To a large extent, the nature of the geothermal system, including the physical state of the fluid and its temperature, dictates the type of geothermal plant that would be feasible for converting the geothermal energy to electricity. Geothermal power plants are variations or combinations of three types of power plants:

Dry Steam. Dry steam power plants draw from a steam reservoir and the steam is piped directly to a turbine/generator unit. There are only two known underground resources of steam in the United States: The Geysers in California and Yellowstone National Park. Since Yellowstone is protected, The Geysers represents the only system of dry steam plants in the country. In 2012, geothermal power plants in the United States had an installed capacity of about 3,200 megawatts; approximately 1,590 megawatts of which was attributed to dry steam plants, all in California ([GEA 2012](#)).

[Figure 2-17](#) is a simplified schematic of a dry steam power plant. Steam directed through the turbine causes its blades and shaft to spin, which in turn spins the attached generator producing electricity. Discharge from the turbine is cooled and condensed before being injected back to the geothermal

Figure 2-17. Simplified Schematic of a Dry Steam Geothermal Power Plant (Source: CGS 2012)

Important considerations for a dry steam power plant are the types and concentrations of any naturally occurring gases or minerals in the steam produced by the geothermal reservoir. Geothermal fluids (steam or hot water) generally contain gases, such as carbon dioxide, hydrogen sulfide, and methane as well as dissolved minerals, such as sodium chloride, boron, arsenic, and mercury (Dickson and Fanelli 2004). Concentrations of the dissolved constituents usually increase with the temperature of the reservoir. Since the condenser cooling system associated with a dry steam power plant is an open system, and the gases do not condense at standard temperature and pressure, there is the potential for these materials to be released to the environment. The gases can leave with the cooling air and the minerals can leave in any small water particles carried out by the air. Depending on the concentrations of these gases and minerals in the extracted steam, additional [air pollution](#) control equipment may be required.

Flash Steam. Flash steam power plants (Figure 2-18) are the most common types of geothermal plants worldwide and use geothermal reservoirs of water with high temperatures (NREL 2012b). The water, which must be under pressure to remain liquid at the temperatures involved, flows up through wells and a portion boils into steam as pressure decreases. The steam is separated from the water and used to power a turbine/generator unit. Separated water and condensed steam are generally injected back into the reservoir; however, as shown in the figure, the separated wastewater has elevated temperature and could be put to other uses. In 2012, flash steam power plants comprised about 900 megawatts of the 3,200 megawatts of installed geothermal capacity in the United States (GEA 2012).

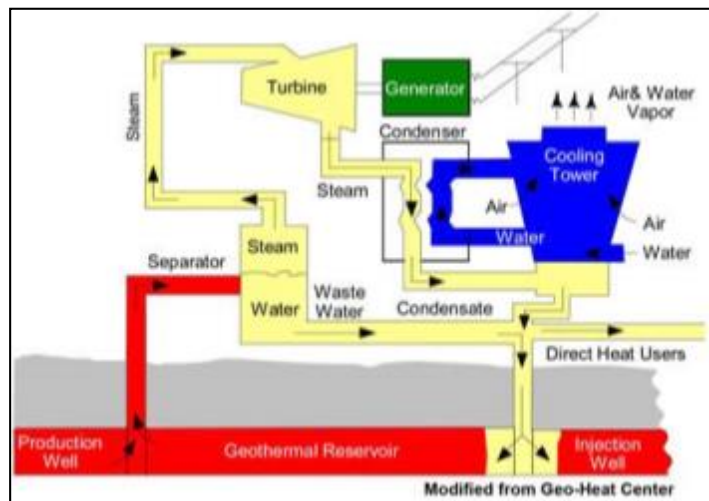

Figure 2-18. Simplified Schematic of a Flash Steam Geothermal Power Plant (Source: CGS 2012)

As with a dry steam plant, when the exhaust steam from the flash steam turbine is condensed, any noncondensable gases that

were originally in the geothermal fluid must be vented, directed to air pollution control equipment (depending on their concentrations), or collected for reinjection with the geothermal fluid going back to the reservoir.

Figure 2-19. Simplified Schematic of a Binary Cycle Geothermal Power Plant (Source: CGS 2012)

Binary Cycle. The development of binary cycle power plants has made it possible to produce electricity from water reservoirs of only moderate temperatures, with current binary plants generally working with geothermal fluids of temperatures of about 225° to 360°F (NREL 2012b). In a binary power plant (Figure 2-19), the hot water is piped to a heat exchanger and its heat is transferred to a working fluid with a low boiling point (usually an organic compound such as isobutane or n-pentane), causing the working fluid to boil. The working fluid vapor is used to power a turbine/generator unit. Both the working fluid and the geothermal water basically are in closed loops (though minor leakage may occur); the working fluid stays in the powerhouse

and the geothermal water is injected back into the subsurface reservoir. Since the working fluid is a pure material, there are no noncondensable gases that need venting during the cycle. Correspondingly, the condenser's cooling system fluid, which can be either air, as shown in the figure, or water, does not come into contact with the working fluid. In 2012, binary power plants made up about 700 megawatts of the installed geothermal capacity in the United States (GEA 2012).

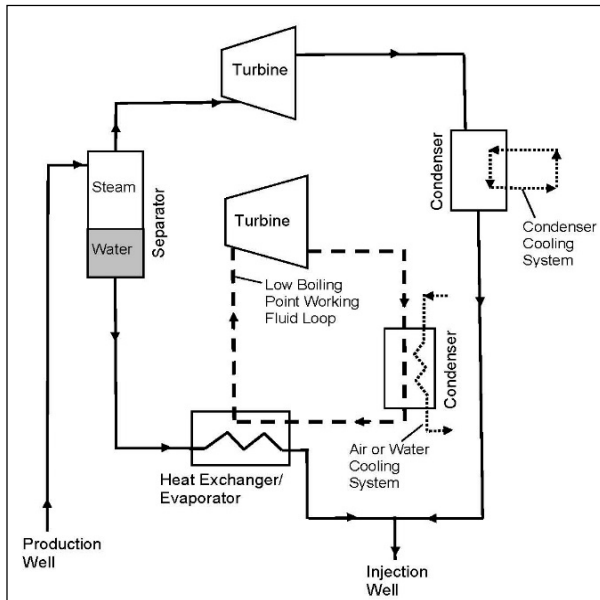

Figure 2-20. Simple Schematic of a Flash-Binary Geothermal Power Plant

Combination System. As noted previously, geothermal power plants may also be variations or combinations of the plant types described above. One such combination is worthy of note because it is used in the Puna Geothermal Venture Power Plant on Hawai'i island. Figure 2-20 is a simple line schematic of a "flash-binary," which combines primary elements of a flash steam system and a binary system. As shown in the figure, the geothermal fluid is first separated into steam and water, with the steam going directly to a turbine as shown in Figure 2-18. However, the separated hot water is then used as the heat source for binary cycle (such as is shown in Figure 2-20), driving a second turbine. The hot water stays in a closed system from the separator to the injection well, but the steam side is generally open to some degree and noncondensable gases naturally occurring in the thermal fluid still have to be removed from the

system. The Puna Geothermal Venture Power Plant is designed to maintain a closed system, using only non-contact air cooling, and sends even the noncondensable gases to the injection well.

Enhanced Geothermal Systems

Conventional hydrothermal power plants are associated with naturally occurring reservoirs with sufficient fluid, heat, and permeability to support power production. Enhanced geothermal systems (EGS) are engineered hot water reservoirs that are created where subsurface fluid and permeability are lacking. In an EGS, one or more of several subsurface techniques is used to stimulate pre-existing fractures to re-open, increasing permeability and allowing fluid to circulate for power production ([DOE 2012j](#)). Hydraulic stimulation, which consists of injecting water under relatively high pressure into a rock formation, is the primary type of reservoir stimulation technology used in EGS development projects to date. EGS is still an evolving technology, but it is now focusing on an approach often referred to as hydro-shearing, in which the goal is to use enough stimulation pressure to open existing fractures and fissures without breaking up the formation with new fractures. This provides a high ratio of contact surface (for optimum heat exchange) to the amount of water that can push through. This is different than the oil and gas industry, where stimulation is done at higher pressures and the goal is to generate new fractures (that is, hydro-fracturing) that will allow rapid draining of the formation. The oil and gas industry also frequently adds materials to the stimulation fluid to aid the fracturing process, while EGS generally relies on just water.

A basic premise of EGS is that it expands the areas where *geothermal energy* might be exploited to well beyond those where there is a naturally occurring hydrothermal circulation system. This includes subsurface areas at the greater depths that can be reached with today's drilling technologies and where there may be higher temperature gradients and low potential for any significant amounts of permeability or *groundwater*. Although the potential for EGS in the United States and around the world is great, the technology is not yet economical on a large scale. However, in April 2013, DOE announced the Ormat Technology Desert Peak 2 Project in Nevada, partially funded by the DOE, as the first commercial EGS project to supply electricity to the electrical power grid. Ormat used EGS to expand power production at an operating geothermal field by 1.7 megawatts of power, an increase of almost 38 percent ([DOE 2013d](#)). There have been several smaller-scale field tests in the United States and abroad that have shown promise, including a project in France that currently is operating a pilot-scale power plant from an engineered reservoir ([GEIE EMC 2012](#)). If EGS can be used to develop geothermal reservoirs with recoverable heat, they would generally be paired with a binary system to generate electricity, as is the case for the French pilot-scale plant.

Additional information on EGS can be found in an MIT study on the potential for the technology, *The Future of Geothermal Energy, Impact of Enhanced Geothermal Systems (EGS) on the United States in the 21st Century* ([MIT 2006](#)), and two DOE reports, *An Evaluation of Enhanced Geothermal Systems Technology* ([DOE 2008b](#)) and *Protocol for Addressing Induced Seismicity Associated with Enhanced Geothermal Systems* ([DOE 2012k](#)). The latter document addresses an effect associated with EGS projects. The slippage along an existing fault or fracture, or other change in the stress patterns in the rock that occurs during hydraulic stimulation, although small, is a seismic event. The inducement of seismic events, such as those caused by hydraulic stimulation, is a common characteristic of several different types of activities that involve deep injection or extraction of large volumes of subsurface fluid ([DOE 2012k](#)), and is a consideration that must be addressed for any planned EGS project.

Hawai'i's geothermal resources are less permeable than most areas of the world where such resources have already been developed. As a result, EGS may possibly be used in future development in Hawai'i even though the existing geothermal power plant in the State is associated with a conventional hydrothermal system. However, Hawai'i's geothermal resources have not yet been characterized to the degree required to support any estimate of the potential of EGS or, more pertinently, to provide any accurate estimate of the State's hydrothermal resources of any temperature ([PICHTR 2013](#)).

Typical Capacity Factors of Geothermal Power Plants

Geothermal power plants, tapping a relatively constant source of energy, are developed primarily as baseload power plants. Consistent with this intent and corresponding design, they typically operate at high capacity factors (the ratio of actual power output to potential output). It is reasonable for geothermal plants to have utilization up to 96 percent, and financial planning for geothermal plants often assumes capacity factors in the area of 85 percent ([NREL 2012b](#)). In 2012, the Puna Geothermal Venture Power Plant on Hawai‘i island produced 266 gigawatt-hours of electricity ([DBEDT 2013h](#)). With a plant capacity of 38 megawatts, this equates to a capacity factor of 80 percent.

2.3.3.2.2 Characterization of Technology Feasibility and Deployment

Feasibility of Geothermal Resource Deployment by Island

[Figure 2-21](#) shows areas within Hawai‘i where geothermal resources are expected to exist. Additional areas may be identified through state-of-the-art resource assessments. As shown in the figure, only the islands of Maui and Hawai‘i are expected to contain high-temperature resources. Because of the older age of volcanic activity on the other islands, geothermal resources that could support electricity production are not likely ([MIT 2006](#)). [Figures 2-22](#) and [2-23](#) provide additional detail on the geothermal resources for Maui and Hawai‘i counties, respectively. The highlighted areas in the figures are areas where there are reasonable expectations of high-temperature geothermal resources, which in this case represents temperatures of 125°C (257°F) or greater. This temperature is based on an estimate of the lower temperature limit at which a binary power plant could produce electricity ([GeothermEx 2005](#)). Because the amount of subsurface data actually available is limited, evaluations of the geothermal resources included statistical simulations to develop estimates of the probability they would be present at usable temperatures and conditions. The calculated probability values vary greatly by island and, for the island of Hawai‘i, by area within the island. The two highlighted areas on Maui are each associated with a 25 percent or less chance of finding a high-temperature geothermal resource. On Hawai‘i, however, there is up to 90 to 95 percent probability that high-temperature resources are present in the large highlighted area around the Kilauea rift zones. The other three highlighted areas (the two Mauna Loa rift zones and Hualalai) each have a 35 percent probability of containing high-temperature geothermal resources ([GeothermEx 2005](#)).

Characterization of Existing Deployment

The Puna Geothermal Venture Power Plant on Hawai‘i island is the only active geothermal power plant in the State. The Puna plant, located near the eastern-most tip of the island, has a 38-megawatt capacity, is connected to the Hawai‘i Electric Light Company (HELCO) grid, and provides about 20 percent of the Big Island’s electrical needs ([DBEDT 2013i](#)). As identified in the preceding discussion, the Puna plant consists of a hybrid flash and binary system.

The only other geothermal project listed in the State Energy Office’s online database is the Ulupalakua Geothermal Project and is in the exploration stage. Under this project, Ormat Technologies, owner of the Puna Geothermal Venture Power Plant, is determining whether a resource exists sufficient to support development of a geothermal power plant facility on land on or adjacent to the Ulupalakua Ranch on Maui. In the third quarter of 2013, ORMAT reported it was in the process of developing an EIS with a goal of filing it with the State by the end of 2013, followed by pursuing necessary leases and permits for exploration activities ([Recovery.gov 2013](#)). The future viability of this project will be determined based on data obtained from exploration wells. Ormat is assumed to be planning for a geothermal power plant similar in scale and design to that in Puna ([DBEDT 2013i](#)).

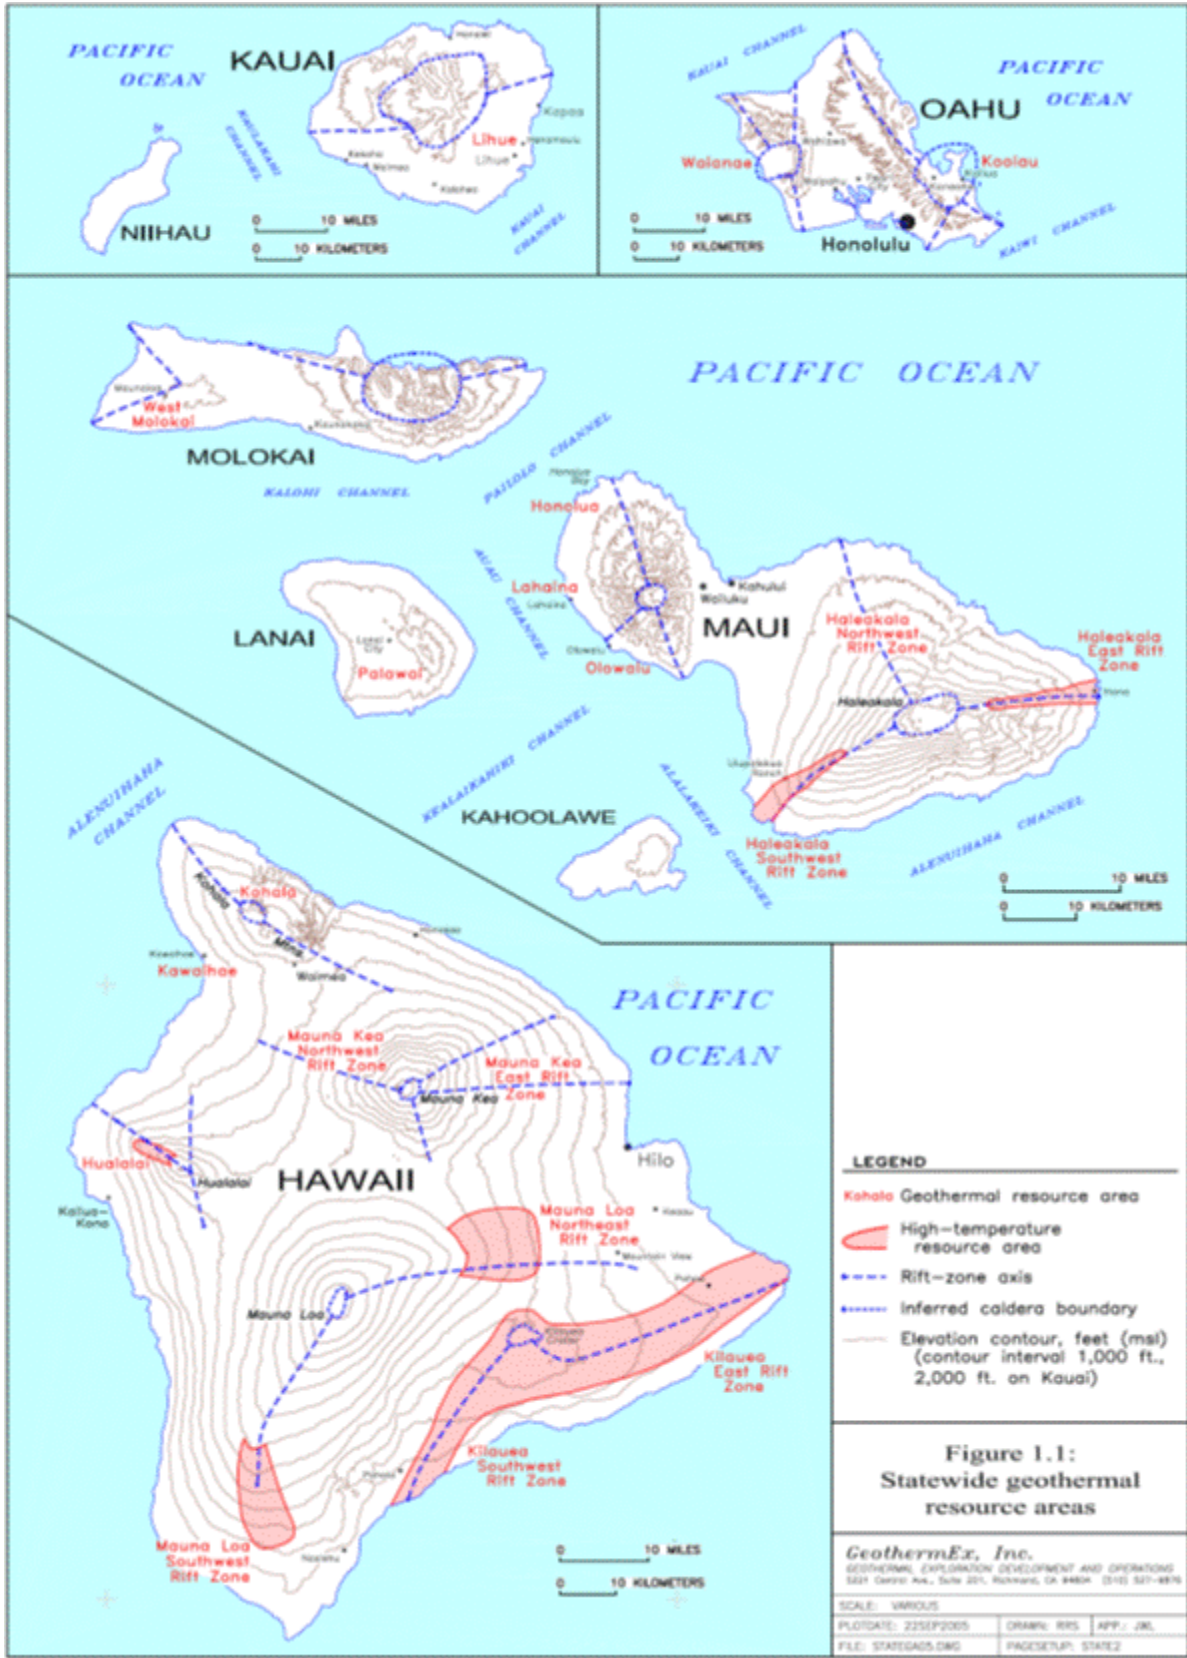

Figure 2-21. Geothermal Resource Areas Within the State (Source: GeothermEx 2005)

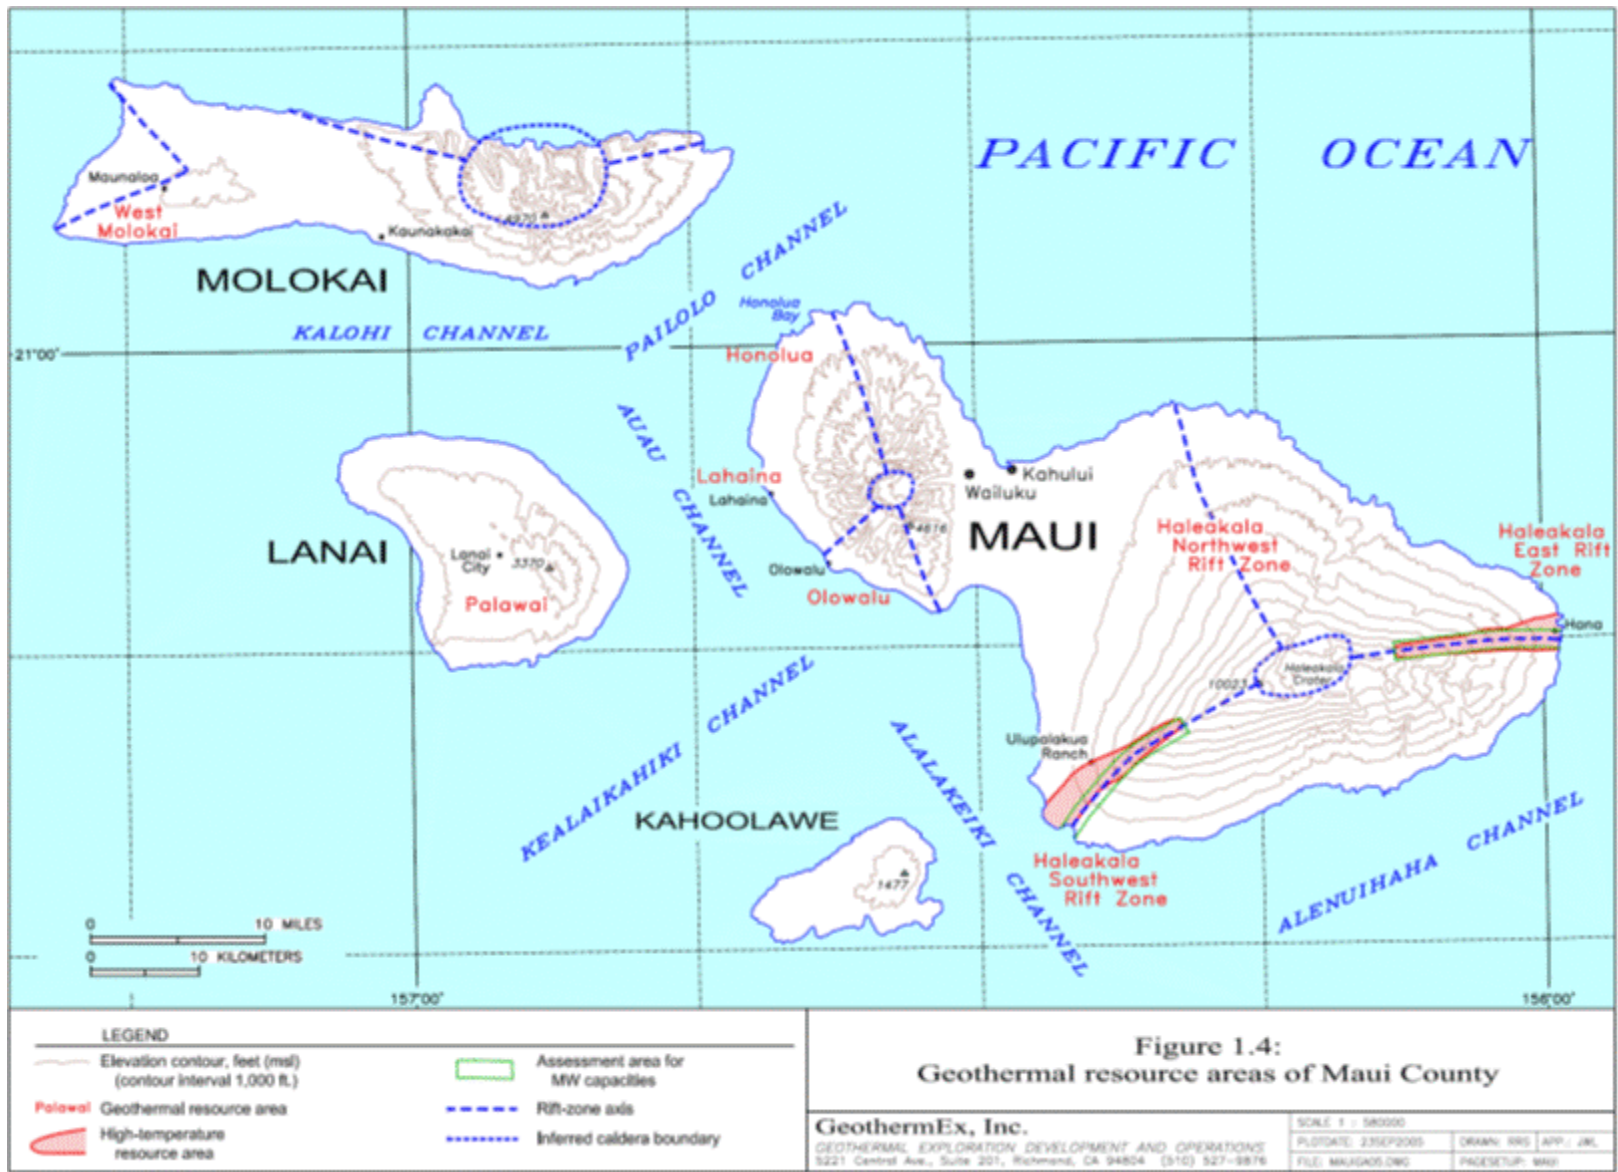

Figure 2-22 Geothermal Resource Areas for Maui County (Source: GeothermEx 2005)

Figure 2-23. Geothermal Resource Areas for Hawai'i County (Source: GeothermEx 2005)

HELCO has solicited bidders for development of additional geothermal resources on the Island of Hawai‘i. The proposals are for an expansion of geothermal energy by up to 50 megawatts. In January 2013, HELCO requested PUC approval to solicit bidders by issuing a Request for Proposals (RFP) ([Smith 2013](#)). Approval was obtained and HELCO issued the Geothermal RFP on February 28, 2013, and requested proposals by the end of April ([HELCO 2013](#)). Six responses to the RFP were received, and in February 2015, HELCO announced it had selected Ormat to provide 25 megawatts of additional geothermal energy on Hawai‘i island. Possible locations of any future geothermal wells have not yet been released.

A Statewide evaluation estimates that geothermal resources on Hawai‘i island (see [Figure 2-23](#) for areas assessed) have a combined minimum capacity of 488 megawatts and a most likely capacity of 1,396 megawatts. The comparable numbers for Maui (see [Figure 2-22](#) for areas assessed) are a minimum capacity of 38 megawatts and a most likely capacity of 139 megawatts. These estimates are intended to reflect the amount of recoverable heat energy, but not necessarily whether that energy can be exploited commercially ([GeothermEx 2005](#)).

Based on scoping performed for this PEIS as well as news releases and posted records of public meetings, there is both public opposition to and support for geothermal energy development in the State. Opposition has been well documented on Hawai‘i island where the existing geothermal power plant is located. Opposition is based primarily on public health and safety concerns, including the potential for emissions of toxic gases and dangerous accidents. There are also concerns with noise, seismicity, and lighting. Some mention also has been made of financial damage due to decreasing property values. Other members of the public have expressed support for geothermal energy development, provided it is done safely. Such concerns, either for or against, also play a significant role in the overall feasibility of future geothermal energy development within Hawai‘i.

In September 2012, Hawai‘i County initiated actions to form a fact-finding group to examine the type and extent of health impacts from geothermal operations on the island. This study group released a final report, *Geothermal Public Health Assessment, Findings and Recommendations*, after public review and comment on September 9, 2013 (<http://www.accord3.com/pg68.cfm>). Among the recommendations contained in the study were the undertaking of additional, specific health studies, establishment of a better monitoring system, and strengthening of communications with the public, including improved alert systems.

2.3.3.2.3 Permitting and Consultation Requirements

In addition to the general permitting requirements discussed in [Section 2.2](#), there are several noteworthy requirements specific to geothermal projects that are listed below. They are grouped into State and county permitting requirements.

- **State permits** – A Geothermal Exploration Permit is required to conduct any exploration activity on State or reserved lands for evidence of geothermal resources. A Geothermal Drilling and Well-Modification Permit is required to conduct geothermal development and/or drilling activities. These permits are issued by the Hawai‘i Department of Land and Natural Resources. Permit applications may be reviewed for impacts to endangered species, archaeological resources, and other natural resources (e.g., coastal lands and waterways) prior to issuance. The HDOH issues permits regulating air emissions, underground injection, noise, and other health impacts as delegated by EPA. An environmental review triggered by these approvals would require an assessment of impacts to cultural resources.

- County permits – A County Zoning or Geothermal Resource Permit is issued by the affected county. This permit is required to conduct geothermal activities within a State agricultural, rural, or urban district. The county also issues all construction permits.

From a permitting perspective, geothermal development in Hawai‘i faces many challenges; some unique to Hawai‘i, some common throughout the world. These challenges include:

- Cultural significance,
- Proximity to residential areas and health concerns raised by residents,
- Proximity to scenic resources, including national parks,
- Evolving regulatory roadmap (county permitting, permitting for exploration), and
- Injection of effluent.

2.3.3.2.4 Representative Project

A representative geothermal energy project for purposes of evaluation in this PEIS is assumed to consist of the exploration, development, and operation of a 25-megawatt power plant. Similar to the existing Puna Geothermal Venture Power Plant on Hawai‘i island, the representative power plant would consist of a combined flash and binary system, so the fate of noncondensable gases would have to be addressed, but all geothermal liquids and condensable gases would be re-injected into the subsurface reservoir. It should be emphasized that this representative project is hypothetical in nature, used only for analytical purposes, and is not intended to represent any actual or planned geothermal project.

Considering the information in [Table 2-14](#) (above), estimates of ground disturbance are as follows:

- Exploration (Total = 5 acres)
 - 5 acres for exploration – There would be a moderate amount of access road work and slim holes or coring wells. Given the relatively confined area of the islands, long access roads would not be expected.
- Drilling Operations and Utilization (Total = 53 acres)
 - 15 acres for drilling and well-field development – Six well pads (at 2.5 acres each) to support four injection wells and five production wells.
 - 8.2 acres for road improvement/construction – 2.25 mile of road (0.25 mile per well) would be needed and assuming a 30-foot wide disturbance.
 - 15.5 acres for power plant construction – About 0.5 acre per megawatt.
 - 4.5 acres for well field equipment and pipelines – This is based on each well pad being about 0.25 mile from the power plant and a 25-foot-wide disturbance corridor for each pad.
 - 10 acres for transmission lines – This is based on 2 miles of new transmission line with a 40-foot-wide disturbance corridor.

Water, not necessarily potable, needed during construction (drilling wells, cementing wells, pipeline construction, and plant construction) is estimated at 7 million gallons ([Clark et al. 2011](#)). Consumptive use of water during plant operations primarily would be due to evaporation losses of the geothermal fluid in the cooling system in the flash process. All other geothermal fluids would be re-injected.

Air emissions during construction would consist of fugitive dust and equipment exhausts. During operations, the noncondensable gases in the geothermal fluid going to the flash system would be lost or controlled. This might be done by injecting the noncondensable gases into the subsurface with the used geothermal fluids or having off-gas treatment systems as scavenger or regenerable catalyst systems. These types of systems involve passing the off-gas through beds of materials designed to react with and remove the gas of concern.

If the scope of the representative project were increased (by a factor of two for example), it is reasonable to assume the associated impact elements (for instance, amount of land disturbance and water needs) would increase by a similar factor.

2.3.3.3 Hydroelectric Systems

Utility-scale hydroelectric power systems operate similarly to small-scale systems (see [Section 2.3.2.2](#)), albeit on a larger scale. In general large-scale facilities use dams to regulate water flow and generate energy, while small-scale facilities use a water diversion design, which is most often run of the river (e.g., water in equals water out, no long term [greater than one hour's worth of power generation] water storage). While there are exceptions, for the purposes of analysis, this PEIS approaches the technology from this general understanding.

2.3.3.3.1 Technology Description

The technical description for this section focuses on impoundment dam hydroelectric facilities. Typically, impoundment facilities fall into DOE's "Large Hydro" category, which is defined as any facility with a capacity larger than 30 megawatts ([DOE 2011b](#)). Impoundment facilities are suitable on a river system with low head and a high flow rate. As shown in [Figure 2-24](#), the main components of an impoundment facility include a dam for water storage, a penstock to carry water from the reservoir to the powerhouse, and a powerhouse containing the turbines and generators. Large impoundment hydroelectric facilities must connect to the electrical power grid, and thus require access to transmission lines.

Traditional impoundment dam systems span the width of a given river system to control the flow of water. These dams vary in size and height depending on the characteristics of the river valley. Dammed rivers then cause the valley behind the dam to fill with water and form a manmade lake, which provides the hydropower system with a regular source of water for power generation.

As described in [Section 2.3.2.2](#), the two main types of turbines used to generate electricity in a hydropower facility are impulse and reaction turbines. Because of the complexity and high cost, reaction turbines are generally limited to large hydropower applications ([DOE 2001](#)), such as those associated with commercial-scale operations.

There are two main reaction turbine designs: the Kaplan and the Francis ([Figure 2-25](#)). The main difference between these two designs is how the water flows around the blades. The Francis turbine, commonly known as a water wheel, spins as water flows through it, and the Kaplan design is basically a boat propeller with adjustable blades that accommodate changes in water levels. Both turbines are in contact with water at all times ([DOE 2011a](#)).

2.3.3.3.2 Characterization of Technology Feasibility and Deployment

Hydropower has a long history of use in Hawai'i for agriculture and small-scale power generation; however, according to an assessment directed by the USACE, the State of Hawai'i has limited potential for large-scale, river-based hydropower projects ([USACE 2011](#)). The assessment included a preliminary

screening of the major populated islands for locations where hydropower might be feasible. Several locations were identified where traditional hydroelectric plants might be feasible, but none with output capacities greater than 2.9 megawatts. Although these are plants that could be connected to the electrical grid, they are below the size that would normally be considered to be of utility-scale. A renewal of hydropower can contribute much to HCEI's goals, but the technologies most likely to be viable in the Hawaiian Islands are those associated with small-scale diversion or in-stream hydropower facilities ([Section 2.3.2.2](#)). However, at least one pumped-hydropower storage facility in the 20- to 25-megawatt range has been proposed on the island of Kaua'i.

Figure 2-24. Cross Section of an Impoundment Hydropower Facility that Uses an Impoundment Dam ([Source: DOE 2011a](#))

Figure 2-25. Illustration of Francis (left) and Kaplan (right) Turbines
 (Sources: [Topomatika 2013](#); [Orengine 2013](#))

2.3.3.3.3 Permitting and Consultation Requirements

As noted above, utility-scale in-stream hydroelectric facilities are not feasible on Hawai‘i. General permitting requirements are discussed in [Section 2.2](#). Technology-specific permitting requirements for small-scale facilities are discussed in [Section 2.3.2.2](#).

2.3.3.3.4 Representative Project

The previously described evaluation by the USACE on the feasibility of hydroelectric facilities in Hawai‘i identified several new sites where hydroelectric plants might be feasible ([USACE 2011](#)). However, none of the sites was estimated to be capable of power output capacities that would be typical of a utility-scale technology. As a result, DOE believes the distributed, small-scale hydroelectric technology ([Section 2.3.2.2](#)) is the more representative technology for what is feasible for Hawai‘i and has chosen not to select a representative project or to evaluate the utility-scale technology in the impacts chapter (Chapter 6).

2.3.3.4 Municipal Solid Waste

Municipal solid waste, more commonly known as trash or garbage, consists of everyday items used and then thrown away, such as product packaging, grass clippings, furniture, clothing, bottles, food scraps, newspapers, appliances, paint, and batteries. These come from our homes, schools, hospitals, and businesses. The municipal solid waste industry has four components: recycling, composting, landfilling, and waste-to-energy via incineration. This section provides technical descriptions of options available for converting municipal solid waste and other forms of waste (e.g., construction and demolition, green waste) to energy. Municipal solid waste-to-energy projects use similar technologies as those described for biomass facilities (see [Sections 2.3.2.1](#) and [2.3.3.1](#)).

2.3.3.4.1 Technology Descriptions

Currently, more than 30 percent of municipal solid waste generated in the United States is recycled annually. The majority of municipal solid waste that is not recycled is typically sent to landfills after it is collected ([EPA 2013a](#)). As an alternative to landfills, waste-to-energy facilities can convert municipal solid waste to electricity. Because no new fuel sources are used other than the waste that would otherwise be sent to landfills, municipal solid waste is often considered a renewable power source. This section

discusses technologies used in such facilities: combustion or incineration, pyrolysis and thermal gasification, and landfill gas.

Combustion or Incineration

Mass burn technology involves the combustion of unprocessed or minimally processed refuse. The major components of a mass burn facility include refuse receiving, handling, and storage facilities; a combustion and steam generation system (a boiler); flue gas cleaning system; power generation equipment (steam turbine and generator); condenser cooling water system; and residue hauling and storage system (fly and bottom ash).

Incoming trucks deposit the refuse into pits, where cranes then mix the refuse and remove any bulky or large non-combustible items (such as large appliances). The refuse storage area is typically maintained under pressure less than atmospheric in order to prevent odors from escaping. The cranes can also move the refuse into the hopper to feed the boiler.

Heat from the combustion process generates steam, which is routed to a steam turbine-generator for power generation. The steam is then condensed via traditional methods (such as wet cooling towers or once-through cooling) and routed back to the boiler. The wet cooling towers or once-through cooling are the largest water uses of the project. Wet cooling towers require make-up water for any water that is lost to evaporation during the cooling process. Other large water uses for the combustion processes includes steam generator blowdown, where the water system is flushed to remove impurities that can accumulate in the steam generators. Other residues produced include bottom ash (which falls to the bottom of the combustion chamber), fly ash (which exits the combustion chamber with the flue gas), and residue from the flue gas cleaning system.

The combined ash and air pollution control residue ranges from 20 to 25 percent by weight of the incoming refuse processed. The ash residue may or may not be considered hazardous, depending on the makeup of the municipal waste. Typical control technologies for controlling air emissions and [greenhouse gas](#) emissions include electromagnetic precipitators and/or baghouses (primarily for particulate capture), and scrubbers for removal of acidic gases and some particulates. Fly and bottom ash is surveyed for [hazardous materials](#) and disposed of in appropriately certified landfills. If the material is not hazardous, it can be reused as supplements to cement, roadbed construction, landfill cover, and many other uses. Scrubber waste can be a liquid, paste, or powder. Its waste is also disposed of; in some cases, it can be reused for products such as drywall ([CEC 2013](#)).

The processed municipal solid waste can be further processed to produce refuse-derived fuel, which removes incombustible materials such as dirt, glass, metals, and very wet organics, and it makes the waste more uniform in size than raw municipal solid waste. The remaining material is then used or sold. The refuse-derived fuel processing facility and municipal solid waste combustion facility are normally located in the same facility or near each other. The major components of a refuse-derived fuel process are the same as those in a mass burn facility.

Key steps in these processes include:

- Size reduction (shredding)
- Air classifying/screening (methods of separating materials and particle sizes)
- Magnetic separation
- Glass and non-ferrous metal separation (mostly aluminum)
- Drying

Pyrolysis and Thermal Gasification

Pyrolysis and thermal gasification technologies are not yet as common as combustion in waste-to-energy systems. Pyrolysis is the thermal decomposition of organic material at elevated temperatures in the absence of gases such as oxygen. The process requires heat and produces a mixture of combustible gases (primarily methane, complex hydrocarbons, hydrogen, and carbon monoxide), liquids, and solid residues. The pyrolysis process starts at about 390° to 570°F.

With thermal gasification, thermal decomposition takes place in the presence of a limited amount of oxygen. The generated gas can then be used in boilers or cleaned up and used in combustion turbines or generators. Gasification converts organic or fossil-based material into carbon monoxide, hydrogen, and carbon dioxide at temperatures greater than 1,290°F.

From a benefits standpoint, pyrolysis and gasification offer more opportunities for recovering products from waste than combustion. When waste is burned in a modern incinerator, the only practical product is energy; whereas, the gases, oils, and solid char from pyrolysis and gasification can not only be used as fuel but also purified and used as a feedstock for petrochemicals and other applications. The processes can also produce a stable granulate instead of an ash, which can be more easily and safely utilized. In addition, processes can target producing specific recyclables, such as metal alloys and carbon black. From gasification, in particular, it is feasible to produce hydrogen, which is becoming an increasingly valuable resource. [Section 2.3.4.4](#) of this PEIS discusses how hydrogen can be used in the transportation arena.

From a challenge standpoint, pyrolysis and gasification are not among the more economical alternatives. The pyrolysis process needs improvements in the quality and consistency of the bio-oil that is produced. With gasification, the main challenge is to reach an acceptable (positive) gross electric efficiency. The high efficiency of converting synthetic gas to electric power is counteracted by significant power consumption in the waste preprocessing, the consumption of large amounts of pure oxygen (which is often used as a gasification agent), and gas cleaning. Another challenge is maintaining long service intervals in the plants to avoid closing down the plant every few months for cleaning.

Key steps in these thermal processes include:

- [Materials Transport](#) – Transport the materials to and from the conversion facility.
- [Shredding and Separating](#) – The municipal solid waste runs through multiple shredding and separation steps to get to an appropriate size and to remove items such as metals, glass, and dirt.
- [Pyrolytic Converter](#) – From the shredding and separating processes, the waste goes through a pair of air lock valves and into the pyrolytic converter (or pyrolysis unit). The air locks are necessary to keep air out because the objective is to decompose organic material at an elevated temperature with no, or minimal, oxygen.
- [Scrubber](#) – Gases pulled from the pyrolytic converter first go through a scrubber to wash out carbon particles that may have traveled with the gas from the converter and to remove some of the condensable gases.
- [Condenser and Demister](#) – From the scrubber, the gas goes through a condenser to remove the rest of the condensable gases, which consist primarily of steam/water but could also include some hydrocarbons. The non-condensable gas then goes through a demister to ensure no liquid remains in the stream ([DOE 2014a](#)).

Landfill Gas

Landfill gas utilization is a process of gathering, processing, and treating the gas typically released from landfills to produce heat, fuels, and various chemical compounds. The number of landfill gas projects, which convert the methane gas that is emitted from decomposing garbage into energy, is growing. The EPA's Methane Outreach Program lists active landfill gas-to-energy projects and landfills with the potential characteristics to sustain recovery operations (<http://www.epa.gov/lmop/>).

Landfill gas is generated through the degradation of municipal solid waste by microorganisms. The quality (higher percent methane gases) is dependent on the composition of the waste, presence of oxygen, temperature, physical geometry, and time elapsed since waste was disposed ([DOE 2014b](#)). Aerobic conditions (presence of oxygen) leads to the generation of predominately carbon dioxide. Anaerobic conditions (no oxygen), as is typical of landfills, produce methane and carbon dioxide in approximately equal amounts. Methane is the important component of landfill gas.

Landfill gas is gathered from landfills through trenches and/or extraction wells (roughly one well per acre is typical) and a collection system ([EPA 2009a](#)). The following are key steps in the process.

- **Landfill gas Collection System** – Landfill gas can be extracted through horizontal trenches or vertical wells. Both systems are effective. Once extracted, a blower or pump blows or draws gas from the collection wells to a main collection header. The blower/pump then sends the gas to be treated or flared (burned off). The main collection header can connect to a collection system to collect condensate forming in the pipes.
- **Flaring** – If gas extraction does not warrant direct use or electricity generation, the gas can be flared off. The purpose of flaring is to dispose of the flammable constituents of landfill gas, particularly methane, safely and to control odor nuisance, health risks, and adverse environmental impacts ([UK Environment Agency 2013](#)). Flares can also help control excess spikes and maintenance down periods. Flares can be either open or enclosed.
- **Landfill Gas Treatment** – Landfill gas is treated to remove impurities, moisture, and particulates. The treatment system depends on the end use. Gas that will be used directly in boilers, furnaces, or kilns requires minimal treatment. Using the gas to generate electricity typically requires more in-depth treatment. Treatment systems are divided into primary and secondary treatment processing. Primary processing systems remove moisture and particulates. Gas cooling and compression are also common in primary processing. Secondary treatment systems employ multiple cleanup processes, physical and chemical, depending on the specifications of the end use. Adsorption and absorption are the most common technologies used in secondary treatment ([EPA 2009a](#)).
- **Gas Distribution** – In some cases, the collected gas goes to a pipeline for distribution to a gas truck line or to a direct serve customer. The pipelines typically are 10-inch high-density polyethylene pipeline (Three Rivers 2013).

Capacity Factors for Renewable Energy Sources

The various solid waste-to-energy technologies can produce base-load or reliably constant capacities based on an even stream of solid waste entering the facility. Base-load capacity is the minimum amount of power that a utility or distribution company must make available to meet minimum demands for its service area. There are several reasons why a plant would have a capacity factor lower than 100 percent. The most common reason is a plant is out of service or operating at reduced output due to equipment failures or routine maintenance.

2.3.3.4.2 Characterization of Technology Feasibility and Deployment

Feasibility

The H-POWER facility on O‘ahu has been converting municipal solid waste to energy since 1990 and recently expanded its capacity to 90 megawatts (meeting approximately 8 percent of O‘ahu’s energy needs) ([Covanta 2013](#)).

On April 25, 2013, Maui County awarded the contract to construct and operate the Maui County Landfill Waste-to-Energy Facility, which, if built, would be located on a 10-acre site next to the existing landfill in Puunene. The facility, expected to begin operations in 2017, would generate up to 15 megawatts of power. The landfill currently accepts about 450 tons of waste daily. The County may decide to sell the generated electricity to MECO. The County is also exploring landfill gas collection opportunities.

The BioEnergy Hawai‘i Waste Conversion facility currently is in the planning stages. The facility would be located on Hawai‘i island. The facility plans to use thermal gasification on waste from the Puuanahulu landfill to generate up to 11 megawatts of electricity. The facility would use the resultant carbon dioxide to feed algae beds, which the facility would convert to biofuel ([DBEDT 2010](#)). The State of Hawai‘i prepared the *Environmental Assessment/Environmental Impact Statement Preparation Notice for the BioEnergy Hawai‘i Waste Conversion Facility* in December 2010 ([DBEDT 2010](#)). The proposed bioconversion facility will use gasification technology to divert up to 75 percent of the 400 tons generated per day of municipal solid waste from West Hawai‘i’s landfill.

EPA’s Landfill Methane Outreach Program has developed a variety of analyses profiling specific landfill sites that it considers candidates for landfill gas projects. Considerations include gas recovery estimates and feasibility assessments conducted to evaluate the landfill gas generation and recovery potential at specific landfills and potential end uses. [Table 2-15](#) lists eight candidate landfills in Hawai‘i for gas recovery.

Table 2-15. Candidate Landfill Gas-to-Energy Landfills in Hawai‘i

Landfill Name	City	County	Waste in Place (tons)	Opening Date	Closure Date	Owner
Central Maui LF	Puunene	Maui	3,666,000	1987	2030	Maui County
Kailua LF	Kealahou	Hawai‘i	500,000	1975	1993	Hawai‘i County
Kalaheo LF	Waimanalo	Honolulu	1,310,000	1987	1990	Honolulu
Kapaa LF Site No. 2	Kailua	Honolulu	2,122,147	1982	1998	Honolulu
Kekaha LF Phase II	Kekaha	Kaua‘i	1,492,886	1953	2015	Kaua‘i County
South Hilo LF	Hilo	Hawai‘i	1,396,049	1965	2016	Hawai‘i County
Waimanalo Gulch LF	Kapolei	Honolulu	5,070,000	1989	2045	Honolulu
West Hawai‘i LF/Puuanahulu	Waikoloa	Hawai‘i	900,000	1992	2070	Hawai‘i County

[Source: EPA 2012.](#)

Developers are exploring three of the landfills: Waimanalo Gulch, Central Maui, and West Hawai‘i (Hawai‘i Energy Futures 2013).

In determining the suitability of a project, the first step for the landfill proponent would be to determine if the landfill is likely to produce enough methane to support an energy recovery project. Screening criteria include whether the landfill contains at least 1 million tons of municipal solid waste, has a depth of 50 feet or more, is still in operation or recently closed, and receives at least 25 inches of precipitation annually. Landfills that meet these criteria are likely to generate enough gas to support a landfill gas project. These are ideal conditions, but success has also occurred at older, smaller, and more arid landfills.

Deployment

The City and County of Honolulu owns the Covanta Honolulu Resource Recovery Venture, locally known as H-POWER (which stands for Honolulu Program of Waste Energy Recovery). The facility is located at Kapolei on O‘ahu on 28 acres of land in the Campbell Industrial Park. The facility processes up to 3,000 tons of municipal solid waste per day and can generate up to 90 megawatts of electricity.

Initially, the facility had two 845-ton-per-day furnace/boilers using refuse-derived fuel. In 2012, the facility added a 900-ton-per-day expansion using the mass burn (combustion) technology, which included the third combustion unit, turbine/generator, and associated air pollution control equipment ([Covanta 2013](#)).

There are no existing landfill gas-to-energy projects in Hawai‘i. During the 1990s, the Kapaa landfill on O‘ahu burned the methane that collected to produce electricity; the landfill dried gravel with the heat from the turbine exhaust.

2.3.3.4.3 Permitting and Consultation Requirements

Municipal solid waste and landfill gas energy projects can be subject to the general permits and regulations discussed in [Section 2.2.5](#), including air quality, solid waste, and water quality regulations and permitting requirements. [HAR Chapter 58.1](#), “Solid Waste Management Control,” regulates facilities designed to reduce volume of solid waste by the use of an enclosed device using controlled combustion. Solid waste used for incineration must not include materials contaminated with hazardous waste as defined in the rules. All solid waste incinerators or refuse-derived fuel processing facilities require a permit and must comply with Sections 11-58.1-04 and 11-58.1-12(a). A site plan and analysis are required.

From a larger Federal and State permit perspective, proposed mass burn facilities would require compliance with permitting regulations, including:

- New Source Performance Standards promulgated under [Section 111 of the CAA](#);
- [National Ambient Air Quality Standards](#) promulgated under [Sections 108](#) and [109](#) of the CAA;
- Prevention of Significant Air Quality Deterioration regulations under [Section 165 of the CAA](#);
- Standards for Residual Disposal (Fly and Bottom Ash) and potential hazardous waste management promulgated under Subtitle C, in accordance with [Section 306 of the CAA](#), of the ARRA at the Federal level, and under [HRS Chapters 342H](#) and [342J](#) at the State level;
- Permits for waste water treatment and disposal and cooling water blow down promulgated under the CWA [Sections 104](#) and [316](#) and [HRS Chapter 342D](#) ; and
- Transmission line tie-in regulations promulgated under Section 216 of the *Federal Power Act* ([16 U.S.C. § 791 et seq.](#)) and [HRS Chapter 269](#).

A comprehensive discussion of permitting requirements for municipal waste combustion facilities can be found at <http://www.combustionportal.org/mswi.html>.

Pyrolysis and thermal generation would have many of the same requirements summarized above.

Landfill gas energy projects may need to obtain NPDES permits for discharging wastewater that is generated during the energy recovery process. This wastewater, as well as wastewater from the system maintenance process, must be removed from the collection process. Subtitle D of the *Resource Conservation and Recovery Act* ([42 U.S.C. § 6901 et seq.](#)) is specific to landfill gas mitigation control. Since October 1979, regulations have required controls on migration of methane gas from landfills. Subsequently, in October 1993, EPA issued landfill standards requiring methane monitoring and performance standards for methane migration control.

Under the New Source Performance Standards of the CAA, EPA requires affected landfills to collect and control landfill gas. The standard targets reductions in the emissions of landfill gas due to odor, possible health effects, and safety concerns. Landfills meeting certain design capacity and emission criteria are required to collect landfill gas and either flare it or use it for energy.

It is important for prospective municipal solid waste and landfill gas developers to consider the feedstock facility when assessing overall facility requirements. Feedstock facilities are often subject to heavy regulation, so the municipal solid waste/landfill gas developer should ensure all current permits are valid and that any new proposed activities do not adversely impact existing facility permits. New activities such as shredding onsite or transporting feedstock materials can trigger additional approvals, including for air emissions, traffic impacts, noise, and run-off.

2.3.3.4.4 Representative Project

For purposes of this PEIS, the representative project is a municipal solid waste-to-energy direct combustion facility designed to produce 5 megawatts of energy on 10 acres of land. Freshwater or saline (saltwater) can be used for cooling. This was chosen as a representative project because it is the type most commonly used in the United States and Hawai'i. The operation of a direct combustion facility would result in potentially higher levels of air emissions and water usage for cooling purposes than the other technologies used to convert municipal waste to energy.

Power plants that burn municipal solid waste are normally smaller than fossil fuel power plants but typically require a similar amount of water per unit of electricity generated. Assuming a 100-percent capacity factor, the 5-megawatt representative project would use about 4 million gallons per month for make-up water and about 1.3 million gallons per month for blow-down water ([EPRI 2009](#)).

The representative project would employ approximately 25 construction workers for an 18 to 24 month period, and 14 full-time equivalent operations staff ([DBEDT 2010](#)).

The representative project would require 165 tons of solid waste per day. This is based on 33 tons of solid waste required to generate 1 megawatt of energy per day.

To minimize transportation-related impacts, the representative project would be co-located with or near a municipal solid waste landfill that supplies the feedstock. Site infrastructure would include those services that are typical of a processing facility (e.g., utilities, waste and wastewater, construction laydown yards, and parking). The facility would provide electricity to the electrical grid or otherwise offsite, and would require 1-mile-long transmission lines to connect the plant to the physical grid (or to any direct serve customer).

2.3.3.5 Marine Hydrokinetic Energy

2.3.3.5.1 Technology Description

Marine hydrokinetic technologies use the *kinetic energy* from moving water (such as waves, tides, and ocean currents) to generate electricity. The amount of energy that can be extracted from a wave is a function of the wave's height and frequency. That is, the higher and more frequent the waves, the more power that can be extracted. Marine hydrokinetic devices can be situated on the shoreline or offshore, depending on the technology (NREL 2009a). This technology is in the early stages of development; consequently, there are numerous designs in various stages of viability for commercial deployment or product testing (Pew 2011). It is expected that over the course of the next decade or so, some of these technologies/designs will emerge as superior energy conversion devices, setting a commercial standard for marine hydrokinetic technologies. The costs associated with development, deployment, and maintenance are largely unknown. Further, much research is still needed on existing devices to determine reliability, optimal siting, commercial operational parameters, and impacts to marine environments (DBEDT 2002c).

Wave Power Technology Types

Wave power, measured in units of kilowatts of power per meter, is the amount of power between wave crests. Each wave power technology category utilizes distinct designs to capture energy based on the kinetic properties of the water. Wave energy generators take advantage of the oscillation of surface waters to produce energy. The devices include attenuators, overtoppers, oscillating water columns, point absorbers, and oscillating wave and surge converters (DOE 2013e). Unless otherwise noted, the following illustrations and explanations are from the DOE's Marine and Hydrokinetic Technology online glossary, http://www1.eere.energy.gov/water/marine_hydro_glossary.html. The intent of this section is simply to introduce the known wave power technologies. More detailed descriptions of the individual technologies, including design specifics, use scenarios, and entities involved with such, are available on the Internet.

Attenuators

Attenuator technology designs are based around a central hinge connecting separate moving arms floating on the surface of the water (Figure 2-26). The device is positioned so that the end of an arm faces the oncoming waves. The force of the waves move the arms, which bend the hinge, which in turn pumps fluid between the arms. The fluid drives a generator, producing electricity. Underwater transmission lines bring the generated power to the grid onshore.

Figure 2-26. Illustration of Attenuator Technology

Resembling semi-submerged cargo containers, a device like that in Figure 2-26 is about 400 feet long by 11 feet wide, rise about 10 feet out of the water, and comprise multiple segments, depending on technology design (OSU 2013a). Such a device has the capacity to generate 750 kilowatts of electricity. These devices are based offshore, requiring mooring lines to keep them tethered to the seabed.

Figure 2-27. Illustration of Overtopping Technology

Overtopping

Overtopping devices are designed to capture and funnel waves over the top of the device through a system of turbines back out to the source water ([Figure 2-27](#)). These devices can be semi-submerged in the water and moored to the ocean floor, or be shore-based to capture waves on the shoreline. Currently, deployed prototype devices range in size, but commercially viable units likely will be about 1,000 feet long by 600 feet wide, and rise about 10 to 30 feet out of the water. Such units will have the capacity to generate 5 to 10 megawatts of electricity. A 10-unit array of overtopping devices could be staggered across a 2.5-mile transect of ocean. As with an attenuator, underwater transmission lines would bring the generated power to the grid onshore.

Oscillating Water Column

Oscillating water columns are partially submerged structures that enclose a column of air above a column of water. The movement of the waves causes the water column to rise and fall, driving the cycling air pressure through a turbine generator ([Figure 2-28](#)). As a wave enters the column, it forces the air in the column up the closed column past a turbine, and increases the pressure within the column. As the wave retreats, the air is drawn back past the turbine due to the reduced air pressure on the ocean side of turbine.

Figure 2-28. Illustration of Oscillating Water Column Technology (Source: [Earthsci.org 2013](#))

The water columns are housed in very large concrete structures that can be built into the shoreline or moored at sea. A shore-based facility with a capacity to generate 500 kilowatts of electricity could be the size of a two-story, 3,000-square-foot structure, positioned half on the shore, half in the water ([Figure 2-29](#)). At-sea designs are still in the development phase; however, current designs range from 0.5 to 3 megawatts and about 100 feet long by 30 feet wide, with the surface floating about 8 feet above water level. At-sea devices would increase in size, depending on capacity ([Oceanlinx 2013](#)). Transmission and electrical distribution requirements would be dependent on proximity to existing infrastructure.

Figure 2-29. The Limpet Wave Power Station in the Isle of Islay, Scotland (Credit: Martin Bond/Science Photo Library)

Point Absorber

Point absorber technology involves harnessing wave energy from a single, or array of wave energy “absorbers.” The absorber can be a floating (buoyant) or submerged device ([Figure 2-30](#)). The rising and falling of the ocean swells cause the device to rise and fall, facilitating the movement of electromagnets inside a coil of wire to generate electricity. Other designs use the ocean’s movement to generate pressure in a cylinder within the device to pump water to a powerhouse onshore. In all cases, associated infrastructure would include underwater transmission cables to carry the generated electricity to a power converter onshore.

Figure 2-30. Illustration of Point Absorber Technology

Devices generally are the size of a lighthouse submerged 75 percent underwater and currently generate around 150 kilowatts per device, with large-capacity devices proposed for future development. For the devices that generate electricity via water pressure onshore, the size and capacity of the system is dependent on the number of buoys and onshore electricity-generating equipment. Technologies currently under development range from tens to hundreds of kilowatts ([OSU 2013b](#)). Transmission and electrical distribution requirements are dependent on proximity to existing infrastructure.

Oscillating Wave Surge Converter

Oscillating wave surge converters utilize the relative back and forth motion of waves near shore to move a large paddle-like flap (Figure 2-31). This device produces electricity by converting mechanical energy from the horizontal motion of the paddle into power, or by pumping water to shore, similar to the point absorber technology above, to generate electricity via hydropower turbine (Folley et al. 2004; Aquamarine 2013). Based on images of deployed devices in the United Kingdom, these wave surge converters are roughly the size of a small airplane hangar, and the power conversion station likely the size of a two-story structure that is between 5,000 and 10,000 square feet (Figure 2-32).

Figure 2-31. Illustration of Oscillating Wave Surge Converter Technology

Water Current/Tidal Power Technology Types

Technologies that rely on the flow of water (that is, currents, free-flowing rivers, and predictable tidal flow) to generate electricity are similar to wind turbines and include axial flow turbines, cross-flow turbines, and reciprocating devices (DOE 2013e). However, these are not viable in Hawai'i due to insufficient water current, and tidal ocean current resources (NREL 2009a). Therefore, this PEIS does not address these technologies further.

Figure 2-32. Oscillating Wave Surge Converter

(Source: <http://www.computescotland.com/images/ibRJzFJ2p4I0OYrXxfUD0ff0bh.jpg>)

2.3.3.5.2 Characterization of Technology Feasibility and Deployment

Despite the technological barriers that some of these technologies face, in terms of commercial scale development, Hawai‘i has one of the most consistent wave regimes in the United States, making it a superior location for wave power deployment ([DBEDT 2002c](#)). DOE estimates that Hawai‘i’s theoretical wave energy resource is 130 terawatt-hours per year ([EPRI 2011](#)). Aside from ocean thermal energy conversion (discussed below in [Section 2.3.3.6](#)), wave energy is the only type of marine hydrokinetic power feasible in the Hawaiian Islands ([NREL 2009a](#)). According to NREL’s Marine and Hydrokinetic Atlas (http://maps.nrel.gov/mhk_atlas), the greatest wave power resources exist along the northern coasts of the Hawaiian Islands. According to Hawai‘i’s 2006 Wave Map, there are numerous areas in and around the islands’ shorelines that have competing uses—military, marine mammal sanctuaries, and fisheries management areas ([Hawai‘i 2006](#))—which may limit the deployment of marine hydrokinetic technologies.

Economically feasible wave resources occur in water around 250 feet deep; shallower depths affect waves due to sea-floor friction reducing wave power. Around the Hawaiian Islands, wave power potential at 250-foot-deep water averages from 10 to 15 kilowatts per meter; however, proximity of the islands to each other creates sheltering from waves and reduces potential power around O‘ahu and Hawai‘i ([DBEDT 2002c](#)). There is a total of 30 gigawatt-hours ocean energy potential on both O‘ahu and Maui, totaling 60 gigawatt-hours for the State ([DBEDT 2012b](#)). As a renewable energy power source located in an area with ample wave resources, deployment of wave power conversion devices would aid in addressing the HCEI goals.

In 2012, DOE ran a \$500,000 solicitation to assist in the testing of a marine hydrokinetic device at the Wave Energy Test Site (WETS) in Kaneohe Bay, O‘ahu ([DOE 2012i](#)). As a result of this solicitation, a wave device is expected to arrive in Hawai‘i mid-2014 to utilize the shallow, grid-connected berth at WETS. An EA and Finding of No Significant Impact ([DoD 2014](#)) for two deeper WETS berths were completed in early 2014. WETS will host pre-commercial, pilot-scale projects. According to the DOE’s [Marine and Hydrokinetic Technology database](#), there are no commercial, grid-connected marine hydrokinetic devices operating in Hawai‘i.

Marine hydrokinetic technology designs are still emerging. Specific representative deployment details are also unclear with respect to the size of the technologies, the expanse of the deployment array, the capacity of the devices, or which devices will ultimately be economically or technically viable in the Hawaiian Islands. However, if deployed, the selected technology likely would fall into one of two categories: onshore and offshore. Generally, the construction of onshore technologies would require the deployment of one or more semi-submerged devices at the shoreline (see descriptions above for oscillating wave surge converter, overtopping, and oscillating water column for ranges of project sizes and technical descriptions), along with the construction of transmission lines, closed-loop water piping, and any necessary power conversion structures on land, and likely would be the size of a small warehouse. Offshore devices, either floating or submerged, would need to be tethered to the sea floor with anchors, and would connect to a power cable running back to shore. Alternatively, such devices may require connection to water piping to transfer pressurized water in a closed loop to and from a powerhouse onshore to drive a turbine.

In almost every case, marine hydrokinetic technology installations will require moorings to secure devices in a given marine location. Moorings can have a single or multiple legs (that is, cables connected to anchors made of chain, wire, or synthetic material), and vary in length depending on the depth of water. Cables can be slack and allow for movement of the device or taut and restrict movement, such that the device is stationary in the water. Depending on the design, buoys may also be attached to some mid-point of the line and be present above or below the water. Anchors would attach cables to the sea floor. The

type of anchors needed are dependent on environmental conditions of the installation area including depth, expected forces on the device from wave activity and/or weight of attached device, and seabed composition. There are many different types of anchors to consider, including deadweight, drag-embedment, pile, and plate anchors. More complex designs intended for minimal site impacts have greater interaction with the seabed (e.g., buried or driven into the seabed rather than just sitting on top of the seabed, like a giant weight). Such designs can also be more expensive due to complexity of the technology and deployment considerations ([OWET 2009](#)).

Deadweight anchors are heavy objects made from steel or concrete and can vary in size depending on how much resistance is needed. Drag anchors are dragged along the sea floor until they penetrate the sea floor, but offer little in the way of resistance to vertical movement because of how the anchor is oriented to the sea floor once it is secured. Piles are metal shafts driven into the sea floor and require specialized equipment for installation. If the seabed is rock (rather than loose sediment), installers must pre-drill holes prior to pile installation. Anchor plates are similar to piles, but instead of cylinders, are flat, like plates with barbs, so they keep in place after installation. Anchor plates are driven into position via pile driver, vibration, or dragging, and then re-oriented perpendicular to the sea floor to prevent the anchor from coming loose if needed. In hard seabed, reorientation is not always necessary, as the friction around the installed anchor may be sufficient (depending on the load requirements of the anchor installation) ([OWET 2009](#)).

The sea floor in waters around Hawai‘i less than 1000 feet deep is composed primarily of a hard surface of active coral reef or compact sand, whereas the sea floor in deeper waters has a generally softer composition of mud and between 20 and 30 percent sand ([DBEDT and SOEST 2010](#)). However, during project development, a detailed site analysis would show that this is not a uniform rule, and sea floor composition varies from site to site. Considering the sea floor characteristics, sensitive environmental conditions (i.e., marine life and coral reefs) in Hawai‘i, and limited resistance to uplift, drag anchors would not be suitable for marine hydrokinetic applications. In addition, if the seabed slope is greater than 10 degrees, deadweight anchors would not be suitable ([OWET 2009](#)). However, all other anchoring options could be utilized, depending on the technical application and size of the device, where the size of the anchors directly correspond to the size of the device being tethered to the sea floor ([OWET 2009](#)).

Offshore devices likely would be connected in large arrays if the deployment was intended for commercial-scale power generation. Array configurations, size, and space requirements are dependent on technology design. In many cases, further testing and investigation are needed to determine optimal placement.

2.3.3.5.3 Permitting and Consultation Requirements

For a discussion of general permitting and regulatory requirements, including requirements for marine-based projects, see [Section 2.2.5](#). In accordance with the provisions of EAct 2005, FERC is responsible for licensing, inspecting, and overseeing hydrokinetic activities. However, EAct 2005 also amended the *Outer Continental Shelf Lands Act* ([43 U.S.C. §§ 1331-1356](#)) to grant the Secretary of the Interior discretionary authority to regulate the production, transportation, or transmission of renewable energy on the Outer Continental Shelf (OCS). In April 2009, the Secretary of the Interior and the Chairman of FERC signed an MOU, clarifying the scope of each agency’s respective responsibilities for regulating renewable energy projects on the OCS. Under the agreement, FERC has authority to issue licenses for all hydrokinetic projects (including those on State submerged lands and on the OCS), and the DOI has authority to issue leases and easements for hydrokinetic projects located partially or wholly on the OCS. For projects within the 3-mile buffer, the project developers need to seek a variety of permits from Federal, State, and county regulatory entities. If a project is located near a protected marine habitat, the developers must also consult with the NOAA NMFS for permits relating to those concerns ([DOE 2009a](#)).

The developers also would consult with the USFWS and the NOAA NMFS on projects impacting protected species, [critical habitat](#), and EFH. Additionally, developers should consult with NPS on projects that could have impacts on sensitive resources of the National Park System and other protected resources. With the abundance of marine recreational and commercial activities in Hawai'i, project siting and stakeholder outreach for marine hydrokinetic projects are critical. Project developers must identify and consult with key stakeholders early in the planning stage. The procedures for authorizing [marine hydrokinetic energy](#) projects involve rigorous environmental review and a substantial level of agency and stakeholder consultation ([DOE 2009a](#)).

Compensatory mitigation under CWA Section 404 could be required if projects involve unavoidable impacts to species and their habitat, including coral reefs. Best management practices such as those presented in Section 3.4.6.2 should be incorporated into project-level analyses to minimize damage from moorings, anchors, anchor lines, and pipelines during construction, particularly in areas near coral reefs. Areas should be designated for moorings and anchors that specifically avoid impacts to corals, and areas of high coral value should be marked with buoys to ensure avoidance of those areas during construction.

2.3.3.5.4 Representative Project

Due to the uncertainty of marine hydrokinetic technology readiness, it is difficult to describe with any accuracy what a representative project might look like, and would ultimately depend on the type of wave technology selected. For the purposes of this PEIS, the potential environmental impacts of marine hydrokinetic technologies (presented in Chapter 6) will consider the range of potential applications identified in [Section 2.3.3.5.2](#) that address potential impacts to the shoreline, near-shore, and offshore environments.

2.3.3.6 Ocean Thermal Energy Conversion

Ocean thermal energy conversion is a renewable energy technology that relies on temperature gradients in the ocean to generate electricity. By utilizing cold deep water and warm surface waters, it is possible to alternately condense and evaporate a fluid to drive a turbine. In general, the larger the temperature difference between the shallow and deep water, the more power a system will be able to produce.

2.3.3.6.1 Technology Description

There are three primary methods of converting ocean thermal energy. The needs of the energy system it is serving and the local ocean characteristics help determine the best method ([DOE 2013f](#)):

- Closed-cycle ocean thermal energy conversion uses warm seawater and a low boiling-point working fluid such as ammonia, propane, or Freon to generate electricity. Pumps draw warm, shallow seawater from the ocean and transfer it to a heat exchanger where it heats the working fluid. The working fluid vaporizes and drives a turbine to produce electricity. The working fluid is then pumped through a second heat exchanger, where it mixes with cold seawater brought up from the ocean depths, condenses back into a fluid, and cycled back through the process.
- Open-cycle ocean thermal energy conversion uses warm seawater to generate electricity directly, rather than through a working fluid. Pumps draw warm, shallow seawater from the ocean and transfer it to a heat exchanger, where it vaporizes into steam. This steam is used to drive a turbine, which produces electricity. The steam is then pumped through a second heat exchanger, where it mixes with cold seawater brought up from the ocean depths and condenses back into a fluid. The resulting liquid is almost completely desalinated and can be used in other applications.

- Hybrid ocean thermal energy conversion combines these methods. Warm seawater vaporizes into steam in a heat exchanger and the steam heats a working fluid. The working fluid vaporizes, which drives a turbine to produce electricity. The working fluid is then pumped through a second heat exchanger, where it mixes with cold seawater brought up from the ocean depths, condenses back into a fluid, and cycled back through the process.

The first documented reference to the use of ocean temperature differences to produce electricity is found in Jules Verne's *Twenty Thousand Leagues Under the Sea* published in 1870 (Vega 2002). Small-scale ocean thermal energy conversion projects have been demonstrated since the 1970s; there are no large-scale commercial ocean thermal energy conversion systems in operation. However, the world's first commercial-scale ocean thermal energy conversion power plant, a 10-megawatt offshore facility, is under development and will be located off the coast of Southern China (OTEC News 2013).

Ocean thermal energy conversion facilities can be located either onshore or offshore. Land-based facilities have a higher internal energy demand relative to offshore plants due to the pumping load required to bring large volumes of water onshore through long intake pipes (NELHA 2012). Offshore facilities would be located in deep ocean water several miles from the shore. First generation commercial OTEC facilities in Hawai'i would likely be offshore facilities (NELHA 2012; Vega 2002). Figures 2-33 and 2-34 illustrate onshore and offshore ocean thermal energy conversion facilities. Figure 2-33 also shows co-production facilities.

Figure 2-33. Onshore Open-Cycle Ocean Thermal Energy Conversion Facility with Desalination Co-production (Source: NOAA 2013a)

Figure 2-34. Offshore-based Closed-Cycle Ocean Thermal Energy Conversion Facility
(Source: [NOAA 2013b](#))

2.3.3.6.2 Characterization of Technology Feasibility and Deployment

Ocean thermal energy conversion technology depends largely on accessible ocean temperature gradients. Although in theory there is a vast amount of energy contained in the ocean's temperature gradients, in reality, a temperature difference of over 36°F between deep and shallow water must exist for an economically viable system ([DOE 2009b](#)). Seawater temperature differences of less than 36°F require ocean thermal energy conversion systems with relatively large seawater flow rates, on the order of 100 cubic feet per second per megawatt of net electricity produced ([Nihous 2013](#)). However, suitable temperature gradients exist in tropical regions such as the Hawaiian Islands with access to deep (i.e., greater than 3,000 feet) ocean water ([Vega 2010a](#)).

According to the NREL Marine and Hydrokinetic Technology atlas, the annual average temperature difference between deep and shallow water off the coasts of the Hawaiian Islands is 36° to 40°F ([NREL 2013b](#)). A larger temperature difference is found on the southwestern coasts, compared with a slightly smaller temperature difference on the northeastern coasts. Sufficiently deep waters are found close to the Hawaiian Islands, due in part to the area's geology, which provides a steep slope to ocean depths that provide the required water temperature variance. Siting considerations include the distance to centers of greatest electricity demand from feasible sites. However, ocean temperatures surrounding the islands are relatively consistent, indicating that a potential developer would have their pick from a number of viable site locations.

The main benefit of ocean thermal energy conversion is that ocean temperatures are relatively stable, and can provide a consistent source of power without downtime. Unlike some renewable energy technologies, the electricity generated can be distributed at utility scales with little intermittency. There are also potential beneficial applications for co-products that can be implemented within a system's distribution range ([DOE 2013f](#)). Cold, deep seawater used to condense the working fluid can be distributed throughout a *district cooling* system to provide air conditioning to buildings within range (Section 2.3.1.5 of this PEIS addresses sea water air conditioning technologies). The cold, deep seawater can also be used in agriculture, aquaculture, and potable water applications. For open-cycle and hybrid systems, desalinated water can be used. High capital costs may be an initial barrier to implementation of commercial OTEC systems. However, ocean thermal energy conversion facilities benefit from economies of scale, with larger-scale systems being more viable.

The following potential environmental issues related to ocean thermal energy conversion facilities require further research ([NOAA 2013c](#)):

- **Withdrawal and Discharge Water** – A 100-megawatt facility would use 10 to 20 billion gallons per day of warm sea water from the surface and cold water from a depth of approximately 3,300 feet. The large volume of water discharged from ocean thermal energy conversion facilities will be cooler, denser, and more nutrient rich due to the composition of the deep cold water being different from the receiving waters. Nutrient rich water (with nitrogen and phosphorus) would be discharged at a depth where the ambient water is warmer and oligotrophic (nutrient poor).
- **Impingement and Entrainment** – Screens would be used for both the warm and cold water intake systems to prevent debris and larger species from entering.
- **Biocide Treatments** – The warm water used in the facility would need to be treated with a biocide (e.g., chlorine) to prevent biofouling (the accumulation of microorganisms, plants, algae, or animals on wetted surfaces) and maintain the efficiency of the heat exchangers. The amount of biocide needed would likely be less than the maximum discharge allowed under the CWA.

Several pilot-scale ocean thermal energy conversion projects have been executed in Hawai‘i since the 1970s. Large-scale ocean thermal energy conversion electricity generation, however, has been slow to emerge. NELHA at Keahole Point in Kona achieved major milestones in ocean thermal energy conversion in the 1980s and 1990s, including a 1-megawatt floating pilot plant, Mini-OTEC (the world’s first demonstration of net power output from a closed-cycle plant) and other demonstrations in both open- and closed-cycle configurations ([DBEDT 2013h](#)). A 1-megawatt onshore demonstration project at NELHA is currently the planning stages, and there is interest in 5- to 10-megawatt and 100-megawatt offshore demonstration projects off O‘ahu ([BOEM 2012](#)). NELHA presently hosts an ocean thermal energy conversion heat exchanger test facility, and there are plans to add a 100-kilowatt generator in 2014 ([DBEDT 2013h](#)).

2.3.3.6.3 Permitting and Consultation Requirements

NOAA's Office of Ocean and Coastal Resource Management is responsible for licensing the construction and operation of commercial ocean thermal energy conversion systems, while DOE’s Office of Energy Efficiency and Renewable Energy Water Power Program is responsible for designating ocean thermal energy conversion demonstration projects ([NOAA 2013b](#)). The majority of Federal, State, and county requirements would be handled through the NOAA licensing process ([HNMREC 2013](#)). See [Section 2.2.5](#) for a discussion on general permitting and regulatory requirements, including marine-based technologies.

Primary environmental risks from ocean thermal energy conversion facilities include the high volume of discharge into the ocean and the impacts of laying a large pipe on the seafloor and coastline. Facility modeling to determine effluent volume, temperature, and composition is needed to provide the permitting agencies the information necessary to assess and mitigate project impacts. Projects would need to conduct extensive biological exploration within the project footprint, both above and under water, to identify protected marine species that potentially could be impacted by the project. If a project is located near a protected marine habitat, the developers must also consult with the NOAA NMFS for permits relating to those concerns ([DOE 2009a](#)). The developers also would consult with the USFWS and the NOAA NMFS on projects impacting protected species, *critical habitat*, and [EFH](#). Additionally, developers should consult with NPS on projects that could have impacts on sensitive resources of the National Park System and other protected resources.

Water quality impairment and cooling water intake for ocean thermal energy conversion facilities is regulated by the CWA Sections 316(b), 402, and 403. Under CWA Section 402, any discharge of a pollutant or combination of pollutants into a waterway requires a valid [NPDES](#) permit, and Section 403 provides for the promulgation of guidelines applicable to NPDES permits for discharge of pollutants into oceans and territorial seas. Clean energy projects would have to apply to HDOH at least 180 days prior to commencement of operations to receive an NPDES permit. The project would then have to meet all conditions set forth in its NPDES permit, including numeric effluent limitations established to protect water quality in the receiving water. Applicants for clean energy projects within federal waters would have to apply to the EPA for this permit.

Section 316(b) provides a means to demonstrate to EPA that the location, design, construction, and capacity of cooling water intake structures for facilities reflect the best technology available for minimizing adverse environmental impacts (33 U.S.C. §§ [1326\(b\)](#), [1342](#), and [1343](#)). Clean energy projects would have to demonstrate to the satisfaction of HDOH and EPA that the intakes for their facilities would meet 316(b) requirements prior to receiving their NPDES permits.

In order to meet the State’s water quality standards, a zone of mixing (per [HAR 11-54-9](#)) may need to be approved under the permitting process. The zone of mixing is a limited area around the discharge outfall

where dilution would be allowed. The permittee would be required to conduct a dilution study to determine the dilution factor representative of the zone of mixing. The permit would then include conditions or limitations with consideration of the dilution factor. If an acceptable zone of mixing could not be established, alternatives such as treating the water (for example, nutrient removal or temperature adjustment) before discharge may need to be considered.

Compensatory mitigation under CWA Section 404 could be required if projects involve unavoidable impacts to species and their habitat, including coral reefs. Best management practices such as those presented in Section 3.4.6.2 should be incorporated into project-level analyses to minimize damage from moorings, anchors, anchor lines, and pipelines during construction, particularly in areas near coral reefs. Areas should be designated for moorings and anchors that specifically avoid impacts to corals and areas of high coral value should be marked with buoys to ensure avoidance of those areas during construction.

2.3.3.6.4 Representative Project

A representative ocean thermal energy conversion project in Hawai‘i would consist of a 50-megawatt closed-cycle system located in deep water 3.5 miles offshore from a land-sea cable transition site. A deep-water pipe 30 feet in diameter and about 3,300 feet deep would draw deep, cold seawater. Deep water would be retrieved at a temperature of 39° to 41°F and surface water at 75° to 82°F. Warm sea water would be drawn through two 33-foot diameter pipes. Seawater flow rates would be 70,000 gallons per second of warm water and 36,300 gallons per second of cold water. The effluent sea water (both warm and cool waters combined) would be returned via two 40-foot-diameter pipes at a depth of 200 feet, in accordance with environmental standards and Zone of Mixing regulations to prevent alteration of natural ocean temperature profiles or disruption of thermohaline cycling.

The floating platform would be 650 feet long with a 128-foot beam and an operating draft of 53 feet. The closed-cycle system would use pressurized anhydrous ammonia as the working fluid, which would pass through evaporating and condensing plate-fin heat exchangers. These exchangers would be located on the floating platform anchored to the ocean floor via mooring lines. The facility would use the anhydrous ammonia at a rate of about 6,100 pounds per second. The project would use chlorine to protect the heat exchangers from biofouling. It has been determined that biofouling from cold sea water is negligible and that evaporator fouling can be controlled effectively by intermittent chlorination (50 to 100 parts per billion of chlorine for 1 hour per day) ([Vega 2010b](#)).

An undersea power cable no more than 5 inches in outside diameter would run approximately 6 miles to an onshore land-sea cable transition site, which would connect to the power grid to power the pumps and to deliver electricity to the entire facility. The floating platform would use auxiliary diesel-powered generators to provide backup power to maintain operation of the ocean thermal energy conversion system.

2.3.3.7 Photovoltaic Systems

As [Section 2.3.2.4](#) covered, PV cells convert sunlight to electricity and are grouped into solar modules. Solar modules for utility-scale systems are part of a larger system, or array, to generate and supply electricity for the utility grid. A system typically includes a number of modules, equipment to collect and convert the electricity generated, sun-tracking devices to improve the ability of the module to collect solar energy regardless of the location of the sun throughout the day, and, in some cases, energy storage capacity. For comparison purposes, a typical distributed PV system generates up to 50 kilowatts of electricity, uses relatively few solar modules, and covers a few hundred square feet. The Anahola Solar Project on Kaua‘i, one of the more recent utility-scale PV projects under construction in Hawai‘i, will generate 12 megawatts of electricity, use approximately 50,000 modules, and take up about 67 acres of land.

Generally speaking, a utility-scale PV system ties into the grid close to where the power is produced, which travels to the consumer via the grid. Energy storage allows excess electricity to be stored and used at times when the demand for electricity on the grid exceeds the amount generated. It also facilitates grid stability, allowing for regulating, or smoothing, intermittency. Utility-scale PV systems historically have not been combined with energy storage options (noting that some installations in Hawai‘i are equipped with storage), whereas utility-scale solar thermal systems are more likely to offer such storage systems. Energy storage is one of a group of technologies that can contribute to a smart grid. A smart grid is designed to improve the efficiency and overall reliability of the utility distribution grid. This PEIS discusses smart grids and energy storage in [Sections 2.3.5.3](#) and [2.3.5.4](#), respectively. More information on both topics can be found online at <http://energy.gov/oe/technology-development/smart-grid>.

The National Renewable Energy Laboratory determined that life-cycle greenhouse gas emissions from solar modules were significantly less than fossil and nuclear electricity generation, as well as many other renewable energy technologies ([NREL 2012a](#)).

2.3.3.7.1 Technology Description

The technology behind PV systems is basically the same whether with a small, distributed system or a utility-scale system. When sunlight shines on a PV cell, the cell absorbs a portion of the light. The energy of the absorbed light transfers to some of the electrons in the atoms of the PV cell’s material. Those electrons escape from their normal positions in the atoms and become part of the electrical flow, or electricity. The amount of energy from the sunlight that converts to electricity depends on a number of factors, including the wavelength of the light, the amount of light absorbed, the temperature of the PV cell, and the resistance of the materials to the electrons’ flow. Capacity factors among the different PV cell materials and designs range from about 6 to 40 percent. Typical commercially available modules used in utility-scale installations range between 15 and 20 percent.

The generated electricity is DC and must be converted to AC before use. One or more inverters convert the generated electricity onsite at the utility-scale PV installations or at other locations where the electricity is going to be used. If the former, the local utility transmits the electricity via distribution grid to the consumer. As with a distributed system, a utility-scale system may or may not include energy storage capabilities, albeit a higher capacity storage system. [Figure 2-35](#) is a diagram of the major items of a utility-scale PV system connected directly to a local utility distribution grid and [Figure 2-36](#) is a diagram of a utility-scale PV system with energy storage capabilities.

2.3.3.7.2 Characterization of Technology Feasibility and Installation

Utility-scale PV systems are a mature and reliable renewable energy technology. The DOE SunShot Initiative is a national collaborative effort to make solar energy cost-competitive with other forms of electricity by the end of this decade ([DOE 2013c](#)). The State of Hawai‘i has ideal sun conditions for the development of electricity from PV systems. Currently 4.3 percent of electrical energy consumption in the State is produced by solar facilities including utility-scale PV systems ([DBEDT 2014a](#)). There are approximately 23 megawatts of capacity operating or close to starting operations in the State, with about 49 megawatts of capacity under development ([SEIA 2013](#)).

Figure 2-35. Diagram of the Major Items of a Utility-Scale Photovoltaic System Connected Directly to a Local Utility Distribution Grid

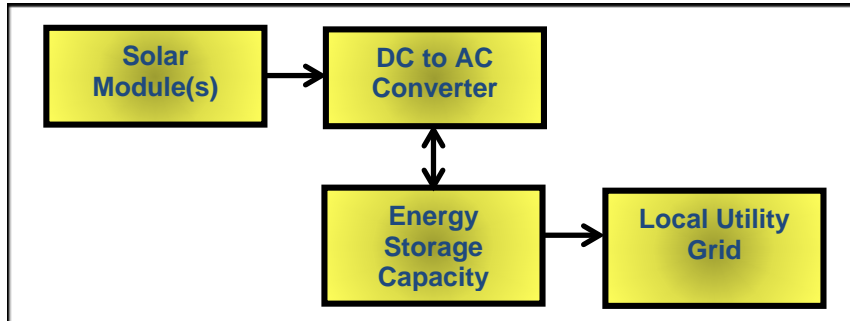

Figure 2-36. Diagram of the Major Items of a Utility-Scale Photovoltaic System with Energy Storage Capacity

2.3.3.7.3 Permitting Requirements

General permitting requirements are discussed in [Section 2.2.5](#). Many PV modules contain substances that could pose a risk to the environment and, potentially, public health if not properly disposed of or recycled. There are industry initiatives to develop recycling guidelines and processes for PV systems. There is also research being conducted on PV cells that are made from plant materials and, while the conversion efficiencies for these cells are currently low (a few percent), future advances could partially address future disposal considerations. Currently some discarded solar modules may need to be managed and disposed of as hazardous waste. There has been recent discussion regarding the use of agricultural lands for renewable energy development in Hawai‘i. Given the State priorities on energy and food independence, careful siting and planning must occur to ensure these priorities are taken into consideration. The FAA and State of Hawai‘i Department of Transportation – Airports Division should also be consulted.

2.3.3.7.4 Representative Project

The representative project involves utility-scale facility with 50 megawatts generating capacity that ties directly into the electrical distribution grid. The representative project would have a footprint ranging from approximately 250 acres, with about 200,000 modules. In general, solar PV projects require about 5 acres of land per megawatt generated. The type and amount of electrical equipment and wiring associated with collecting, converting the DC electricity to AC electricity, and tying the system into the utility grid would be proportional to the size of the project. For purposes of analysis, the representative project transmits electricity directly to the distribution grid and does not have energy storage capabilities.

2.3.3.8 Solar Thermal Systems

2.3.3.8.1 Technology Description

Solar thermal energy converts solar energy into thermal energy (heat) that can be used for thermal loads or for the production of electricity. One big difference from solar PV technology is that solar thermal power plants generate electricity indirectly. Heat from the sun's rays is collected and used to heat a fluid. The steam produced from the heated fluid powers a generator that produces electricity. This is similar to the way fossil-fuel-burning power plants work except the steam is produced by the collected heat rather than from the combustion of fossil fuels. Solar thermal facilities are capable of producing one or a few to hundreds of megawatts of power.

High-temperature collectors concentrate sunlight using mirrors or lenses and are generally used for larger-scale electric power production. Utility-scale thermal systems use high-temperature collectors (up to and over 400°F) and are often called concentrating solar power systems ([EIA 2013b](#)).

Solar thermal units use concentrated sunlight to produce electricity by capturing heat using mirrors or lenses, which turn to follow the course of the sun during the day. The mirrors focus the reflected sun's heat on a heat-absorbing working liquid. The heat is then transferred from the working fluid to a conventional steam generator or organic rankine cycle generator. A thermal energy system can store heat, thus allowing electricity production into the evening and after the sun goes down or on cloudy days ([EIA 2013b](#)).

Solar thermal power technology uses concentrator systems to achieve the high temperatures needed to heat fluid. The three main types of solar thermal power systems are parabolic trough with linear concentrations, solar power tower, and solar dish ([EIA 2013b](#)). Although solar dish technology has the potential to become one of the least expensive sources of renewable energy, this technology is still in the engineering development stage and faces challenges concerning the solar components and commercial availability ([SolarPACES.org 2013](#)). Therefore, this PEIS does not analyze that technology further.

Parabolic Trough Power Plants

Parabolic trough power plants (the most common type of solar thermal plant in the United States) use curved, mirrored modules shaped like a trough to reflect the direct sun's rays onto the receiver (a glass tube containing a fluid), which runs the length of the trough ([Figures 2-37](#) and [2-38](#)). The trough is parabolic, or U-shaped, along one axis and linear along the axis of the receiver. The trough tilts east to west so that direct sunlight hits the receiver at all times. Seasonal changes in the angle of sunlight do not require adjustment of the mirrors, since the light concentrates on the receiver.

A heat transfer fluid passes through the receiver and becomes very hot. Common fluids are synthetic oil, mineral oil, molten salt, and pressurized steam. Using gravity, the fluid containing the heat flows to a heat engine, where about one-third of the heat converts to electricity ([DOE-EERE 2013b](#)). Located at Keahole Point is the world's first Concentrating Solar Power project based on the MicroCSP technology using a regenerative Rankine Cycle Engine (see [Section 2.3.3.8.2](#)) ([Sopogy 2013](#)). The Rankine Engine uses refrigerant as its working fluid rather than steam ([Northwestern University 1997](#)).

Figure 2-37. Depiction of a Parabolic Trough Solar Thermal Power System

Figure 2-38. Parabolic Trough Solar Farm with High-Temperature Solar Collectors and Support Facilities, Cooling Towers, White Water Tanks, and Generation Equipment (Source: DOE-EERE 2013b)

If the receiver contains oil or molten salt as the heat-transfer fluid (HTF), then the thermal energy can be stored for later use (DOE-EERE 2013b). The HTF is supplied to the power plant where it passes through a series of heat exchangers, turning water into high-pressure steam that drives a Rankine steam turbine. The HTF is then returned to the solar collector field to be heated once again, creating a closed-loop system. Heat storage allows a solar thermal plant to produce electricity at night and on overcast days. This enables the use of solar power for baseload generation (backed up by liquid or gaseous fuels) as well as peak power generation. Several thermal storage technologies are in use, including the two-tank direct system, two-tank indirect system, and single-tank thermocline system.

Two-tank direct systems store solar thermal energy in the same fluid used to collect it. The fluid is stored in a closed loop in two tanks, one at high temperature and the other at low temperature. Fluid from the low-temperature tank flows through the solar receiver, where solar energy heats it to a high temperature, and then continues to the high-temperature tank for storage. Fluid from the high-temperature tank flows through a heat exchanger, where it generates steam for electricity production. The fluid exits in the heat exchanger at a low temperature and returns to the low-temperature tank (DOE-EERE 2013b).

Two-tank direct

The single-tank thermocline system (Figure 2-39) stores thermal energy in a solid medium, most commonly silica sand, in a single tank. Inside the single tank, parts of the solid are

Figure 2-39. Graphic Presentation of the Single-Tank Thermocline System (Source: DOE-EERE 2013b)

kept at low to high temperatures, in a temperature gradient, depending on the flow of fluid. For storage purposes, hot heat-transfer fluid flows into the top of the tank and cools as it travels downward, exiting as a low-temperature liquid. This process moves the thermocline, or transition layer, downward and adds thermal energy to the system storage. Reversing the flow moves the thermocline upward and removes thermal energy from the system to generate steam and electricity. Buoyancy effects help to stabilize and maintain the thermocline ([DOE-EERE 2013b](#)). Parabolic trough systems typically require 6 to 10 acres of land to generate 1 megawatt of power ([NREL 2013d](#)).

Solar Power Towers

Power towers (also known as central power plants or heliostat power plants) capture and focus the sun's thermal energy with thousands of tracking mirrors (called heliostats) in approximately a 2-square-mile field ([Figure 2-40](#)). Heliostats focus concentrated sunlight on a receiver that sits atop a tower, which is positioned in the center of the heliostat field. Within the receiver, the concentrated sunlight heats salt to more than 1,000°F. Like the parabolic trough systems, HTF is an integral part of the power tower system.

Figure 2-40. Operating Solar Power Facility in Spain

The HTF is composed of either water or molten nitrate salt and as it moves through the receiver it is heated to temperatures over 500°C. The heated HTF is then sent to a heat exchanger where the water is turned into steam, which then drives a turbine generator. More advanced systems that use molten salt as the HTF can take advantage of the higher heat capacity of the fluid and can store the heat energy, which allows the system to continue to generate electricity for several hours longer compared with those without storage capability, which effectively increases a power tower's capacity factor.

The advantage of this design compared with the parabolic trough design is the higher temperature attained. Thermal energy at higher temperatures can be converted to electricity more efficiently and is less expensive to store for later use. Furthermore, solar power facilities are not limited by the topography of a prospective site. The mirrors can move independently so they point at the receiver. However, the fact that the mirrors make the design more complex, in that each mirror must have its own dual-axis control; whereas, in the parabolic trough design, a single array of mirrors can share single axis tracking.

The land-to-power ratio is estimated at 9 to 10 acres per 1 megawatt ([NREL 2013d](#)). NREL has estimated that by 2020, electricity could be produced from power towers for 5.47 cents per kilowatt-hour and for 6.21 cents per kilowatt-hour from parabolic troughs. The capacity factor for solar towers and parabolic troughs is estimated at about 25 percent, but can reach 40 percent or greater in plants with thermal storage ([NREL 2012c](#)). Tower heights can range from approximately 300 to 650 feet. Tower height and field size vary depending on individual project economics. An economic optimization analysis takes into consideration the capacity factor and capital costs. The amount of solar energy collected is a function of the number of heliostats installed. However, as the number of installed mirrors increases, the height of the tower must also increase. Determining the optimal tower height and field size is driven by the economies of scale.

2.3.3.8.2 Characterization of Technology Feasibility and Deployment

Hawai‘i’s tropical location provides a lot of sun energy that is poised to be utilized more effectively in the future. Basic site location considerations for a utility-scale solar thermal energy plant include proximity to the electrical grid, sufficient sun light, and topography. For utility-scale parabolic trough plants, project siting would generally avoid environmentally sensitive areas and population centers. The use of public lands can offer suitable sites ([DOE and BLM 2003](#)). Level land with a southern exposure is generally preferable because it provides the longest duration of sunlight.

There are no existing solar thermal energy projects in Hawai‘i, and currently none under development according to the Hawai‘i State Energy Office.

2.3.3.8.3 Permitting and Consultation Requirements

Additional information on more general permitting requirements can be found in [Section 2.2.5](#). There are several requirements specific to solar thermal energy projects of potential interest in terms of environmental evaluations:

- Due to potential reflectivity issues, the Federal Aviation Administration recommends all solar projects with reflective potential consult them early in the planning stages.
- For solar power towers more than 200 feet tall, the Federal Aviation Administration guidelines for marking and lighting facilities could require warning lights that flash white during the day and twilight and red at night ([BLM and DOE 2010](#)). Daylight lighting might be avoided in some cases by painting the power tower orange and white according to the Administration guidelines, but this practice could result in large increases in visual contrast for the tower during the day (resulting in a negative visual resources impact; see Section 6.8).
- Proximity to cultural and scenic resources, including national parks; any NPS park units within the viewshed of the proposed solar power facility (and associated facilities and transmission corridors) should be consulted early in the planning process.

2.3.3.8.4 Representative Project

The representative solar thermal facility would be a parabolic trough facility with 5-megawatt capacity on 30 to 50 acres of land ([NREL 2013d](#)). The construction and operation of solar collectors and support structures would be confined to that acreage and spaced to avoid shading the collector modules.

A parabolic trough solar thermal facility, with a dry cooling system, would use 30 to 80 gallons of water per megawatt-hour of electricity produced ([NREL 2012c](#)). Using a mid-value of this range (i.e., 55

gallons per megawatt-hour) and a 25 percent capacity factor, the annual water need for the 5-megawatt facility is estimated at about 600,000 gallons. Construction of a 5-megawatt facility would result in about 10 construction jobs for a period of up to one year; operational full-time jobs would range from 10 to 15 employees ([IndyStar 2013](#)).

The facility would include the key elements discussed in [Section 2.3.3.8.2](#) and depicted on [Figure 2-37](#), in addition to road access, parking, and maintenance facilities. During construction, the site would experience land clearance activities and require lay-down yards. The project also assumes a transmission tie-in of at least 1 mile.

2.3.3.9 Land-Based Wind Power

2.3.3.9.1 Technology Description

As described in [Section 2.3.2.5](#) for small wind turbines, utility-scale wind turbines convert the kinetic energy of the wind to mechanical power. In the typical horizontal-axis wind turbine, wind flowing over the airplane-wing-like blade causes a pocket of low-pressure air on one side of the blade and the low-pressure generates “lift” and pulls the blade toward it, causing the blade to move and the rotor to turn, which spins a generator to make electricity. The category of utility-scale, land-based wind turbines is generally considered to encompass turbines with capacities greater than 100 kilowatts and includes units with multiple megawatt capacities ([DOE 2013g](#)). The two basic groups of wind turbines are the horizontal- and vertical-axis varieties. Representative configurations for these two groups are depicted in [Figure 2-41](#). The horizontal axis wind turbine shown in the figure is the most common type; however, there is a wide variety of potential blade configurations for vertical-axis wind turbines, particularly in smaller wind turbine sizes (see [Section 2.3.2.5](#)).

Utility-scale, horizontal-axis wind turbines are designed to face into the wind and they contain internal equipment and controls that automatically rotate the turbine housing and rotor to keep the rotor in an upwind position. The vertical axis wind turbine has the advantage of being able to intercept wind coming from any direction without changing its own orientation. A primary limiting factor for the vertical axis turbine is the rotating shaft must remain rigid and stable, which requires the lower barring to be very solid or the top of the unit be fixed with an upper barring and guy wires. In comparison to horizontal axis wind turbines, the vertical axis wind turbines are less efficient and are generally installed at lower elevations where wind is less energetic and more often subject to turbulence caused by other structures or topography changes. The increased turbulence decreases energy production and increases wear ([DOE 2012m](#)). Utility-scale wind turbines and the associated wind farms are dominated by horizontal-axis machines and, accordingly, the technology description presented in this section will focus on this configuration.

Figure 2-41. Basic Wind Turbine Configurations

[Figure 2-42](#) shows the primary components of a utility-scale, horizontal-axis wind turbine. Several of these elements are described as follows:

- Rotor (Hub and Blades) – The rotor consists of the hub and blades. The majority of utility-scale wind turbines have three blades made of composite laminates. The blades, designed to be moved by wind, rotate the hub, which is connected to a shaft; thus, converting wind energy to rotational shaft energy. The amount of power that can be produced is a direct function of the swept area of the blades. Since the swept area increases by the square of the blade length, to double a wind turbine’s capacity, the blade length would have to be increased by a factor of about 1.4. For example, a 1.5-megawatt wind turbine requires a rotor diameter of about 216 feet ([DOE 2011e](#)), so a wind turbine with twice the power capacity, or 3.0 megawatts, needs a rotor diameter that is 1.4 times greater in size, or about 300 feet. That is, provided both machines were designed for the same wind velocity (see Tower description).
- Tower – The tower supports the rotor and nacelle (the housing that contains the gear box, shafts, generator, controller, and brake) with the objective of putting the rotor blades into a zone of higher wind velocity and lower wind turbulence than occurs near the ground. Towers can be made from tubular steel, concrete, or steel lattice ([DOE 2013h](#)), but the most common towers on modern utility-scale wind turbines are of tubular steel. There is no required relationship between the height of the tower and the size of the wind turbine, but power production varies by wind speed, which increases with height about the earth’s surface. Wind turbines in the 2.5 to 3 megawatts range are offered with towers heights of 260 feet or slightly higher, but may be 330 feet and higher.
- Drive Train – The major mechanical components inside the nacelle are part of the drive train that includes the following:
 - Gear Box – The gear box contains a multi-stage series of gears that convert the 8 to 15 rpm of the slow shaft to about 1,200 to 1,800 rpm for the high-speed shaft and which is the rotational speed required by most electric generators ([NREL 2012c](#)). The gear box is a heavy and expensive component of the wind turbine and ongoing research and development is pursuing generators that can operate directly from the low-speed shaft, which would eliminate the need for the gear box ([DOE 2013b](#)). It is estimated that more than 10 percent of the global turbine supply already consist of direct-drive drivetrains and the technology is already found among the wind turbines in Hawai‘i. To date, the direct-drive generators are larger and heavier than their high-speed counterparts ([NREL 2012c](#)), so some of their advantage is lost.
 - Generator – The electric generator produces AC electricity, at 60 hertz in the United States, and is generally an off-the-shelf induction generator.

Additional detail on the components of a typical horizontal wind turbine can be found in NREL’s *Renewable Electricity Futures Study*, available only from http://www.nrel.gov/analysis/re_futures/.

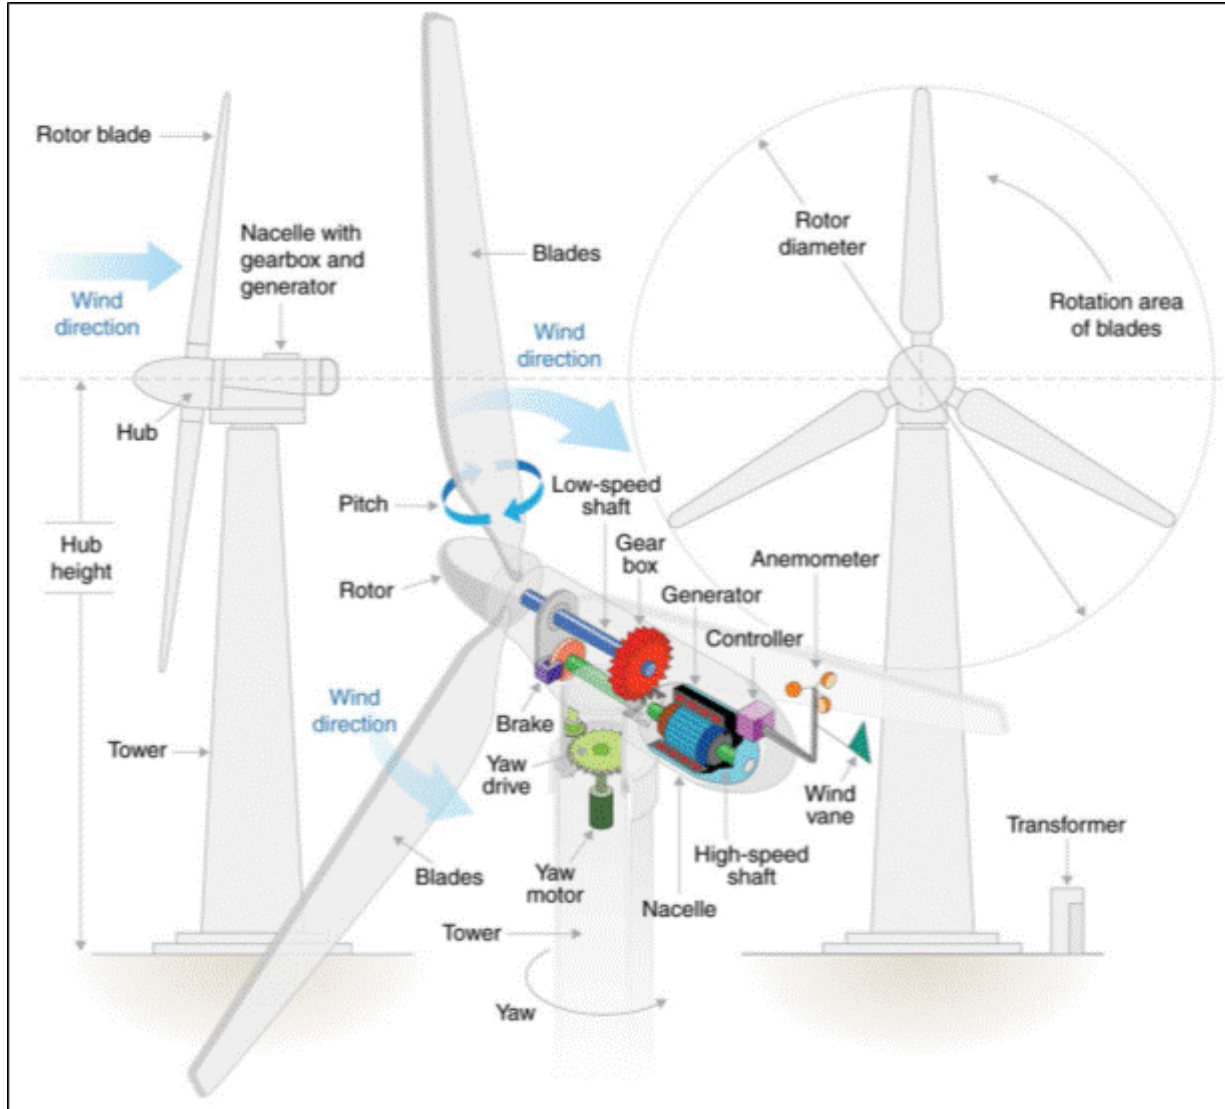

Figure 2-42. Schematic of the Primary Components of a Utility-Scale, Horizontal Axis Wind Turbine ([Source: NREL 2012c](#))

Vertical-axis wind turbines have many of the same components as described above for the horizontal axis variety. The rotor and blades would be different and a vertical-axis wind turbine likely would have nothing resembling a housing positioned up in the air, but the necessary functions would still be there.

Various entrepreneurs are pursuing alternative approaches of horizontal and vertical wind turbines to harnessing wind energy. It is relatively easy to find websites describing various means of using tethered devices similar to kites, wind sails, or even rigid wing-like items to generate power from wind. Some of these devices may hold great promise as future utility-scale energy producers, but for purposes of this document they are considered to be too early in development to address in any detail.

Evolution of Wind Turbine Sizes

Utility-scale wind turbines are intended to provide electricity to a distribution system, therefore their design is not centered on any specific power level. Rather, it is basically driven by a desire to provide as much output as possible, as efficiently as possible. In order to maximize turbine performance,

manufacturers have pursued more advanced turbine components and larger turbines. As a primary example, the development of stronger and lighter blades has facilitated design of wind turbines with larger rotor diameters. The current, state-of-the-art turbine produces about 1.5 to 3.5 megawatts. In 2011, the average installed turbine size in the United States was about 2 megawatts ([DOE 2013i](#)). At least one manufacturer is already promoting a land-based wind turbine with a capacity of 4.5 megawatts ([Gamesa 2012](#)).

Wind Needs and Typical Capacity Factors

It is generally preferred that candidate sites should have average wind speeds of at least 14 miles per hour at the hub height for these large turbines to be economically feasible ([DOE 2011f](#)). The relationship between wind speeds and wind turbine operations can be grouped into four wind speed regions explained further in [Table 2-16](#). As noted in the table, the wind turbine does not operate in regions I and IV; region I being too low and region IV being too high.

Capacity factor is a terminology often used in describing power generating technologies. It is defined as the ratio of a technology's actual output over a period of time (typically a year) to its potential output, where the potential output is the device operating continuously over that period of time at its rated, or nameplate, capacity. For a wind turbine to operate at or near a 100 percent capacity factor, the wind speed would have to be constantly in the region III category shown in [Table 2-16](#). The capacity factor that can be achieved by a single wind turbine is dependent on its location and the wind available at that location, as well as other influences such as curtailment and maintenance periods. The higher the average wind speed, the more time the wind turbine would be expected to spend in region III and the upper end of region II. Capacity factors have increased as wind turbine hub heights have increased because of the better wind resources at greater distances from the ground. Along with the average wind speed, the characteristics of the site's wind consistency are also very important. If a site has a high average wind speed primarily because of the amount of time it's at 55 miles per hour or higher, that could easily be a poorer candidate site than one with a lower, but more consistent average wind speed, with less time of excessive wind.

Table 2-16. Wind Speed Regions in Comparison with Wind Turbine Operations

Wind Speed Region	Wind Speeds (in mph) ^a		Description of Wind Turbine Operation
	Lower Limit	Upper Limit	
I	0	7	Below a cut-in wind speed of about 7 mph the wind turbine's controller keeps the rotor from turning.
II	7	27	Between the cut in speed and the wind speed at which the wind turbine is rated (27 mph in this case), the rotor turns at a rate that varies with the wind speed.
III	27	55	By changing the pitch on the blades, the wind turbine's controller keeps the rotor turning at a constant rate, independent of the wind speed, producing the wind turbine's rated output.
IV	55	> 55	Once a cut-out wind speed of about 55 mph is reached, the wind turbine's controller fully furls the blades and stops the rotor from turning.

Source: [NREL 2012c](#).

a. These are representative values for utility-scale wind turbines that can change by minor amounts by manufacturer and wind turbine model. For example, cut-in wind speeds are generally in the range of 7 to 9 mph, fully rated powers are generally achieved at wind speed ranges of 27 to 29 mph, and cut-out wind speeds are generally in the range of 55 to 65 mph.

mph = miles per hour (meters per second = mph × 0.447).

Although capacity factors are largely site specific, evaluating data over a large number of turbines provides a good indication of what can be expected. According to evaluations performed by U.S. Department of Energy’s National Renewable Energy Laboratory (NREL), capacity factors for wind plants installed from 2004 through 2010 in the United States have ranged between 30 and 35 percent. This is compared to an average capacity factor of 25 percent for the wind plants installed in 1999 ([NREL 2012c](#)).

Site-specific capacity factor data for several Hawai‘i wind farms are as follows: 65 and 45 percent, respectively, for the Pakini Nui and Hawi wind farms, both on Hawai‘i island, and 47 percent for Kaheawa I on Maui. These capacity factors were based on 2011 data and the high values were attributed to the “robust and consistent” wind regimes available within the State ([DBEDT 2013h](#)).

Land Needs for Utility-Scale Wind Turbines

NREL has also collected and evaluated information on the amount of land required for wind farm projects ([NREL 2009b](#)). Theoretical evaluations propose optimum land requirements of about 30 to 50 acres per megawatt of wind turbine capacity. However, data on 161 wind farm projects representing about 25 gigawatts of proposed or installed capacity within the United States were considered to characterize typical “real world” land requirements. This evaluation determined an average land requirement of 84 acres per megawatt.

As a comparison to the above land area requirements, [Table 2-17](#) provides a summary of land areas associated with wind projects in Hawai‘i. The acreage per megawatt installed ranges from 3.2 to 23.8, with an average for the seven projects of 9.7 acres per megawatt. These low values in comparison to the NREL study are likely attributed to the limited size of the data sets, but may also be due to the fact that very few Hawai‘i wind farms have multiple strings of wind turbines so projects in the table may not include spacing between rows.

The NREL study also looked at the amount of land that would actually be disturbed as part of wind turbine projects. This is a much smaller amount of land than described above because most surrounding land uses, for example agriculture or ranching, can coexist with both the installation and operation of a wind farm. The study analyzed both permanent impacts from such items as the turbine area, access roads, and substations and temporary impacts such as staging areas, temporary roads, and construction disturbances outside the structure footprint. The study concluded the average permanent direct impact was about 0.7 acre per megawatt of capacity and the average temporary direct impact was about 1.7 acres per megawatt of capacity ([NREL 2009b](#)). Although this study was based on mainland wind turbine projects where more land was probably available to be disturbed, it is assumed these are reasonable, rough estimates for Hawai‘i because projects on the mainland likely would choose sites where construction of ancillary items such as substations and access roads could be minimized.

Table 2-17. Summary of Land Areas Associated with Hawai‘i Wind Project^a

Project Name	Year Installed	Island	Developer	Capacity (MW)	Acres	Acres per MW
Hawi Renewable Development	2006	Hawai‘i	Hawi Renewables	10.5	250	23.8
Kaheawa I Wind Farm	2006	Maui	First Wind	30	200	6.7
Pakini Nui Wind Farm ^b	2007	Hawai‘i	Tawhiri Power	20.5	67	3.3
Kahuku Wind Farm	2011	O‘ahu	First Wind	30	578	19.3
Kawailoa Wind Farm	2012	O‘ahu	First Wind	69	650	9.4
Kaheawa II Wind Farm	2012	Maui	First Wind	21	143	6.8
Auwahi Wind	2012	Maui	Sempra Generation	21	68	3.2

a. Source: [DBEDT 2013h](#).

b. Actual footprint is 26 acres. Personal communication, Steven Pace, 4/26/13. Parcel size is 67 acres.
MW = megawatt.

2.3.3.9.2 Characterization of Technology Feasibility and Deployment

Feasibility of Utility-Scale Wind Resources Deployment by Island

[Figure 2-43](#) shows average wind speeds within the State at an elevation of 80 meters, or about 260 feet above the ground. This is the wind map typically used in evaluating the potential for utility-scale wind turbines because of their heights. It can be seen that the wind speed categories shown in the map are in units of meters per second. As a point of reference, 14 miles per hour, the lowest generally accepted average wind speed for utility-scale wind turbines, equates to 6.3 meters per second.

The NREL has also developed wind maps for each of the primary islands based on average wind speeds at 50 meters, or about 160 feet, above the ground, so they are slightly different than what is shown in [Figure 2-43](#). The 50-meter wind maps can be found at <http://www.nrel.gov/gis/mapsearch/>.

It should be noted, of course, that these large area wind maps show where wind speeds are likely sufficient to support development of utility-scale wind turbines, but they do not depict where existing land uses and topography are compatible with such development. Also, wind farm planning and design are often preceded by collection of site-specific meteorological data to insure the necessary wind resources are available over time.

As an example of a previous wind potential assessment conducted in Hawai‘i, the *HIREP Planning Information Study* ([AECOM 2012a](#)) includes an evaluation of wind resources on the islands of Molokai, Lāna‘i, and Maui. This evaluation started with the 50-meter wind maps, then established land use, topography, and other factors that would or would not be appropriate for a wind farm. In this manner, the evaluation screened out portions of each of the three islands it deemed unacceptable (based on the criteria) for wind farm consideration and thereby identifying the acceptable portions. The specific criteria used in the evaluation are as follows:

1. Technical Feasibility – Using 50-meter wind map data, locations with average wind speeds of about 14 miles per hour or higher (corresponding to Wind Power Classes of 3 and above) were retained.
2. Size – A 50-megawatt power facility minimum size.
3. Topography – Excluded areas with slopes greater than 20 percent.
4. Census Designated Area – Excluded census tracts with greater than 10 percent of the island population.
5. Conservation zones – Excluded officially designated reserves (except game management areas), national parks, preserves, and sanctuaries.
6. Land Use Designations – Excluded State land use areas zoned “Urban.”
7. Hawaiian Homelands – Excluded Department of Hawaiian Home Lands areas with documented development restrictions.

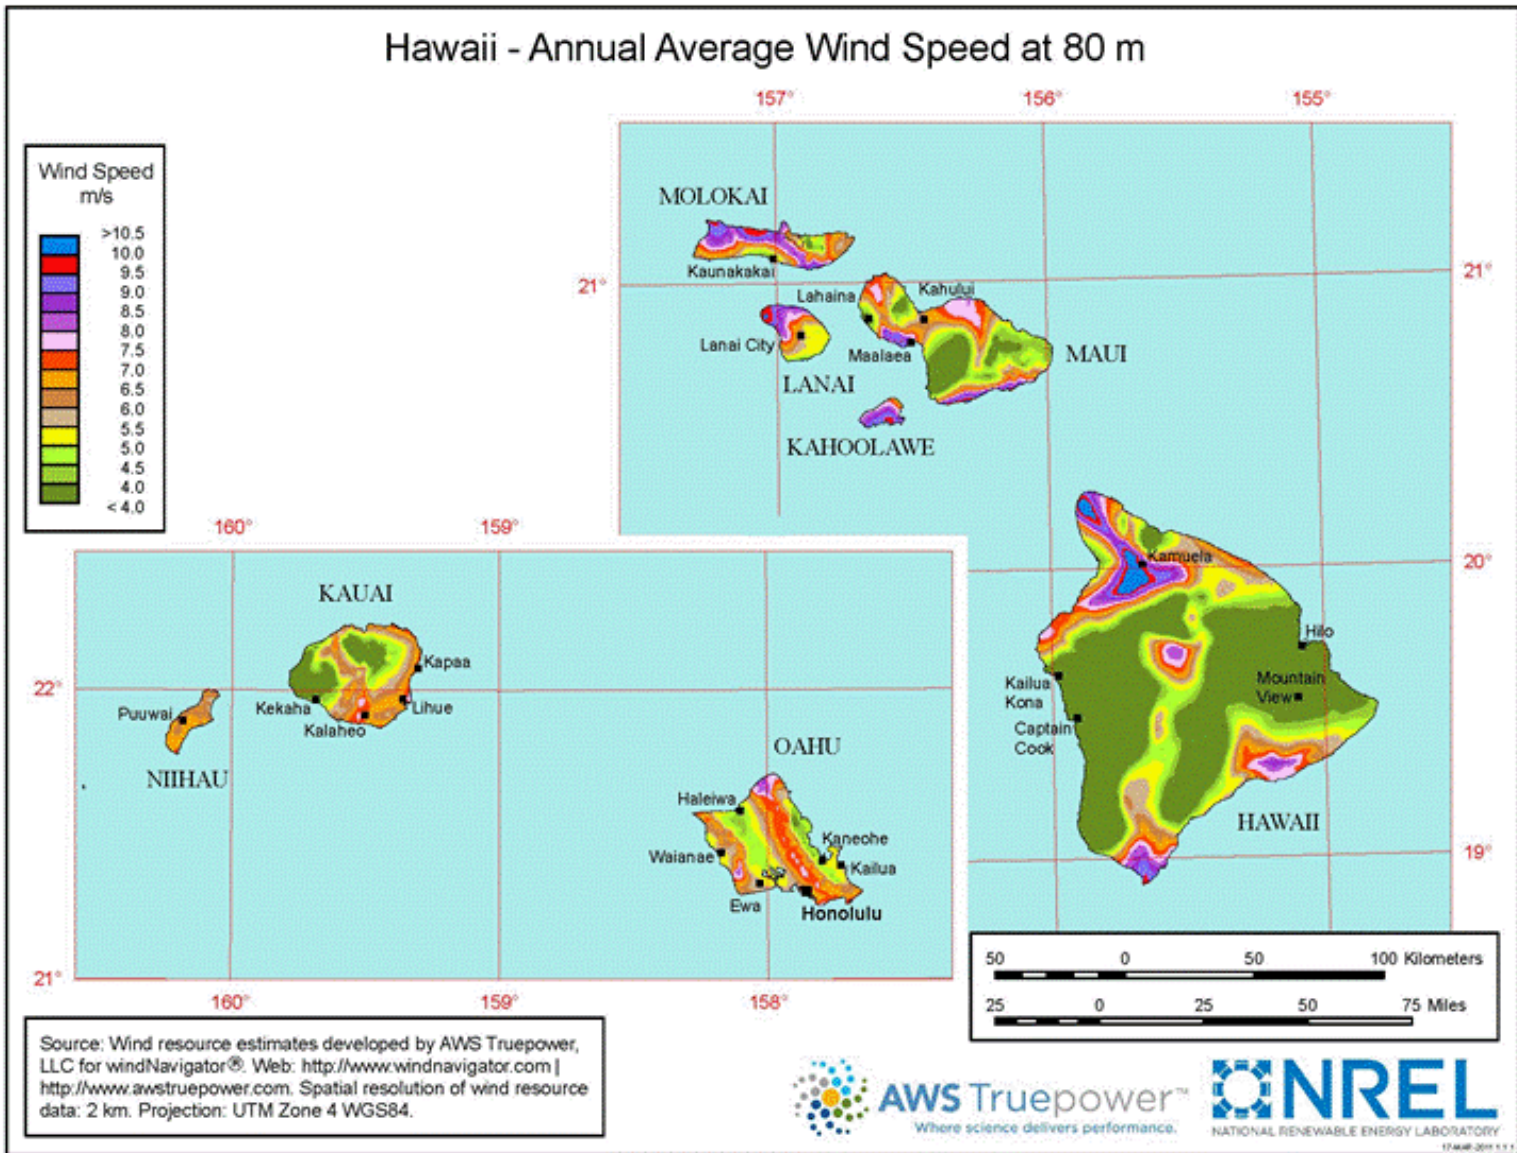

Figure 2-43. Average Wind Speeds at 80 Meters, or about 260 Feet, Above the Ground (wind speed in meters per second multiplied by 2.24 equals miles per hour)

2.3.3.9.3 Characterization of Existing Deployment

[Table 2-18](#) shows existing utility-scale wind turbine projects in Hawai‘i. Information in the table is a “snap shot in time,” but updated information can be found at the HSEO website, <https://energy.ehawaii.gov/epd/public/re-projects-home.html>.

Table 2-18. Utility-Scale Wind Turbine Projects

Project Name	Island	Year Installed	Capacity (MW)
Existing Projects (Source: DBEDT 2013h)			
Hawi Renewable Development	Hawai‘i	2006	10.5
Kaheawa I Wind Farm	Maui	2006	30
Pakini Nui Wind Farm	Hawai‘i	2007	20.5
Kahuku Wind Farm	O‘ahu	2011	30
Kawaiiloa Wind Farm	O‘ahu	2012	69
Kaheawa II Wind Farm	Maui	2012	21
Auwahi Wind	Maui	2012	21
TOTAL			202

MW = megawatt.

2.3.3.9.4 Permitting and Consultation Requirements

In addition to the general permitting and regulatory requirements discussed in [Section 2.2.5](#), there are also several permit-related issues associated with land-based wind projects that should be noted, as follows:

- Given Hawai‘i’s heavy military presence, one of the first things a wind developer must do is consult with local Department of Defense installations to see if the targeted project site conflicts with any military training areas or flight paths.
- An FAA Notice of Proposed Construction or Alteration in Airspace would be required to construct any structure more than 200 feet in height above the ground, with additional requirements for structures closer than 20,000 feet to the nearest point of the nearest runway of specified airports. The notice must be submitted to the FAA in accordance with [14 CFR Part 77](#).
- Local community outreach is also a priority for wind turbines, given Hawai‘i’s scenic beauty and limited landscapes that increase wind farm visibility. Proper outreach includes providing accurate visual simulations of the project to local community groups, leaders, and neighborhood boards. Developers may need to adjust their project. This could include visuals for night and day operations, as the required aviation safety (red) lighting has been described as an environmental impact. In addition to visual impacts, large wind farms that obstruct access to frequently visited areas or that could involve cultural or archaeological implications would be expected to garner community opposition, so finding a solution to satisfy all stakeholders requires early consultation.
- Because of Hawai‘i’s smaller, more winding roadways, approval from the Hawai‘i Department of Transportation may be required for turbine transport. In certain instances, roadways would require closure to all other traffic and traffic lights may need to be temporarily removed to achieve the necessary width or turning radius. Although harbor facilities would typically be designed to deal with movement of large items, tower components and particularly rotor blades could require advanced planning and authorizations.

- With regard to Kaua‘i, it would be extremely difficult to develop utility-scale wind power with today’s technology due to the island’s extremely high population of [endangered](#) sea birds.
- Developers should consult with NPS on projects that could have direct or indirect impacts on sensitive, cultural, natural, scenic, visual, and recreation resources of the National Park System and other protected resources.

2.3.3.9.5 Representative Project

A representative utility-scale wind project for purposes of evaluation in this document is assumed to consist of the construction and operation of a 25-megawatt facility consisting of ten 2.5-megawatt wind turbines. It is further assumed that the each turbine is a horizontal axis unit, with a 390-foot rotor diameter (the blade lengths are about 190 feet), and mounted on a 360-foot monopole. Noise produced by each wind turbine is 106 dBA at the source at standard power. Air emissions would be limited to fugitive dust and heavy equipment use during construction activities. Water use would be relatively minor, consisting of dust control measures plus that used in the formulation of concrete for footings. A spread footing foundation for a 2.5-megawatt wind turbine could require about 450 cubic yards of concrete ([Morgan and Ntambakwa 2008](#)). At about 35 gallons of water per cubic yard of concrete, that equates to about 16,000 gallons of water per wind turbine. Land required for the entire project, at an estimated 10 acres per megawatt (based on the identified examples within the State), is 250 acres. Within the 250 acres, the amount of land permanently disturbed (under turbine, road, and other structure foot prints), at 0.7 acre per megawatt, is 17.5 acres and the amount of land that would be temporarily disturbed, at 1.7 acres per megawatt, is 42.5 acres. Connection to the grid is assumed to be at a distance of one mile from the edge of the wind farm property (that is, from the edge of the 250-acre property). In 2010, the average installed cost for a land-based wind turbine project in the U.S. was about \$2.2 million per megawatt of which 70 to 75 percent was attributed to the cost of the wind turbine ([NREL 2012c](#)).

If the scope of the representative project were increased by some factor (for example, by a factor of two), the number of wind turbines, the land required for the entire project, the land permanently disturbed, and the land temporarily disturbed would all be expected to increase by about the same factor. However, there may be some project aspects that would not require scaling up; for instance, the same access road into a site might serve a project of either size. However, this is, to a large extent, site specific, so for purposes of evaluation, this PEIS based the estimates of land disturbance solely on the “acres per megawatt” values discussed previously.

2.3.3.10 Offshore Wind Power

Offshore, utility-scale wind turbines function in the same manner as land-based wind turbines. That is, they convert the [kinetic energy](#) of the wind to mechanical power and the turning rotor spins a generator to make electricity. As of early 2013, no offshore wind projects have begun construction in the United States. There are 33 announced projects in various stages of development, but only 9 have advanced to a stage where they have any of the following: (1) a lease approved for State or Federal waters, (2) conducted baseline studies at the proposed site, or (3) signed a power purchase agreement with a power off-taker. Of these nine more mature projects, five are to be along the northeastern coast (one off Rhode Island, one off Massachusetts, and three off New Jersey), three along the gulf coast (all off Texas), and one on a Great Lake (in Ohio). The one with the smallest proposed capacity (a 25 megawatt wind farm off New Jersey) also has the nearest target completion date, which is 2013. The other eight projects have target completion dates of 2014 to 2018. The combined target capacity for all nine projects is 3,380 megawatts from 646 to 746 wind turbines ([Navigant 2013](#)). Since there are no offshore wind projects currently in the United States, the technology elements described in this section are based on what has

been employed in other parts of the world, what is being promoted by manufacturers, and what is being planned and projected for the United States.

2.3.3.10.1 Technology Description

Early in the history of offshore wind turbines, which were pioneered in Denmark in the late 1990s and early 2000s, the devices were basically land-based machines with adaptations to make them more survivable in a marine environment. In more recent years, however, offshore wind turbines have been designed and manufactured exclusively for offshore placement, incorporating features to better withstand the demands of the marine environment and to reflect fewer limitations on size. For example, transporting large wind turbine blades is not constrained by the ability to maneuver long loads over existing roads, and the sound levels generated at locations well away from the shore is less likely to be of concern. The fact that wind quality is generally better offshore and at lower elevations (depending on the distance from shore, there is little, if any affect from nearby surface irregularities) has allowed use of lower towers, also providing impetus for development of larger wind turbine capacities ([NREL 2010a](#)) because it is easier and less expensive to create a lower tower that will hold the additional weight. Across the world, the typical operating offshore wind turbine (new and old) has a capacity greater than 1 megawatt. Offshore wind turbines installed between 2007 and 2010 had average capacities ranging from about 3 to 3.3 megawatts and in 2011 the average size of newly installed machines was almost 4 megawatts ([Navigant 2013](#)); that's 2 megawatts larger than the average utility-scale, land-based wind turbine installed in the United States in 2011 (see [Section 2.3.3.9.1](#)). Most manufacturers of offshore wind turbines are currently testing prototypes with capacities of 5 to 7 megawatts, with rotor diameters roughly 400 to 500 feet and more. In addition, some manufacturers and research facilities have started to develop devices with capacities of 10 to 15 megawatts ([Navigant 2013](#)).

Consistent with their evolution from land-based devices, today's offshore wind turbines are predominantly of a horizontal-axis configuration with three-bladed, upwind rotors. As such, their workings and primary components are the same as shown in [Figure 2-42](#) and described in the accompanying discussion (see [Section 2.3.3.9.1](#)). Descriptions of the primary components are not repeated here, with one exception regarding direct-drive generators. While direct-drive generators are being deployed in a small portion of land-based machines, they have advantages that make them particularly attractive for offshore systems; namely, they hold the promise of increased reliability by eliminating the gear box, having fewer moving parts, and operating at low rotational speeds. Since one of the challenges for offshore wind turbines is accessibility for repair and maintenance, the possibility of reducing the frequency of such needs is very attractive. Direct-drive turbines are already being used globally in about 18 percent of operating offshore wind turbines ([Navigant 2013](#)). Research and development is focused on reducing the size and mass penalties often associated with the technology. However, the direct-drive technology does not yet have an extensive performance record, so the promise of superior performance and reliability is not yet proven ([Navigant 2013](#)).

Both horizontal-axis and vertical-axis turbines are applicable to offshore wind technology. There are ongoing research and development efforts specific to vertical-axis wind turbines and there are proponents of vertical-axis turbines that believe they have characteristics that make them particularly well suited to offshore deployment. These characteristics include having the drive train located near the surface. This provides a lower center of gravity, which improves stability for floating platforms; reduces gravity fatigue on key structural components; and makes most maintenance easier. The reduced complexity of the vertical-axis wind turbine should also act to reduce maintenance needs. There are also recognized challenges in pursuing offshore deployment of these wind turbines. These include cost effective production of the complex blades needed for vertical-axis wind turbines and development of an aerodynamic breaking system (such as provided by the blade pitch control system in horizontal-axis wind

turbines) ([Sandia 2012a](#)). [Section 2.3.3.9.1](#) discussed other limiting factors associated with vertical axis wind turbines.

Offshore Wind Turbine Substructures

A primary difference between land-based and offshore wind turbine technology is the substructure upon which the wind turbine and tower is mounted. The substructures, or pads, for land-based turbines are based on traditional construction techniques, such as compacted foundations or piers and concrete pads; whereas, offshore wind turbines are supported by a variety of devices and systems, many of which are only in the testing and development stages. Because of their complexity, substructures currently used in offshore wind turbine applications account for roughly 20 percent of the total project costs ([Navigant 2013](#)). Offshore substructures comprise the area beginning at the lower flange of the tower and extending to the structural elements that attach it to the seabed. Categories of substructures are generally grouped by the depth of water for which they are designed (which in general corresponds to the maturity of the systems' development), as follows ([NREL 2010a](#)):

- Shallow-water substructures – These substructures are used in water depths of less than about 100 feet (30 meters).
- Transitional technology substructures – These are used in water depths between about 100 and 200 feet (30 and 60 meters).
- Floating technology substructures – These are envisioned for water depths greater than about 200 feet (60 meters).

As can be seen in [Figure 2-44](#), wind turbines deployed in shallow and transitional depths generally rely on rigid substructures reaching all the way to the seabed. At the deeper depths, however, it is generally believed that offshore wind turbines will have to move to floating platforms held in place with guys or cables that are anchored to the seabed. The following discussion provides additional detail on the categories of substructures being used or planned for offshore wind turbines.

Figure 2-44. Categories of Substructures Deployed for Offshore Wind Turbines (Source: [NREL 2010a](#))

Shallow-Water Substructures – [Figure 2-45](#) provides typical configurations for five different substructures used in the shallow and transitional depth categories. The monopile, suction caisson, and gravity base types are those typically used in shallow water (suction caisson is currently being developed for shallow water). A monopile substructure consists of a long cylindrical steel tube driven into the

Figure 2-45. Typical Offshore Wind Turbine Substructure Configurations used at Shallow and Transitional Depths (IPCC 2011)

element is a large-diameter cylindrical structure fixed to the seabed by pumping the water out of the structure to create a vacuum and seating the substructure by hydrostatic pressure ([NREL 2010a](#); [Navigant 2013](#)). In a 2010 report, it was noted that the suction caisson system had not yet been used in a commercial project ([NREL 2010a](#)).

The global wind power capacity of installed offshore wind turbines was about 4,100 megawatts at the end of 2011; of this, the vast majority, about 94 percent, is in Europe (the remainder is in China and Japan). In terms of the number of wind turbines installed, there were 1,472 at the end of 2011; again, about 94 percent of those are in Europe. Of all the European offshore wind turbines, 75 percent were constructed with monopile substructures and 21 percent were constructed with gravity base systems ([Navigant 2013](#)). That is, as of 2011, about 96 percent of Europe's offshore wind turbines have been deployed at relatively shallow depths of roughly 100 feet or less.

The European offshore wind projects under construction in 2012 indicate a trend change, with only 62 of the wind turbines using shallow-depth substructures (all monopile). The remaining 38 percent were designed with transitional depth systems ([Navigant 2013](#)). While substructures suitable for transitional depths also would be suitable for shallow applications, associated costs make it unlikely such systems would be used in shallow water.

Eight of the nine U.S. projects in mature development phases are at depths of less than 100 feet. Most of these, however, have not yet identified which type of substructure they plan to use ([Navigant 2013](#)).

seabed and a transitional piece that connects it to the wind turbine tower. In order to maintain the necessary monopile stiffness and avoid resonance issues, the monopile diameter and thickness must increase with water depth. This, coupled with the increased difficulty in driving the monopile, makes this substructure less feasible than alternatives at about 100 feet in depth ([NREL 2010a](#)).

The gravity base and suction caisson configurations are also intended for shallow depths, but in areas that are more protected and particularly where seabed geology makes it difficult to drive monopiles. The gravity base system relies on a conical or cylindrical casing constructed onshore and, once placed on the seabed, filled with ballast (for example, concrete, sand, rock, or iron ore). The mass and force of gravity are the only elements providing stability for the wind turbine and substructure. In the case of the suction caisson, the primary stabilizing

Transitional Technology Substructures – The tripod and jacket systems shown in [Figure 2-45](#) are primary examples of substructures designed for the deeper transitional water depths, though there are variations. These substructures are still attached directly to the seabed but require a wider base to counteract overturning forces and to meet stiffness requirements. The jacket or lattice substructure is derived from the common fixed-bottom offshore oil rig and consists of a four-sided, framed structure that is pinned or anchored with an individual piling at each corner. The tripod substructure consists of a three-legged structure assembled from steel tubing connected to a central shaft and is anchored to the seabed with multiple pilings similar to the jacket system. The jacket system entails more fabrication and assembly, but uses less material than the tripod system ([Navigant 2013](#)).

Only three European wind farm projects have been deployed at transitional water depths and they represented about 4 percent of Europe’s operating offshore wind turbines at the end of 2011. The substructures for these wind turbines were basically split evenly between jacket and tri-pod configurations. As noted previously, 38 percent of the offshore wind turbines under construction in Europe in 2012 were designed with transitional depth substructures; 20 percent jacket systems and 18 percent tri-pod systems ([Navigant 2013](#)).

Floating Technology Substructures – Floating wind technology was recently given approval on February 5, 2014, by the Secretary of the Interior to proceed with plans for a 30-megawatt pilot project that uses floating wind turbine technology off the coast of Coos Bay, Oregon. [Figure 2-46](#) shows renderings of three conceptual designs for floating wind turbines: spar-buoy, tension leg platform, and semi-submersible. The spar-buoy consists of a buoyant structure, or spar, stabilized by a large ballast in its lower portion and maintained in a general location by mooring lines and drag-embedded anchors. The buoyancy and ballast of the spar structure provide stability during the pitching and heaving of wave action and loading; the mooring lines maintain position. A semi-submersible substructure is stabilized by a group of interconnected buoyant structures, generally three in a triangular form, and again is held in its general location by mooring lines and drag embedded anchors. The tension leg platform consists of a buoyant platform-like structure below the water surface and is fixed to the seabed with taut mooring lines. In this case, the mooring lines provide the source of stability and the platform provides buoyancy.

Although the preceding descriptions of floating technologies were based on the configurations shown in [Figure 2-44](#), the various wind turbine platforms could use different mooring devices, particularly the way they are fastened to the sea floor, based on what would work best given the characteristics of a specific site.

Application of floating technologies has currently gone no further than full-scale tests. A spar-buoy with a 2.3-megawatt wind turbine was installed off the coast of Norway in 2009. This device is designated the Hywind concept by Statoil, an international energy company headquartered in Norway, and was deployed in water about 660 feet deep. Statoil reports that based on two years of data, the concept has been verified and performance has been better than expected ([Statoil 2012](#)). The only other full-scale test implemented is a semi-submersible platform with a 2-megawatt wind turbine deployed off the coast of Portugal by Principle Power in late 2011 ([Navigant 2013](#)).

In late 2012, DOE announced funding to seven offshore wind turbine technology demonstration projects. These initial awards were for engineering, site evaluation, and planning phases of projects targeted at demonstrating offshore wind technologies with a credible potential for lowering the levelized cost of energy and developing viable and reliable options for the United States. Depending on the results of the initial effort, DOE will select up to three of the projects for additional funding to implement full-scale wind turbine projects, with the goal of commercial operation by 2017. Three of the seven initial projects proposed to use innovative floating platform technologies. The other four tentatively proposed new

Figure 2-46. Renderings of Three Conceptual Designs for Floating Wind Turbines ([Source: Navigant 2013](#))

approaches to bottom-mounted substructures, but specific elements of all the projects are yet to be finalized ([DOE 2013j](#)).

Although the development of floating platforms for offshore wind turbines is generally expected to be a long-term process, the timeframe under which they will be commercially viable will ultimately depend on whether prototypes or other concepts continue to show promise and if industry continues to receive or make significant investment.

Other Offshore Considerations

In addition to the wind turbine hardware, other offshore wind farm needs include the electrical system infrastructure to move electricity from the wind turbines to the onshore grid. Wind farms typically are arranged in arrays that take advantage of prevailing winds, with individual turbines spaced far enough apart to minimize losses from array turbulence, while balancing the cost of electrical cabling between the turbines (NREL 2010a). Depending on the size of the array and the distance from shore, a substation or electrical service platform may be collocated with the wind farm. Power from each wind turbine would be collected at the substation and transmitted through a number of buried high-voltage lines to an interconnection point on the shore from which transmission lines would then run to the regional electrical grid. Technologies such as horizontal directional drilling could be used to get the electrical lines from the

offshore wind farm through the sea-land transitional area with minimal disturbance if necessary to avoid sensitive resources (see Chapter 7, Section 7.9). (Note: Discussions of sensitive resources or community issues that might be involved with the deployment of offshore wind are part of the potential environmental impacts sections.) Horizontal directional drilling and when it might be used is only mentioned here as an associated technology. [Section 2.3.5.2](#) of this PEIS, also considers use of this type of drilling in the land-sea transition zone and provides additional detail on the technology.

If the wind farm is small or close to shore, the substation likely would be onshore. If the substation or electrical service platform were at the wind farm site, it would be designed to function as a central service facility that includes such items as a helicopter landing pad, control and monitoring equipment rooms, a crane, a rescue boat, communications station, firefighting equipment, emergency generators, and staff and service facilities. Costs for these electrical infrastructure systems extend beyond those for comparable components of a land-based wind farm.

Electrical cables running from the offshore wind turbines to the shore and, as applicable, between wind turbines are a significant element of an offshore project. In order to protect them from damage that can be caused by such things as dropped anchors or fishing (a fishing method of particular concern in this regard is bottom trawling, but such fishing is not allowed in Hawai'i waters), it may sometimes be necessary for these cables to be buried into the sea floor. High-voltage direct current (HVDC) cable installation may occur in two primary ways: laying on the surface of the ocean floor or burial through shallow trenches on the ocean floor. Burial depths of about 3 feet may be sufficient to protect from damage in some cases, but depths of 6 to 15 feet may be necessary in some situations, such as areas where large ships may anchor ([Sharples 2011](#)). If required to be buried, cables can be installed using a variety of trenching methods and in most cases equipment is designed and operated to be a one-pass operation, such that the cable is placed immediately behind the trenching device and the sea floor materials fill- or settle-in once the device has moved on. Mechanical plows, which look and work much like an agricultural plow, are one type of device commonly used in the placement of undersea cables. Mechanical plows are towed from the surface, across the sea floor with the electrical cable being fed down the inside of the blade device, behind the cutting edge. The cutting depth is varied by raising or lowering the hydraulically controlled skids on either side of the blade. The skids drag along the floor as the blade cuts into the sediments. Jet plows are another example of trenching devices. These use pressurized sea water to cut a trench as they are being towed. The cable is fed down through a slot behind the water nozzles much like the mechanical plow and the suspended sediments settle back into the trench to cover the cable. Jet plows have also been configured to operate on remotely operated vehicles that can move along the sea floor. Dredging and rock saws have also been used to facilitate cable laying and burial, although rock sawing generally has to be at depths that are within diver limitations. In instances where burial is not feasible or in areas with a high likelihood that the cable could eventually be exposed, concrete could be used to lay over the cable for protection. [Sharples \(2011\)](#) includes additional descriptions of cable installation (available from <http://www.bsee.gov>).

Wind Needs and Typical Capacity Factors

In addition to having basically the same components, offshore wind turbines operate at basically the same wind regimes as described for land-based wind turbines in the preceding sections. Further, the same wind speed categories apply to offshore wind turbine operations (see [Table 2-19](#)); that is, the wind turbines operate in speed regions II and III (which begins at the turbine's rated wind speed) and not in wind regions I and IV. Because the offshore wind turbines typically are larger machines (larger rotors and larger capacities), the cut-in wind speeds may be 1 or 2 miles per hour higher and similarly for the rated wind speeds. Correspondingly, evaluations of wind resources for offshore wind farms generally start at minimum acceptable wind speeds that are slightly higher (at about 16 miles per hour) than for onshore winds (at about 14 miles per hour).

Capacity factors for offshore wind turbines are measured in the same manner as described for land-based wind turbines. That is, for a wind turbine to have a capacity factor of 100 percent, wind speeds would have to be in region III ([Table 2-19](#)) constantly so that the wind turbine could operate at its rated capacity constantly. Since wind turbine capacity factors are primarily a function of the wind characteristics, they are largely site specific. However, evaluating data over a large number of turbines provides a good indication of what can be expected. Based on reports from a number of European projects, typical offshore capacity factors have ranged from 29 to 48 percent ([NREL 2012c](#)). As another data point, evaluations for the Cape Wind Energy offshore project in Massachusetts, one of the nine planned U.S. projects, use a 40-percent capacity factor that is based on the average wind speed of their site ([DOI 2009](#)).

Spacing Needs for Offshore Wind Turbines

There is no consensus on the optimum spacing between wind turbines in an offshore wind farm. The wind disturbance or wake generated by a wind turbine can adversely affect operation of a nearby downwind turbine. This adverse effect is primarily in the form of reduced efficiency in the downwind device, and the further away it is the less severe the effect. While the tendency is to optimize efficiency by spacing the wind turbines further apart, wind farm configurations must be balanced with space limitations (or the desire to make efficient use of space) and the added costs for interconnecting electrical cables and even installing and maintaining wind turbines that are farther apart. Logically, spacing also depends on the configuration of the water area available and the nature of the wind at the site. For example, if the space available supports a single row of wind turbines perpendicular to the prevailing wind, there would be much less concern for effects on downwind devices, and wind turbines within the row could reasonably be spaced closer together than under other circumstances.

The spacing of wind turbines in wind farm arrays is often described in terms of the number of rotor diameters between the wind turbines and literature often describes arrays being designed to maintain 5 to 10 rotor diameters between the devices. For evaluation purposes, this PEIS assumes that an offshore wind farm array might be designed to maintain 8 rotor diameters between wind turbines. For a typical 5-megawatt wind turbine, this equates to roughly 1 square kilometer (or 0.39 square miles) per wind turbine ([NREL 2010a](#)). Restated, this equates to about 0.08 square mile per megawatt.

2.3.3.10.2 Characterization of Technology Feasibility and Deployment

Feasibility of Offshore Wind Resources Deployment by Island

[Figure 2-47](#) shows average offshore wind speeds in the vicinity of the Hawaiian Islands at an elevation of 90 meters, or about 295 feet above the water surface. This is the type of wind map typically used in evaluating the potential for offshore wind turbines. If the minimum wind speed for economic feasibility of an offshore wind turbine is about 16 miles per hour, only those areas of the figure showing yellow or green would be excluded from being viable offshore wind turbine locations based on wind speed, and the dark green would be marginal.

The figure also provides water depth contours (indicated by a number followed by “m” for meters) close to the islands and shows the rapid drop just beyond the land areas. This characteristic of the islands acts to limit the amount of area beyond the land surface that would be grouped in either the shallow (less than 100 feet) or transitional (100 to 200 feet) water depths. This is further highlighted by the information presented in [Table 2-19](#), which shows results of an NREL evaluation ([NREL 2010b](#)) of Hawai‘i’s offshore wind resources. The table shows estimates of the potential for wind turbine installed capacity, in gigawatts, by wind speed interval, water depth, and distance from shore. As shown in the table, the estimated total installed capacity for the State, out to 50 nautical miles (57.5 miles) is 637.4 gigawatts. It can also be seen that only about 1.2 percent of this total would be from wind turbines deployed in water depths of 200 feet or less, and almost 90 percent of the capacity is at water depths greater than 200 feet at distances of 3 to 50 nautical miles (3.5 to 57.5 miles) from any shoreline.

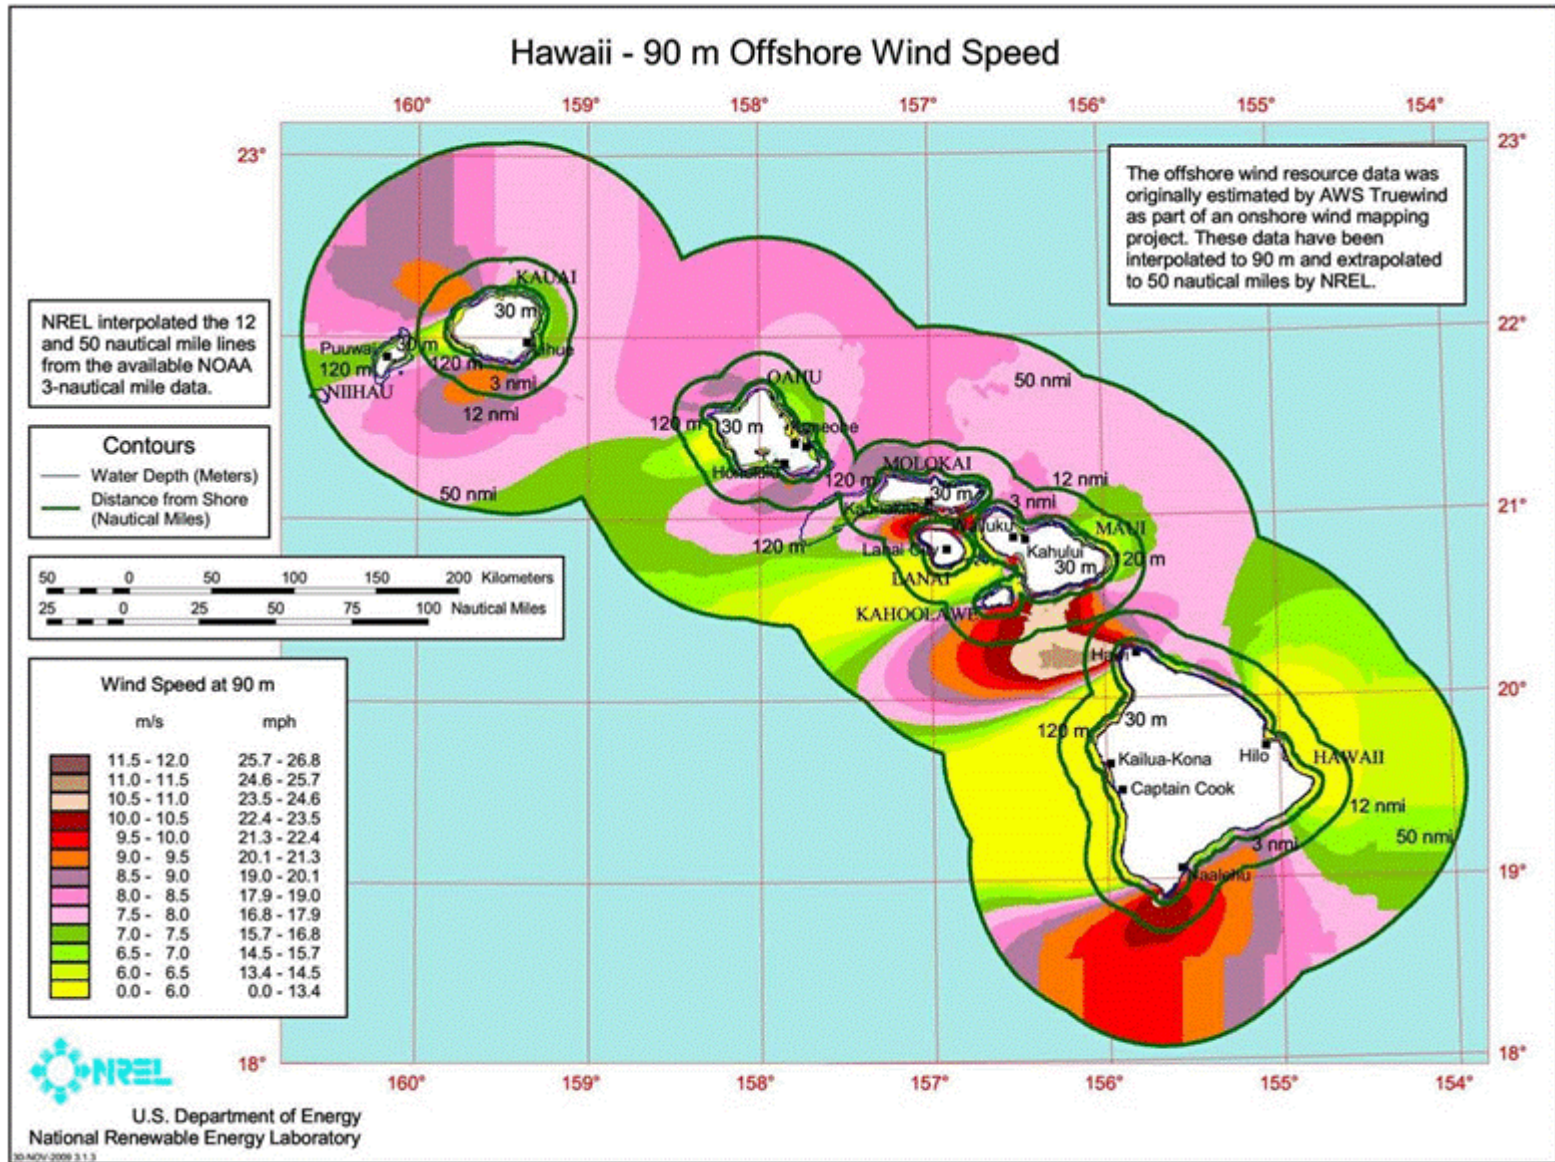

Figure 2-47. Average Offshore Wind Speeds at 90 Meters, or about 300 Feet, Above the Water Surface

Table 2-19. Hawai‘i Wind Resource Potential (in gigawatts of installed capacity) by Wind Speed Interval, Water Depth, and Distance from Shore

a. The values here were converted from “meters per second” used in the reference. In the reference, the wind speed groups are present in spans of 0.5 meter per second increments starting with 7.0 to 7.5.

mph = miles per hour; nm = nautical miles (nm times 1.15 equals miles); GW = gigawatts.

Characterization of Existing Deployment

As noted previously, there currently are no offshore wind farms in the United States. Several potential offshore wind developers have indicated an interest in Hawai‘i, but are still in early site identification and planning stages as of August 2013.

The vast majority (almost 99 percent) of the State’s wind resources are at locations where the water depth is greater than 200 feet. Although the remaining potential (7 to 8 gigawatts of installed capacity) is still significant, it appears ([Figure 2-47](#)) to be well distributed over the islands, so should projects arise that pursue deployment of offshore wind turbines at shallow or transitional depths, they likely would be relatively small wind farms. Any substantial projects to take advantage of State’s overall offshore wind resource may be delayed until floating platform technologies become more mature.

2.3.3.10.3 Permitting and Consultation Requirements

See [Section 2.2.5](#) for a discussion on general requirements, including marine-based technologies. This section presents additional permitting and consultation requirements specific to offshore wind projects and judged to be of possible concern in environmental evaluations. Given the high use of Hawai‘i’s marine waters for recreation, commercial activities, and military operations, finding a suitable location for an offshore wind farm could be a challenge. A prospective offshore wind farm operation would require intensive outreach with various sectors of stakeholders (e.g., military, NPS, commercial fishers, commercial marine operations, recreational marine groups, aviation agencies, airlines, environmental groups and agencies, species protection groups/agencies). Hawai‘i’s rough seas and hurricanes also would require projects to be designed, manufactured, and constructed in a manner to withstand such conditions. For purposes of evaluating proposed offshore wind facilities, the pertinent standards of [49 CFR 77.17](#) require that any structure 200 feet above ground level be considered an obstruction to air navigation and requires that an aeronautical study be conducted by the FAA to determine what marking and lighting may be required to ensure safety of the airspace. FAA airspace jurisdiction extends to 12 nautical miles from shore, while U.S. territorial seas extend to 24 nautical miles. Offshore wind farms located between 12 and 14 nautical miles from shore would have to contact the DoD Clearinghouse and request a formal review rather than submit a notice to FAA. In accordance with the provisions of EAct 2005, FERC is

responsible for licensing, inspecting, and overseeing *marine hydrokinetic* activities. However, EPLA 2005 also amended the Outer Continental Shelf Lands Act (43 U.S.C. §§ 1331–1356) to grant the Secretary of the Interior discretionary authority to regulate the production, transportation, or transmission of renewable energy on the Outer Continental Shelf (OCS). In April 2009, the Secretary of the Interior and the Chairman of FERC signed an MOU, clarifying the scope of each agency’s respective responsibilities for regulating renewable energy projects on the OCS. Under the agreement, FERC has authority to issue licenses for all hydrokinetic projects (including those on State submerged lands and on the OCS), and the DOI has authority to issue leases and easements for hydrokinetic projects located partially or wholly on the OCS. In addition, the visual impacts from the land must be addressed through stakeholder outreach early in the process.

If an offshore wind project was proposed to be located near a protected marine habitat, the developers must also consult with the NOAA NMFS for permits relating to those concerns ([DOE 2009a](#)). The developers also would consult with the USFWS and the NOAA NMFS on projects impacting protected species, *critical habitat*, and *EFH*. Additionally, developers should consult with NPS on projects that could have impacts on sensitive resources of the National Park System and other protected resources.

Compensatory mitigation under CWA Section 404 could be required if projects involve unavoidable impacts to species and their habitat, including coral reefs. Best management practices such as those presented in Section 3.4.6.2 should be incorporated into project-level analyses to minimize damage from moorings, anchors, anchor lines, and pipelines during construction, particularly in areas near coral reefs. Areas should be designated for moorings and anchors that specifically avoid impacts to corals, and areas of high coral value should be marked with buoys to ensure avoidance of those areas during construction.

2.3.3.10.4 Representative Project

A representative offshore wind project for purposes of evaluation in this PEIS is assumed to consist of the construction and operation of a 50-megawatt facility consisting of ten 5-megawatt wind turbines. It is further assumed that the turbine is a horizontal-axis unit with a 420-foot rotor diameter (the blade lengths are about 205 feet), and mounted on a 280-foot-long monopole. The wind turbines would be deployed about 4.3 nautical miles (5 miles) from the shoreline and away from the nearshore environment in water with a depth greater than 200 feet on floating platforms with a semi-submersible design. Noise produced by the representative wind turbine would be 108 dBA at the source at standard power. Air emissions would be limited to heavy equipment use during installation and construction activities. Water use would be minor. Area required for the entire project, in terms of limiting the installation of other wind turbines in the area is assumed to be 3.9 square miles (0.39 square mile per wind turbine). Connection to the electrical grid is assumed to be approximately 1 mile from the nearest shoreline. The representative project would use a mechanical or jet plow towed from the surface to install and bury the electrical cable leading onto the shore, so there would be a pathway of disturbed sea floor into the nearshore area where the horizontal direction drilling would exit. Three catenary mooring lines (i.e., hanging freely) and electrical cables would hang near each wind turbine, all extending from the floating platform to the sea floor. Such mooring lines typically are long enough so they would drape onto the sea floor near the anchor much of the time. The electrical cable extending down from each platform would generally have ballast- or buoy-type devices to control the cable’s angles at the transition point to the buried cable. Assumed costs are based on 2010 data, with the average installed cost for an offshore wind turbine project at about \$4 million per megawatt, of which 30 to 50 percent was attributed to the cost of the wind turbine ([NREL 2012c](#)).

If the scope of the representative project were increased by some factor (for example, a factor of two), the number of wind turbines and the area required for the entire project would all increase by the same factor. The larger array of wind turbines would provide economies of scale associated with the electrical

components. Power from each turbine would collect at one of the platforms, which would contain a substation, allowing the run of a single cable (or group of cables placed together) to shore.

2.3.4 ALTERNATIVE TRANSPORTATION FUELS AND MODES

In addition to State-mandated renewable energy and energy efficiency goals for electricity generation, the HCEI includes a goal to reduce oil used for ground transportation by 70 percent by 2030, and a goal to meet as much of in-State demand for renewable fuels as feasible by 2030. It was envisioned that these goals would be accomplished through a combination of fuel economy improvements, accelerated deployment of electric vehicles and hybrid-electric vehicles, reduced vehicle miles traveled, improvements to public transportation, incorporation of alternative transportation modes, and renewable fuels. Alternative fuels such as natural gas and liquefied petroleum gas are also being analyzed to help achieve HCEI transportation goals, as these fuels would be a substitute for oil and may be considered transitional fuels (until a more commercially viable renewable fuel is available). However, unlike the electricity generation sector, transportation does not have statute-mandated goals. With this in mind, the HCEI is in its second phase and is expanding to include efforts to establish a renewed commitment on a set of goals and a timeline to reduce petroleum-based fuels for transportation. The State Energy Office is scheduled to wrap up a series of stakeholder consultations in mid-2015 and issue a final report offering a set of actionable steps that can be realistically implemented to reduce consumption of petroleum-based fuels in the transportation sector.

The alternative transportation fuels and modes discussed in this section include:

- Biofuels
- Electric Vehicles
- Hybrid-Electric Vehicles
- Hydrogen
- Compressed and Liquefied Natural Gas, and Liquefied Petroleum Gas
- Multi-Modal Transportation (Activity)

A common representative project was developed to assess the potential impacts (positive and negative) of all alternative transportation fuels and modes technology options. The common alternative transportation fuels and modes representative project was structured to deliver an annual petroleum reduction of 20 million gallons of gasoline or diesel in 2030. The potential to scale up some of the fuel and technology options is much higher than 20 million gallons, but a lower volume was selected because not all of the evaluated transportation fuel and vehicle technologies are currently available at a commercial scale in the State.

2.3.4.1 Biofuels

Biofuels are fuels derived from biomass or waste feedstocks. Biomass includes wood, agricultural crops, herbaceous and woody energy crops, and municipal organic wastes such as fats, oils, and grease. Recycling fats, oils, and grease from restaurants diverts waste, reduces pollution, and supports local businesses. Through various conversion technologies, such as hydrolysis, fermentation, gasification, pyrolysis, or transesterification (discussed in more detail below), these feedstocks can be transformed into conventional biofuel products (such as ethanol and biodiesel), and advanced biofuel products (such as cellulosic ethanol, biobutanol, Green Diesel, synthetic gasoline, and renewable jet fuel). Using these renewable biofuels, local communities benefit from reductions in soot, sulfur dioxide, and greenhouse gas emissions. The following sections discuss the conversion technologies, the feasibility, and existing and future deployment of the technologies in the State of Hawai‘i.

2.3.4.1.1 Technology Description

Conventional Biofuels

Conventional, or first-generation, biofuels are produced mainly from agricultural crops traditionally grown for food and animal feed purposes.

- **Ethanol** – Ethanol is a fuel also known as ethyl alcohol, grain alcohol, and EtOH traditionally produced by fermentation of sugars. On the mainland, fuel-grade ethanol primarily comes from corn, but can also be made from sugar cane. After production and prior to transport for use, refineries denature the ethanol, typically by blending in 5-percent gasoline, and distributing it in the same manner as gasoline or diesel ([Siah and Zapka 2009b](#)). The use of ethanol is widespread—almost all gasoline in the U.S. contains ethanol in a low-level blend. E10 or “gasohol” is a blend of 90 percent gasoline and 10 percent ethanol. For perspective, one gallon of E10 has 96.7 percent of the energy of one gallon of gasoline ([DOE 2013i](#)). Also available is E85, a gasoline-ethanol blend containing up to 85 percent ethanol, depending on geography and season, used in flex-fuel vehicles. The energy content of one gallon of E85 is approximately 73 - 83 percent of the energy of one gallon of gasoline ([DOE 2013i](#)).
- **Biodiesel** – Biodiesel is a renewable fuel that can be manufactured from new and used vegetable oils, animal fats, and recycled restaurant grease through a process called transesterification. The production process converts oils and fats into chemicals (fatty acid methyl esters), also called long-chain mono alkyl esters, or biodiesel. In general, oil or fat reacts with short-chain alcohol (usually methanol) in the presence of a catalyst (usually sodium hydroxide or potassium hydroxide) to form biodiesel. The production of biodiesel results in a glycerin byproduct that can be used for various applications. While oils, animal fats, and restaurant waste are currently being used to produce biodiesel in Hawai‘i, additional research is currently being conducted to study the potential of developing algae as a biodiesel feedstock. The development of algae as a potential feedstock can produce high yields from a smaller area of land or water when compared to vegetable oils.

Biodiesel’s physical properties are similar to those of petroleum diesel, but it is a cleaner-burning alternative. It differs from diesel because it contains oxygen atoms, giving it different physical properties. Compared with petroleum diesel, biodiesel substantially reduces tailpipe emissions ([DOE 2013k](#)). Similar to ethanol, biodiesel comes in several blends, including B5 (5-percent biodiesel and 95-percent petroleum diesel), B20 (20-percent biodiesel and 80-percent petroleum diesel), and B100 or pure or neat biodiesel. No vehicle modifications are required for using B5 in diesel engines since the standard specification for diesel fuel used in vehicles allows up to 5-percent biodiesel (ASTM D975).¹⁰ However, vehicles that use more than 5 percent biodiesel require vehicle modifications that need to be certified by a vehicle manufacturer for safe use.

Advanced Biofuels

The biofuel market is rapidly advancing and continuously evolving. Compared with conventional biofuels, advanced biofuels are expected to be better in terms of energy balances, greenhouse gas reduction, land use requirements, and competition for food, fiber, and water. However, some conversion technologies are still in the research and development stages and not yet commonly produced at a

¹⁰ ASTM D975, “Standard Specification for Diesel Fuel Oils,” allows up to 5-percent biodiesel in petroleum-based diesel.

commercial scale. The following discussion focuses on those fuels that potentially offer distinct advantages to a future fuel distribution system in Hawai‘i ([Siah and Zapka 2009b](#)).

- **Cellulosic Ethanol** – Cellulosic ethanol comes from cellulose, hemicellulose, or lignin— all nonfood-based feedstocks. Technologies to convert cellulose-based crops into ethanol include acid hydrolysis, enzymatic hydrolysis, and thermal gasification (which produces a synthetic gas that can be further converted into ethanol and other fuels, including substitutes for diesel and jet fuel). Cellulosic ethanol is anticipated to be the most commercially viable biofuel in the near future. In fact, the Renewable Fuel Standard targets that approximately 16 out of 36 billion ethanol gasoline equivalents or 44 percent of all total biofuels in 2022 be produced from cellulosic biofuels; this however is still subject to EPA ruling ([Gruenspecht 2013](#)). In Hawai‘i, major feedstocks that have been identified for potential production of ethanol include banagrass (*Pennisetum pupureum*), guinea grass (*Panicum maximum*), sugar cane (*Saccharum officinarum*), sweet sorghum (*Sorghum vlgare*), varieties of eucalyptus (*Eucalyptus sp.*), and leucaena (*Leucaena leucocephala*) ([Turn 2012](#)). Many other additional feedstocks are still being explored, including algae.
- **Biobutanol** – Biobutanol is produced from biomass feedstock and is currently used as an industrial solvent in many wood finishing products ([DOE 2013i](#)). New technological advances and the discovery of new microbes have improved the efficiency and cost of the biobutanol production process. It has a greater energy density than ethanol, with an energy content that is 10 percent less than that of gasoline ([S.K. Ritter 2013](#)). Although biobutanol is not currently an EPA approved additive, biobutanol is more chemically similar to gasoline than ethanol, which means it can be integrated into internal combustion engines more easily than ethanol and in higher ratios. Existing ethanol production plants also can be retrofitted to produce biobutanol, avoiding the need for a separate liquid fuels infrastructure.

In a life-cycle cost analysis of biobutanol funded by the EPA, gasoline emits 2.17 kilograms of carbon dioxide more than biobutanol produced from food waste.¹¹ When compared with corn ethanol, the process for producing biobutanol produced less carbon dioxide. The life-cycle cost analysis confirmed that biobutanol is more sustainable and better for the environment than both gasoline and ethanol ([EPA 2009b](#)).

- **Hydrogenation-Derived Renewable Diesel (Green Diesel)** – Green, or renewable, diesel is a fuel chemically similar to traditionally refined oils in that it is a pure hydrocarbon without ester bonds (i.e., oxygen). The production methods, similar to oil refining technologies, include hydrotreating, thermal conversion, and biomass-to-liquid. In hydrotreating (or hydrodesulfurization), feeds are treated with hydrogen to remove impurities. Conversion temperatures range from 600° to 700°C, with pressures ranging from 40 to 100 standard atmosphere. During thermal conversion, biomass converts into bio-oil at temperatures ranging from 570° to 660°C, with pressure sufficient to keep the water primarily as a liquid (i.e., at 100 to 170 standard atmosphere), and then refined into a diesel-like fuel. In both methods, reaction times vary depending on the catalysts used in the process. The biomass-to-liquid process is a multi-step process that uses a high-temperature gasification system to convert biomass into a synthetic gas, and then uses a Fischer-Tropsch process to catalytically convert the synthetic gas into a fuel.

¹¹ The basis for the assessment was the energy content of 1 kilogram of butanol, 33.3 mega Joules per kilogram.

FISCHER-TROPSCH PROCESS

The Fisher-Tropsch process produces liquid transportation fuels by converting syngas—a mixture of carbon monoxide and hydrogen produced from biomass or fossil fuels, such as natural gas and coal—into Fischer-Tropsch (F-T) diesel. F-T diesel can substitute for conventional petroleum diesel to fuel diesel vehicles without modifying the engine or fueling infrastructure. The key to F-T synthesis is the catalysts—substances that facilitate chemical reactions without being consumed by the reaction. The process includes three steps that occur in the presence of catalysts:

1. **Syngas Formation**
Old Hydrocarbon + Oxygen → Syngas
2. **Fischer-Tropsch Reaction**
Syngas → New Hydrocarbon + Water
3. **Refining**
New Hydrocarbon → Fuels, Chemicals

Source: [DOE 2013m](#).

Green Diesel is a “drop-in” fuel or a fuel that can be used in existing fuel tanks without changes to the existing infrastructure. Four of the most commonly used feedstocks to produce Green diesel include soybean oil, palm oil, waste grease, and canola, and rapeseed oils. Byproducts during the production of Green Diesel include naphtha and liquefied petroleum gas (this PEIS discusses liquefied petroleum gas in Section 7.5).

- **Pyrolysis Oils** – Pyrolysis is the process of heating biomass to 450° to 500°C in the absence of oxygen. As the biomass feedstock decomposes, and when products are brought to ambient conditions, the result is a mixture of solid char, permanent gases, and a liquid referred to as bio-oil or pyrolysis oil. Pyrolysis oil is 50-percent dissolved water weight and the remaining mass, but the actual chemical compositions vary based on the feedstock and the processing conditions (i.e., the particle size of the biomass, the residence time, and the reactor type). Biomass-derived pyrolysis oil is rich in carbon and can be refined in ways similar to crude petroleum.
- **Hydrotreated Renewable Jet Fuel** – Hydrotreated renewable jet fuel is a synthetic liquid fuel produced by hydroprocessing biomass feedstocks such as plant/bio oils (i.e., carbon-based jatropha, camelina, and algae oils), animal fats, or waste grease. The fuel produced is chemically identical to conventional petroleum-based jet fuel and is therefore considered a “drop-in” fuel. As such, hydrotreated renewable jet fuel is compatible with the existing petroleum infrastructure. Further, renewable jet fuel can provide a 65- to 80-percent reduction in greenhouse gas emissions relative to petroleum-based jet fuels.

2.3.4.1.2 Characterization of Technology Feasibility

Biofuels have the potential to replace a significant volume of petroleum fuels in the State of Hawai‘i. Liquid fuels are essential to the State since they are the primary fuel source of ground, air, and marine transportation. Different biofuels are produced by different processes, all of which have merits in terms of physical properties (such as net energy and impacts on the environment) or economic and feedstock considerations.

Conventional Biofuels

Ethanol

While ethanol is widely used, it is not yet routinely transported in pipelines over long distances. As mentioned above, lower ethanol blends such as E10 are mixed with gasoline and transported, stored and dispensed in existing infrastructure. Higher ethanol blends, such as E85, however, would require separate infrastructure because it cannot be used in all vehicles, and can corrode some materials. The challenge of a future ethanol distribution system is dealing with its strong tendency to attract and absorb water from the atmosphere, strong solvent characteristics, and stress corrosion in storage and transport containments. Ethanol's properties require special materials for tanks, pipelines, transport containments, sealants, pipe fittings, and fuel transfer equipment and other components. While the handling of ethanol is an established operation in the chemical and petrochemical industry, the handling of large volumes of fuel-grade ethanol could present operational challenges, such as the potential for large ethanol fires and large ethanol spills.

Biodiesel

Unlike petroleum diesel, biodiesel has a higher flashpoint, or temperature at which it gives off vapor to ignite in air, which makes it safer to handle. It is also a stronger solvent than petroleum diesel, which enables it to dissolve accumulated particulates and sediments found in diesel storage and engine fuel systems. The dissolved impurities, however, can cause problems in distribution and equipment infrastructure. Biodiesel can also degrade and break down certain plastics with prolonged exposure. Certain gaskets, hoses, seals, and O-rings found in older fuel systems may experience leaks or seepage problems.

Biodiesel has a greater chemical attraction to water than petroleum diesel, which can result in operational problems when water contaminates the fuel, such as corrosion and filter plugging in fuel systems. Storage tanks, transport containers, and pipelines that contain certain compounds, such as soft metals (brass, bronze, copper, lead, tin, or zinc) can be subject to operations problems due to corrosion and creation of sediments. Unfortunately, such compounds are found in many fuel systems, causing material incompatibility problems with existing distribution infrastructure. As such, pure biodiesel (B100) should be transported and stored only in fuel systems that are designed for or known to be compatible with the fuel.

Given Hawai'i's temperate climate, biodiesel flow and mixing problems would not be an operational concern. However, biodiesel may be susceptible to impurities from contaminants, particulates, and water sources. As such, storage and transport vessels must be thoroughly cleaned and dried before being used for biodiesel. A dedicated distribution infrastructure would be preferable to avoid material incompatibility, cross contamination, and operational complications.

Biodiesel contains no hazardous materials and is considered safe for use. Typically, methyl esters biodegrade much more rapidly than conventional fuel, which mitigates fuel spills and decreases the environmental impacts of the fuel.

Advanced Biofuels

Cellulosic Ethanol

While corn and sugar cane can produce conventional ethanol, high production costs and increased land value are major barriers to their use in Hawai'i. As such, cellulosic ethanol, which uses lignin (plant material) rather than extracting sucrose from plants, is currently being explored as a feasible alternative to conventional ethanol production. However, cellulosic ethanol is in the research stages and there are

limited commercial-scale facilities in operation (e.g., the Abengoa biorefinery near Hugoton, Kansas, which has a capacity of 10 million gallons per year of ethanol). Current estimates of cellulosic ethanol yield and production are based on field-scale studies and in controlled conditions. As such, additional studies are still required to identify the best feedstocks for commercial-scale production.

Denatured ethanol, or ethanol mixed with additives to render the alcohol undrinkable, has about 70 percent of the energy density by volume of neat gasoline. Therefore, about 40 percent more volume has to be stored and transported to supply the same amount of energy content of motor gasoline (BP 2009).

Biobutanol

Butanol is currently produced using propylene, a petrochemical, but, as noted above, the same raw materials that produce ethanol (corn and sugar cane) can also produce biobutanol.

Biobutanol has a higher toxicity than ethanol, and can give off a bad odor when hydrolyzed, or chemically broken down by water. The capital costs for production and operation including all the equipment and labor has made biobutanol an expensive process. Currently, biobutanol is in the piloting stages for scaled up commercial production. At this time, there is a major focus to increase early adopters by retrofitting ethanol plants. Additional push for biobutanol is underway to help producers meet the Renewable Fuel 2 Standards (RFS2) and as ethanol subsidies decline.

Green Diesel

Green Diesel is a renewable fuel that can be produced using the same types of feedstock oils as biodiesel. Green Diesel is an aromatic and sulfur-free diesel fuel, has a very high cetane blending value¹², and good cold flow properties. It is as stable as petroleum diesel, and does not require special precautions or handling/dispensaries. As such, it can be widely used for any type of oil feedstock to produce a diesel substitute and is compatible for blending with the standard mix of petroleum-derived diesel fuels. Despite its low production costs, feedstock costs remain high. Therefore, while green diesel has been demonstrated for use on commercial and military flights, few companies are producing Green Diesel on a commercial scale. This is expected to change as more second-generation renewable feedstocks (such as camelina, jatropha, and algae) become available. As an alternative to conventional transportation fuels, Green Diesel has the smallest carbon dioxide footprint when compared with petroleum and biodiesels.

Pyrolysis Oils

There is currently ongoing research and development to produce pyrolysis oils of sufficient quality for transportation applications. Plant operations face challenges from feedstock particle size and plugging of process parts during operation, and reducing the amount of solids in the oil. In addition, the various types of feedstock that can be used to produce pyrolysis oils introduce challenges related to quality control and feedstock traceability. Although pyrolysis oils can be more cost competitive than other biofuels and show great potential for market penetration, the cost of feedstock and operational materials can still be relatively expensive (VTT 2012).

Transportation and handling of pyrolysis oils are subject to the American Society for Testing and Materials requirements, specifically, ASTM D7544. Caution is urged due to both acid content and the risk of static electricity generation and dissipation. Pyrolysis oil is stable at the ambient temperature experienced in Hawai'i. Nonetheless, due to the acidity of pyrolysis oil, tanks would have to be stainless steel or polymer, but need not be pressurized, heated, or cryogenic. As such, pyrolysis oils are not flexible with the existing infrastructure.

¹² A high cetane value indicates that the fuel will ignite faster than those with a lower value.

Hydrotreated Renewable Jet Fuel

Hydrotreated renewable jet fuel is in the research and development stages for scaled-up commercial production. Due to the limited feedstock availability, including feedstock competition with biodiesel producers, production capacity of renewable jet fuel is limited. A limited number of test, demonstration, commercial, and military flights have been conducted using drop-in hydrotreated renewable jet fuel at a 50-percent blend with standard jet fuel including in 2012, when the Navy demonstrated a 50-percent blend during the Rim of the Pacific Exercise in Hawai‘i. On the mainland, commercial airlines such as United Airlines are starting to purchase hydrotreated renewable jet fuel for anticipated flight use in 2014 ([Sapp 2013](#)).

2.3.4.1.3 Characterization of Future Deployment

The amount of land available for feedstock production is the key metric to measuring the biofuel technology’s potential. Studies conducted regarding the availability and feasibility of biofuel technology for the State show that approximately 136,000 acres of arable land could be available to maximize production of biofuel (combination of biodiesel and ethanol) feedstocks in order to reduce imports and associated costs ([Braccio et al. 2012](#)). In particular, there is space on O‘ahu, Maui, Kaua‘i, and Hawai‘i to grow biofuel feedstock; however, various economic, social, and environmental issues would need to be considered. Additional consideration should also be given to the amount of water resources available; such is the case on the islands of Molokai (limited land and competing crops for water resources) and Lāna‘i (which receives very little precipitation). Additional information regarding the different types of crops available as feedstock biofuel production, and the land available (including maps) for use in the State is available in the following resources. Other studies are currently being conducted to assess the biofuel potential of other crops for use in the State.

- *Hawai‘i Bioenergy Master Plan – Land and Water Resources Section* ([HNEI 2009b](#))
- *Biofuels Assessment* prepared for the State of Hawai‘i DBEDT ([Black and Veatch 2010](#)),
- *Rocky Mountain Institute - Hawai‘i Biofuels Summit Briefing Book* ([RMI 2006](#)).

In addition to local production of biofuels, the future biofuel supply for the State would most likely require imports of refined biofuel and feedstock, and the development of a future distribution system similar to [Figure 2-48](#).

As shown in [Figure 2-48](#), biofuels would likely would continue to be imported through O‘ahu, with direct imports of biofuel products and/or feedstocks to neighboring islands. Biofuel producers in O‘ahu would distribute the biofuel in O‘ahu via truck and the neighboring islands using marine transport modes. Alternatively, neighboring island feedstock production and biofuel conversion plants could satisfy local demand and export volumes of refined biofuels to O‘ahu or other neighboring islands; or neighboring islands without biofuel conversion plants would have facilities to unload fuel transported from fuel production inside the State and from direct biofuel imports to Hawai‘i ([Siah and Zapka 2009b](#)). However, as port facility capacity is currently tight, the State would need to make adjustments to schedules and implement port expansion plans ([HNEI 2012d](#)).

Biofuels can be transported as liquid or solid feedstock. However, the State of Hawai‘i has not updated material regulations to consider the various types of biofuels and biofuel feedstock. The State treats the materials as “chemicals,” which triggers special requirements when being transported via ocean barge or vessel¹³ ([HNEI 2012d](#)).

¹³ Transport via isotainer is a currently approved method for chemicals and thus for biofuel feedstock; the gap in regulation is for transportation via bulk liquid vessel.

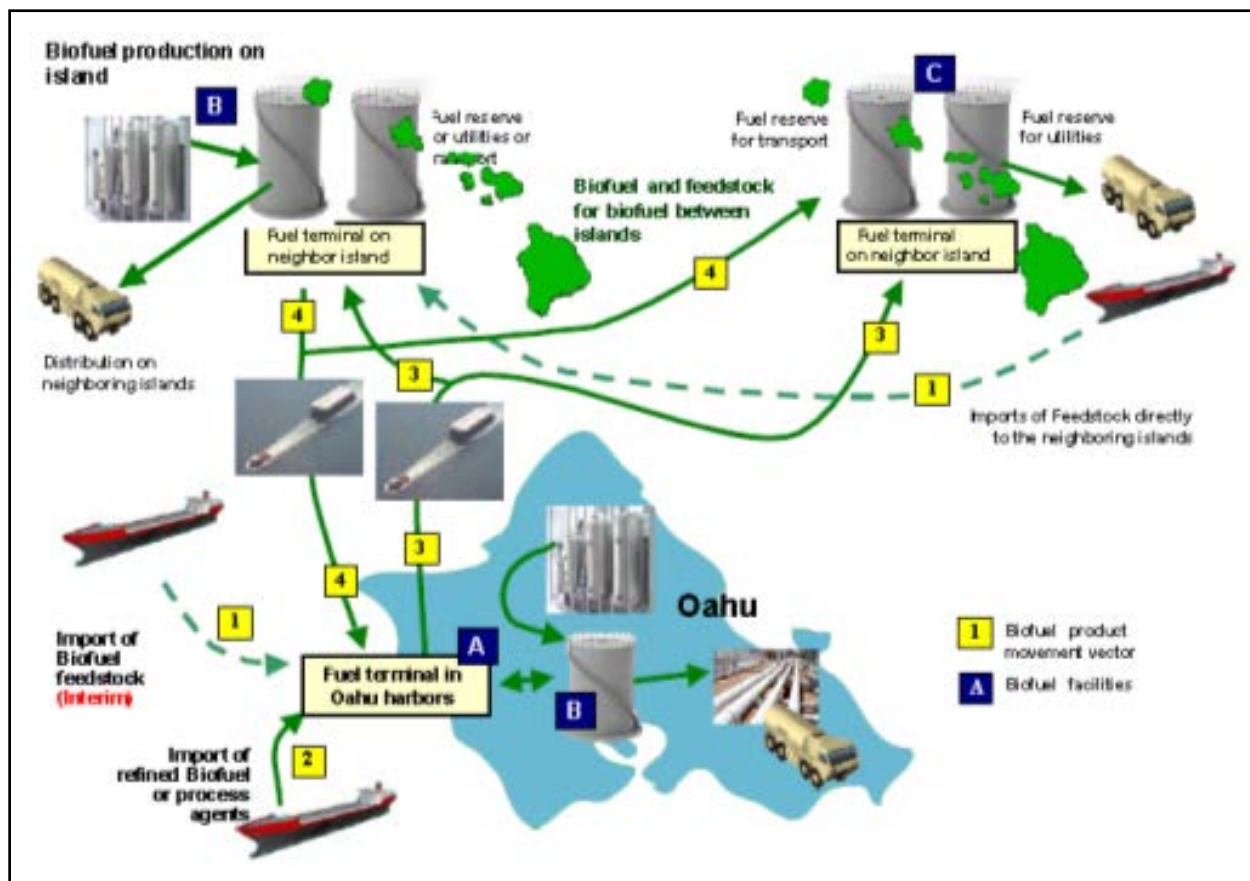

Figure 2-48. Biofuel System Supply for Hawai'i (Source: [Siah and Zapka 2009b](#))

2.3.4.1.4 Characterization of Existing Deployment

Production and Distribution

Biofuel supply in the State is largely composed of imports of ethanol for blending with gasoline to produce an E10 blend. Ethanol is not currently being manufactured in the State, and E85 fuel has yet to be sold for public use.¹⁴ Ethanol is imported from the mainland to O'ahu, and delivered to and blended with gasoline terminals on O'ahu, Maui, and the island of Hawai'i then sold through regular gasoline stations. As part of the 2015 Legislative Session, the Hawai'i State Legislature passed Senate Bill 717, which would repeal the existing requirement that gasoline for motor vehicles be composed of ten per cent ethanol. This bill is currently with the Governor for final approval or veto.

Biodiesel produced in the State at this time is used for transportation and power generation, such as the Campbell Industrial Park Generating Station and the Honolulu International Airport Emergency Power Facility (currently under development). The bulk of the biodiesel in the State is produced by Pacific Biodiesel, a company that has built several production facilities in other states and countries. However, the company's local production of biodiesel comes primarily from waste oil feedstock on O'ahu, Maui, and Hawai'i island ([Pacific Biodiesel 2013](#); [RMI 2006](#)). Some of this biofuel has been contracted to HECO and the HDOT for a biofuel-powered emergency generating power plant at Honolulu International Airport ([DBEDT 2012c](#)) and may be used at other existing facilities (such as HECO's 110MW Campbell

¹⁴ There currently are three E85 fueling stations in the State. However, the E85 fueling stations are limited to Navy use.

Industrial Park CT-1 power plant). Some fuel is also used in local fleets, including by the City and County of Honolulu. Local biodiesel production may change as technological shifts continue to change the biofuels outlook through improved agronomic and conversion technologies for feedstocks, the continuous and rapid evolution of production of cellulosic ethanol, and further improved biofuels chemistry overall.

The infrastructure currently available to support biofuel technology largely exists for ethanol on O‘ahu where storage, transport, and blending of petroleum and ethanol fuels has been handled successfully by the local fuel industry. However, future increases in the volume and range of renewable fuels will likely present additional scaling challenges for the State. Increased volumes of biofuels will require modifications to the existing distribution infrastructure to meet the growing demand, including the addition of new infrastructure to expand the State’s biofuel industry. This includes expansion of the following components: storage tanks, pipelines, fuel installations in the harbors (for marine transport), tanker trucks, and blending facilities.

Vehicle Systems

Despite the State’s ability to produce various biofuels, vehicle sales patterns in Hawai‘i show a relatively low turnover of vehicles, with approximately 50,000 vehicles replaced per year ([Braccio et al. 2012](#)). This is supported via vehicle registration data show in [Figure 2-49](#). Given the approximately 1 million vehicles in the State and an average of 50,000 vehicles being replaced each year, the average life of a vehicle in Hawai‘i is estimated to be approximately 20 years, hindering the State from replacing older, less efficient cars on the road with newer, more sustainable vehicles ([Braccio et al. 2012](#); [DBEDT 2012d](#)).

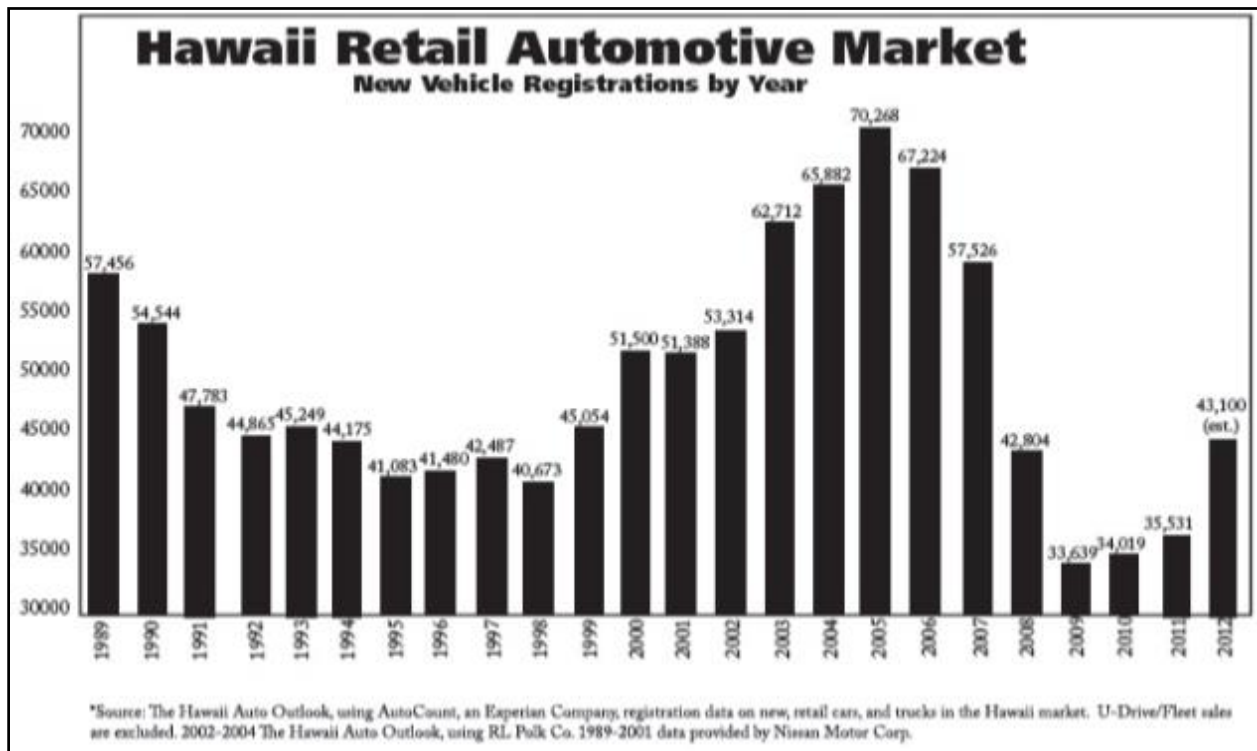

Figure 2-49. Hawai‘i Vehicle Registration Data, 1989–2012

This is further complicated as alternative-fueled vehicles require alternative fueling infrastructure. For example, flex-fuel vehicles represent approximately 5 percent of the light duty vehicles in use in the Nation ([EIA 2012c](#)). In Hawai‘i, this percentage is estimated to be less than 1 percent due to the limited

amount of fuel and fueling stations currently available.¹⁵ Therefore, although E85 ethanol is considered a possible petroleum fuel reduction strategy to help meet the State's transportation goals, the actual existing penetration rate of E85 ethanol (in particular) as a transportation biofuel is projected at this time to be minimal in the State. Although these numbers are projected to continue to increase, for large impacts to truly be realized, one study recommended that drop-in replacement fuels (e.g., Green Diesel or green gasoline which can be easily utilized in existing standard vehicles) would likely be better candidates for deployment in the future for the State ([RMI 2006](#)).

To help facilitate biofuel support and usage, Federal and State and incentives are available and discussed in [Section 2.3.4.1.5](#) below.

Other Transportation Systems

It is noted that several U.S. Government agencies, including the DoD and NOAA, have used biofuels in ground transport and aboard marine vessels to spur initiative and for testing. However, while biofuels have performed relatively well for ground transportation, there are no pending specifications or large-scale fueling facilities for marine-grade biofuels ([Nayyar 2010](#)). The DoD is currently researching biofuel for jet fuel use. In August 2011, the secretaries of Agriculture, Energy, and the Navy announced a memorandum of understanding to develop or retrofit domestic commercial- or pre-commercial-scale biofuel plants and refineries to support the Navy's goal of deploying a Green Strike Group and a Great Green Fleet by 2016 with a 50/50 blend of drop-in hydrotreated renewable jet fuel ([DBEDT 2012c](#)).

2.3.4.1.5 Incentives and Programs

As noted above, the Federal Government and State of Hawai'i have created laws and incentives to help increase biofuel support and usage. These include the following:

- An alternative fuel standard requiring that alternative fuels provide 15 percent of highway fuel demand by 2015, 20 percent by 2020, and 30 percent by 2030;
- A biofuel land use allowance and exemption where lands originally zoned for agricultural land use may be used for renewable energy production, storage, distribution, and the production of biofuels—the exemption releases biofuel production facilities from subdivision requirements for leases and easements within agricultural land use districts until July 1, 2020 (HRS Chapters [201N-14](#), [205-2](#), and [205-4.5](#));
- A biofuels procurement preference where State and county agency contract awards give preference to bids for biofuels and biofuel blends for the purchase of diesel fuel;
- A discounted tax rate for alternative fuels, an ethanol production incentive;
- Advanced vehicle acquisition requirements for the State and county; and
- An energy feedstock program that includes feedstock to produce biofuels.

2.3.4.1.6 Permitting and Consultation Requirements

Project permitting would be required for the production, conversion, and distribution activities and networks with accompanying infrastructure for the construction and operational phases of the project

¹⁵ Information based on 2011 data, the latest information available (Source: [EIA 2013c](#)).

from various Federal, State and county agencies. See [Section 2.2.5](#) for a discussion on general permitting and regulatory requirements.

Because of the nature of the biofuel technologies, projects would have to comply with the Inventory Reporting permitting requirements of the *Hawai'i Emergency Planning and Community Right-to-Know-Act* ([HRS Chapter 128E](#)). Further details can be found in the *Guide to Renewable Energy Facility Permits in the State of Hawai'i – Version 1* ([DBEDT 2013a](#)).

Proper facility siting is critical to facility permitting and biofuel facilities should be sited in industrial areas or far away from residences. The following are some biofuel facility permitting nuances in Hawai'i:

- The regulatory requirements associated with import of certain microorganisms can be complex and time-consuming and could require compliance with Hawai'i's environmental assessment/environmental impact statement law ([HRS Chapter 343](#)).
- Approval of a traffic impact assessment is required for feedstock or product trucking and may require *mitigation measures* (e.g., restrictions on truck volume and transport times, load security/cover requirements).
- Some feedstocks host the many endangered avian species found in Hawai'i. Feedstock harvest cycles may need to be adjusted to accommodate species mating or birthing seasons.
- A project could potentially trigger [HRS Chapter 343](#) under “oil refinery” or “waste-to-energy” facility.
- Project should include a rigorous regulatory review of facility effluent to ensure no invasive species are exhausted from the facility (e.g., genetically modified crops and algae).
- Competition for water, perceived pollutions risks, increased traffic, and use of agricultural land for nonfood crops can increase public opposition to the project.

There are also a few laws specific to biofuel facilities:

- City and County of Honolulu, Table 21-3, Revised Ordinances of Honolulu, includes a special use category called “Biofuel processing facilities,” making it clear where such a facility can be permitted.
- HRS Chapters [205-2\(d\)\(5\)](#) and [205-4.5\(a\)\(16\)](#) state which biofuel facilities are permitted in State Agricultural Districts.

2.3.4.1.7 Representative Project

Due to the uncertainty of biofuel technology readiness, it is difficult to describe with any accuracy what a representative project might look like, and would ultimately depend on the type of biofuel technology selected. For the purposes of this PEIS, the potential environmental impacts of biofuel technologies (presented in Chapter 7) considers the range of potential applications identified in [Section 2.3.4.1.2](#) and the potential impacts resulting from the development and utilization of biofuels from feedstock production and processing, to the slow integration of biofuels into the market, the fueling infrastructure, and vehicle use.

2.3.4.2 Electric Vehicles

Electric vehicles operate with an electric motor (or motors) powered by rechargeable battery packs. Some electric vehicles run solely on electrical power from the grid, others use a combination of gasoline and electricity. There are definite advantages and disadvantages of electric vehicles compared to internal combustion engine ([DOE and EPA 2013a](#)):

Advantages

- Energy efficient – Electric vehicles convert about 59 to 62 percent of the electrical energy from the grid to power at the wheels—conventional gasoline vehicles convert only about 17 to 21 percent of the energy stored in gasoline to power at the wheels.
- Environmentally friendly – When operating on battery power, electric vehicles emit no tailpipe pollutants, although the power plant producing the electricity may emit them. Electricity from nuclear-, hydroelectric-, solar-, or wind-powered plants causes no air pollutants.
- Performance benefits – Electric motors provide quiet, smooth operation and stronger acceleration and require less maintenance than cars with internal combustion engines.
- Reduce energy dependence – Electricity produced from renewable resources is domestically produced.

ELECTRIC VEHICLES

Battery Electric: Operates without internal combustion engine or fuel tank and relies solely on power from electrical grid.

Hybrid-Electric: Operates with a combined internal combustion engine and energy storage system; refuels with gasoline.

Plug-in Hybrid-Electric: Operates with a combined internal combustion engine and energy storage system; primarily uses grid-supplied electricity.

Disadvantages

- Driving range – Most currently available electric vehicles can only go about 100 to 200 miles before recharging—gasoline vehicles can go over 300 miles before refueling.
- Recharge time – Fully recharging the battery pack can take from 4 to 8 hours. A “quick charge” to 80-percent capacity typically takes 20 minutes.
- Battery cost – The battery packs are expensive and may need to be replaced one or more times throughout the life of the vehicle.
- Bulk and weight – Battery packs can be heavy and take up considerable vehicle space.

The DOE Alternative Fuels Data Center website (<http://www.afdc.energy.gov>), the joint DOE/EPA Fuel Economy website (<http://www.fueleconomy.gov>), and the Electric Drive Transportation Association (<http://www.electricdrive.org>) are all very good resources for learning more about electric drive technologies.

Electric vehicles are currently available in light-duty, such as passenger cars (from microcars to large sedans), and in medium-duty vehicles, such as delivery vans, transit buses, and shuttle buses. Battery electric vehicles do not have an internal combustion engine or fuel tank (e.g., gasoline, diesel, or

compressed natural gas). Instead, battery electric vehicles solely use power stored in a battery pack and an electric powertrain to propel the vehicle. Hybrid-electric vehicles combine a combustion engine and an energy storage system to provide power. The engine is typically an internal combustion gasoline engine, but any engine/fuel combination is possible. Plug-in hybrid-electric vehicles are hybrid-electric vehicles with a larger-energy capacity battery pack, a higher-power capability electric powertrain, and the ability to plug into an electrical power source to charge the battery pack.

This section discusses technologies specific to electric vehicles that primarily use grid-supplied electricity for propulsion: battery electric vehicles and plug-in hybrid-electric vehicles. [Section 2.3.4.3](#) discusses hybrid-electric vehicles.

2.3.4.2.1 Technology Description

Vehicle Types

Full-Speed Battery Electric Vehicles

Full-speed battery electric vehicles are capable of replacing a conventional gasoline vehicle and can use any road with any speed limit, assuming the driving range is sufficient. While any battery chemistry can be used (e.g., lead-acid, nickel metal hydride, zinc-air, lithium-ion, and lithium-air), lithium-ion is the only battery type in commercial use because of its power, cost, life, and safety, among other factors. However, as batteries improve in range, power, cost, and life, improved lithium-ion batteries or other battery chemistries likely will join, or replace, lithium-ion at some time.

These vehicles are fully functional and are potential replacements for conventional gasoline and diesel vehicles. However, due to battery cost the vehicles can typically only drive for about 100 miles between charges. The Federal Highway Administration data and General Motors Company internal data determined that 40 miles meets 86 percent and 100 miles meets 100 percent of the daily driving demands of more than 90 percent of passenger vehicle trips in the United States ([FHWA 2008](#); [Savagian 2011](#)). So, while this means the 100-mile travel range would be adequate, smaller, lighter, and larger-capacity batteries undoubtedly would make these vehicles that much more competitive.

Neighborhood Battery Electric Vehicles

Neighborhood electric vehicles are small battery-powered, low-speed vehicles. Their performance and vehicle safety equipment must conform to Federal Motor Vehicle Safety Standard 500 “Low-speed Vehicles” ([USDOT 2011a](#)). The standard requires a minimum set of safety equipment (e.g., safety belts, windshield, headlights, taillights, stop lamps, front and rear turn indicators, a horn, and a parking brake). These standards and Hawai‘i State law restrict neighborhood electric vehicle operation to a maximum speed of 25 miles per hour and only on roads with speed limits up to 35 miles per hour. Neighborhood electric vehicles have a much simpler powertrain than a full-speed electric vehicle and typically run with a lead-acid battery pack of 48 or 72 volts DC that can be replaced at a relatively low cost (less than \$1,000). Neighborhood electric vehicles have an onboard charger, which can plug into any standard 3-pronged, 120-volt AC outlet.

Plug-In Hybrid-Electric Vehicles

Plug-in hybrid-electric vehicles use grid-supplied electricity for the majority of daily driving trips. As a result, a plug-in hybrid-electric vehicle displaces more petroleum than a hybrid-electric vehicle, but less than a battery electric vehicle. Plug-in hybrid-electric vehicles refuel by both filling the fuel tank and plugging into an electrical power source to charge the battery pack. Plug-in hybrid-electric vehicles also recover braking energy to recharge the battery while driving. Most plug-in hybrid-electric vehicles can drive between 10 and 40 miles solely on electricity (without the use of the gasoline-powered combustion

engine) between charges. Plug-in hybrid-electric vehicles are often referred to by their all-electric driving range. For example, a type PHEV-10 is a plug-in hybrid-electric vehicle with a 10-mile all-electric driving range.

Plug-in hybrid-electric vehicles have the potential to cost less than battery electric vehicles because they have a lower-energy capacity battery and may have lower electric-power throughput on the electric drive components, which result in lower powertrain costs. This is especially true for plug-in hybrid-electric vehicles with lower electric range. However, in today's marketplace, the purchase price for some plug-in hybrid-electric vehicles is more than that of battery electric vehicles depending on the make and model. Battery electric vehicles cost less to operate than plug-in hybrid-electric vehicles because they operate solely on grid-supplied electric power. Even so, because the per vehicle petroleum savings does not scale linearly with battery capacity, having a larger-capacity battery pack [e.g., a battery electric versus a plug-in hybrid-electric vehicle with a 40-mile electric range (PHEV-40), or a PHEV-40 versus a PHEV-10] does not necessarily result in significantly lower petroleum use. In 2008, the Deputy Assistant Secretary for the DOE Office of Renewable Energy and Energy Efficiency stated that plug-in hybrid-electric vehicles with a 10-mile range (PHEV-10) with financial incentives seemed to be a better option than PHEV-40 (Rodgers 2008). This was because the PHEV-10 battery pack was less expensive, which resulted in earlier market penetration and a much larger amount of fuel being saved. The result is more consumers may be attracted to plug-in hybrid-electric vehicles and more inclined to purchase them.

Extended Range Electric Vehicles

Extended range electric vehicles is a term coined by General Motors Company to describe the Chevrolet Volt in an attempt to differentiate it from other plug-in hybrid-electric vehicles. Under most conditions, the Volt operates as an electric vehicle. It switches to conventional hybrid-electric vehicle operation when the battery is depleted (i.e., a charge-depleting plug-in hybrid-electric vehicle). Since an extended range electric vehicle is simply a different name for a plug-in hybrid-electric vehicle, this PEIS does not address it separately.

Electric Vehicle Charging Equipment

Electric vehicles must be connected to a supply of electricity using specialized equipment to recharge the battery. All currently available vehicle chargers use conductive charging, which is the same method used by most electric devices in the United States. All electric vehicle chargers must be installed by a licensed electrician and must comply with local, State, and Federal codes and regulations to ensure proper and safe installation. The following sections briefly describe relevant charging equipment. For more detailed information, readers are directed to the DOE's Alternative Fuels Data Center (<http://www.afdc.energy.gov/>) and HECO's electric vehicle technologies website ([HECO 2013e](#)).

Level 1 Electric Vehicle Chargers

Level 1 electric vehicle chargers are the lowest power output, least expensive, and slowest method to charge a battery pack. Level 1 electric vehicle chargers connect to a 3-pronged, 120-volt AC circuit (a standard household electrical outlet), and deliver between 1.3 and 1.7 kilowatts of power. Most commercially available, on-road electric vehicles include an integrated onboard Level 1 electric vehicle charger to ensure they are always able to charge as long as a 120-volt outlet is available. A special cordset connects the vehicle to a proper outlet.

A general rule of thumb is a Level 1 charger provides a full-speed battery electric vehicle between 2 and 5 miles of driving range per 1-hour of charging. (The actual mileage depends on the particular vehicle's energy consumption.) Because of this slow recharge rate, electric vehicles with a large battery pack would take a long time to recharge (e.g., it could take about 20 hours to charge a fully depleted battery), and may need a higher charge rate to meet consumer demand. The decision will be user and vehicle dependent. Plug-in hybrid-electric vehicles, however, have a lower-capacity battery pack and, thus, a shorter charge

time. Level 1 charging is likely to be used primarily for overnight or workplace charging when the vehicle would be connected for many hours for both battery electric and plug-in hybrid-electric vehicles. Level 1 charging is not suited for public charging locations where vehicles would be connected for much shorter durations, since it would not replace much charge.

Level 2 Electric Vehicle Chargers

Level 2 electric vehicle chargers have a higher power output than Level 1 chargers and connect to either a 240-volt AC, two-phase circuit (typical in residential applications) or a 208-volt AC, three-phase circuit (typical in commercial applications). Level 2 electric vehicle chargers are installed on a dedicated circuit with a current capacity between 20 and 80 amps and deliver between 3.3 kilowatts and 6.6 kilowatts of power (roughly 2 to 4 times the power of Level 1). This power output allows all currently available electric vehicles to recharge overnight. Most homes in Hawai‘i have 240-volt AC electrical service for operating appliances such as clothes dryers. The service can also be used for a Level 2 electric vehicle charger. Plug-in hybrid-electric vehicles have lower battery capacities than electric vehicles, so Level 2 charging may not be necessary for home charging since the less-expensive Level 1 charger will likely be able to charge the battery overnight. A general rule of thumb is a Level 2 charger provides between 10 and 20 miles of driving range per 1-hour of charging. (The actual mileage depends on the particular vehicle’s energy consumption.)

Direct Current Fast Chargers

Direct current fast chargers use a 480-volt DC input. Direct current fast charger units are much more expensive than Level 2 chargers (on the order of \$20,000 to \$40,000) ([Plug In America 2014](#)). The typical total installed cost (charger hardware and labor) ranges from \$75,000 to \$100,000. The low cost range is \$40,000 to \$50,000, but total installed costs can be as high as \$150,000 ([T. Ritter 2014](#)). The wide cost variation results from site-specific differences. As a result, this type of charger is only applicable to public recharging such as a charging station (the electric vehicle equivalent of a gasoline/diesel station). A general rule of thumb is a direct current fast charger provides between 60 and 80 miles of driving range in a 20-minute charging session. (The actual mileage depends on the particular vehicle’s energy consumption.)

Wireless Charging

Wireless charging, also known as inductive charging, does not use a direct physical connection between the vehicle and charger to transfer power. Rather, the charger transfers power to the vehicle via an inductive coupling through a magnetic field. In the 1990s, General Motors used inductive charging for the EV-1. In this application, a paddle was inserted into the charger slot at the front of the car to charge the battery. Today, wireless charging technology, still under development, uses a charging pad installed in the ground ([Figure 2-50](#)). The vehicle parks so the vehicle-mounted charging pad is over the ground-installed pad.

Figure 2-50. Wireless Charging Concept Demonstrator Concept
(Source: [HECO 2013f](#))

2.3.4.2.2 Characterization of Technology Feasibility and Deployment

Feasibility of Technology

Electric vehicles have been used and promoted in Hawai‘i since the mid-1990s. The Hawai‘i Electric Vehicle Development Program (now the Hawai‘i Center for Advanced Transportation Technologies) implemented a program to demonstrate electric vehicles in service at HECO and State agencies. In 1999, the Center extended the program to make Hawai‘i the first electric-

vehicle-ready state by installing a network of direct current fast chargers. The Electric-Vehicle-Ready State program expanded with the addition of 15 Hyundai electric vehicles as the company saw Hawai‘i’s unique climate and operations opportunity related to the geography and short typical driving distances ([ENOVA 2001](#)). All of these efforts showed that electric vehicles were a practical transportation option for Hawai‘i. The vehicles involved with the program used battery technology of the day (lead-acid and nickel metal hydride), which had limited driving range and power. Current electric vehicles have much higher driving range and power, so are expected to be accepted by a wider range of drivers.

Vehicle usage data provided by DBEDT show that the average annual vehicle miles travelled per vehicle has been relatively steady at 9,050 miles per year (1990 to 2011). U.S. Department of Transportation, Bureau of Transportation Statistics data show the vehicle miles travelled to be lower, at 7,014 (2000 data) ([USDOT 2002](#)). Regardless of the difference, these data correlate to low daily driving distances of about 20 to 25 miles per day, which is well below the driving range for all production battery electric vehicles and within the all-electric driving range for many commercially available plug-in hybrid-electric vehicles (e.g., Chevrolet Volt). It should be noted that these data are for the State of Hawai‘i; island-specific data are not available, so a more refined discussion was not possible. While it is not possible to quantify at this point, given the available data, one could assume that battery electric vehicles and the all-electric driving range of plug-in hybrid-electric vehicles could satisfy trips with double or triple the average daily mileage. Ultimately, it is not anticipated that there will be a significant differences in the applicability and use of electric vehicles between the islands. Electric vehicles on the island of Hawai‘i likely will be driven longer distances than on the smaller islands, but the use would not exceed normal usage on the mainland, so electric vehicles are still a viable technology.

Existing Deployment of the Technology Vehicles

[Figure 2-51](#) shows the vehicle registration trend for electric vehicles ([HSEO 2013b](#)). The Hawai‘i EV Ready program, funded by ARRA, provided additional financial incentives for purchasing electric vehicles and chargers to promote electric vehicles and jump start the wider public adoption ([HSEO 2013c](#); [DBEDT 2013j](#)). The program ran from August 2010 through December 2012 and increased the number of registered electric vehicles by more than 700 percent, ending with a total of 1,182 registered vehicles.

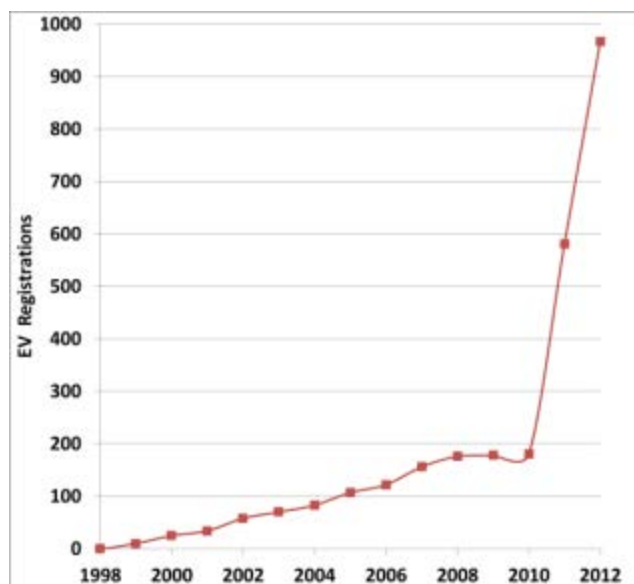

Figure 2-51. Electric Vehicle Registration in Hawai‘i

Charging Infrastructure

The Hawai‘i EV Ready program also awarded funds to several awardees (AeroVironment, Better Place, the County of Kaua‘i, the City and County of Honolulu, GreenCar Hawai‘i, and Plug in America) to install publicly available charging infrastructure. The program was responsible for installing 277 Level 2 charging spots and six direct current fast chargers at 98 locations across Hawai‘i.

HSEO compiles and makes available locations of public electric vehicle charging stations ([HSEO 2013d](#), [2013e](#)); the same information for public and private commercial stations is compiled by the Alternative Fuels Data Center (<http://www.afdc.energy.gov>). [Figure 2-52](#) summarizes the distribution of chargers and

Figure 2-52. Electronic Vehicle Charging Infrastructure by Island

charging ports installed across the State. (Note: chargers can have multiple charging ports.) Private residential charging locations are not included in either reference.

2.3.4.2.3 Electric Vehicles in 2030

As explained in [Section 2.3.4](#), the HCEI transportation sector goal is to reduce petroleum use for ground transportation. One way of achieving this is to replace conventional gasoline vehicles with electric vehicles across the State.

2030 Electric Vehicle Definition

The Hawai‘i vehicle fleet predominantly comprises light-duty vehicles (e.g., passenger cars and light trucks), so transitioning this class of vehicles to more energy-efficient vehicles is key to reducing petroleum and energy use. In addition, there are many current and near-term electric vehicle options for light-duty vehicles (mainly passenger cars).

Annual Hawai‘i light-duty vehicle sales data show that the Statewide light-duty vehicle mix is approximately 50 percent passenger cars and 50 percent light trucks (includes sport utility vehicles, crossover utility vehicles, and pickup trucks).

VEHICLE FLEET

For this PEIS, the term “fleet” has two purposes:

1. The general usage refers to the entire vehicle population in Hawai‘i.
2. When used in the discussion about the representative project, fleet refers to the collective group of all electric vehicles included in the electric vehicle population needed to achieve the 20-million-gallon gasoline use reduction.

The average annual sales in Hawai‘i is approximately 50,000 vehicles per year, which roughly equates to a 20-year fleet turnover rate for the State’s approximately 1 million vehicles. This means that most of the fleet’s current vehicles will be replaced by the 2030 HCEI target year.

Average driving distance data available from HSEO show that the annual per vehicle driving distance has remained very steady since 1999; slowly decreasing from 9,058 miles to 9,020 miles in 2011. Assuming a constant 9,020 miles

per year and an average gasoline passenger car fleet combined fuel efficiency of 25 miles per gallon (includes a combination of highway and city driving), the average vehicle consumes 361 gallons of gasoline per year.^{16,17}

One study compared the fuel economy improvement of plug-in hybrid-electric vehicles with that of an electric vehicle; the study did not include a comparison with conventional vehicles ([NRC 2010](#)). The fuel economy improvement of hybrid-electric vehicles compared with plug-in hybrid-electric vehicles varies

¹⁶ The 2030 passenger car fleet average fuel economy will be higher, but is not yet known. So data from various model years of Toyota Camry and Toyota Corolla were used as the basis to develop 25 miles per gallon.

¹⁷ Light-duty diesel vehicle penetration is currently very low. Even though this may change by 2030, the fuel savings from diesel were not included in this example.

by manufacturer, vehicle, battery capacity, what the baseline vehicle used for comparison, and other factors. [Table 2-20](#) summarizes these results.

Table 2-20. Per Vehicle Fuel Consumption Comparison of Conventional, Hybrid-Electric, and Electric Vehicles

Vehicle Type	Current Commercial Examples	Average Annual Gasoline Consumption (gallons)	Annual Fuel Consumption Reduction Relative to Conventional Gasoline Vehicle (gallons)	Annual Fuel Reduced Compared with Conventional Gasoline Vehicle (%)
Conventional Gasoline	Toyota Camry, Toyota Corolla	361	0	0
HEV	Toyota Prius, Honda Civic Hybrid, Ford Fusion	216	144	40
PHEV-10	Toyota Prius Plug-In Hybrid	173	188	52
PHEV-20	Ford Fusion Energi, Ford C-Max Energi	148	213	59
PHEV-40	Chevrolet Volt	97	263	73
BEV	Nissan Leaf, Ford Focus Electric, Fiat 500e, Chevrolet Spark EV, Honda Fit EV, Mitsubishi i-MiEV	0	361	100

BEV = battery electric vehicle; HEV = hybrid-electric vehicle; PHEV = plug-in hybrid-electric vehicle.

Potential Benefits

The primary benefit of the 2030 electric vehicle fleet will be a dramatic reduction of petroleum use and exhaust emissions, assuming renewable energy is the primary energy source. The electrical energy demand for the electric vehicles accounts for 5.2 percent¹⁸ of current firm power potential. By the 2030 target date, it may be possible to meet the demand with renewable generation. Using current system efficiencies, even if the electricity was generated primarily from fuel oil there would be about a 30 percent reduction in petroleum energy use for an electricity-powered mile compared with a gasoline-powered mile ([DBEDT 2012d](#)).

Potential Initial Issues

Electric vehicle charger installations for commercial or residential use may require trenching to run electrical cable conduit from the circuit panel to the electric vehicle charging equipment and/or to run additional electrical service to the building if the existing service cannot accommodate the additional load. A study of commercial properties on O‘ahu showed that only 3 of the 22 properties required trenching to install their chargers. Of the locations that needed trenching, the trenching distance ranged from 10 to 150 feet per charger ([HCC 2012a](#)). Electrical work crews initially would require more time to install the chargers; however, installation times would decrease as crews became more familiar with the new equipment.

Potential In-Use Issues

¹⁸ This figure is based on the assumption that the estimated daily total energy required to charge the total number of 2030 electric vehicles of 800,000 kilowatt-hours would require generation capacity of roughly 133 megawatts and a Statewide total firm generation power capacity of 2,484 kilowatts (discussed further below).

Electrical Grid Issues

The combined power capacity required to charge a large number of electric vehicles could pose a challenge to the utility and could increase petroleum use. Hawai‘i electrical energy consumption has decreased by 7 percent (770 gigawatt-hours) since it peaked in 2004 ([HSEO 2013f](#)) ([Figure 2-53](#)**Error! Bookmark not defined.**). There may be electrical generation and distribution capacity for adding electric vehicle loads, especially if the time of electricity use for electric vehicle charging is controlled. HCEI energy conservation programs will continue to result in decreased electrical energy usage. Increased renewable electricity generation will only improve the power availability for electric vehicles.

The Hawaiian Electric Companies (HECO in O‘ahu; MECO in Maui, Lāna‘i, and Molokai; and HELCO on Hawai‘i island) have pilot programs for residential and business customers that provide incentives when users charge electric vehicles during off-peak hours (9 p.m. to 7 a.m.) ([HECO 2013g, 2013h](#)). The rate structure varies somewhat depending on whether the electric vehicle charger is metered separately. For commercial accounts, the rate ranges from \$0.05 below to \$0.02 above typical rates; for residential accounts, the rate ranges from \$0.06 below to \$0.05 above typical rates. The Hawaiian Electric Companies also recently began offering two new electricity rate schedules intended to facilitate the deployment of a direct current fast charging infrastructure to alleviate range anxiety. (Range anxiety is the concern that an electric vehicle has insufficient driving range to reach its destination, leaving the occupants stranded.) The new Schedule EV-F rate is a time-of-use rate without a demand charge. Without this rate structure, fast charging could dramatically increase demand charges, while also potentially occurring at peak electricity usage periods. The second rate schedule allows the Hawaiian Electric Companies to install up to 25 publicly accessible direct current fast charging facilities on O‘ahu, in Maui County, and on Hawai‘i island ([DBEDT 2013k](#)). Information for the Kaua‘i Island Utility Cooperative was not available.

First Responder Issues

First responders (e.g., fire, police, and ambulance) have been properly trained to safely help electric vehicle drivers who are involved in accidents. The National Alternative Fuels Training Consortium has a First Responder Safety Training class that can be used by local emergency responders.

Potential End of Vehicle Life Issues

Electric vehicle powertrain components (e.g., batteries, electric motors, power electronics, and cabling) have a potential negative impact if they reach a landfill. The materials are all recyclable and should be captured through municipal and corporate reuse and recycling processes. Recycling practices and protocols for lithium-ion batteries have been in place for decades and are being further developed to handle the various types of lithium-ion batteries used in vehicles ([Coy 2011, 2012](#)). Batteries in electric vehicles are considered to have reached their end-of-life when a battery charge provides only 80 percent of the new battery’s energy capacity. At this point, technicians can recondition and use the batteries for non-vehicle applications, such as an energy storage buffer for solar or wind generation and utility grid support. Such reuse avoids costs and energy to produce new batteries, as well as costs associated with recycling. Batteries that cannot be reconditioned or repurposed ultimately will be recycled.

Figure 2-53. Electricity Use Decrease since 2004 Peak

2.3.4.2.4 Permitting and Consultation Requirements

Electric vehicles are purchased in the same manner as a conventional vehicle. However, installation of the electric vehicle chargers is the new aspect that must be addressed. The Hawai‘i EV Ready program included the development of the *Guidebook for Commercial Vehicle Charging Station Installations* ([Plug In America 2012](#)). This detailed reference describes the complete electric vehicle charger installation process, including planning, permitting, installation, and operation.

General permits are required before installation activities begin to ensure project conformity to Federal, State, and county laws, codes, and standards, as well as industry codes and standards (see [Section 2.2](#)). This section summarizes required permitting and provides references for more information if required.

All commercial electric vehicle charger installations require a permit. All permanently installed residential electric vehicle chargers require an electrical, building, and/or plumbing permit (the specific permitting requirements differ by county). Level 1 electric vehicle chargers likely do not require a permit since they can use any 120-volt AC outlet. Portable Level 2 electric vehicle chargers designed to plug into a 240- or 208-volt AC outlet likely do not require a permit, provided a dedicated outlet is in place. The “County Permitting Agencies for Charger Installations” section of the guidebook provides contact information for the permitting agencies for each county ([Plug In America 2012](#)). County planning and permitting contact information is provided in [Section 2.2.5](#).

The majority of early electric vehicle charger permits for installations on commercial properties on O‘ahu took between two and three weeks to receive approval ([HCC 2012a](#)). Should a more comprehensive zoning permit be required, permitting timelines and costs would increase. In many cases, a third-party electric vehicle charger installer, if used, handles the permitting process. DBEDT prepared a report that included a summary of the permitting issues and suggestions for improving and streamlining the permitting processes among the islands. One specific suggestion was to extend online electric vehicle charger installation permits for commercial installations ([DBEDT 2012d](#)). The City and County of Honolulu used funding from the Hawai‘i EV Ready program to make residential building permits available online for the installation of charging stations to help expedite residential charging station installations. Residential installation permits are attainable online for electric vehicle chargers that have been approved by the City and County of Honolulu.

2.3.4.2.5 Representative Project

The representative electric vehicle project is to increase the light-duty electric vehicle population to avoid use of 20 million gallons of gasoline fuel by 2030. This fuel avoidance amount is being used across all relevant sections in this PEIS to provide a consistent basis for comparison.

Using the 2030 electric vehicle discussion above (see [Section 2.3.4.2.3](#)), the representative project assumes that the Statewide vehicle mix remains 50 percent passenger cars and 50 percent light trucks. The representative project also assumes that only passenger cars will transition to electric vehicles (i.e., no light trucks). This assumption is based on two factors: (1) high vehicle costs, primarily related to battery costs, which scale with vehicle size, and (2) light-trucks are more likely to be used to transport loads (materials, people, towing), which would either decrease the driving range or require a larger, more expensive battery pack. Reinforcing this assumption, currently no EV sport utility, crossover utility vehicles, or pickup trucks are available for sale in Hawai‘i. Only one model of battery electric compact crossover utility vehicle is commercially available. No plug-in hybrid-electric or any battery electric vehicles are available in the other light truck classes.

The representative project includes a mixture of battery electric vehicles and different levels of plug-in hybrid-electric vehicles (e.g., PHEV-10, PHEV-20, and PHEV-40) to mimic a potential future fleet mix. Using data from [Table 2-20](#), the representative project uses the following values:

- **PHEV-10** – PHEV-10 reduces fuel consumption by 20 percent compared with a hybrid-electric vehicle (52 percent compared with a conventional gasoline vehicle) ([NRC 2010](#)).
- **PHEV-40** – An average PHEV-40 reduces fuel consumption by 45 percent compared with a hybrid-electric vehicle (73 percent compared with a conventional gasoline vehicle) ([NRC 2010](#)).
- **PHEV-20** – The PHEV-20 category was not included in the study, but is included here since this is the logical middle ground and PHEV-20 vehicles are currently available. Interpolating between the estimated PHEV-10 and PHEV-40 gives an estimated 32 percent lower fuel consumption compared with a hybrid-electric vehicle (59 percent compared with a conventional gasoline vehicle).

2030 Electric Vehicle Fleet to Meet Fuel Reduction Target

The representative project assumes the 2030 electric vehicle fleet mix will be:

- 40 percent PHEV-10
- 30 percent PHEV-20
- 20 percent PHEV-40
- 10 percent battery electric vehicle

The weighting takes into account higher adoption rates of less-expensive vehicles and conversely lower adoption rates of more-expensive vehicles. As [Table 2-21](#) shows, reaching the 20-million-gallon petroleum reduction would require adoption of approximately 88,000 electric vehicles (roughly 6 percent of the total number of 2030 vehicle fleet).

Table 2-21. Estimated 2030 Electric Vehicle Fleet Composition and Gasoline Reduction Potential

Vehicle Type	Percentage of 2030 Electric Vehicle Fleet	Number of 2030 Electric Vehicle Fleet	Total Annual Gasoline Consumption Reduction (gallons)
PHEV-10	40	35,139	6,592,676
PHEV-20	30	26,354	5,610,304
PHEV-40	20	17,570	4,627,552
BEV	10	8,785	3,169,556
TOTALS	100	87,848	20,000,088

BEV = battery electric vehicle; PHEV = plug-in hybrid-electric vehicle.

[Table 2-22](#) shows the installed battery capacity and estimated daily energy required to charge the batteries. The National Academy of Science report stated a PHEV-10 would require about 2 kilowatt-hours of installed battery capacity and a PHEV-40 would require about 8.0 kilowatt-hours. These numbers are roughly half of that used in the commercialized vehicles mentioned in [Table 2-21](#).

So to be more accurate, the representative project uses representative battery capacity values from current commercially available vehicles. Data from HSEO show the average daily trip distance in Hawai‘i is roughly 25 miles. Because of this, vehicles with an all-electric driving range greater than 25 miles (e.g., PHEV-40 and battery electric vehicles) will not be fully depleted at the end of the day, so the battery pack will not require a full charge. The total daily energy required to charge the electric vehicle fleet was estimated using the usable battery capacity, an overall 75 percent battery charging efficiency. The battery

charging efficiency includes transmission and distribution efficiency (about 94 percent) ([EIA 2010](#)), battery charger efficiency (about 90 percent) ([Chae 2011](#)), and battery-level losses (about 90 percent).

Table 2-22. Summary of Electricity Capacity Required To Charge the 2030 Electric Vehicle Fleet

Vehicle Type	Installed Battery Capacity Per Vehicle (kilowatt-hour)	Estimated Daily Battery Capacity Used Per Vehicle (kilowatt-hour)	Estimated Daily Total Energy Required (kilowatt-hours)
PHEV-10	4.4	4.4	210,000
PHEV-20	8.0	8.0	285,000
PHEV-40	16.0	10.0	235,000
BEV	24.0	6.0	70,000
TOTALS	NA	NA	800,000

BEV = battery electric vehicle; NA = not applicable; PHEV = plug-in hybrid-electric vehicle.

Electrical Energy Required to Charge the 2030 Electric Vehicle Fleet

Assuming a 6-hour charge, 800,000 kilowatt-hours would require generation capacity of roughly 133 megawatts. This equates to 5.2 percent of the firm generation power capacity in Hawai'i for each avoided 20 million gallons of gasoline ([Table 2-23](#)). This is additional demand on the grid that would have to be included in energy use forecasts. The majority of electric vehicle charging loads will occur off-peak when sufficient production is available. It is critical that the vehicles charge after the evening peak (typically 9 p.m.), otherwise electric vehicle charging will increase the demand on the grid. This is one of the reasons that the utilities have pilot time-of-use electric vehicle charging rate programs that provide incentives for off-peak charging (see the [Potential In-Use Issues](#) section above). The additional electric vehicle charging loads would require that sufficient renewable power generation is available to meet the HCEI goals. There are currently 202 megawatts of wind power, 31 megawatts of hydroelectric power, and 38 megawatts of geothermal power generation capacity (271 megawatts total), which, combined, have the potential to charge the electric vehicle fleet in this representative project. Some of these loads face curtailment, especially at night, so would be available for electric vehicle charging. The renewable generating capacity would be higher in 2030, so may be able to meet the electric vehicle charging demand.

Table 2-23. Power Generation Capacity in Hawai'i

Utility Company (Islands)	Firm Generation Power (megawatt)	Non-Firm Generation Power (megawatt) ^a
HECO (O'ahu)	1,783	88
MECO (Maui, Lāna'i, Molokai)	284	48

Electric Vehicle Charger Installations to Support the 2030 Electric Vehicle Fleet

The typically short average driving distances and the island geography mean that home charger installations could meet a significant portion of the regular charging infrastructure need, especially for plug-in hybrid-electric vehicles. It is reasonable that Level 1 chargers will be sufficient for PHEV-10 and PHEV-20. It was assumed that Level 2 chargers will be required as the primary (i.e., home) charging method for PHEV-40 and battery electric vehicles given the larger battery capacity. This results in a scenario where approximately 62,000 Level 1 chargers and 27,000 Level 2 chargers would be installed where the vehicles park overnight.

Even with Hawai‘i’s limited geographic boundaries, range anxiety serves as a major impediment to purchases and public acceptance of battery electric vehicles. (Range anxiety is not a concern for plug-in hybrid-electric vehicles since they switch over to operating as a conventional hybrid-electric vehicle when battery charge reaches certain threshold.) This is true for residents and tourists who could rent or lease electric vehicles. Range anxiety will be the biggest concern for atypical, longer distance, trips, such as driving from town centers to major beaches and remote popular destinations. Range anxiety could also be an issue for residents with commutes that are close to the maximum driving range, especially if they encounter side trips, road construction detours, or unexpected traffic delays. As a result, public charging stations will be needed in frequented locations (e.g., work, shopping malls, major beaches, and popular tourist attractions) to encourage electric vehicle acceptance for residents and tourists. Level 1 or Level 2 chargers could be used for workplace charging since the vehicles would remain idle for sufficient time to replace a useful amount of battery capacity. High-power Level 2 chargers could be installed in public locations where the vehicles park for only an hour or two (e.g., shopping malls, colleges, civic center, major beaches, medical complexes, and popular tourist attractions). A network of direct current fast chargers also likely would be necessary for electric vehicle users who do not park their vehicles for long periods during the day (e.g., pick up/drop off at bus terminal/airport, scenic drive around the island), or to give the battery a boost charge to ensure the vehicle gets home. A properly designed combined solution of Level 1, Level 2, and direct current fast charge stations will enable the electric vehicle market to grow by removing a significant potential detractor for vehicle purchaser and renters.

2.3.4.3 Hybrid-Electric Vehicles

Hybrid-electric vehicle powertrains combine a conventional combustion engine (gasoline or diesel), a battery, and an electric motor. The wheels are driven by the internal combustion engine, the electric motor, or a combination of the two. There are various hybrid powertrain configurations. In a parallel hybrid-electric car, the conventional engine and the electric motor are mechanically connected to the driveshaft and the wheels of the car. In a series hybrid-electric car, the combustion engine is only used to generate electricity, which then powers an electric motor that drives the wheels. Hybrid-electric vehicles reduce fuel use mainly by recovering braking energy, an approach called regenerative braking. Regenerative braking converts the vehicle’s kinetic energy into electrical energy to charge the battery, rather than wasting it as heat energy as conventional brakes do. All hybrid-electric vehicles also have an idle-stop feature, which turns the engine off when the vehicle stops to save more fuel.

[Section 2.3.4.2](#) of this PEIS discusses electric vehicles which includes battery electric vehicles and plug-in hybrid-electric vehicles. This PEIS addresses hybrid-electric vehicles separately because they all use an internal combustion engine so rely more on conventional fuel than electricity to propel the vehicle. Hybrid-electric vehicles are currently available in light-duty vehicles, such as passenger cars (from microcars to large sedans) and sport utility vehicles/crossover utility vehicles), and in medium- and heavy-duty vehicles, such as delivery vans, transit buses, and shuttle buses.

The DOE Alternative Fuels Data Center website (<http://www.afdc.energy.gov>), the joint DOE/EPA Fuel Economy website (<http://www.fueleconomy.gov>), the Electric Drive Transportation Association (<http://www.electricdrive.org>), and the joint EPA/USDOT National Highway Transportation Administration documentation supporting the 2017–2025 Corporate Average Fuel Economy legislation ([EPA and USDOT 2012](#)) are all very good resources for learning more about hybrid-electric vehicle technologies.

2.3.4.3.1 Technology Description

Vehicles Types

This section defines the different levels of vehicle “hybridization.” While definitions differ somewhat depending on the data source (e.g., government agency, vehicle manufacturer, and research study), the definitions provided in the following sections, and summarized in [Table 2-24](#), are from a recent Society of Automotive Engineers symposium ([Anderman 2013](#)) and provide practical guidelines for the types of hybrids. All hybrid-electric vehicles are full-function vehicles and are direct replacements for conventional gasoline or diesel internal combustion engine vehicles.

Table 2-24. Comparison of Hybrid System Types

Hybrid Type	Battery Type	Battery Voltage (VDC)	Electric Assist Power (kW)	Electric Range (miles)	Fuel Use Savings (%)	Benefits
Micro-0	Advanced lead-acid	14	0	0	2 – 6	Engine stop-start, some idle loads
Micro-2	Advanced lead-acid and Li-ion	14+	0	0	8 – 20	More idle loads for longer engine off
Mild	Advanced lead-acid and Li-ion	48	7 – 12	~0		Engine off during coasting
		100 – 140	10 – 16	~0		Launch assist
Moderate	NiMH and Li-ion	100 – 150	10 – 20	~0	Limited power assist	
Full/Strong	NiMH and Li-ion	>200	25 – 50	1 – 3 (at low speeds)	15 – 50	Extended power assist

Source: [Anderman 2013](#).

kW = kilowatts; Li-ion = lithium-ion; NiMH = nickel-metal hydride; VDC = volts direct-current.

Micro-Hybrid-Electric Vehicles

Micro-hybrid-electric vehicles (micro-hybrids) are sometimes referred to as stop-start hybrids since their primary purpose is to shut the engine off when the vehicle is stopped (e.g., traffic lights, stop signs, or stop-and-go traffic). Micro-hybrids also are referred to as 12-volt stop-start hybrids, idle-stop hybrid, or 12-volt direct current micro-hybrid ([EPA and USDOT 2012](#)). The Micro-0 level of micro-hybrids uses a single 12-volt direct current battery (primarily advanced lead-acid). Micro-0 hybrids are the least sophisticated, capable, and costly of the hybrids. Integration with the combustion engine is typically via a belt-alternator starter arrangement, where a drive belt delivers power to start the engine, rather than using a conventional starter motor ([EPA and USDOT 2012](#)). Micro-0 systems cannot adequately power all vehicle electrical loads (e.g., radio, power windows, air conditioner) when the engine is stopped for long periods, so the engine will restart automatically when needed to ensure the loads are met even if the vehicle is still stopped. The Micro-2 level of micro-hybrids uses a more capable single 14-volt direct current battery that enables limited regenerative braking and the ability to power all electrical loads when the engine is off.

The fuel use reduction of micro-hybrids is low (from 2 to 8 percent, depending on the drive cycle and the number of stop-start events); however the system cost is also very low (about \$250 for Micro-0 up to about \$525 for the Micro-2). The low cost is anticipated to result in a large number of vehicle purchases (especially light-duty vehicles) to use micro-hybrid systems. The resulting combined fuel savings would be appreciable. Current micro-hybrids use either advanced lead-acid or lithium-ion batteries. Other battery types and energy storage configurations are being tested to improve performance and lower cost. There are no commercially available micro-hybrids currently available in the United States; however, they

are becoming common in light-duty vehicles in Europe and Japan. No medium- or heavy-duty micro-hybrids have been produced or are expected to be produced in the future.

Mild Hybrid-Electric Vehicles

Mild hybrids, also referred to as “higher voltage stop-start” and “belt integrated starter generator,” use an advanced lead-acid or lithium-ion battery between 48 and 140 volts direct current and a low-power, 10- to 15-kilowatt, electric motor to improve on the Micro-2 hybrid’s performance to increase the regenerative braking performance (higher power and energy capture rate) and allow for limited electric-only driving (for instance, driving out of a parking garage). Some examples use the belt-alternator starter configuration (discussed earlier). Mild hybrids cost more than Micro-2 systems, but are still an affordable option, so are anticipated to be widely used. European automakers are leading the development of the 48-volt direct current hybrid systems ([Anderman 2013](#); [PSA 2013](#)). For instance, PSA Peugeot Citroën has stated a goal of producing a system that has reasonable performance (from 10 to 15 percent fuel use reduction) that is affordable by the largest number of customers ([PSA 2013](#)). Higher-voltage mild hybrid systems are available in a limited number of models in the United States, currently in mid-sized passenger cars from both mass market and luxury brands. No medium- or heavy-duty micro-hybrids have been produced or are expected to be produced in the future.

Moderate Hybrid-Electric Vehicles

Moderate hybrids, also referred to as “integrated motor assist” and “crank integrated starter generator,” systems ([EPA and USDOT 2012](#)) have higher electrical power capabilities than mild hybrids and provide electric launch and power assist (i.e., do not supply full launch or propulsion power) functionality. Moderate hybrid systems use an integrated motor/generator located between the engine flywheel and transmission to capture and deliver power to the driveline. Honda is the only light-duty vehicle manufacturer currently producing moderate hybrid-electric vehicles. Lower-power vehicles (e.g., Honda Fit and Insight) use nickel metal hydride batteries, while higher-power vehicles (e.g., Honda Civic and CR-Z) use lithium-ion batteries ([Anderman 2013](#)). Moderate hybrids are available from several commercial vehicle manufacturers or propulsion system manufacturers.

Full Hybrid-Electric Vehicles

Current full hybrid-electric vehicles, also referred to as “strong” hybrids, have higher electric motor and battery capabilities and performance than moderate hybrids. They can operate solely on electric power for speeds up to 60 miles per hour. As with other hybrids, the combustion engine turns on once the power demand is above what the hybrid system can deliver. In general, full hybrids improve fuel consumption by between 16 and 50 percent compared with a comparable conventional vehicle. Most mass-market passenger car full hybrids reduce fuel consumption between 40 and 50 percent. Full hybrid pickup trucks, sport utility vehicles, and luxury cars reduce fuel consumption by 12 to 20 percent.

Light-duty full hybrid-electric vehicles are available in passenger cars (from subcompact to large sedans), sport utility vehicles/crossover utility vehicles, and pickup trucks. Current light-duty full hybrids primarily use nickel metal hydride batteries. Lithium-ion batteries recently entered the full hybrid market; however, not all manufacturers are making the switch right away (e.g., Toyota says it will continue to use nickel metal hydride battery in its hybrid vehicles ([Takahashi 2013](#))). According to [Anderman \(2013\)](#), all new light-duty full hybrid models will use lithium-ion batteries, as related costs are expected to decrease by 2016/2017. Commercially available full hybrids are also available in medium-duty (e.g., utility trucks, package delivery trucks, school buses, and shuttle buses) and heavy-duty vehicles (e.g., refuse trucks, delivery trucks, and transit buses). As with electric vehicles, battery development is the key focus for improving hybrid-electric vehicles for power, cost, weight, and battery pack life; therefore, improved lithium-ion batteries or other battery chemistries, such as lithium-air or lithium-sulfur, likely will join, or replace, lithium-ion at some point.

Vehicle Fuel Consumption

This PEIS compares fuel consumption for mild, moderate, and full hybrids with their respective internal combustion engine model. [Table 2-25](#) summarizes the results of this comparison, where an average representative fuel consumption was used.

Table 2-25. Per Vehicle Fuel Consumption Comparison of Conventional and Hybrid-Electric Vehicles

Vehicle Type	Current Commercial U.S. Vehicle Model Examples	Fuel Reduced Compared to Baseline Vehicle (%)	Average Annual Petroleum Use (gallons)	Fuel Use Reduction Relative to Baseline (gallons)
Baseline	Toyota Camry, Toyota Corolla, Ford F-150, Toyota Tacoma	0	462	0
Micro-Hybrid ^a	NA	4	444	18
Mild Hybrid	Chevrolet Malibu eAssist, Mercedes-Benz E400 Hybrid	12	407	55
Moderate Hybrid ^b	Honda Civic Hybrid, Honda CR-Z	21	366	96
Full Hybrid	Toyota Prius, Ford Fusion Hybrid, Hyundai Sonata Hybrid, Volkswagen Touareg Hybrid, Chevrolet Silverado 15 Hybrid	27	339	123

Source: [DOE and EPA 2013a](#).

- a. Micro-hybrids are not commercially available in the United States, so fuel consumption reduction was estimated based on current information on systems in Europe and Japan from [Anderman \(2013\)](#).
- b. No moderate hybrids for trucks currently exist. This value estimates the potential moderate hybrid performance for trucks, using the difference between car and truck fuel reductions for full hybrids as a gauge.

Vehicle Fueling Infrastructure

Hybrid-electric vehicles refuel in exactly the same way, and at the same fuel stations, as conventional internal combustion engine vehicles. Hybrid vehicles can use any fuel, but as mentioned earlier all hybrid-electric vehicles currently sold in the United States use gasoline. One could conclude that as more hybrid vehicles are in use, the amount of gasoline consumed will decrease. Furthermore, the fuel consumption reductions from hybrid-electric vehicles and other vehicle fuel efficiency improvements will mean an overall decrease in the consumed fuel. So over time the number of fueling stations will likely decrease since per station fuel throughput will decrease.

2.3.4.3.2 Characterization of Technology Feasibility and Deployment

Hybrid-electric vehicles have been available and used in Hawai‘i since Honda released the original 1999 Insight. Because they are operated the same as conventional vehicles, there is no learning curve to dissuade potential users. On the infrastructure side, all hybrid-electric vehicles are fueled the same as a conventional internal combustion engine vehicle, so no special fueling station is required.

Existing Deployment of the Technology

As can be seen in [Figure 2-54](#), hybrid-electric vehicle sales (as indicated by registration trend) in Hawai‘i were low in the first several years, but picked up as consumers became more familiar with the technology, vehicle prices decreased, the price of gasoline increased, and Federal tax incentives became available

(from 2005 to 2010) ([DOE and EPA 2013b](#)). The current number of hybrid-electric vehicles in Hawai‘i through July 2013 is about 15,500. The majority of these are full hybrids, followed by moderate hybrids.

As discussed above, hybrid-electric vehicles are available for light-duty passenger vehicle and medium- and heavy-duty commercial vehicle applications. Medium- and heavy-duty vehicles use significantly more fuel on a per-vehicle basis than light-duty vehicles, which makes them good candidates for hybridizing. Further, the vehicle’s application (e.g., refuse truck, transit bus, or longer-distance delivery) is important because frequent stop-starts maximizes the hybrid system’s benefits. The incremental vehicle costs (price above a conventional vehicle) are also much higher than light-duty vehicles, and options for medium- and heavy-duty hybrid-electric vehicles currently are much fewer. Commercial fleets purchase vehicles based on a business case analysis and vehicle purchase decisions typically are made based on the lowest total cost of ownership (e.g., vehicle purchase, fuel costs, maintenance costs, labor costs, insurance, and salvage value). Medium- and heavy-duty hybrid-electric vehicles have lower fuel saving potential, but offer a better business case (when compared with plug-in hybrid-electric vehicles) because of their lower incremental cost. Overall, the medium- and heavy-duty vehicle population [roughly 1,000 vehicles out of 1 million vehicles (0.1 percent)] is very small compared with light-duty vehicles, so the cumulative fuel savings potential is much lower than for the light-duty fleet.

Conversely, as discussed earlier, there are many current and near-term options in most light-duty classes. Light-duty vehicles use less fuel, but light-duty hybrid systems have much lower incremental costs (as low as a few hundred dollars for micro-hybrids). The high fuel costs in Hawai‘i make a compelling case for increased adoption of light-duty hybrid-electric vehicles of all types.

2.3.4.3.3 Hybrid-Electric Vehicles in 2030

As explained in [section 2.3.4](#), an HCEI goal is to reduce the petroleum used for ground vehicles. One way to achieve this is to replace conventional gasoline vehicles across the State with hybrid-electric vehicles.

2030 HEV Vehicle Definition

Vehicle usage data provided by DBEDT show that the average annual vehicle miles traveled per vehicle has been relatively steady at 9,050 miles per year (1990 to 2011); USDOT, Bureau of Transportation Statistics data show this number to be lower, at 7,014 ([USDOT 2002](#)). Regardless of the difference, these annual numbers correlate to low daily driving distances of roughly 20 to 25 miles per day. Note that these data are based on the population of the State; island-specific data are not available.

Benefits

As discussed above, the primary benefit of the 2030 hybrid-electric vehicles will be a reduction of petroleum use. Exhaust emissions also will be reduced due to the lower petroleum use.

Figure 2-54. Hybrid-Electric Vehicle Registration Trend in Hawai‘i (Source: [HSEO 2013a](#))

Potential Initial Issues

Hybrid-electric vehicles are a known technology and are already successfully integrated into the public and private automobile marketplace. Increasing the number of registered hybrid-electric vehicles to meet the 2030 goal (on average 23,700 sales per year, or roughly 2,000 per month, based on the data in [Figure 2-54](#)) may sound aggressive based on historical sales. However this projection includes a large percentage of significantly lower cost options, micro-hybrids and mild-hybrids (60 percent and 10 percent, respectively, in the representative project discussed in [Section 2.3.4.3.5](#)). Micro-hybrid adoption is expected to be nearly universal on most non-hybrid vehicles due to the cost-effective fuel reduction. The high adoption rates will be driven by wider availability, hybrid system costs bring driven lower by sales volume (for all hybrid configurations), and by reaching a value point for consumers for reducing fuel costs. Vehicle manufacturers will commercialize and sell all types of hybrids to first meet their consumers' expectations, but also to comply with Corporate Average Fuel Economy requirements.

Maintenance and Service

The vehicles are serviced at the dealer in the same manner as a conventional vehicle, except that new and unique service is done for hybrid system components. Many vehicle manufacturers already have hybrids on the market so already have this capability in place.

First Responder Issues

First responders (e.g., fire, police, and ambulance) have been properly trained to safely help distressed drivers of hybrid-electric vehicles. Many departments likely have these training programs and requirements in place since hybrids have been on the market for more than ten years. In addition, the National Alternative Fuels Training Consortium has a First Responder Safety Training course that local emergency responders can take.

Potential End of Vehicle Life Issues

Hybrid-electric vehicles have additional components compared with conventional vehicles (e.g., batteries, electric motors, power electronics, and cabling). Each of these has a potential negative impact if they were to reach a landfill. Many of the materials are high value so should be captured through municipal and corporate reuse and recycling processes. Recycling practices and protocols for lead-acid, nickel-metal hydride, and lithium-ion batteries have been in place for decades and are being further developed to handle the various types of lithium-ion batteries used in vehicles ([Coy 2011, 2012](#)). Batteries in hybrid-electric vehicles are considered to have reached their end-of-life when the battery capacity after a full charge is 80 percent of the new battery's capacity. At this point, technicians can recondition and use the batteries for non-vehicle applications, such as an energy buffer for solar or wind generation and utility grid support. Such reuse avoids costs and energy to produce new batteries, as well as costs associated with recycling. Batteries that cannot be reconditioned or repurposed ultimately will be recycled.

2.3.4.3.4 Permitting and Consultation Requirements

Hybrid-electric vehicles are purchased in the same manner as conventional vehicles, so no new or different processes or permits are required. The vehicles are fueled using existing conventional fuel stations, so no additional infrastructure or permitting is needed to fuel or operate them.

2.3.4.3.5 Representative Project

The representative hybrid-electric vehicle project in the State is to increase the light-duty hybrid-electric vehicle population to avoid use of 20 million gallons of gasoline fuel by 2030. This fuel avoidance amount is being used across all relevant sections in this PEIS to provide a consistent basis for comparison.

The representative project assumes that the Statewide vehicle mix remains at 50 percent passenger car and 50 percent light truck (see [Section 2.3.4.2.3](#)).

Average driving distance data available from the Hawai‘i Energy Office show that per vehicle driving distance has remained very steady since 1999 (slowly decreasing from 9,058 miles to 9,020 miles per year). The representative project assumes 9,020 annual travel miles per vehicle. Using the Toyota Camry, Toyota Corolla, Toyota Tacoma, and Ford F-150 as representative baseline vehicles, the representative project further assumes an average conventional passenger vehicle fuel efficiency of 25 miles per gallon (based on 80 percent urban driving), for a calculated fuel consumption of 361 gallons of gasoline per year. The representative project does not include light-duty diesel vehicles because they are not used enough to affect the outcome. Using the same baseline vehicles, the representative project assumes an average conventional pickup truck fuel efficiency of 16 miles per gallon, for a calculated consumption of 564 gallons of gasoline per year. Applying the 50 percent passenger car to 50 percent light truck ratio, this equates to an average of 462 gallons of gasoline consumed per year. This is within the range indicated by actual fuel and vehicle data for Hawai‘i [on-highway gasoline demand in calendar year 2012 was 444,268,297 gallons, which fueled a vehicle population that included 998,883 gasoline and 12,141 hybrid-electric vehicles, for an average gasoline fuel consumption of 439 gallons per vehicle ([DBEDT 2013](#))].

The representative project assumes that only passenger cars and light trucks will transition to hybrid-electric vehicles. Further, the representative project assumes 60 percent of the hybrids will be micro-hybrids and 25 percent will be full hybrids. This is based partly on the lower cost of micro-hybrids and DOE’s forecast that 85 percent of all hybrid sales in 2030 will be of micro-hybrids ([Chase 2013](#)). Moderate hybrids are assumed to account for only 5 percent of hybrid sales. This is because moderate hybrids are currently only available from one manufacturer and they are expected to be replaced by other, more cost-effective hybrid configurations ([EPA and USDOT 2012](#)). As shown in [Table 2-26](#), reaching the 20-million-gallon petroleum reduction would require roughly 383,000 hybrid-electric vehicles (meaning hybrid-electric vehicles would account for roughly 30 percent of all light-duty vehicles in 2030).

Table 2-26. Estimated 2030 Hybrid-Electric Vehicle Statewide Composition and Petroleum Reduction Potential

Vehicle Type	2030 HEV Fleet (%)	Number of Vehicles in 2030 Fleet	Total Annual Petroleum Consumption Reduction (gallons)
Micro (0 and 2)	60	113,441	4,250,000
Mild	10	18,907	2,120,000
Moderate	5	9,453	1,850,000
Full	25	47,267	11,780,000
TOTALS	100	383,242	20,000,000

2.3.4.4 Hydrogen

This section discusses hydrogen as a transportation fuel. [Section 2.3.2.3](#) addresses hydrogen fuel cells.

2.3.4.4.1 Technology Description

Hydrogen is the simplest and most abundant element in the universe and can be produced from fossil fuels including oil, coal, or natural gas as well as biomass, organic waste, water, or salt water. Hydrogen is obtained through various methods including chemical processes, electrolysis, steam reforming, methanol cracking, and hydrogen purification. The versatility and ability to produce hydrogen from several resources is a key element in the development of hydrogen as a transportation fuel. When

produced from renewable resources, hydrogen is often touted as the sustainable transportation fuel of the future. As a transportation fuel, the energy content in 2.2 pounds of hydrogen gas is about the same as the energy content in 1 gallon of gasoline. Due to its low volumetric energy density compared with gasoline, however, hydrogen fuel on a vehicle requires larger storage tanks than most conventional vehicles to achieve the same vehicle range between refueling stops.

The following discussion describes various ways that hydrogen can be used to power vehicle systems.

Hydrogen Internal Combustion Engine Vehicle

Hydrogen can be used in internal combustion engines that are modified with hardened valves and valve seats (for longer life on dry fuels), stronger connecting rods, non-platinum-tipped spark plugs (platinum is a catalyst causing hydrogen to oxidize with air), a higher-voltage ignition coil, fuel injectors designed for a gas instead of a liquid, larger crankshaft damper, stronger head gasket material, modified (for supercharger) intake manifold, positive pressure supercharger, and a high-temperature engine oil. When hydrogen is burned in an internal combustion engine, the only byproducts are water vapor and nitrogen oxide exhaust (when combined with air). The energy efficiency is 20 to 25 percent higher than that of a gasoline internal combustion engine ([Ogden 2002](#)). Maintenance is similar to a gasoline internal combustion engine.

Hydrogen Fuel Cell Vehicle

Hydrogen can be used in fuel cells to power electric motors. Hydrogen fuel cells used in vehicles consist of an electrolyte and two catalyst-coated electrodes, providing electricity in a manner similar to that provided by batteries in an electric vehicle (see [Section 2.3.4.2](#)). However, rather than having batteries recharged, a fuel cell vehicle has its hydrogen tank refilled. When used in fuel cells, hydrogen does not produce [air pollutants](#) or [greenhouse gases](#). Hydrogen fuel cell vehicles also have an efficiency rate that is two to three times higher than a gasoline vehicle ([DOE and EPA 2013c](#)). However, as noted above, it is important for a fuel cell vehicle to store enough fuel onboard to have a driving range sufficient to meet the required range of the vehicle. [Section 2.3.2.3](#) of this PEIS provides a general tutorial on hydrogen fuel cells. The following discussion is specific to hydrogen fuel cells for transportation applications.

- [Proton Exchange Membrane Fuel Cells](#) – Proton exchange membrane fuel cells, or polymer electrolyte membrane fuel cells, are the most common type of fuel cells used in transportation applications. Proton exchange membrane fuel cells use a solid polymer as an electrolyte and porous carbon electrodes containing a platinum catalyst and need only hydrogen, oxygen from the air, and water to operate. [Section 2.3.2.3](#) of this PEIS provides further discussion on proton exchange membrane fuel cells. [Figure 2-55](#) provides a schematic diagram of a hydrogen fuel cell vehicle.
- [Hybrid-Electric Fuel Cell Vehicle](#) – Hybrid-electric fuel cell vehicles combine the powertrain of an all-electric, battery-powered vehicle with fuel cells. This configuration allows vehicle designers to cost-effectively size energy (battery and hydrogen) storage systems and fuel cells without sacrificing vehicle performance. The combined powertrain offers an extended operating range, which is especially crucial in early phases of deployment ([DOE 2013n](#)).

As with other vehicles, fuel cell vehicles can be equipped with other advanced technologies to increase efficiency, such as regenerative braking systems, which capture the energy lost during braking and store it in a large battery. These vehicles are still at an early stage of development; however, research and development efforts are bringing them closer to commercialization ([DOE and EPA 2013c](#)).

Figure 2-55. Hydrogen Fuel Cell Vehicle Schematic
(Source: [DOE and EPA 2013c](#))

2.3.4.4.2 Characterization of Technology Feasibility and Deployment

Although hydrogen is abundant and versatile, hydrogen fuel is not a primary energy source and requires energy from other sources for production. In Hawai‘i, hydrogen fuel can potentially be produced economically from indigenous resources and incorporated directly into the State’s energy economy.

[Figure 2-56](#) shows the potential future energy system with hydrogen incorporated. As shown, hydrogen can be stored and distributed using methods similar to the existing utility gas and propane infrastructure.

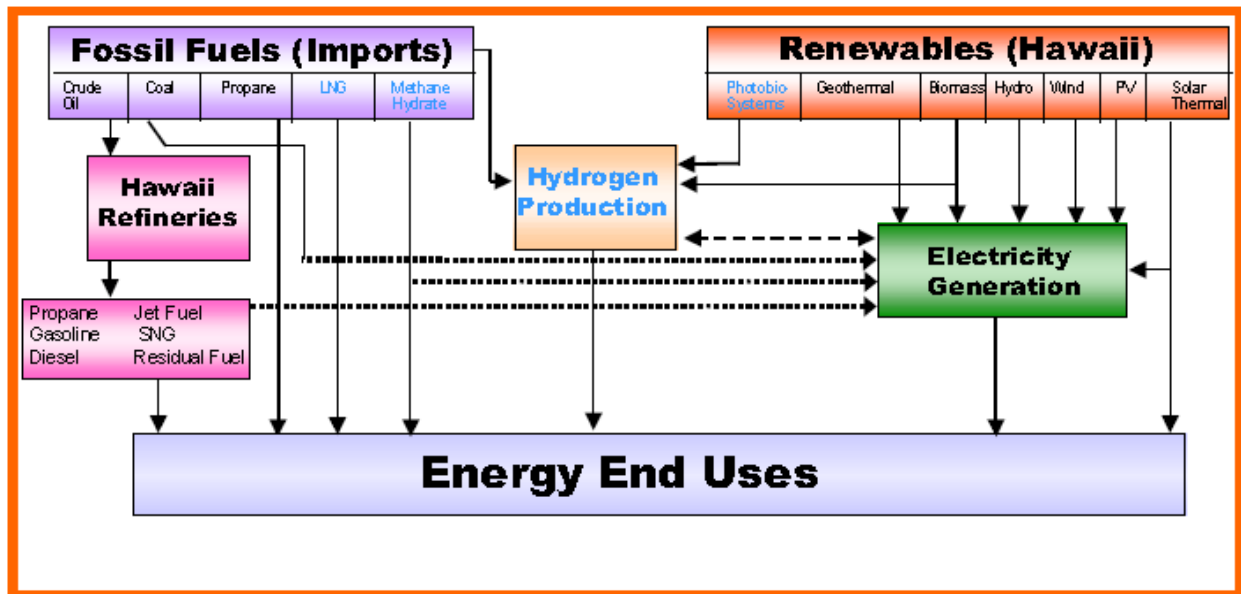

Figure 2-56. Hawai‘i’s Potential Future Energy System Incorporating Hydrogen (Source: [HNEI and Sentech 2004](#))

Of the fossil fuels, a study conducted in 2007 for the State of Hawai‘i showed natural gas as the least expensive feedstock for hydrogen. Unfortunately, as with other fossil fuels, natural gas supplies are not

indigenous to the island and need to be imported from the mainland. In addition, natural gas is not emissions free, may be subject to price volatility, and may face competing demands ([FGE 2007](#)).

Hydrogen can be produced several ways via renewable sources but would be most cost-effective if produced via geothermal, solar and—despite the hurdles discussed above—natural gas. Wind energy can produce hydrogen, but its intermittent nature results in low-capacity factors and higher-cost hydrogen. Other renewable energy technologies are still too early in the deployment stage to be considered for the production of hydrogen fuel ([HNEI and Sentech 2004](#)).

The following discussion addresses the potential production of hydrogen on each Hawaiian Island and its contribution to HCEI goals.

- Maui/Kaua‘i – Both Maui and Kaua‘i offer tremendous potential for biomass and solar resources to produce hydrogen. A dispersed population makes transportation and utility uses the highest likely value ([Sentech 2008](#)). However, the feasibility of importing hydrogen to these islands still needs to be explored.
- O‘ahu – O‘ahu represents the greatest opportunity to use hydrogen and fuel cells, as it is the most populous of the Hawaiian Islands and includes the urban center of Honolulu. Transportation applications on O‘ahu include tourist transport, military transport, airport support vehicles, and other fleet applications, creating a large potential opportunity for a clean hydrogen-fueled fleet. However, there is limited availability of renewable resources on the island, which limits potential hydrogen production. Hydrogen from imported oil is available from existing refineries, but this does not offer a secure long-term solution to meet transportation fuel demands on O‘ahu ([HNEI and Sentech 2008](#)). As such, the import of hydrogen to the island may be required.
- Molokai/Lāna‘i – The most promising renewable energy technology available in Molokai and Lāna‘i include wind and solar, both of which could be utilized to produce hydrogen. However, at present, hydrogen production from wind and solar is very costly since the hydrogen is produced via electrolysis (see [Section 2.3.2.3](#) for hydrogen fuel cells). Furthermore, hydrogen production and distribution on both islands does not appear feasible due to the small populations in both islands.
- Hawai‘i island – Renewable energy resources present on Hawai‘i island include solar, wind, biomass, and geothermal. Hawai‘i island is the only island with a geothermal power plant and the electricity demand patterns typically able to yield available off-peak electricity from which to make hydrogen ([HNEI and Sentech 2004](#)). As such, the island has been specifically favored as a unique and ideal location to test and validate the potential for a hydrogen-fueled transportation system. In 2008, an analysis of geothermal- produced hydrogen on Hawai‘i island was conducted for the State. According to the study, only 3.3 percent of Hawai‘i island’s transportation requirements could be served by the existing geothermal plant. Further, this would be possible only if 24 megawatts of the geothermal capacity was used in producing hydrogen ([Sentech 2008](#)). In order to provide a geothermal hydrogen future for the State, a three phased approach was recommended: (1) test and validate the infrastructure; (2) conduct an expanded demonstration; and (3) implement an aggressive expansion, investment, and commercialization of hydrogen as a fuel ([Sentech 2008](#)). [Figure 2-57](#) shows the hydrogen capacity required to meet Hawai‘i island’s transportation needs.

Hydrogen as a transportation fuel is ideal for use in fuel cells, which would provide a highly efficient energy conversion system for vehicles. It is anticipated that hybrid-electric fuel cell vehicles may cost-

effectively compete with conventional internal combustion engine vehicles in 2025. However, as noted in [Section 2.3.4.1](#) of this PEIS vehicle sales patterns in the State show a relatively low turnover of vehicles and an average vehicle life of approximately 20 years, hindering the replacement of older, less fuel-efficient cars with newer, more sustainable vehicles. As such, only fuels that could be used in existing vehicles (e.g., biodiesel and green gasoline) would be useful to the State in meeting HCEI goals. As such, the future deployment of hydrogen transportation fuel would be dependent on consumer marketability and reduced vehicle turnover ratio. Additional concerns noted in [Section 2.3.4.1](#) that also apply here include the increased electricity generation required for electricity production if renewable energy is developed or used to generate electricity for hydrogen production.

Figure 2-57. Capacity Required to Meet Hawai‘i island’s Transportation Needs (Source: [Sentech 2008](#))

2.3.4.4.3 Existing Deployment of the Technology

Hydrogen production, distribution, and deployment are still in the research and development stages in the State. However, the State and industry have undertaken major efforts to test and develop the technology for implementation. The following sections discuss some of the key efforts taken to date.

- [The Hawai‘i Center for Advanced Transportation Technology](#) – The mission of the Hawai‘i Center for Advanced Transportation Technology is to develop and demonstrate technologies for future military and commercial transportation systems. The Center has a list of accomplishments and ongoing projects to further develop a hydrogen future for the State. These include the

development and introduction of fuel-cell-powered demonstration vehicles, the development and installation of a modular/deployable hydrogen production and fueling station, the development and installation of a PV-powered fueling station, the evaluation of hydrogen internal combustion engine Ford Escapes, supplementing the fueling station with wind turbine power, and, most recently, working on a hydrogen-powered tug and hydrogen-powered weapons loader for the military ([HCATT 2013](#)).

- **Hawai‘i Hydrogen Initiative** – The Hawai‘i Hydrogen Initiative is an innovative partnership among 13 agencies, companies and universities that seeks to develop hydrogen infrastructure in Hawai‘i with the goal of displacing petroleum imports by operating vehicles with renewable hydrogen ([H2I 2013](#)).
- **Hawai‘i Natural Energy Institute** – The Hawai‘i Natural Energy Institute is a research arm of the University of Hawai‘i at Manoa. The Institute performs research, conducts testing and evaluation, and manages public-private partnerships across a broad range of renewable and enabling technologies to reduce the State of Hawai‘i’s dependence on fossil fuel. The Institute conducts specific research and deploys pilot projects for the production and deployment of hydrogen in the State, including the Hawai‘i Hydrogen Power Park, photoelectrochemical hydrogen production, biological hydrogen production, hydrogen for Hawai‘i Volcanoes National Park vehicles, hydrogen for General Motors Equinox vehicles, and hydrogen from biomass. Several of these are discussed in more detail below. For more information, readers are directed to the Institute’s recently completed draft environmental assessment for a project that will demonstrate the use of hydrogen as a potential energy storage technology ([HNEI 2012c](#)).

Production

Hydrogen is produced through various methods including chemical processes, electrolysis, steam reforming, methanol cracking (splitting methanol and steam in the presence of a copper-zinc catalyst), and hydrogen purification. With the exception of electrolysis, most production methods still result in smog and greenhouse gas emissions, albeit less than conventional vehicles. Proponents of hydrogen as a fuel indicate that the most promising production pathway would be hydrogen produced through electrolysis of water using renewable energy (e.g., solar or wind power). While this would eliminate carbon emissions, the challenge lies in the high costs associated with hydrogen production. At this time, the Office of Naval Research is currently researching water desalination techniques using energy-efficient microbes to produce hydrogen. Others, such as Virginia Tech, have developed a way to extract hydrogen from sugars using any kind of plant ([VT News 2013](#)). Other research includes the production of hydrogen from wastewater or brackish water. However, this technology is not ready for commercial production/use.

HAWAII GAS, formerly The Gas Company, LLC, currently produces approximately 50 percent of its hydrogen supply using reverse osmosis recycled water from the Honolulu Waste Water Treatment Plant. The water combines with methane and carbon monoxide in two separate reactions to produce hydrogen in a chemical conversion process. The other half of hydrogen HAWAII GAS produces is from petroleum feedstock ([The Gas Company 2012](#)). HAWAII GAS is also piloting a renewable natural gas plant, which would convert various types of renewable feedstocks into fuels, including hydrogen.

Vehicle Systems Technology

Fuel cell vehicles are still too expensive for most consumers to afford. Until the associated technology costs are lower, no light-duty hydrogen fuel cell vehicles have been commercially produced for sale to the public. Ford, Mercedes-Benz, and Nissan have indicated a target year deployment of fuel cell vehicles by 2017; however, this news remains speculative ([Cunningham 2013](#)). Currently, Hyundai is the first carmaker to start manufacturing fuel cell vehicles on a production line, and intends to be the first

automaker to offer a fuel cell vehicle to the general public. Hyundai estimates it will build approximately 1,000 fuel cell cars by 2015 at its factory in Korea ([Sunderland 2013](#)). Test vehicles, mainly heavy-duty hydrogen fuel cell vehicles, are available in limited numbers to demonstration fleets with access to hydrogen fueling stations. As discussed in [Section 2.3.2.3](#) of this PEIS, DOE awarded the State of Hawai‘i several contracts to develop a hydrogen power park, operating an integrated hydrogen energy system including hydrogen fueling stations and the deployment of hydrogen-fueled vehicles.

Infrastructure

In addition to the high production and technology costs to develop hydrogen-powered vehicles, the existing infrastructure in the State is not set up for hydrogen fuels. A viable hydrogen infrastructure requires the ability to deliver hydrogen from where it is produced to where it will be used, such as a dispenser at a refueling station or stationary power site. Infrastructure includes the pipelines, trucks, storage facilities, compressors, and dispensers involved in the process of delivering fuel.

There are plans for installation of a hydrogen fueling station at a location near the Hawai‘i Volcanoes National Park. Future plans for the State include the use of hydrogen plug-in hybrid-electric buses in coordination with the Hawai‘i Volcanoes National Park¹⁹, as well as a Hawai‘i hydrogen highway on Hawai‘i island ([HNEI 2013a](#)). Additional fueling stations are planned for future phased deployment on Hawai‘i island as the hydrogen economy on the island expands. Additional detail can be found in the *Analysis of Geothermally Produced Hydrogen on the Big Island of Hawai‘i: A Roadmap for the Way Forward* ([Sentech 2008](#)).

In O‘ahu, there are currently plans to deploy hydrogen through the existing 1,100-mile HAWAII GAS pipeline (in O‘ahu) using pressure swing adsorption technology as part of the Hawai‘i Hydrogen Initiative. The pressure-swing adsorption process removes carbon dioxide and other impurities from the gas stream, leaving essentially pure hydrogen. This can be made possible at the point of use, i.e., once the gas is distributed to 20 to 25 hydrogen refueling stations in O‘ahu for fuel-celled vehicles. Full-scale production is anticipated to commence in approximately 2015. As part of the Hydrogen Highway Initiative General Motors also operates a service center in Honolulu to test and maintain a fuel-cell vehicle fleet ([H2I 2013](#); [Char 2012](#)). Plans to deploy hydrogen to the other islands are not available at this time.

According to the Sentech study, the hydrogen-related policies and financial incentives currently in place in the State have helped initiate the necessary business and infrastructure growth for hydrogen as a fuel; however, additional, larger incentives will be required in the future, depending on the level of expansion in the State ([Sentech 2008](#)). Major policy considerations must include the following: (1) siting, permitting, and land-use planning to accommodate geothermal and other renewable electricity development on a scale to produce hundreds of megawatts of renewable electricity; (2) an electricity policy that will result in electricity pricing that supports alternative fuel (i.e., a transportation tariff); and (3) an incentive strategy for early purchasers of hydrogen vehicles and fleet operators. This would also require large involvement from partners such as geothermal renewable electricity developers and providers, hydrogen production and refueling infrastructure providers, hydrogen and hybrid vehicle providers, and users ([Sentech 2008](#)).

¹⁹ The 2008 Sentech study indicated that due to high sulfur levels experienced at the Hawai‘i Volcanoes National Park site and the susceptibility of fuel cells to sulfur, the demonstration would use hydrogen internal combustion engine buses instead of hydrogen fuel cell buses. However, according to HNEI, these buses would be hydrogen plug-in hybrid-electric buses ([Sentech 2008](#); [HNEI 2013a](#)).

2.3.4.4.4 Permitting and Consultation Requirements

Hydrogen projects in Hawai‘i would be part of a regulatory environment that is administered by Federal, State, and county agencies. See [Section 2.2.5](#) for a discussion on general permitting requirements.

Permits would be required before construction activities could begin to ensure project conformity to Federal, State, and county laws, codes, and standards concerning construction and pollution control. During operations, the production, transport and distribution of hydrogen fuel would require compliance with storage, handling, and dispensing requirements by Federal, State, and county agencies including the local county departments of planning and public works, and other departments.

2.3.4.4.5 Representative Project

The representative project involves the production and distribution of hydrogen as an alternative transportation fuel source to displace approximately 20 million gallons per year of gasoline. This would require the production of approximately 44 million pounds of hydrogen, or 20 million kilograms per year of hydrogen. The representative project assumes production of hydrogen via a combination of two sources: (1) a 25-megawatt geothermal facility on Hawai‘i island; and (2) a 50 megawatts of solar energy on O‘ahu. This would require the installation and development of distribution infrastructure including pipelines, storage tanks, and fueling stations on Hawai‘i and O‘ahu. The representative project would have the option of using tanker trucks instead of distribution pipelines, or a combination of both.

Assuming a [heating value](#) of 52.5 kilowatt-hours per kilogram of hydrogen (assumes a 75 percent efficiency system based on the higher heating value of hydrogen), the representative project would require approximately 1,050,000 megawatt-hours, or 1,050 gigawatt-hours (1,050,000,000 kilowatt-hours) of electricity production to generate 20 million kilograms of hydrogen per year; half of which (525,000 kilowatt-hours) would be produced annually via a geothermal facility and the other half (525,000 kilowatt-hours) annually via solar energy. Marine transport would distribute the hydrogen to the other Hawaiian Islands, such as Maui and Kaua‘i.

2.3.4.5 Compressed and Liquefied Natural Gas and Liquefied Petroleum Gas for Transportation

Natural gas is an odorless, nontoxic, gaseous mixture of hydrocarbons consisting primarily of methane. Most natural gas is domestically produced on the mainland from wells, or extracted in conjunction with crude oil production. Natural gas can also be mined from subsurface porous rock reservoirs through extraction processes, such as hydraulic fracturing. As such, most natural gas that is produced is not considered renewable. Renewable natural gas is an emerging fuel produced from decaying organic materials, such as waste from plants, landfills, wastewater, and livestock ([DOE 2013o](#)).

Natural gas as an alternative transportation fuel for vehicles comes in two forms: compressed natural gas and liquefied natural gas. The fuel is used in natural gas vehicles, more commonly in compressed natural gas- powered vehicles, which are similar to gasoline or diesel vehicles with regard to power, acceleration, and cruising speed. However, natural gas vehicles generally have less driving range than comparable gasoline and diesel vehicles because less overall energy content can be stored in the same size tank of natural gas vehicles than the more energy-dense gasoline or diesel fueled vehicles. While emissions generally vary with engine design, natural gas vehicles generate no evaporative emissions and less exhaust and [greenhouse gas](#) emissions when burned compared to comparable gasoline or diesel powered vehicles; this is the reason why natural gas is viewed as a cleaner-burning fuel. However, it is noted that natural gas primarily consists of methane, which is the second most prevalent greenhouse gas emitted in the United States from human activities. In 2011, methane accounted for about 9 percent of all U.S.

greenhouse gas emissions from human activities ([EPA 2013b](#)). However, it is noted that natural gas primarily consists of methane, which has a [global warming potential](#) 21 times that of carbon dioxide.

Propane is the primary component of, and the name commonly used for, liquefied petroleum gas. When stored under pressure inside a tank, liquefied petroleum gas is a colorless, odorless liquid. As pressure is released, the liquid vaporizes and turns into gas that is used for combustion. While liquefied petroleum gas is a fossil fuel and, therefore, not considered a renewable resource, it is considered an alternative fuel for transportation that could reduce the State's dependence on imports of foreign oil. Liquefied petroleum gas is beneficial from the standpoint of fuel diversification and produces lower level of carbon emissions than other hydrocarbon fuels such as coal or oil. When used for transportation applications (i.e., vehicles), it is referred to as liquefied petroleum gas (rather than propane). Liquefied petroleum gas can also be used in construction equipment, ground maintenance and service equipment, such as forklifts.

Detailed descriptions of these gases and associated topics can be found online at the DOE's Alternative Fuels Data Center, <http://www.afdc.energy.gov/fuels/>.

This PEIS addresses natural gas and propane as potential transportation fuels and not for electricity generation as they do not meet the definition of "renewable" or "clean" energy source, in accordance with HCEI guidelines.²⁰

2.3.4.5.1 Technology Description

Compressed Natural Gas

Compressed natural gas-powered vehicles store natural gas under high pressure (typically 3,000 to 3,600 pounds per square inch). Compressed natural gas is used in light-, medium-, and heavy-duty applications ([DOE 2013o](#)). Auto manufacturers offer a variety of both dedicated (operates exclusively on natural gas) and dual-fuel (can operate on both natural gas and gasoline) compressed natural gas vehicles. These vehicles get about the same fuel economy as a conventional gasoline vehicle on a gasoline gallon equivalency basis; the gasoline gallon equivalency for compressed natural gas is 5.66 (i.e., 1 gallon of gasoline gets the same mileage as 5.66 pounds of compressed natural gas). Most natural gas fueling stations dispense compressed natural gas, which is compressed onsite in most cases. Since compressed natural gas is odorless, colorless, and tasteless, an odorant is added to give the natural gas a smell for safety reasons.

Liquefied Natural Gas

Liquefied natural gas is produced by purifying natural gas and super-cooling it to -260°F to turn it into a liquid. This reduces the space natural gas occupies by more than 600 times, making it more practical to store and transport ([FERC 2012](#)). When liquefied natural gas reaches its destination, it is regasified and

²⁰ There are complexities surrounding the decision to develop LNG importation capacity for Hawaii as an electricity generation option, particularly given the islands' isolated geographical location and the various uncertainties and risks associated with long-term infrastructure investments, global commodity prices and energy markets. DBEDT's strategy regarding LNG as an electricity generation option has therefore been designed with these uncertainties and mitigation options specifically in mind.

distributed as pipeline natural gas, primarily used for heating and cooling on the mainland. Because it must be kept at cold temperatures, LNG is stored in double-walled, vacuum-insulated pressure vessels.

Liquefied natural gas is a hazardous liquid because of three of its properties: cryogenic temperatures (related to its low temperatures), dispersion characteristics, and flammability characteristics. Because of these characteristics, the following hazards can occur: Extremely cold liquefied natural gas can directly cause injury or damage such as frostbite; a vapor cloud formed by a liquefied natural gas spill could drift downwind into populated areas; and natural gas in vapor form can be combustible when in the concentration range of five and 15 percent in the air if it encounters an ignition source. If in a confined space, combustible mixtures will burn explosively ([CEC 2013](#)). A large array of laws, regulations, standards, and guidelines from the National Fire Prevention Association,²¹ the USDOT, and other agencies is currently in place to prevent and reduce the consequences of liquefied natural gas releases. These requirements affect LNG facilities' design, construction, operation, and maintenance.

Liquefied natural gas is typically used in medium- and heavy-duty vehicles due to its complex storage requirements; not only is installation of liquefied natural gas tanks and engines expensive, but the ideal vehicle for liquefied natural gas is one where the natural tendency of liquefied natural gas to result in vapor loss is countered by heavy use. As such, liquefied natural gas is considered appropriate for trucks requiring a longer range because liquid is more dense than gas and, therefore, more energy can be stored by volume in a given tank. One gasoline gallon equivalency equals about 1.5 gallons of liquefied natural gas ([FGE 2012](#)).

Liquefied Petroleum Gas

Liquefied petroleum gas, composed primarily of propane, butane, or a mixture of the two, is a by-product of petroleum refining and natural gas processing. Liquefied petroleum gas is a gas at atmospheric temperatures and, like liquefied natural gas, is pressurized for storage in liquid form. The propane fuel grade used in vehicles is called HD-5. Aboard a vehicle, propane is stored in a tank pressurized to about 150 pounds per square inch—about twice the pressure of an inflated truck tire. Under this pressure, propane becomes a liquid with an energy density 270 times greater than the gaseous form. Propane stores less energy per gallon than gasoline, requiring more gallons to drive the same distance.

There is currently a limited availability of propane-powered light-duty passenger vehicles. On the mainland, most propane light duty vehicles are limited to custom-ordered law enforcement vehicles ([PERC 2013](#)). For a list of currently certified propane gas vehicles, see http://www.autogasusa.org/uploadedFiles/Fuel/Fueling_With_Propane/Feb%202013%20OTR%20Manuf%20acturer%20Listing%20Public%20View.pdf.²² However, existing internal combustion engine vehicles can be converted relatively inexpensively. Conversion kits include a regulator/vaporizer that changes liquid propane to a gaseous form and an air/fuel mixer that meters and mixes the fuel with filtered intake air before the mixture is drawn into the engine's combustion chambers ([DOE 2003](#)). Vehicle conversions must occur via licensed technicians associated with vehicle manufacturers and must be certified to meet EPA requirements. This ensures that equipment is properly installed, is safe and durable, and meets the emissions standards of the vehicle model year ([PERC 2013](#)).

²¹ The National Fire Prevention Association is an international nonprofit leading advocate of fire prevention and is an authoritative source on public safety. The Association develops, publishes, and disseminates more than 300 consensus codes and standards intended to minimize the possibility and effects of fire and other risks (see <http://nfpa.org>).

²² The Propane Education and Research Council maintains a list of propane autogas vehicles that have earned certifications from the EPA or the California Air Resources Board.

2.3.4.5.2 Characterization of Feasibility and Deployment of Technology

Existing Production/Distribution and Infrastructure Systems

To date, only about one-tenth of 1 percent of natural gas is used for transportation fuel in the United States. In the State of Hawai‘i, even less than that is used since it has to be manufactured from refined products, and is very expensive to produce.

Natural gas used in the State is synthetic natural gas produced by HAWAII GAS (formerly The Gas Company), the local utility supplier. HAWAII GAS transforms naphtha, a byproduct of oil refining, into synthetic natural gas at the Synthetic Natural Gas Plant in Campbell Industrial Park and distributes the synthetic natural gas to the greater Honolulu area through 1,000 miles of underground utility pipeline. The synthetic natural gas is used by residential, commercial, and industrial customers primarily for water heating, cooking (range and oven), and dryers ([HAWAII GAS 2013a](#)).

Compressed and Liquefied Natural Gas

Vehicle Systems – As there is currently no compressed and liquefied natural gas production/distribution/fueling station infrastructure available for natural gas vehicles, no natural gas vehicles utilize compressed natural gas or liquefied natural gas for transportation applications in Hawai‘i.

Marine Vessels – At this time, no marine vessels in Hawai‘i run on natural gas because there is very limited experience with conversions of marine vessels to run on natural gas in the State. Assuming the State imported large volumes of natural gas, ships could convert their engines to run on natural gas, but this would be expensive due to storage tank requirements. There are currently three natural gas engine technologies available for large marine vessels including: (1) spark-ignited lean burn, (2) dual-fuel diesel pilot ignition with low-pressure gas injection, and (3) dual-fuel diesel pilot ignition with high-pressure gas injection) ([FGE 2012](#)).²³

Liquefied Petroleum Gas

Propane in Hawai‘i is purchased and shipped either from local refinery operations on O‘ahu or from foreign sources to bulk distribution terminals in Hawai‘i, Kaua‘i, and Maui via tanker ships. Propane is also moved between islands by propane barges and stored in tanks for distribution. Propane is then distributed to non-utility customers via truck delivery to individual tanks ([HAWAII GAS 2013a](#)).

HAWAII GAS, O‘ahu Gas Service, and other propane suppliers serve all the islands with propane ([FGE 2012](#)). As a transportation application, liquefied petroleum gas is used as for passenger vehicles and specialty vehicles, such as forklifts ([The Gas Company 2012](#)). There are three public propane fueling stations in the State of Hawai‘i, two in Honolulu and one in Hilo ([DOE 2013p](#)).

Vehicle Systems – As noted above, the availability of liquefied petroleum gas-fueled light-duty passenger vehicles is limited across the United States. Propane vehicles are available in Hawai‘i, but due to the limited infrastructure, are few in numbers.

Marine Vessels – As noted above, no marine vessels are currently known to operate on propane; although future research and development may be in progress.

Future Projected Production/Distribution and Infrastructure Systems

As noted in [Section 2.3.4.1](#) of this PEIS, the vehicle sales patterns in the State show a relatively low turnover of vehicles, with approximately 50,000 vehicles being replaced per year. As indicated therein,

²³ Spark-ignited engines operate exclusively on natural gas, while diesel pilot ignition engines can operate on a range of fuels including natural gas ([FGE 2012](#)).

the average vehicle life of a vehicle in the State is approximately 20 years, hindering the State from replacing older, less-efficient cars with newer, more sustainable vehicles ([Braccio et al. 2012](#)). As such future deployment of compressed and liquefied natural gas and propane gas as a transportation fuel in the State will be dependent on consumer marketability and reduced vehicle turnover ratio. The following discussion addresses the import and production of natural gas, propane and associated infrastructure Hawai‘i.

Compressed and Liquefied Natural Gas for Transportation

There are complexities surrounding the decision to develop LNG importation capacity for Hawai‘i as an electricity generation option, particularly given the islands’ isolated geographical location and the various uncertainties and risks associated with long-term infrastructure investments, global commodity prices, and energy markets. DBEDT’s strategy regarding LNG as an electricity generation option has therefore been designed with these uncertainties and mitigation options specifically in mind. It is anticipated that natural gas likely would be imported to Hawai‘i to supplement electricity generation first.²⁶

Bulk natural gas supplies are anticipated to be imported in the future by utility companies, pending Federal, State and other regulatory approval, a portion of which could be used for transportation fuel. Based on a study conducted for the State, the potential natural gas demand for ground transportation in the State ranges from 30 to 90 kilotonnes (2.4×10^{-3} to 7.2×10^{-3} million tons) in 2030, increasing to 50 to 200 kilotonnes (4.0×10^{-3} to 1.6×10^{-2} million tons) by 2035 ([FGE 2012](#)).

As the natural gas production and distribution infrastructure is limited in the State, so is the vehicle fueling infrastructure. Therefore, once the import source and shipment logistics are determined, liquefied natural gas would need to be regasified to compressed natural gas and the installation of natural gas fueling stations would be required. Fueling stations for both compressed natural gas and liquefied natural gas vary considerably. Compressed natural gas stations require more equipment and configuration, while liquefied natural gas stations require less equipment, but more safety precautions during fueling.

There are two types of compressed natural gas stations, including fast-fill and time-fill stations²⁷. The type of station that would be required is dependent on the application. Typically, retail stations use fast-fill, and fleets with central fueling and overnight use capability, use time-fill stations. As natural gas can be a safety hazard, safety guidelines need to be considered when developing natural gas infrastructure, including the National Fire Prevention Association’s NFPA 52 Vehicular Gaseous Fuel Systems Code, which applies to the design and installation requirements of compressed natural gas refueling facilities ([DOE 2013q](#)).

Liquefied natural gas stations are structurally similar to gasoline and diesel stations since it is a liquid fuel. There are three options for liquefied natural gas fueling including mobile, containerized, and customized large stations. Because liquefied natural gas is stored and dispensed as a super-cooled liquefied gas, protective clothing and gloves are required when fueling a vehicle. In mobile fueling, liquefied natural gas is delivered by a tanker truck that contains metering and dispensing equipment on-

²⁶ On March 6, 2014, the Hawai‘i Public Utilities Commission approved HAWAII GAS’s proposal to import natural gas into the State. Natural gas is anticipated to be imported to Hawai‘i in several phases starting in 2014 ([Hawai‘i PUC 2014](#)).

²⁷ Fast-fill stations fuel vehicles from dispensers and are generally suited for light-duty vehicles such as vans, pickups, and sedans where drivers experience similar fill times to gasoline fueling stations—i.e., less than five minutes. Time-fill stations fuel vehicles directly from the compressor (fuels at a lower volume) and are used primarily for fleets and work vehicles with large tanks that refuel at a central location nightly. The time it takes to fuel a vehicle is dependent on the number of vehicles, compressor size, and the amount of buffer storage ([DOE 2013w](#)).

board. A containerized station, or a starter station, includes a storage tank, dispensing equipment, metering, and required containment. A custom station has greater storage capacity and is tailored to meet a fleet's needs ([DOE 2013q](#)).

Due to the State's geographical location and the uncertainties and risks associated with long-term infrastructure investments, global commodity prices, and energy markets, development of LNG importation capacity is a complex decision for the State. To ensure that cost-savings benefits to Hawai'i are realized, projects must carefully consider sourcing, terminal siting options, and good regulatory controls in developing Hawai'i's natural gas infrastructure. Local infrastructure additions could include a floating storage and regasification unit as well as small-scale, land-based storage of LNG.

Vehicle Systems – The potential introduction of natural gas vehicles in the State would make the transportation sector the second (after electricity generation) biggest potential user of natural gas in Hawai'i by 2035. As noted above, compressed natural gas vehicles are available as light-, medium-, or heavy-duty vehicles. While the number of light-duty natural gas vehicles from original equipment manufacturers is limited, it is growing. There is a wide variety of new, heavy-duty natural gas vehicles available from original equipment manufacturers. Fleets and consumers also have the option of economically and reliably converting existing light-, medium-, or heavy-duty gasoline or diesel vehicles to natural gas operation using qualified system retrofitters. All conversions must meet the emissions and safety regulations and standards instituted by the EPA, the National Highway Traffic Safety Administration, and Hawai'i agencies. However, vehicle conversion to natural gas is still very costly for light-duty vehicles due to the complex storage requirements associated with natural gas. As such, natural gas is practical only for heavy-use vehicles and would likely be desirable only for heavy-duty fleets (e.g., garbage trucks) and public transportation systems (e.g., transit buses) in the State. [Section 2.3.4.5](#) of this PEIS discusses alternative fuels and public transportation. There is also concern that liquefied natural gas-fueled vehicles require more maintenance, but additional study is required to support this concern ([DOE 2013r](#)).

Marine Vessels – The conversion of marine vessels to natural gas operation is expensive. Estimated costs to convert a medium-sized tugboat to operate on natural gas are up to \$7 million and almost \$11 million to convert a large car and passenger ferry. Approximately one-sixth of this cost relates to converting vessel engines, and the rest is for installation of natural gas storage tanks and related safety systems and ship modifications. Given the high costs of conversion, the only viable candidates are those marine vessels used often and that use a lot of fuel relative to its size and power ([Bradley 2012](#)).

Liquefied Petroleum Gas

Limited information is available regarding the future production, distribution, and infrastructure systems of liquefied petroleum gas as an alternative transportation fuel in the State. As liquefied petroleum gas is a byproduct of petroleum and natural gas refining, it is anticipated that refining would continue to occur on O'ahu, but this would be dependent upon the existing refineries' decision to continue operations. FGE (2012) provides analyses of the potential demand for liquefied petroleum gas for transportation in Hawai'i.

Vehicle Systems – Future propane vehicle use in the State would be dependent on the infrastructure that is made available in Hawai'i. At this time, information regarding the projected amount of propane vehicles planned for future use in Hawai'i is very limited and speculative.

Marine Vessels – At this time no propane marine vessels are projected for use in Hawai'i.

2.3.4.5.3 Permitting and Consultation Requirements

Because of potential concerns for toxic (fumes), combustion (flammable), and overpressure (explosions) hazards in areas surrounding storage, handling, and distribution facilities of compressed or liquefied natural gas or liquefied petroleum gas, projects in Hawai‘i would be part of a regulatory environment that is administered by Federal, State, and county agencies (see [Section 2.2.5](#)). Additional guidelines regarding natural gas infrastructure should also be adhered to in accordance with NFPA guidelines to ensure safety concerns are addressed.

Permits would be required before construction activities could begin to ensure project conformity to Federal, State, and county laws, codes, and standards concerning construction and pollution control ([DBEDT 2013a](#)). For smaller, distributed gas storage, a Boiler or Pressure Vessel Installation Permit is likely required from the Hawai‘i Department of Labor and Industrial Relations. Development and distribution of natural gas in the State could require additional agency compliance, including with requirements from the National Fire Protection Association and the USDOT.

2.3.4.5.4 Representative Project

The representative alternative transportation fuel project for natural gas would involve the import of approximately 10 million gallons per year gasoline gallon equivalency of natural gas, or approximately 15.36 million gallons (10 million gallons per year \times 1.5362) of liquefied natural gas per year to O‘ahu from the West Coast, supplemented by approximately 10 million gallons per year gasoline gallon equivalency of liquefied petroleum gas, or approximately 13.5 million gallons per year of liquefied petroleum gas. Combined, the representative project would offset a total of 20 million gallons per year of gasoline. The use of natural gas as transportation fuel would only occur if the infrastructure for import and use of natural gas for electricity generation were already in place. As liquefied petroleum gas is currently produced locally, the representative project assumes existing suppliers would increase liquefied petroleum gas production and that the existing gas distribution network would be modified and/or expanded as necessary.

The representative project assumes natural gas vehicles would not be imported, as car conversions would occur, albeit costly. Passenger vehicles would mostly be converted to compressed natural gas- and propane powered vehicles, while medium and heavy-duty vehicles, including transit buses, waste collection and transfer vehicles, airport shuttles and vehicles, and City and State vehicles would be converted to run on liquefied natural gas.

2.3.4.6 Multi-Modal Transportation

Multi-modal transportation options reduce the number of miles traveled by personal vehicles for work commuting and personal trips. Multi-modal transportation options include public transportation (bus, rail, and marine), ridesharing, car and bike sharing, biking, walking, and telecommuting/teleworking. Examples of multi-modal transportation include:

- [Public Transportation](#) – Public transportation involves the use of shared passenger transportation services, with modes including bus (e.g., transit, commuter, trolley, shuttle, and bus rapid transit), rail (e.g., light rail, commuter/inter-city, and high-speed), and marine (e.g., intra- and interisland ferries).
- [Ridesharing](#) – Ridesharing includes carpooling and vanpooling and is focused on increasing the number of passengers in each vehicle to reduce the number of cars on the road to ease congestion as well as reduce the total miles traveled and fuel usage.

- Car Sharing – These services provide a flexible way for people to rent a vehicle for a short period of time (such as a couple hours) to go shopping or visit friends. Available cars are located and reserved online or by phone and are picked up in central, mainly urban locations by an identification card that unlocks the car (the exact process varies by company).
- Bike Sharing - Bike sharing is a low-cost, flexible public transportation service that provides on-demand access to a network of publicly rentable bicycles. Public bicycles are distributed across a service area at fixed destination-based station locations. With the ability to make point-to-point trips, bike sharing systems generally accommodate shorter trips (from 1 to 3 miles) that replace less-efficient automobile and transit trips.
- Active Transit (biking and walking) – Leaving the personal vehicle at home to walk or bike to work or for personal trips eliminates the vehicle miles traveled and fuel used. Use of this type of program is limited for various reasons, including lack of infrastructure and facilities, proximity to work, weather, fitness level, and personal motivation, but can likely be expanded by increasing awareness and incentives.
- Telecommuting/Teleworking – Employees work one or more days per week from home or telework centers located near their home.

Alternative Work Schedules – Modified employee work schedules from a typical 8-hour day, from 9 a.m. to 5 p.m., 5 days a week while remaining full time. While this option does not remove vehicles from the road, it is intended to put fewer cars on the road at any one time, thereby reducing congestion and decrease total miles traveled. Less congestion results in less energy loss in traffic.

The applicability of each transportation option varies by person and circumstance, but all have the potential for Hawai‘i residents to reduce fuel usage while reducing their commute and increasing personal mobility. All of the multi-modal transportation options reduce the number of vehicles on the road and thus the total vehicle miles traveled, the required fuel usage, and roadway congestion. Well designed, comprehensive, and connected multi-modal transportation systems provide people with additional transportation options, increased cost savings, and reduced dependency on single-occupancy vehicles, while improving quality of life. To encourage more widespread use of multi-modal transportation systems, additional incentives could also be considered, including road congestion pricing; parking pricing; implementation of different taxes (parking, vehicle miles traveled, non-energy efficient vehicles); pay-per-use (only pay taxes, insurance, and other fees based on amount of miles traveled); and commuter benefits programs. Additional considerations should also be taken during land use planning by incorporating transit-oriented/mixed-use development principles in the urban environment to support mobility, and accessibility to multi-modal transportation systems. While multi-modal transportation systems can be adopted all over the state, it is even more feasible in urban centers such as Honolulu, where vehicle-miles traveled is forecast to increase to more than 15 million miles per day by 2035, thereby also increasing traffic congestion, vehicle hours traveled, and travel delays ([HCC 2015](#)). By combining these two principles, maximum system efficiency can be achieved. The benefits of increased travel options located within a densely populated area or near residential homes, and within proximity of multiple land uses, provides a convenient, optimal configuration to travelers; thus greatly reducing the need for single-occupancy vehicles and vehicle miles traveled.

[Table 2-27](#) summarizes the multi-modal options used by commuters in Hawai‘i. The data are presented by county and reflect work-related travel (that is, they do not include personal trips). As can be seen in the table, driving alone is the predominant transportation option. Ride-sharing options (carpool and vanpool) are the second most popular option in all counties. Mass transit is much more prevalent on O‘ahu (both

percentage of population and number of individuals). Working from home is popular on Maui and Hawai‘i, and in the City and County of Honolulu. The following sections discuss each commuting option.

2.3.4.6.1 Public Transportation

Technology Description

Public transportation involves the use of shared passenger transportation services, with modes including bus (e.g., transit, commuter, trolley, shuttle, and bus rapid transit), rail (e.g., light rail, commuter/inter-city, and high-speed), and marine (e.g., intra- and interisland ferries). Public transit uses much less energy per passenger mile than personal vehicles, resulting in fewer vehicles on the roads, less congestion, and increased throughput.

Although public transportation modes utilize various energy sources, the primary source currently in use in Hawai‘i is fossil fuels. As Hawai‘i progresses toward the HCEI goals, there would be increasingly more opportunities for all public transportation modes to use a higher percentage of alternative fuels or electricity produced from renewable sources. Human factors that increase public transportation usage include concern for the environment, concern for the global climate, a desire to reduce commuting cost, stress, and time, and the cost of owning and operating a personal vehicle. Other factors that also affect public transportation usage include convenience, safety, reliability, and accessibility. Details of the modes of transportation currently in use or with potential in Hawai‘i are provided in the following sections.

Table 2-27. Multi-Modal Option Summary for Commuters by County (2006 to 2010)

County	Total Population	Percentage of Population					
		Drive Alone	Walk	Ridesharing	Public Transit	Work from Home	Other
Kaua‘i	65,460	78.8	1.6	12.1	0.4	4.8	2.4
Honolulu	936,984	64.5	5.5	15.6	7.9	3.4	3.1
Maui	150,711	70.2	3.3	14.7	1.7	7.7	2.4
Hawai‘i	180,382	68.0	2.7	16.6	1.5	8.9	2.3
County	Total Population	Number of Individuals					
		Drive Alone	Walk	Ridesharing	Public Transit	Work from Home	Other
Kaua‘i		51,582	1,047	7,921	262	3,142	1,571
Honolulu		604,355	51,534	146,170	74,022	31,857	29,047
Maui		105,799	4,973	22,155	2,562	11,605	3,617
Hawai‘i		122,660	4,870	29,943	2,706	16,054	4,149
Totals		884,396	62,425	206,188	79,551	62,658	38,383

Characterization of Technology Feasibility and Deployment

Increasing the use of some public transportation modes would require major construction to develop the infrastructure where it currently does not exist (e.g., the Honolulu Authority for Rail Transit project) ([HART 2013a](#)). Other modes will require less (e.g., enlarged or new transit bus facilities and on- or offsite fueling infrastructure). New infrastructure in Hawai‘i will need to support the adoption of “Complete Streets,” as mandated by [Act 54](#) and county ordinances [e.g., the City and County of Honolulu’s Complete Street Ordinance ([Bill 26](#))]. Complete Streets are road networks, including bike paths, lanes, and sidewalks, that are connected and designed to be safer and more attractive to all types of users and commuters, including bicyclists, public transport users, pedestrians, motorists, and riders of all ages and abilities.

[Act 54](#) requires that the State of Hawai‘i Department of Transportation (HDOT) and county transportation departments ensure the accommodation of all users of the road, regardless of their age, ability, or preferred mode of transportation. It also calls for the creation of a Statewide task force to review existing State and county highway design standards and guidelines and requires the HDOT and county transportation departments to adopt a Complete Streets Policy.

Bus Transit

Transit bus services operate on conventional roads, have a relatively low per vehicle passenger capacity, and are ideal for shorter trips such as intra-city travel or commuter transportation between or into urban areas. Bus transit service is subdivided into traditional fixed-route/fixed schedule service and paratransit/demand response service. Fixed-route service operates on a set of fixed routes with designated bus stops for picking up and dropping off passengers. Paratransit service differs from traditional transit service in several ways: it is primarily used by persons with disabilities and the elderly. There are no fixed routes or schedules; rather passengers request service for pick-up and drop-off at requested locations (e.g., a person’s home, doctor’s office, and shopping center).

Transit buses are the most common public transportation mode used in Hawai‘i for commuting to work, school, and for personal business. Transit buses are available with a wide range of fuels and powertrains; however, conventional diesel, natural gas, and diesel-fueled hybrid-electric are the most common powertrains across the United States. Transit buses are predominantly custom-designed as heavy-duty buses, are blunt-faced, and have at least two sets of doors (one at the front and one or more in the middle of the vehicle) for passenger access. Somewhat smaller, less-rugged medium-duty cutaway chassis cab buses are used for routes with lower passenger throughput. Smaller, less-rugged heavy-duty van-cutaway type minibuses are the most common paratransit demand-response vehicle type; however, taxi cabs and passenger vans also transport on-demand passengers. [Figure 2-58](#) shows the 2011 fuel use mix for transit properties across the United States ([FTA 2011c](#)). Data for Hawai‘i show 99.5 percent of fuel use as diesel and 0.5 percent as gasoline. No natural gas buses are in use in Hawai‘i.

Figure 2-58. U.S. Transit Fuel Usage Mix (non-electric) (Source: [FTA 2011c](#))

Note that the available Hawai‘i-specific fuel use data only include O‘ahu and did not include any biodiesel use. In late 2012, the bus mass transit agency on O‘ahu, “TheBus,” began an initial biodiesel-blended fuel field evaluation ([HCC 2012b](#)). Even so, petroleum remains the dominant fuel in the transit market in Hawai‘i.

A brief description of each transit bus fuel and/or powertrain technology (e.g., hybrid-electric) is given below. Many online sources are available for more detailed information. This PEIS uses information from the following sources:

- Appendix G of the *Kaua‘i Bus Multimodal Land Transportation Plan* ([Kaua‘i Bus 2012](#))
- *Guidebook for Evaluating Fuel Choices for Post-2010 Transit Bus Procurements* ([TRB 2011](#))
- *Alternative Fuel Study* ([FTA 2006](#)).

Diesel Buses

Diesel-fueled buses are the standard bus in Hawai'i and across the United States. Of the 45,010 diesel-fueled buses in use in the United States (32 percent of urban transit buses), 689 are used in the State of Hawai'i (86 percent of urban transit buses in the State) ([FTA 2011d](#)). Diesel engines meeting the current 2010 and later EPA emissions regulations are also referred to as *clean diesel* because the exhaust emissions (e.g., particulate matter and nitrogen oxides) are significantly lower compared with earlier-generation engines.

Hybrid-Electric Buses

Hybrid-electric buses combine an internal combustion engine (typically diesel) and an energy storage system (typically electrochemical batteries) to provide propulsion power to the wheels. Hybrid technology can be used with any fuel; however, because diesel-fuel is the standard transit fuel, diesel hybrid-electric buses are the most common.

Of the 3,311 hybrid-electric buses in use on the United States (2.4 percent of urban transit buses), 78 are used in the State of Hawai'i (10 percent of urban transit buses in the State) ([FTA 2011d](#)). However, gasoline hybrid-electric buses are also in use, albeit not in Hawai'i (199 on the mainland, or 0.14 percent of all urban transit buses). Hybrid-electric buses reduce fuel use mainly by recovering braking energy, reusing the energy later for accelerations, and by allowing the vehicle's control system to manage fuel energy use to minimize fuel consumption. See [Section 2.3.4.3](#) of this PEIS for a detailed discussion on hybrid-electric vehicles.

Biodiesel Buses

Biodiesel accounts for 6 percent of transit fuel use nationwide and is used to a very small extent (i.e., less than 1 percent of total fuel usage) in Hawai'i. Biodiesel fuel is suitable for use in all modern compression ignition engines. Biodiesel can be used in engines in its pure form or in biodiesel blends with petroleum diesel without modifications. Each engine manufacturer has a maximum recommended (or allowed) biodiesel blend percentage. Transit fleets commonly use B20 fuel (20 percent biodiesel/80 percent petroleum diesel blend by volume) because it is a good balance between emission benefits, improved sustainability, fuel cost, and risk of potential field problems. [Section 2.3.4.1](#) of this PEIS includes a detailed discussion of biodiesel. The Honolulu Clean Cities website also provides information about biodiesel fuel use: <http://www.honoluluclancities.org/biofuels/biodiesel-biofuels/>. Buses with Cummins diesel engines (ISB, ISL, and ISM models) are certified for use up to B20 biodiesel blends. Buses with Detroit Diesel engines are certified for use up to B5 biodiesel blends.

Gasoline Buses

Gasoline accounts for 8.9 percent of transit bus fuel use nationwide and 0.5 percent in Hawai'i. Of the 5,270 gasoline-fueled buses in the United States (3.8 percent of urban transit buses), 80 are used in Hawai'i (15.5 percent of urban transit buses in the State) ([FTA 2011d](#)). Gasoline buses are only available in the lighter end of cutaway type buses, ranging from 11,500 to 20,000 pounds gross vehicle weight rating. These buses are primarily built on medium-duty cab chassis that are fit with a bus body. These buses have a shorter minimum useful life (4 to 5 years, 100,000 to 150,000 miles) compared with 12 years and 500,000 miles for a heavy-duty purpose-built transit bus, so are not suitable for heavy use ([FTA 2007](#)). More information on gasoline as a transit fuel can be found in the references ([TRB 2011](#); [FTA 2006](#)).

Natural Gas Buses

Natural gas is the second most commonly used transit bus fuel nationwide (17.5 percent of fuel use). The natural gas can be stored either in compressed or liquefied form. Natural gas is not a natural resource in

Hawai'i. However, HAWAII GAS processes synthetic natural gas for residential and commercial use on O'ahu, so could be used for natural gas-fueled transit buses. [Section 2.3.4.5](#) of this PEIS discusses natural gas as an alternative fuel source.

Of the 9,189 compressed natural gas buses in use in the United States (6.5 percent of urban transit buses), none is used in Hawai'i ([FTA 2011d](#)). HAWAII GAS' natural gas pipeline serves approximately 28,000 residential customers ([HAWAII GAS 2013b](#)). The same pipeline could be used to provide renewable natural gas or gasified liquefied natural gas ([HAWAII GAS 2013c](#)). While the synthetic gas is not used by TheBus, natural gas-fueled buses could be a potential future transit bus fuel if a connection to the pipeline was available at bus fueling locations or offsite fueling stations.

Liquefied Petroleum Gas Buses

Liquefied petroleum gas, also known as propane, is the most commonly used alternative fuel worldwide ([DOE-CC 2013](#)), typically in light-duty vehicles. In the United States, liquefied petroleum gas accounts for only 0.4 percent of vehicle fuel use. Of the 324 liquefied petroleum gas buses in use in the United States (0.2 percent of urban transit buses), none is used in Hawai'i ([FTA 2011d](#)). Currently available liquefied petroleum gas-fueled medium-duty engines suitable for transit use range from 5.4 to 8.0 liters. These engines are available on several cutaway chassis that can accommodate small to large cutaway buses, but not heavy-duty transit buses. All liquefied petroleum gas used in Hawai'i is shipped into the State, which decreases the ease and economic case for its use.

Battery Electric Buses

Battery electric buses are the transit equivalent to light-duty battery electric vehicles discussed in [Section 2.3.4.2](#) of this PEIS. Battery electric buses do not have an internal combustion engine or fuel tank (e.g., diesel, gasoline, and compressed natural gas). Rather, they use energy stored in batteries (all currently available bus models use lithium-ion batteries) to power the vehicle. The battery pack recharges by connecting to an electrical power source. The connection can be physical or wireless (i.e., inductive). The limited range, model availability, high cost, typically long charge times, limited driving range, and other limitations have resulted in a low adoption rate [of the 51 buses in use in the United States (less than 1 percent of urban transit buses), none is used in Hawai'i] ([FTA 2011d](#)). Battery electric buses can take advantage of 10- to 20-minute "boost" charging, during passenger loading and unloading and other similar wait periods. Such methods are being further refined to improve the daily bus utility ([Proterra 2013](#)).

Most battery electric buses require a 20-minute charge every hour, which places limits on the potential applications and routes. However, some applications, such as airport or hotel shuttle buses, are likely good test applications.

Hydrogen Fuel Cell Buses

Hydrogen fuel cell buses are 100 percent electrically propelled. Buses store hydrogen fuel onboard and use it to produce electricity using a fuel cell, which propels the bus. Fuel cell buses typically include a battery pack to perform the same regenerative braking and launch assist functions as in a hybrid-electric vehicle, which improves the energy efficiency and increases the fuel cell stack service life. Fuel cell technology is in the development phase, yet there are a handful of technology demonstrator buses deployed in fleets for use in fare collection service to gather performance and maintenance data. The Hawai'i Center for Advanced Transportation Technologies operated a fuel cell shuttle bus field demonstration project at Hickam Air Force Base from 2004 to 2009 (http://www1.eere.energy.gov/hydrogenandfuelcells/tech_validation/pdfs/36412.pdf). The DOE National Renewable Energy Laboratory has performed data analysis of in-use fuel cell bus field demonstrations, which also provides relevant information (http://www.nrel.gov/hydrogen/proj_fc_bus_eval.html). The

Federal Transit Administration's National Fuel Cell Bus Program is another good resource about fuel cell buses (<http://www.fta.dot.gov/about/14617.html>) (FTA 2013). More information can also be found in [Section 2.3.2.3](#) of this PEIS.

Hydrogen Internal Combustion Buses

Hydrogen internal combustion engines are a similar concept to natural gas fueled engines, except that compressed hydrogen gas is used instead of natural gas. Hydrogen internal combustion engines are seen either as an intermediate step to hydrogen fuel cells (developing the fueling infrastructure while fuel cell technology matures) or as the end goal to eliminate the costly fuel cells while still significantly reducing greenhouse gas and other exhaust emissions. There have been many demonstrations of hydrogen internal combustion light-duty vehicles, shuttles, and transit buses from a range of manufacturers. Ford produced a limited number of hydrogen internal combustion shuttle buses in the early 2000s, but ceased after a few years. The Hawai'i Center for Advanced Transportation Technologies partnered with the U.S. Army to evaluate 10 hydrogen internal combustion Ford Escapes in real-world conditions (http://www1.eere.energy.gov/vehiclesandfuels/avta/pdfs/hicev/ford16v_hice_fs.pdf).

Trolley Buses

Trolley buses are electrically powered buses whose energy is supplied via overhead electric wires. This type of bus has several names, including trackless trolley, electric trolley bus, trolley coach, trackless tram, or trolley. A strict definition of electric trolley buses would allow for the buses to be propelled solely via electric power from overhead wires. However, there are two types of electric trolley buses: electric trolley buses with emergency backup power and dual-mode buses. Buses with an emergency power backup system operate on electricity under normal conditions. The emergency backup power is used in the event of a dewirement (i.e., the catenary poles lose contact with the overhead wires) or if the bus needs to move around an obstacle (e.g., a broken down vehicle, accident scene, or a construction site) beyond the reach of the catenary poles. The backup power source, typically a battery pack or a generator set, provides less power than the primary catenary propulsion power, but is enough to propel the bus so that it can reconnect to the overhead wires, preventing a bus from being stranded (Vossloh 2013). Dual-mode electric trolley buses are capable of full operation on either electric or another power source (such as a diesel engine). One situation where dual-mode trolleys are beneficial is in a long tunnel where diesel exhaust may not be allowed. Boston and Seattle used dual-mode trolleys for this reason.

The number of trolley buses in the United States is low; of the 572 in use in the United States (0.41 percent of all urban transit buses), none is used in Hawai'i. Currently in North America, only five U.S. cities and two Canadian cities use trolley buses. The reasons for this include high installation costs for new or expanded electric trolley lines, limited vehicle options, and aesthetic issues related to the visible catenary network.

Rail Transit

Light Rail Transit

The Transportation Research Board defines light rail transit as “a metropolitan electric railway system characterized by its ability to operate single cars or short trains along exclusive rights-of-way at ground level, on aerial structures, in subways, or occasionally, in streets and to board and discharge passengers at track or car floor level” (TRB 2000). Compared with a heavy rail system, light rail is intended for lighter loads and is designed to be flexible and adaptable to a variety of environments including streets, freeway medians, railroad rights-of-way (operating or abandoned), pedestrian malls, underground or aerial structures, and even in the beds of drained canals. Because of this design flexibility, light rail transit generally is less costly to build and operate than other fixed guideway modes (e.g., heavy rail, commuter rail, trolley buses, aerial tramways, and cable cars). Light rail transit vehicles can fit more passengers than buses and are narrower and shorter than heavy rapid rail or commuter trains since they have to navigate

mixed traffic and fit in city streets. The dedicated infrastructure of rails and power wires, typically above the tracks for safety, limit light rail transit's flexibility for system restructuring and rerouting.

Rapid Rail Transit

Like light rail transit, rapid rail transit (also referred to as heavy rail systems) are electrically powered. Common terms for rapid rail transit include subway, underground, metro, or elevated railway depending on location and where the trains travel. Unlike light rail, rapid rail trains are designed to carry more passengers, stop at each station more frequently, and operate on a grade separation from general traffic (underground, on elevated tracks, or at grade but separated from other traffic). Rapid rail transit trains typically are powered via an electrified third rail (rather than a catenary like a trolley). Rapid transit operates in highly urbanized areas combining high capacity and frequency with minimal land usage. The Honolulu Authority for Rail Transit project (<http://honolulutransit.org/hart.aspx>) is in this category.

Commuter rail and high-speed rail are other rail transit options available on the U.S. mainland and worldwide. Neither rail variants are feasible options in Hawai'i given the combination of the islands' physical sizes and the islands' population and population densities.

Marine Transit – Ferries

Ferries are marine transportation vessels, usually a boat or a ship, that transport passengers and potentially vehicles across a body of water. Ferries are useful for locations where waterways frequently occur or when frequent and lower cost (than air) travel between islands is necessary. Ferries are, or have been, used for intra-island and interisland trips in Hawai'i.

Characterization of Existing Deployment

This section summarizes the current and past usage of each multi-modal transportation mode on each of the six main Hawaiian Islands.

Kaua'i

- **Bus** – The Kaua'i Bus operates 55 diesel cutaway buses, two gasoline paratransit vans, six Park & Ride lots, 18 routes, including express, local shuttles, and paratransit/demand response service ([FTA 2011d](#); [Kaua'i 2013a](#)). The Kaua'i Bus has no planned route/system expansion. The agency purchased one hybrid-electric bus in 2010 to use in fare collecting route service. Operation, usage, and maintenance data are being collected to evaluate the bus' performance to determine if additional hybrid-electric bus purchases are warranted ([Kaua'i 2010](#)). Kaua'i's *Multimodal Land Transportation Plan* identified B20 as its near-term transit bus solution ([Kaua'i 2013b](#)). As of October 2012, the County of Kaua'i has been discussing B20, compressed natural gas, and electrically powered (battery electric and fuel cell) buses for longer-term alternative fuel options for the transit fleet ([Kaua'i 2013c](#)). The B20 would use locally produced biodiesel blended with petroleum diesel.

O'ahu

- **Transit Bus** – TheBus (<http://www.thebus.org/>) is the public transit bus system on O'ahu. It is operated by O'ahu Transit Services, Inc. As expected from the island's larger population, TheBus is the largest transit fleet in the State. As of 2011, the entire TheBus vehicle fleet included 516 transit buses, including ([FTA 2011d](#)):
 - 35 diesel transit buses (less than 40-foot),
 - 333, 40-footdiesel transit buses,

- 40, 40-foot diesel hybrid-electric transit buses,
- 70, 60-foot articulated diesel transit buses,
- 38, 60-foot articulated diesel hybrid-electric transit buses

- B20 biodiesel. Starting in 2012, 20 transit buses began fueling with B20 biodiesel as part of the Honolulu Clean Cities' Hawai'i Clean Diesel Initiative ([HCC 2012b](#)). The City and County of Honolulu has used B20 as the primary diesel fuel for its diesel fleet vehicles since 2004, and began use in transit buses in 2012.

- Hybrid-electric vehicles. TheBus fleet includes 78 hybrid-electric buses. It had originally planned to convert half of the transit bus fleet to hybrid-electric buses by 2013. High implementation costs and lower than expected fuel savings (20 versus 60 percent) has put the plan on hold ([FTA 2011d](#)).

- **Bus Rapid Transit** – The City and County of Honolulu implemented limited bus rapid transit service in the early 2000s, with limited routes and limited bus rapid transit features. Performance and support to continue and grow the service waned and attention shifted to rapid rail service. Bus rapid transit service will continue until it is replaced by the rapid rail system currently under development.

- **Paratransit/Demand Response** – TheHandi-Van (<http://www1.honolulu.gov/dts/riders.htm>) is the public transit service for persons with disabilities who are unable to use the city's bus service, TheBus. The service includes 132 cutaway buses (102 diesel and 30 gasoline). Van service includes 59 sedans and 382 passenger vans, minivans, and sport utility vehicles.

- **Rail** – There is no rail service currently in Hawai'i. The concept for commuter rail was first suggested in the 1960s, and was finally approved in 2005. The Honolulu High-Capacity Transit Corridor Project (now known as Honolulu Authority for Rail Transit) is currently planning, developing, and constructing the system including (but not limited to) tracks, stations, parking lots, and larger Park & Ride lots ([HART 2013a](#)). The system is projected to open in three phases between 2015 and 2019 with an estimated ridership of 116,300 weekday passenger trips by year 2030. The system is planned to extend 20 miles from Kapolei to Ala Moana Center ([HCC 2013](#)). The rail system development is being tied to neighborhood Transit-Oriented Development to build up communities (residential, business, and commercial) around rail stations. A good summary of Transit-Oriented Development can be found at the following websites: <http://www.honoluluapp.org> and <http://honolulucleancities.org/vmt-reduction/public-transportation/>.

- **Ferry** – A high-speed ferry (the Hawai'i Superferry) operated for a short time between 2007 and 2009 between O'ahu, Maui, and Kaua'i before legal challenges to the environmental review process caused service to terminate ([HISF 2013](#)).

TheBoat commuter ferry service was operated as part of the City and County of Honolulu's mass transit system between downtown Honolulu at Aloha Tower Marketplace and Kalaehoa Harbor at Barber's Point in Kapolei ([Honolulu 2007](#)). Service ran from 2007 to 2009.

Molokai (Maui County)

- **Bus** – Maui Economic Opportunity, Inc. provides limited bus service on Molokai via County of Maui grant funds ([MEO 2013](#)). The service operates free bus shuttle service for locals and visitors. There is no information regarding hybrid-electric or alternative fuel use.

- Ferry – The Molokai Ferry provides ferry service that connects Molokai and Maui. Molokai residents use the ferry to travel to and from Maui for work, shopping, medical appointments, and pleasure.

Lāna‘i (Maui County)

- Bus – Maui Economic Opportunity, Inc. provides limited bus service on Lāna‘i via County of Maui grant funds ([MEO 2013](#)). The service operates some shuttles for rural shopping, senior nutrition, and Medicaid trips, but no traditional public transportation service. There was no information regarding hybrid-electric or alternative fuel use.
- Ferry – Expeditions Maui-Lāna‘i Ferry provides ferry service that connects Lāna‘i and Maui. Lāna‘i residents use the ferry to travel to and from Maui for work, shopping, medical appointments, and pleasure ([Expeditions 2013](#)).

Maui

- Transit Bus – Maui County manages the Maui Public Bus Transit System, which is operated by Roberts Hawai‘i ([Maui 2013a](#)). The system includes 13 routes that provide service in and between various Maui communities. The fleet includes 12 diesel buses (less than 40-foot), six 40-foot diesel transit buses, and 23 diesel cutaway buses. A review of the *Short Range Transit Plan* indicated no plans for hybrid-electric or alternative fuel use now or in the future ([Maui 2005](#)).
- Commuter Bus – The Maui Public Bus Transit System’s commuter bus system is also managed by Maui County and operated by Roberts Hawai‘i ([Maui 2013b](#)). The commuter bus system includes four routes and picks up passengers at Park & Rides, shopping centers, community centers, the War Memorial Stadium, hotels, and traditional cross-street roadside stops. As with transit buses, there are no apparent plans for hybrid-electric or alternative fuel use.
- Ferry – Expeditions Maui-Lāna‘i Ferry provides ferry service between Maui and Lāna‘i. Residents and tourists use the ferry for shopping and pleasure trips. Molokai Ferry provides ferry service between Maui and Molokai. Residents and tourist use the ferry for shopping and pleasure trips ([Expeditions 2013](#)).

Hawai‘i

- Bus – The Hawai‘i County Mass Transit Agency operates the Hele-On Bus (<http://www.heleonbus.org>) transit bus service. The service includes 18 routes, 36, 40-foot diesel transit buses, 12 diesel transit buses (less than 40-foot), 5 diesel medium-duty cutaway buses, and 3 gasoline-fueled minivans (paratransit/demand response) ([NTD 2011c](#)). There was no information regarding hybrid-electric or alternative fuel use.

2.3.4.6.2 Rideshare

Ridesharing includes carpooling, vanpooling, and bus transit. Bus transit was addressed above so this section addresses just carpools and vanpools. The objective of both activities is to reduce the number of vehicles on the road by increasing the number of passengers in a vehicle. Reducing the number of vehicles decreases fuel consumption and exhaust emissions roughly by a factor of the number of people in

the vehicle.²⁸ Removing vehicles from the roadways also decreases congestion, which in turn decreases fuel wasted in traffic and allows vehicles to operate in conditions optimal for maximized fuel economy. Carpools can be formed by any group of people whether they know each other (e.g., neighbors or work colleagues) or not. The carpool group decides the structure, costs, the vehicle(s), the driver(s), and the schedule that will be used.

HDOT operates several programs to encourage ridesharing ([HDOT 2013a](#)), including high occupancy vehicle and zipper lanes reserved for buses, carpools, vanpools, and motorcycles and the carpool/school pool matching service that connects potential groups together for forming a carpool/school pool ([HDOT 2013b](#)). People add their contact, commute, and other relevant information to the database. This information is used to locate and create private carpool/school pool groups. Other private rideshare matching services such as eRideshare exist for people to locate and form carpools on their own.

Vanpools operate in a similar way as carpools, except the vehicle is provided by a service rather than a personally owned vehicle. vRide is the commercial vanpool service provider in Hawai'i. The vanpool group can be formed by a group of people who know each other, or vRide can assemble the group. The vans are available in 7-passenger (minivan), 10-passenger (traditional van), and 15-passenger (traditional van) sizes, which equates to removal between 6 and 14 cars from the road. The monthly fee is per vehicle, so the per-person costs depends on the number of people in the vanpool. The monthly fee includes the vehicle, fuel, maintenance, parking, and insurance. vRide has a calculator tool to estimate the monthly savings (<http://www.vride.com/locations/hawaii>). The actual savings are situation dependent; for instance, a 30-mile round trip commute in a vehicle that gets 20 miles per gallon at about \$4.00 per gallon is estimated to provide a monthly saving of \$153. The monthly savings would increase to \$274 when parking and reduced personal car insurance rates were included.

The City and County of Hawai'i offers a shared ride taxi service in the urbanized areas of Hilo and Kailua-Kona. Six taxi companies participate in the program ([Hele-On Bus 2013](#)). Door-to-door service is available for trips up to 9 miles and costs as little as \$2 (or as much as \$6, depending on the) per person per trip. The taxi operators may combine and consolidate rides.

2.3.4.6.3 Car Sharing

Car sharing services are similar to car rental services, but are intended for use for short periods, for customers who make only occasional use of a vehicle, as well as others who would like occasional access to a vehicle of a different type than what they use day-to-day. Car sharing services target people who do not own a car, but do not restrict car owners from using the service. Most vehicle types are offered, such as cars, trucks, sport utility vehicles, and vans; however, availability in Hawai'i and at each location varies. There are two general types of car sharing services: commercial services that provide vehicles and commercial services that help users organize to share their personal vehicle(s). The commercial services include fuel, insurance, mileage, and parking.

Commercial Services Providing Vehicles

Commercial car sharing has not been widely implemented in Hawai'i. One reason could be that car sharing vehicles were being taxed at the same rate as rental cars, despite a rental duration of only 20 or 30 minutes compared with a 24-hour rental duration on traditional rental cars. The State tax law was modified during the last legislative session, and starting January 1, 2015, car sharing vehicles have a

²⁸ The reduction would be somewhat less due to additional miles required to pick up and drop off each passenger on either side of the trip.

surcharge of \$.25 per half-hour for rentals of up to three hours. It is anticipated that Hawai‘i will see more car sharing vehicles as part of its multi-modal transportation system starting in 2015.

Car sharing is a membership-based service available to all qualified drivers in a community. No separate written agreement is required each time a member reserves and uses a vehicle. Car sharing organizations offer their members access to a dispersed network of shared vehicles 24 hours a day, seven days a week at unattended, self-service locations. The membership and rental process varies by company, but there is generally a one-time membership enrollment fee and a recurring (monthly or annual) membership charge.

Car sharing is primarily designed for shorter time and shorter distance trips as an extension of the transportation network, providing a public service designed to enhance mobility options. Longer trips may be available. Car sharing organizations help members save money of individual car ownership by encouraging members to drive less often, planning trips more, using other modes of transportation more, and sharing fuel-efficient vehicles when a car is needed.

ZipCar is the largest car sharing service in the United States but does not operate in Hawai‘i. Enterprise CarShare operates small fleets on the University of Hawai‘i at Manoa campus, the Hawai‘i Pacific University, Windward Campus, and on Kaneohe Bay Marine Base. Green Car Hawai‘i (<https://www.greencarhawaii.com/>) is similar to Enterprise CarShare, but caters to tourists; however, it is also available to Hawai‘i residents. The service is currently only available at one hotel in Waikiki.

Commercial Services Not Providing Vehicles

Relay Rides is a car sharing program that provides the reservation, insurance, and operations support for vehicle owners to rent/share their personal vehicles. Similar to the commercial services providing vehicles, Relay Rides rentals can be for various amounts of time (from hours to days). Currently, there are only eight vehicles enrolled in Hawai‘i: two on Hawai‘i island, two on Maui, and four on O‘ahu.

2.3.4.6.4 Bike Sharing

Bike share is a low-cost, flexible public transportation service that provides on-demand access to a network of publicly rentable bicycles. Public bicycles are distributed across a service area at fixed destination-based stations. With the ability to make point-to-point trips, bike sharing systems generally accommodate shorter trips that replace less-efficient vehicle trips (trip lengths average between one and three miles). With more than 30 systems operating in the United States as of January 2014 and more than 100 more in planning or pre-implementation stages, bike sharing is a growing form of public transportation. Not only is bike sharing a healthy option on an individual scale, it reduces emissions, inner-city road congestion, and vehicle wear and tear in participating communities.

Hawai‘i is planning to implement a Statewide bike share system. Phase I of this system will be in urban Honolulu. The intent is to become the final stage of an integrated multi-modal system, helping commuters with their last leg of travel after using the rail, bus, and/or other mode of public transportation.

2.3.4.6.5 Active Transit

Active transit is human-powered transportation (i.e., walking and biking) that reduces the number of vehicles on the road ([DOE 2013s](#)). The impact is decreased fuel consumption and exhaust emissions. Removing vehicles from the roads also decreases congestion, which decreases fuel wasted in traffic and allows vehicles to operate in conditions optimal for maximized fuel economy. The potential per trip impact of biking and walking is logically lower than other modes, such as public transportation (bus, rail) or carpools since most people would only opt for these modes for relatively short distance. As can be seen in [Table 2-27](#), the potential pool of people who would walk or ride their bike is a small subset of the

population. Regardless, both are important options that play a part in reducing vehicle miles travelled. Both require adequate infrastructure including crosswalks, overpasses, sidewalks, and bike lanes or paths to provide a safe environment. State and county laws protecting pedestrians and bicyclists help improve the safety of active transit.

The State of Hawai‘i developed the *Statewide Pedestrian Master Plan* and *Bike Plan Hawai‘i Master Plan* to address the infrastructure and safety aspects for enabling and improving both modes ([HDOT 2013c](#), [2013d](#)). [Act 54](#), the State’s mandate supporting “Complete Streets,” would also ensure accommodation of all users of the road, regardless of their preferred mode of transportation (see [Section 2.3.4.6.1](#)).

2.3.4.6.6 Telecommute/Telework

Telecommuting involves people working remotely via either a home computer or by driving to a telework center. The term for telecommuting is also known as teleworking, since the name puts the focus on working, rather than the trip to and from work. In a teleworking arrangement, employees work one or more days per week either from home or a business center located near their home ([DOE 2013t](#)). Formal agreements are commonly made between employer and employee to determine, among other things, the number of days per week the employee will telework. In general, teleworking has been shown to be a useful tool for retaining employees by allowing for a better balance between work and home life. Worker productivity has also been shown to be higher for teleworkers since they have fewer distractions from co-workers during the day. Teleworking is not universally applicable since some jobs must be done at the company workplace (e.g., car sales, tourism, and restaurants).

Teleworking from home has the highest petroleum use and traffic congestion benefits. Teleworking at telework centers has somewhat lower petroleum use reduction because workers must drive to the telework center; albeit it a shorter distance and oftentimes less congested location than their work office.

As shown above in [Table 2-27](#), the percentage for those working from home (which includes teleworking) is higher than mass transit on all islands except O‘ahu. Overall, across the State, the number of telecommuters almost equals the number taking mass transit. Increasing teleworking can be an important factor to reducing petroleum use and meeting the HCEI goals.

2.3.4.6.7 Alternative Work Schedules

Alternative work schedules is simply working a non-typical 8-hour day, from 9 a.m. to 5 p.m., 5 days a week while remaining full time. While this option does not remove vehicles from the road, it is intended to put fewer cars on the road at any one time, thereby reducing congestion and decrease total miles traveled. Less congestion results in less energy loss in traffic ([DOE 2013t](#)). Example alternative work schedules include the following:

- [9/80 work week](#) – Employees work 80 hours over 9 work days (10 percent reduction in average weekly miles).
- [4/40 work week](#) – Employees work a 40-hour week in 4 days (20 percent reduction in average weekly miles)
- [3/36 work week](#) – Common in health facilities and fire and police departments; employees work three 12-hour shifts (40 percent reduction in average weekly miles).

- Staggered work hours – Work hours are shifted to spread out the traffic density. The benefit to the workers is a shorter driving time and a more consistent commute. Some fuel savings may result, however, higher average speeds may negate that benefit.
- Flexible working hours – Employees are given the flexibility to work the hours they want and can change on a daily basis. Most flex-time programs require employees to be present during a core period of time (such as from 9 a.m. to 3 p.m.) to allow for the necessary interactions with co-workers and clients. Fuel-related benefits include a shorter commute time if driving earlier/later than rush hour(s). However, higher average speeds may negate that benefit.

2.3.4.6.8 Permitting and Consultation Requirements

The permitting and consultation requirements required for multi-modal transportation are general in nature. See [Section 2.2.5](#) for a discussion on general permitting and regulatory requirements.

2.3.4.6.9 Representative Project

The representative project could include any number of combinations of the above multi-modal transportation options. Aside from public transportation, the current and potential future petroleum reduction impact is either difficult or impossible to accurately estimate. Therefore, the representative project is specific to increasing transit ridership (bus and rapid rail) to avoid personal vehicle travel and eliminate 20 million gallons of petroleum fuel use in 2030.

2030 Public Transit Fleet Improvements to Meet 20-Million-Gallon Fuel Reduction Target

Increasing public transportation use and the sustainability of the operations is important on all islands, but the representative project considers only O‘ahu. As of 2010, O‘ahu accounted for 70 percent of Hawai‘i’s population, and, as such has a greater chance of affecting increased mass transportation use Statewide ([DBEDT 2011](#)). The representative public transportation project could include three features: (1) to increase public transit usage, (2) to transition to more fuel-efficient transit vehicles, and/or (3) to replace petroleum diesel with renewable biofuels and/or electricity. However, such a variety would lend itself to a matrix of impacts; therefore, the project assumes only conventional diesel bus fixed-route service²⁹ and rapid rail to provide a realistic project analysis later in this PEIS. (Hybrid-electric buses and biodiesel fuel blends are currently used on a limited basis on O‘ahu, but are not included in this analysis.) The project also assumes that the fuel consumption of conventional diesel buses will not improve between now and 2030. While this assumption is not likely, it was accepted for two reasons: (1) any potential improvements likely would not represent a major reduction and (2) the avoided passenger car gasoline use far outweighs the diesel bus fuel consumption. Fuel usage system summary usage data (e.g., annual vehicle revenue miles, annual passenger miles, and annual trips) ([USDOT 2011; FTA 2011a](#)), and average passenger trip length ([TheBus 2013](#)) were used to calculate the average diesel fuel use per passenger trip (0.0742 gallon). The average fuel use for completing the same trip in a personal vehicle was estimated assuming the same fuel economy and fleet weighting used in [Section 2.3.4.3](#) (Hybrid-Electric Vehicles) (i.e., 0.4195 gallon).³⁰ The fleet mix and average fuel economy of the 2030 fleet vehicles will be higher because of increasing fuel costs and Federal Corporate Average Fuel Economy requirements. The result is that the savings presented here will be somewhat higher than expected. The

²⁹ Traditional transit bus service (i.e., not paratransit/demand response service) accounts for the vast majority (98.5%) of transit service on O‘ahu.

³⁰ Passenger cars (25 miles per gallon average, 50 percent of fleet) and light trucks (16 mile per gallon average, 50 percent of fleet).

fuel saved per transit trip is the difference between the personal car fuel use and the bus transit fuel use (0.3453 gallon).

The Honolulu Rail Authority Transit estimates the system, at its anticipated usage level, would reduce transportation energy demand by the equivalent of 5.9 million gallons in 2030 from avoided personal car travel ([HART 2013b](#)). The calculations included the additional energy use for operating the trains, so the 5.9 million gallons is the net fuel savings. The representative project uses this estimation without modification.

The remaining 14.1 million gallons of avoided fuel use would come from increased transit bus ridership. [Table 2-28](#) presents the ridership increase and the number of new trips (assumes the same average bus trip length) that must be added to reach the total 20-million-gallon petroleum use reduction. An estimated number of additional buses needed to provide the increased ridership (assumes the same utilization, ridership, and fuel consumption per bus and per passenger car trip) is also shown.³¹

Table 2-28. Diesel Transit Bus Increases Needed to Meet 20-Million-Gallon Fuel Use Reduction Target

Transit Bus Ridership Increase (%)	Number of New Transit Bus Trips Added (million)	Approximate Number of New Transit Buses Needed
55	40.9	282

The representative project assumes the following:

- Decreased petroleum usage resulting from switching from personal vehicle trips to transit bus and rapid rail trips for people who own vehicles, and providing a robust set of transportation options for those that do not own vehicles;
- Reduced traffic congestion that would occur from increased mass transit use. Exhaust emissions and greenhouse gas emissions for the island overall also would decrease (assuming that as transit bus fleet emissions increase, personal vehicle emissions would decrease at a much higher rate).
- Increased ridership resulting in increased fare revenue for TheBus, which could be invested to accelerate environmentally sound vehicle purchase and facility upgrade plans to enhance energy usage reductions.

Two maintenance facilities and one heavy maintenance facility service the current fleet of transit service buses on O‘ahu ([FTA 2011b](#)). The representative project assumes the maintenance and heavy maintenance facilities are at or near capacity, and therefore, likely would require building one more maintenance facility or expanding one or both of the two existing facilities to meet the 20-million-gallon petroleum reduction.

2.3.5 ELECTRICAL TRANSMISSION AND DISTRIBUTION

Energy efficiency within Hawai‘i’s electrical transmission and distribution system would contribute to HCEI goals and would benefit both fossil fueled power generation and renewable power generation sources that use the transmission and distribution systems. Proposed projects would proceed with the intent of balancing HCEI goals with utility system stability and reliability.

³¹ The current transit bus fleet includes 516 fixed-route transit buses.

Even though they are not specifically included in one of the HECI key sectors of the energy economy, the technologies included in this clean energy category are all complementary to the generation and efficient end-use of electricity from renewable sources. The electrical grids on each island in Hawai‘i are operated independently because there are currently no transmission lines or cables that allow transmission between islands (see [Sections 2.3.5.1](#) and [2.3.5.2](#)). In order to provide additional grid stability for the islands and to fully use the renewable energy resources of the State, an undersea transmission cable may be implemented to transmit energy between islands. To improve the efficiency, reliability, and security of the electrical grid, new computerized and other automated technologies are being used to monitor and manage the supply and demand of electricity. These technologies are called a smart grid (see [Section 2.3.5.3](#)). Another component of the electrical distribution system is energy storage. Energy storage systems improve the stability and reliability of electricity distribution when variable, renewable sources such as wind or solar are attached to an electrical grid (see [Section 2.3.5.4](#)). The electricity transmission and distribution technologies options discussed in this section include the following:

- On-Island Transmission
- Undersea Cables
- Smart Grid
- Energy Storage

Due to their unique features, no common approach was used to develop the representative projects for electrical transmission and distribution technology options. The representative projects developed for each of the above technologies are specifically addressed in each of the following subsections.

2.3.5.1 On-Island Transmission

2.3.5.1.1 Technology Description

On-island transmission of electricity includes connections from the power generation source, transmission over a short or long distance, and connection to the power user. This system is often referred as the island electrical grid or simply “power grid” (see [Figure 2-59](#)). The power grid is how the majority of people and companies get their electricity. The generating station shown on the left in the figure may be current fossil fired power plants, auxiliary generators to help regulate power throughout the grid, or any of the various renewable power generation sources (e.g., sun, wind, biomass, hydropower, geothermal) as described in the previous sections of this PEIS. The power source connection may include meters, switchgear, circuit breakers, inverters, transformers, and connection to transmission lines.

The transmission line may be aboveground or buried to distribute the power to customers. At the power user, connections would also include switchgear, circuit breakers, inverters, transformers, meters, and connection to customer facilities. Some customers with renewable power generation capability may be both users and/or suppliers of power to the grid.

Figure 2-59. Simple Diagram of Electric Power Supply via Transmission Lines to Customers (commonly known as the power grid)

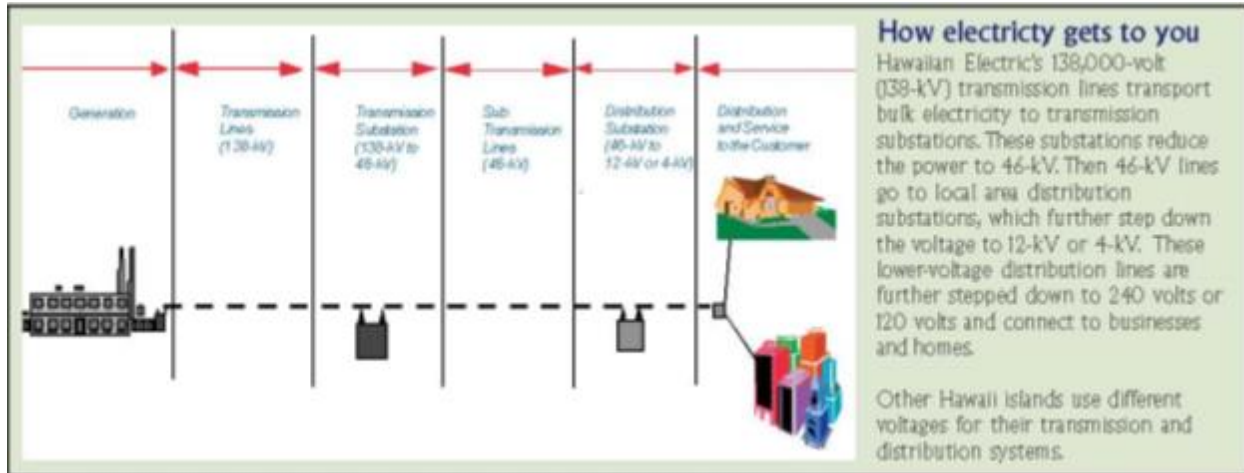

Figure 2-59. Simple Diagram of Electric Power Supply via Transmission Lines to Customers (commonly known as the power grid)

2.3.5.1.2 Characterization of Technology Feasibility and Deployment

Power for the six islands of Hawai‘i, Maui, Lāna‘i, Molokai, O‘ahu, and Kaua‘i is supplied by four electric utilities: HECO, Hawai‘i Electric Light Company (HELCO), Maui Electric Company (MECO), and Kaua‘i Island Utility Cooperative (KIUC). HELCO and MECO are subsidiaries of HECO and those three companies supply power to about 95 percent of the population of Hawai‘i.

In order to assure a stable electrical grid and to minimize disruption to service quality and reliability, the electrical grid will need to be modified to compensate for the variations in power output from renewable power generation sources (e.g., wind power varies with the wind flow; solar varies with the day/night cycle, clouds, and shading). As added renewable energy begins to reach a larger portion of the State’s goals, the old power network will not be able to ensure a stable electrical grid ([NREL 2012d](#); [NCEP 2004](#)). Adding new renewable power sources and changing the existing, older fossil-based power sources for any of the Hawaiian Islands will require continuing additions and changes to the existing transmission and power grid infrastructure to properly match the power generation sources and users on the grid. Those changes could include:

- New local connections to the power grid (e.g., residential or commercial customers);
- Transmission lines from new power sources to the existing grid (e.g., connection of solar power plant via above- or belowground transmission line);
- Upgrade of the existing grid to increase capacity to handle added power (e.g., replace sections of transmission lines and substations that become overloaded);
- Better balance of grid to handle new variable renewable power sources [e.g., solar and wind power vary with the weather; therefore, the electrical power supply must constantly be balanced to provide reliable power to all users. Adding power storage devices (see [Section 2.3.5.4](#)) to the grid may compensate for power spikes by storing power when there is too much and later releasing power to mitigate momentary spikes.]

- Storing energy to address the varying demand for power; energy storage can take electricity that is generated at one point in time and store it for use at a different time in the day (see [Section 2.3.5.4](#))
- Interconnection of existing grids (e.g., connect together two independent grids to share power supply resources for better overall power reliability and service) (see [Sections 2.3.5.2](#) and [2.3.5.3](#)).

Currently, the power grid on all six islands is connected to most of the residents and businesses on each island. For those already connected, adding local residential or commercial renewable energy sources may not require extensive change to the existing grid at the point of connection. Programs like net energy metering and feed-in tariff are examples of these changes that are underway. Net energy metering allows residential and commercial utility customers with renewable energy sources to connect to the electrical grid and receive credit for power supplied to offset the cost of power used from the grid ([HECO 2013i](#)). The feed-in tariff program provides an opportunity for renewable energy projects to sell electricity to the HECO companies through a tariff payment for the power supplied ([HECO 2013i](#))

Larger utility-scale power sources such as solar farms, wind farms, large biomass generators, hydropower facilities, or geothermal plants will need to be constructed in locations that are favorable to their type of power generation (see [Section 2.3.3](#)). In these examples, it is likely that the power source will be some distance (e.g., several miles) from the nearest grid connection location. Typical transmission voltages used throughout the six islands are shown in [Table 2-29](#). The voltages vary from very high at 138 kilovolts to low at 120 volts. The high levels allow for efficient movement of power (e.g., 138 kilovolts, 69 kilovolts); whereas, the lower levels (e.g., 220 volts or 120 volts) allow safer use in household and commercial settings ([NCEP 2004](#)). [Table 2-30](#) shows typical transmission line voltage levels, corridor width, and tower or pole height for similar transmission lines. Higher voltage transmission, which is generally more efficient at power transmission, will usually require wider corridors and taller towers, which likely will result in greater impacts (e.g., land disturbance or visual impacts).

Grid modernization plays a strategic role in helping Hawai‘i achieve its 2020 and 2030 clean energy objectives. The State believes grid modernization will encourage private investment and take advantage of both utility-scale and distributed generation resources. The State’s grid modernization strategy involves: (1) adopting rules and standards as recommended by the Reliability Standards Working Group established by the PUC, (2) developing sufficient storage capacity and advanced grid upgrades, and (3) continuing to consider connecting the islands through integrated, modern grids as a means to utilize Hawai‘i’s best natural resources at a scale that would reduce electricity costs and improve overall system efficiency, provided Hawai‘i’s communities are a key part of this discussion as the State balances economic, technical, environmental, and cultural considerations.

Table 2-29. Expected Transmission and Interconnection Voltages

	Hawai‘i (HELCO)	Maui, Molokai, Lāna‘i (MECO)	O‘ahu (HECO)	Kaua‘i (KIUC)
Transmission	69kV	69kV	138kV	57.1kV
Subtransmission	34.5kV	23kV	46kV	-
Distribution varies depending upon location of facility	e.g., 25kV, 12kV, 4kV	e.g., 25kV, 12kV, 4kV	e.g., 25kV, 12kV, 4kV	12.47kV
Household and commercial connection	e.g., 220V, 120V	e.g., 220V, 120V	e.g., 220V, 120V	e.g. 220V, 120V

HECO = Hawai'i Electric Company; HELCO = Hawai'i Electric and Light Company; KIUC = Kaua'i Island Utility Cooperative; kV = kilovolt; V = volt.

Table 2-30. Typical Transmission Line Voltage Levels, Corridor Width, and Tower or Pole Height

Transmission Line Voltage (in kilovolts)	Width (in feet)	Height (in feet)
138	100 - 150	70 - 95
69	70 - 100	50 - 70
46	70 - 100	50 - 70

New renewable energy projects will include appropriate connection to the power grid. Issues such as transmission efficiency and losses due to voltage step-up and down-stepping at substations will also be considered ([NCEP 2004](#)). The utilities and PUC in Hawai'i have processes in place for developing safe and efficient interconnection with the transmission grid. New projects should consult the utilities during their early design phases.

2.3.5.1.3 Permitting and Consultation Requirements

Permits or utility coordination may be needed to construct a particular project would include interconnection with the power grid and permits that maybe required due to specific land used and local environmental characteristics (e.g., cultural surveys, endangered species take permit). General permitting and regulatory requirements are discussed in [Section 2.2.5](#). Additional permitting considerations include:

- Consultation with the NOAA National Weather Service to avoid interference with weather surveillance radars.
- Consultation with the Federal Communication Commission for microwave or telecom interference.

2.3.5.1.4 Representative Project

To illustrate a potential transmission and distribution project that may be encountered on any of the six islands, the analysis in this PEIS considers a representative project that would involve an electrical connection to a large, renewable energy generation project. The representative project is not intended to reflect any known or planned project and is developed for analytical purposes only. The renewable generator maybe a large (100-megawatt) solar farm, wind farm, biomass/biofuel, or geothermal generator. The project assumes that the generation source is 20 miles from the nearest transmission line and the transmission line operates at 69 kilovolts. For this example, the analysis uses a transmission line that would have a 100-foot-wide, 20-mile-long, 0.38-square-mile disturbed area for easement, and a 70-foot pole or structure height. [Not included in this example are other possible requirements at the generator end to convert power to 69 kilovolts. Such equipment may include inverters, transformers, and electrical switchgear. When a project is about to be connected, the utility will require a transmission line approval (see [Table 2-30](#), DBEDT Permit Packet S-50) and any other equipment needs will be determined.]

Characteristics of this representative project are:

- Almost all linear except for small areas for substation or switching yard,
- Aboveground structures (such as poles),

- Easement access (either right of way or roads),
- Construction labor/cost and minimal operational personnel (once constructed, maintenance requirements should be small),
- Construction noise (e.g., heavy equipment),
- Construction use of water (e.g., dust suppression, ground compaction),
- Operational control of the easement (e.g., control of vegetation to avoid interference with the power lines, and
- Little to no operational water use, waste, or hazardous waste streams other than normal human considerations for operational personnel.

2.3.5.2 Undersea Cables

Undersea power cables, also called submarine cables, transmit power across large bodies of water, whether from one island to another, or from an offshore energy facility (e.g., an offshore wind turbine platform) to an on-island electrical network. Undersea cables lay on the sea bed and connect to on-island power grids via a land-sea cable transition site. Any type of electrical power can transmit across undersea cables, including renewable energy sources such as solar, wind, and biomass.

2.3.5.2.1 Technology Description

Undersea cables between islands in Hawai‘i is not a new concept. Currently, Hawai‘i has many telecommunications cables running between islands, as [Figure 2-60](#) shows, but no power cables.

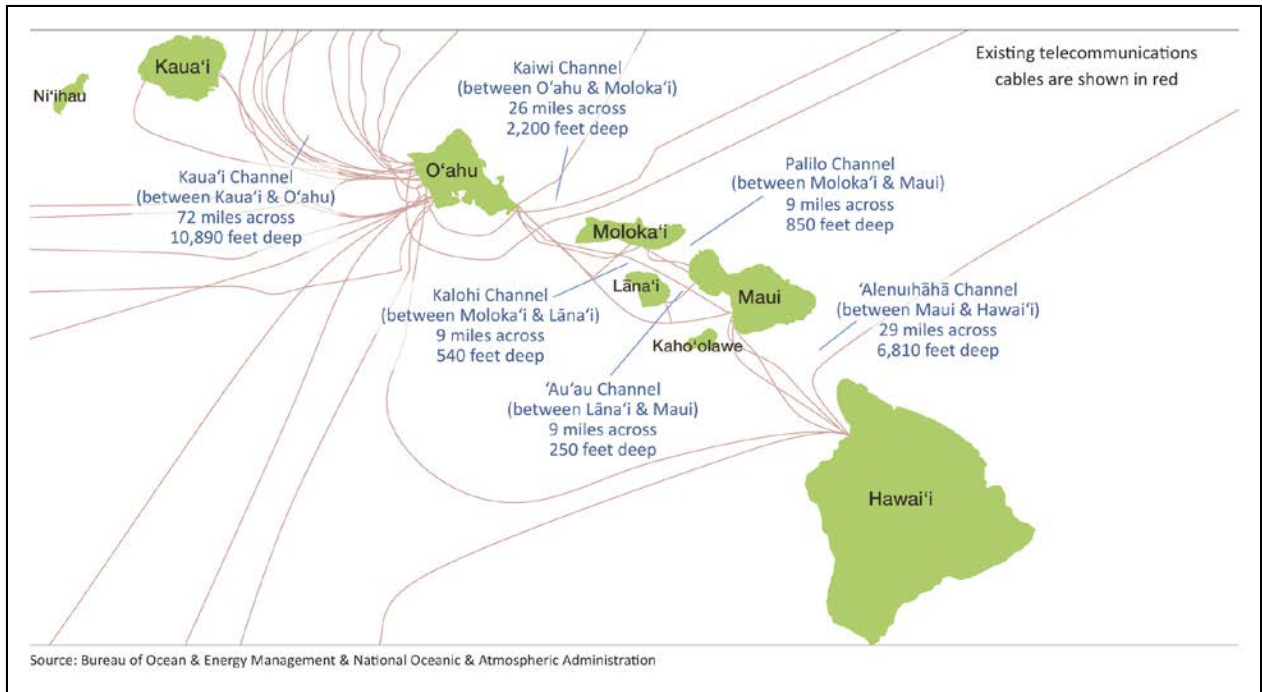

Figure 2-60. Existing Undersea Telecommunications Cables in Hawai‘i (Source: [DBEDT 2013h](#))

Two undersea cable transmission technology options are available: alternating current (AC) and HVDC. HVDC cables offer the benefit of increasing power system stability when connecting to land-based AC power systems, although this requires additional conversion equipment. Transmission losses are lower for HVDC than for AC, so AC undersea cables are more suitable for transmitting lower power levels over

shorter distances. For example, AC undersea cables commonly connect offshore wind farms, which operate at less than 5 miles from shore (see [Figure 2-44](#)) to onshore power generation stations.

Both AC and HVDC undersea power transmission cables are generally larger and more robust than telecommunication cables. Depending on the current-carrying capacity and insulation, undersea power cables can have a diameter as wide as 12 inches, whereas undersea telecommunications cables typically are 0.5 to 2 inches in diameter ([ICPC 2011](#)). A 500-megawatt HVDC transmission cable is about 4 inches in diameter and, when combined with a telecommunication cable and insulation, the bundle, or cable package, is about 10 inches in diameter ([DBEDT 2013h](#)). [Figure 2-61](#) illustrates the sizes of a 500-megawatt HVDC transmission cable and insulation, which, when combined, form a typical undersea cable package.

Figure 2-61. HVDC Undersea Cable, 500-megawatt Capacity (Source: [DBEDT 2013c](#))

Several undersea cable systems are currently operational in the United States:

- Cross Sound Cable - Installed in 2002, the 24-mile-long HVDC undersea cable transmits 330 megawatts of electricity between New York and Connecticut.
- The Neptune – Installed in 2007, the 50-mile-long HVDC undersea cable transmits 660 megawatts of electricity between Long Island and New Jersey
- Trans Bay Cable – Installed in 2010, the 53-mile-long HVDC undersea cable transmits up to 660 megawatts of electricity under the San Francisco Bay Area.
- The Hudson Project – Installed in 2013, the 4-mile-long HVDC undersea cable transmits 660 megawatts of electricity between New York and New Jersey.

Undersea cables are common throughout world. The largest undersea cable in the world has a capacity of 2,000 megawatts, which is more than the State of Hawai‘i’s entire electricity demand ([DBEDT 2013m](#)). For illustrative purposes, [Table 2-31](#) provides statistics of some of the world’s major undersea cable systems.

An undersea power cable typically comprises one or more insulated electrical conductors, held together by sheathing, and surrounded by protective layers and armor-encased in a tough outer covering ([Figure 2-62 below](#)). The protective layers and armor keep out moisture and protect the cable from abrasion. Screens function to shield the electric field. The electrical conductor is usually copper but can be aluminum, insulation is made from polymer materials (such as high-density crosslinked polyethylene), the metal sheath is made of lead, and the armor is galvanized steel wires. Specific designs vary by manufacturer and seabed conditions, with more armor added where needed, such as where waves and currents are strong ([ICPC 2011](#)). The life expectancy for an undersea transmission cable is between 30 and 40 years ([DBEDT 2013h](#)). There are systems in Europe that have been in place since the early 1960s and are still functioning.

Electrical charge movement through AC and HVDC undersea cables generate electromagnetic fields (EMF). Electrical fields are proportional to the voltage in a cable, and magnetic fields are proportional to the current ([NOAA 2007](#); [OSPAR 2012](#)). Electromagnetic fields also come from natural sources, such as the earth’s magnetic field. Electrical fields are retained within the cabling through industry-standard shielding; however, magnetic fields are not completely retained within an undersea cable.

Table 2-31. Features of Major Undersea Power Cable Systems

Statistic	Name	Location	Cable Type	Voltage (kV)	Capacity (MW)	Length (miles)	Diameter (inches)	Maximum Depth (feet)	Year Installed	
Longest AC undersea power cable:	101 miles	Martin Linge Field	Northern North Sea-Norway	AC	145	55	101	6.5 – 8.1	1,214	Proposed
Longest HVDC undersea power cable:	360 miles	NorNed	Netherlands-Norway	HVDC	450	700	360	Unknown	1,345	2008
Deepest undersea power cable:	5,380 feet	SAPEI	Italy	HVDC	500	1,000	261	Unknown	5,380	2011
Highest capacity undersea system:	2,000 MW	Cross-Channel	UK-France	HVDC	270	2,000	28	Unknown	5,249	1986
Year of installation of first HVDC undersea power cable:	1954	Gotland	Sweden	HVDC	100	20	60	Unknown	Unknown	1954

Sources: [ABB 2010, 2012](#); [DBEDT 2013h](#).

kV = kilovolt; MW = megawatt.

In order to facilitate the distribution of electricity through undersea cables, transition sites between undersea cables and land-based grids must be developed (see [Section 2.3.5.1](#) of this PEIS). Land-sea cable transition sites manage the transfer of electricity between power generation sites and undersea cables, and between cables and on-island grids. Power can be transferred in either direction. An interisland (i.e., island-to-island) undersea cable would require land-sea cable transition sites at both ends of the cable, while an undersea cable from a marine-based alternative energy source, such as an offshore wind turbine or ocean thermal energy conversion facility, would require a single land-sea cable transition site.

The main features of a land-sea transition site are the converter station, which would be built onshore (see [Figure 2-62](#)), and the connecting cables, which would be installed on land to reach power generation and distribution sources and in shallow water to reach the end point of the undersea cable.

Converter stations typically include rectifiers (which convert AC to DC) and inverters (which convert DC to AC). The conversion equipment is housed inside a building, which provides electromagnetic shielding and noise reduction to the external environment. Transformers and switching gear equipment characteristic of transmission substations would be located adjacent to the building. A chain-link security fence would enclose the entire site, and an access road(s) may be constructed to allow for routine maintenance.

LAND-SEA CABLE CHARACTERISTICS

Land-sea cable transition sites would use AC cables to connect to on-island grids.

A typical converter station consists of transformers, switches, and other high-power electrical components. Its function is to convert AC into DC (and vice versa) and to step up or step down cable voltage.

Marine-based alternative energy sources usually connect to land-sea cable transition sites using AC undersea cables. For AC undersea cables, the converter station would only function to step up or step down cable voltage.

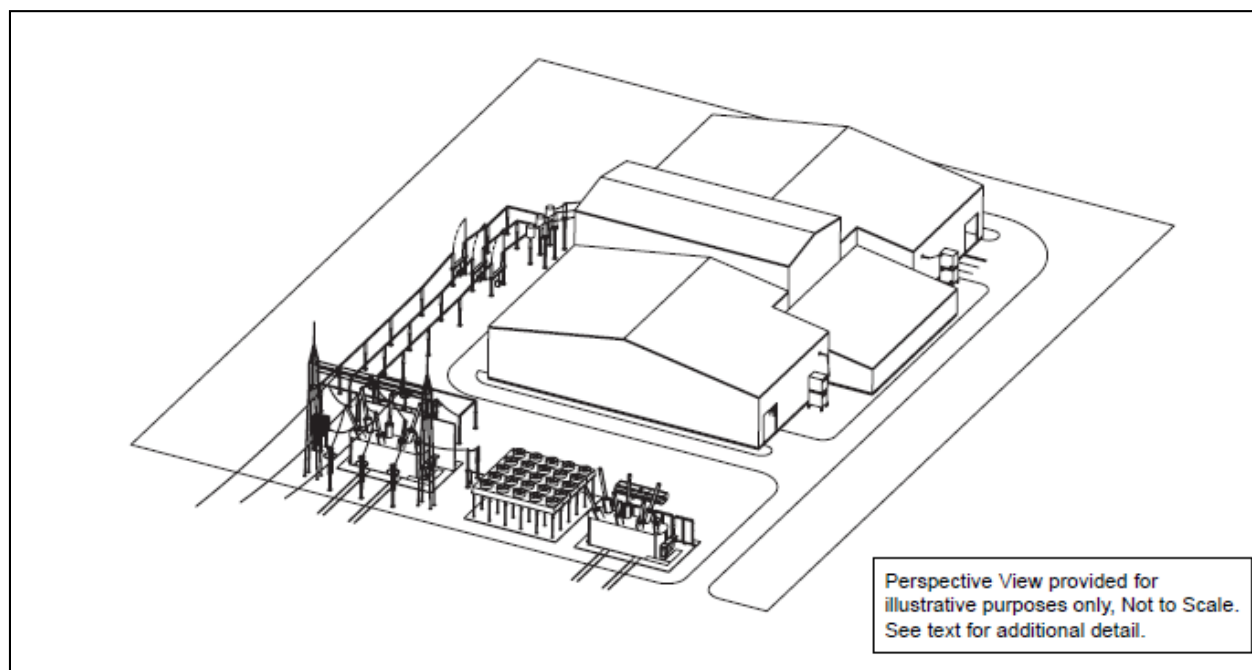

Figure 2-62. Schematic of Typical Converter Station

2.3.5.2.2 Characterization of Technology Feasibility and Deployment

In its current configuration, each island in Hawai‘i maintains its own isolated power grid. An undersea cable could be used to interconnect these island grids. Power generated on an island where renewable energy potential is high but demand is low could be transmitted to a location where the demand for energy is high, but viable amounts of renewable energy resources to meet the demand are limited. An interisland cable also could provide emergency backup electricity between islands because electricity could flow through the cables in either direction.

HVDC or AC undersea cable could be used to connect an island to offshore energy facilities. Interisland cables most likely would be HVDC because more power can be transmitted more efficiently over longer distance with lower losses and at lower capital costs. From a technical perspective, an AC interisland undersea cable could be used to interconnect Molokai and Lāna‘i, and even to Maui, but an AC cable cannot currently be used to efficiently connect O‘ahu to any of the other islands because of the longer distance ([NREL 2011b](#)). AC undersea cables are typically heavier than HVDC cables, which could further complicate installation in deeper waters. [Figure 2-63](#) shows the distances and depths for the major channels between the islands, along with a cutaway diagram of an HVDC undersea cable.

Figure 2-63. Characteristics of Deep Sea Channels in Hawai‘i and HVDC Undersea Cable Diagram (Source: [BOEM 2013](#))

Potential undersea power cable routes depend on the location of energy generation sources and suitable land-sea cable transition sites. Once the end point areas are identified, existing bathymetry, critical habitats, and seafloor data for the study area are analyzed. The contour of the ocean bottom includes hills, valleys, and plateaus, just like the surface of dry land. Additional ocean floor studies may be necessary to address data gaps. To the extent feasible, cable corridors would be sited to minimize cable length and trenching between end points. Cable length may be extended to avoid sensitive areas. Deep-water areas with a muddy seafloor are often preferred for siting cable corridors, as they would facilitate burial of an

undersea cable. Existing and proposed undersea telecommunication cables and pipelines would be avoided to the extent practicable. Future ocean surveys would verify the positions of existing undersea telecommunication cables.

Challenges in siting interisland undersea cable corridors in Hawai‘i include ([DBEDT and SOEST 2010](#)):

- Minimizing corridor length in whale sanctuary and other environmentally sensitive or restrictive areas (connecting Molokai, Lāna‘i, and Maui would require cables in the Hawaiian Islands Humpback Whale National Marine Sanctuary);
- Avoiding deep-water obstacles, such as former reefs, and dumped materials and munitions;
- Avoiding coral reefs, which fringe all the islands and living (including precious) corals and extremely rugged seafloor dominate between east Lāna‘i and west Maui (Kihei);
- Presence of submarine canyons and landslides west of Molokai due to steep slopes; and
- Minimizing crossing existing telecommunication cables, including military telecommunication cables, which will require coordination with DoD.

While there are no undersea power cables or land-sea cable transition site in Hawai‘i, they are technically feasible. Current substation distribution would play a factor in siting the converter stations, as well as environmental siting considerations. Space requirements would be minimized and potential sites would likely be within 0.5 mile of the shoreline ([AECOM 2012a](#)). Specific configurations for the converter station are dependent on the power requirements of the undersea cable.

2.3.5.2.3 Permitting and Consultation Requirements

[Section 2.2.5](#) above discusses general permitting requirements for clean energy projects in Hawai‘i. A detailed listing of regulatory review requirements, permits, and approvals for an undersea cable is included in Appendix C of the 2012 [HIREP Reference Information Report](#). The following text regards some of the key permitting and consultation requirements specific to undersea cables.

Permitting an interisland cable and associated generation and conversion facilities would require extensive coordination with many Federal, State, and county agencies (at least two counties would be involved). In addition to the required environmental, land use, and construction permits, cable developers must obtain the right to use the sea floor from BOEM (3 miles and farther from the coastline) and the Hawai‘i DLNR for seafloor use within 3 miles of the coastline. It is important that developers coordinate with these two agencies to ensure the submerged land use approvals coincide with each other and the proposed cable route. Developers should also consult with DoD and NPS early in the design process to ensure the proposed cable route and construction activities do not impinge on military operations and to avoid conflicts with NPS resources. In addition, projects should be designed to minimize impacts to Hawai‘i’s ocean-based commercial and recreational activities. Developers should consult the Hawai‘i Office of Planning on proper ocean spatial planning issues. If an undersea cable route were proposed to be located near a protected marine habitat, the developers must also consult with the NOAA NMFS for permits relating to those concerns ([DOE 2009a](#)). The developers also would consult with the USFWS and the NOAA NMFS on projects impacting protected species, *critical habitat*, and [EFH](#). Additionally, developers should consult with NPS on projects that could have impacts on sensitive resources of the National Park System and other protected resources and with the NOAA Office of Marine Sanctuaries if the cable route crosses the Hawaiian Islands Humpback Whale National Marine Sanctuary.

Planning undersea power cable routes along existing telecommunication cable routes has benefits and drawbacks; for example, adjacent siting of a new cable may minimize environmental and ecological impacts and potentially leverage existing environmental reviews; however, new cables cannot have the potential to interfere with existing cable operations.

Compensatory mitigation under CWA Section 404 could be required if projects involve unavoidable impacts to species and their habitat, including coral reefs. Best management practices such as those presented in Section 3.4.6.2 should be incorporated into project-level analyses to minimize damage from moorings, anchors, anchor lines, and pipelines during construction, particularly in areas near coral reefs. Areas should be designated for moorings and anchors that specifically avoid impacts to corals, and areas of high coral value should be marked with buoys to ensure avoidance of those areas during construction.

Regulations for an Undersea Power Cable

On June 27, 2012, the Hawai‘i Legislature signed [Act 165](#) into law establishing a regulatory framework for the installation and implementation of proposed interisland electric transmission cable systems ([DBEDT 2013d](#)). The PUC was granted review and approval authority for proposed undersea cable systems. In addition, certification criteria for the selection and approval of potential cable developers were established. It is important to note that that the statute does not mandate an interisland cable, or stipulate where the cable goes or the source of the energy that it may carry ([Hawai‘i State Legislature 2012](#)). It only establishes the regulatory structure.

Agency Jurisdictions for Interisland Electrical Power Transmission Cables

Under EPA Act 2005, BOEM has authority to issue right-of-way grants for proposed undersea cables located on Federal submerged lands of the Outer Continental Shelf located 3 to 200 nautical miles offshore. The right-of-way grants are 200 feet in width, centered on the cable, unless safety and environmental factors during construction and maintenance of the associated cable or pipeline require a greater width ([BOEM 2013](#)). BOEM is not authorized to issue right-of-ways within the National Park System, National Wildlife System, National Marine Sanctuary System, or National Monument. Where the prospective project requires access on, across, or through these lands or waters, a special use permit from NPS under [36 CFR 1.6](#) will be necessary.

The NOAA Office of National Marine Sanctuaries oversees policies and permit guidance for installing and maintaining undersea cables in National Marine Sanctuaries pursuant to Section 304(d) of the National Marine Sanctuaries Act ([16 U.S.C. 1431–1445](#)). NOAA’s *Policy and Permit Guidance for Submarine Cable Projects* was developed to provide guidance on review of applications to install and maintain submarine cables in National Marine Sanctuaries ([NOAA 2011](#)). Because some National Marine Sanctuaries have varying jurisdictions and activities, several sanctuaries are subject to different review and approval processes than those in the guidelines, including the Hawaiian Islands Humpback Whale National Marine Sanctuary. However, in all National Marine Sanctuaries, if another Federal permit or license is required to install an undersea cable, the Federal agency issuing the permit must consult with the Office of National Marine Sanctuaries in accordance with [Section 304\(d\) of the National Marine Sanctuaries Act](#).

2.3.5.2.4 Representative Project

As with the other representative projects identified in Chapter 2, the representative undersea cable project has been developed for analytical purposes only and is not intended to represent any real, proposed project by either the DOE, the State of Hawai‘i, or any private entities. The representative project would involve interconnecting two islands with a 10-inch-diameter HVDC undersea cable. The undersea cable would have two-way transmission capability and would transmit 200 megawatts of renewable energy without grid instability. The cable would be 150 kilovolts.

The undersea cable would transfer power between two islands, bounded by two land-sea cable transition sites with a converter station at each end. Both converter stations would be designed to transmit and receive power. Each station would be designed to receive AC power from a renewable energy generation source (e.g., PV or wind turbine) or an island grid and convert that power to high-voltage DC for undersea cable transmission, and then receive high-voltage DC power from an undersea cable, convert that power back to AC, and transmit it to the island's electrical grid for distribution. Construction of the converter stations would take approximately 24 months. The grading and foundation work would require 20 construction workers, and building erection would require 10 to 15 construction workers. AC and DC electrical installation would require 20 additional construction workers. The tallest structures of the converter stations would extend up to 40 feet above ground level and be properly shielded and insulated to minimize noise and electromagnetic interference. The stations each would have a total footprint of 6 acres (3 acres plus an additional 3 acres for laydown and future expansion) ([AECOM 2012b](#)). They would each be located within 0.5 mile from the shoreline and within 10,000 feet of the endpoints of the cable.

Connection cable lengths and the amount of trenching needed would be minimized; however, cable length may be extended to avoid sensitive areas. Connecting cables from the converter station to the undersea cable connection point is particularly challenging, as the cable route may potentially cross sensitive nearshore coral zones. Horizontal directional drilling (HDD), a form of trenchless drilling that minimizes construction impacts, would be used to install cables in shore crossings ([AECOM 2012b](#)):

- HDD is a method of drilling an underground hole from a surface location along a prescribed bore path, suitable for installation of cable conduit. This technology was developed and utilized extensively by the oil and gas industry, making its use for an undersea cable landing safe and tested. Knowledge of the geology along the proposed bore route is extremely important for successful drilling.
- HDD bore diameter will be approximately twice the cable diameter.
- Directionally drilled micro-tunnels used in shore areas to minimize impacts can be up to three-quarter-mile long.
- HDD boring equipment requires a relatively short set-up time and a directional drilling rig can be set up and begin boring within a very short time. Labor requirements are minimal, as it only takes a small crew to operate a directional drilling rig. The temporary land requirement for a directional drilling setup is approximately 1 acre.
- The process starts with the positioning of the drilling rig at the desired start point and a small pilot hole is drilled. The directional drill rig then pushes a small-diameter bore head connected to a hollow steel drill pipe into the ground at an angle, where the rotating drill bit starts to drill. As each section of drill pipe is pushed into the ground a new section is added behind it. This process continues until the drill has reached its destination point.
- The drilling machine pumps a high-pressure jet of drilling slurry, which is generally a mixture of bentonite clay and water, through the pipe to the drill head. Selection of the drilling fluid varies on the soil conditions and geology of the region. Drilling is accomplished through the cutting action of the rotating drill bit and the high-pressure fluid jet. The drilling slurry performs several tasks: cutting the soil, lubricating and cooling the rotating drill pipe, and sealing the inner surface of the bore hole.
- Drilling waste includes the drilling fluid and solids removed from the bore, both of which require disposal. Temporary pits for drilling waste storage are dug at the points where the pilot hole is

drilled. The solids suspended in the drilling fluid are separated and removed, and the fluid is then recycled back into the drill pipe. Drilling waste disposal options are determined on a site-specific basis.

- The most commonly used equipment for determining the location of the bore head while it is submerged is a transmitter and receiver system, with the transmitter located behind the bore head and the receiver box located above grade or in a small boat on the water. The transmitter registers the drill bit angle, rotation, magnetic direction, and temperature data and sends an encoded signal to the receiver to decode and relay to the operator. If needed, divers would position a remote antenna over the drill head to send signals back to the surface.
- When the drill bit reaches the exit point, workers remove the drill bit and install a hole-reaming bit. The HDD equipment then pulls the drill bit back through the bore toward the point of entry, rotating the drill pipe with as many passes as required to reach the correct diameter of the hole for installation of the main conduit pipe. Drilling rates for smaller pilot holes can range from 100 to 300 feet per day, depending on how well the location and depth of the drill head can be monitored by divers and how hard the undersea soil or rock conditions are. The longer the hole, the heavier the drill fluid would need to be to seal and lubricate the drill shaft.
- Once the correct size of the bore hole is reached for the cable conduit, workers would remove the reamer bit and reel the cable conduit out, and divers would attach the cable to the end of the drill pipe. Workers would arrange the assembled cable conduit and the HDD would pull it back through the bore hole. Throughout this process, bore fluid is being continually pumped into the hole to ensure that the hole is sealed with no void left between the drill pipe and the native soil.
- The connection point to the undersea cable would be located at least 10,000 feet from the shoreline due to the extent of HDD drilling reach, and endpoint connections are generally covered with rock or concrete to protect the emergence point of the cable.

The undersea cable would connect to the land-sea transition sites 10,000 feet from the shoreline using the HDD drilling method described above. Technical requirements for installing the interisland cable between these connections points are as follows ([DBEDT and SOEST 2010](#)):

- The lay rate for the cable-laying ship would be 2 to 3 knots in good conditions.
- Existing cable technology and laying techniques (direct lay or buried) can be used at ocean depths up to one-half mile;
- For cable protection, burial from 3 to 5 feet below the ocean floor is desirable in waters up to 328 feet deep, and may be considered for all water depths; and
- To the extent feasible, cables should route around steep slopes, sharp changes in slopes, suspended spans, sharp turns, or protected area.

General construction activities for the installation of an undersea cable could include the following ([AECOM 2012b](#)):

- The cable is laid on the seabed utilizing a cable-laying ship. A large cable reel located at the back of the cable-laying ship lets out the cable onto the ocean floor using a global positioning system.

- Starting at the land-sea cable connection point, the ship lets out the cable using floats, pontoons, or a barge to position the cable for attachment to an anchor point. Once the cable is anchored, the pontoons are removed and the cable is lowered to the ocean floor; the ship moves along its designated path toward the cable endpoint, and the cable continues lowering to the ocean floor.
- Once the ship approaches the end of the cable route, the cable on the ship is attached to the pontoons to enable the cable to be pulled to the point of connection (i.e., a connection point to a land-sea cable site).
- Before the final connection is made at the endpoint, an underwater robotic cable installation machine or remotely operated vehicle buries the cable, usually 3 to 5 feet below the ocean floor. Cables can be installed below the seabed at cable lay time or later after the cable has been laid on the ocean floor surface.
- There may be a need to cross seabed obstructions, especially in areas that are congested with submarine pipelines and other cables. In such case, use concrete mattresses to support the cable over obstructions, and/or cover the obstruction with protective cable sleeves.
- Cable-laying speed is faster in shallow waters than deeper waters because (1) it is easier to control the cable-laying direction and (2) the ship can travel faster and still maintain cable installation location.
- Shallow waters tend to hamper the movement of the ship, requiring that the cables be moved to shore using smaller vessels, such as tugs and barges, to pull the cables to the connection point.
- HVDC cable installation may occur in two primary ways: laying on the surface of the ocean floor or burial through shallow trenches on the ocean floor. For those instances when the cable is buried, the following activities would be implemented:
 - Cables placed and installed at the same time employ a larger robotic cable installer using a plow located at the front of the machine, which simultaneously plows a trench ahead of the cable and lays the cable into the plowed trench.
 - Cables placed onto the ocean floor surface and installed later after the cable is positioned use a remotely operated water jet installer, which is usually smaller and quicker to deploy. The robotic cable installer travels along the cable and lifts it up while high-pressure water jets excavate a trench, just wide enough for the cable. The installer machine then lays the cable back down in the trench as it propels itself along. The trench fills itself in over a short period of time due to natural wave and sediment movement along the ocean floor.
- If large rocks or formations are encountered, the cable installation machine sends a signal back to the operator and halts installation.

2.3.5.3 Smart Grid

Smart grid has become a widely used term-of-art across the utility industry. While specific goals and impacts of smart grid deployment vary from utility to utility, the benefits of investments in smart grid projects generally fall into five areas ([ElectricityPolicy.com 2011](http://ElectricityPolicy.com)):

- Projects designed to reduce peak capacity. These range from demand response (turning off loads at designated time) to energy storage (moving demand from on peak to off peak).

- Projects designed to improve operational efficiency. These include smart meters, smart transformers, and relays. All are focused on better and less costly operation of the grid.
- Projects that are designed to improve reliability. These range from micro grids to phasor measurement units. All are focused on reducing or preventing both short-term and long-term outages.
- Projects that are designed to improve the overall efficiency of the grid (i.e., less kilowatt-hours for a given performance). These range from consumer energy management and smart appliances to more efficient cables and devices. All are focused on reducing the amount of energy required and resulting emissions.
- Projects that are designed to integrate new clean technologies into the grid. These include smart electronic vehicles, renewables, and batteries. All are focused on reducing the emissions per megawatt-hour on the grid.

In 2007 the DOE released a study that described the key technologies required to create a smart (modern) grid. The study included the following findings regarding the uses of these technologies:

- Increased use of digital information and controls technology to improve reliability, security, and efficiency of the electrical grid.
- Dynamic optimization of grid operations and resources, with full cyber security.
- Deployment and integration of distributed resources and generation, including renewable resources.
- Development and incorporation of demand response, demand-side resources, and energy-efficiency resources.
- Deployment of smart technologies (real-time, automated, interactive technologies that optimize the physical operation of appliances and consumer devices) for metering, communications concerning grid operations and status, and distribution automation.
- Integration of “smart” appliances and consumer devices.
- Deployment and integration of advanced electricity storage and peak-shaving technologies, including plug-in electric and hybrid-electric vehicles, and thermal- storage air conditioning.
- Provision to consumers of timely information and control options.
- Development of standards for communication and interoperability of appliances and equipment connected to the electrical grid, including the infrastructure serving the grid.
- Identification and lowering of unreasonable or unnecessary barriers to adoption of smart grid technologies, practices, and services.

National-level policy makers often refer to the national grid as having three main interconnections: the Eastern Interconnect, the Western Interconnect, and the Electric Reliability Council of Texas. These are three largely independent and extremely complex systems whose design and operations have their own

unique features and challenges. Both Hawai‘i and Alaska have their own unique grids and that both states actually have more than one grid.

In addition to national efforts, on April 23, 2013, the Governor of Hawai‘i signed into law [Act 34](#) of 2013, relating to electric systems and addressing smart grid technologies. The bill authorizes the PUC to consider the value of implementing advanced grid modernization technology in the State. In addition, local utilities have smart grid programs that vary in scope and timelines with much of the emphasis on grid stability and variable source integration.

2.3.5.3.1 Technology Description

Understanding how the electrical grid works is key to understanding how the abovementioned smart grid technologies work and how they can be deployed. [Section 2.3.5.1.1](#) of this PEIS provides a brief tutorial on the electric power cycle. While new technologies and companies are emerging all the time, the five basic areas of related technology innovation are illustrated in [Figure 2-64](#) and described in the following text.

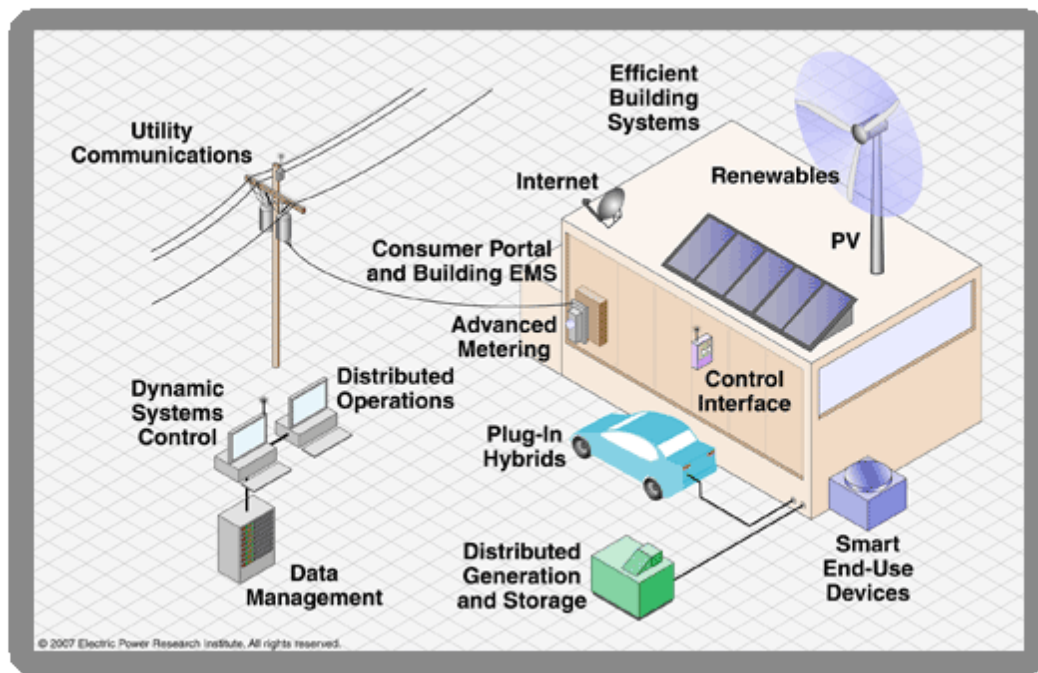

Figure 2-64. Diagram of Smart Grid Integration

- **Integrated Communications** – High-speed, fully integrated, two-way communication technologies that make the modern grid a dynamic, interactive “mega-infrastructure” for real-time information and power exchange. An open architecture creates a plug-and-play environment that securely networks grid components and operators, enabling them to talk, listen and interact.
- **Advanced Components** – Advanced components play an active role in determining the electrical behavior of the grid. These power system devices apply the latest research in materials, superconductivity, energy storage, power electronics, and microelectronics to produce higher power densities, greater reliability and power quality, enhanced electrical efficiency that produces major environmental gains and improved real-time diagnostics.

- Advanced Control Methods – New methods and algorithms monitor power system components, enabling rapid diagnosis and timely, appropriate response to any event. They also support market pricing and enhance asset management and efficient operations.
- Sensing and Measurement – Technologies that enhance power system measurements and enable the transformation of data into information. They evaluate the health of equipment and the integrity of the grid, and they also support advanced protective relaying. They enable consumer choice and demand response, and help relieve congestion.
- Improved Interfaces and Decision Support – The modern grid will require wide, seamless, often real-time use of applications and tools that enable grid operators and managers to make decisions quickly. Decision support and improved interfaces will enable more accurate and timely human decision-making at all levels of the grid, including the consumer level, while also enabling more advanced operator training.

Many utilities have programs underway as a normal course of business that modernize their systems. For example, utilities replace aging transformers, capacitor banks, and relays at a certain rate each year with state-of-the-art equipment that can be monitored and operated remotely. Utilities are upgrading their information technology infrastructure with more sophisticated communication platforms as well as software that automates various processes including engineering, operations, and customer management.

Smart meters are often thought to be synonymous with smart grid, when they are just one technology (or set of technologies) of a smart grid system. Smart meters remotely measure the amount of electricity a specific customer uses. Many utilities have found that using smart meters at the edge of the grid offers many benefits, including the ability to actively monitor power outages and restorations, remotely connecting and disconnecting customers, and managing line voltages to tighter tolerances.

2.3.5.3.2 Feasibility and Deployment of Smart Grid

Hawai‘i has several smart grid projects in various stages of deployment. The early successes of many of these projects have already begun to demonstrate the feasibility of implementing smart grid in Hawai‘i. Four of the most substantial and relevant projects are outlined below.

Maui Smart Grid Project

The Maui Smart Grid Project (<http://www.mauismartgrid.com>) is a demonstration project that was funded by the DOE’s Renewable and Distributed Systems Integration program through the ARRA. The total budget for the project was \$15 million from 2009 to 2013, with \$7 million in DOE funds and \$8 million cost share with partners. The HNEI (based at the University of Hawai‘i at Manoa) and MECO led the project team. The Maui Smart Grid Project tested the feasibility of smart grid technology on Maui and evaluated new smart grid technologies to enable a cleaner, more efficient energy system on the island. This pilot project took place in the Maui Meadows neighborhood in South Kihei on a voluntary, opt-in basis. All participants had a smart meter professionally installed at their house and received access to a personalized energy data website. Through this website, participants can easily monitor and control their energy consumption. The project will collect data for at least one year and submit a report to the DOE, evaluating the technologies and impacts on volunteer energy usage on Maui. Project results will be compared with other demonstration projects throughout the United States and also be used for decision-making on future smart grid initiatives in Hawai‘i.

Project objectives are as follows ([HNEI 2009c](#)):

- Reduce distribution circuit peak loading by greater than 15 percent by demand response, switching peak loads to energy storage, and reducing voltage.
- Improve service quality by using integrated voltage/variance control and outage management.
- Enable consumers to manage their energy use to minimize electric bills by using customer portals and advanced home energy gateways for a few homes.
- Support grid stability with controllable loads, storage, and improved voltage/current information.
- Enable greater utilization of as-available renewable energy sources by providing measurement and estimation of distributed PV to the utility operator.

Kaua'i Smart Grid Demonstration Project (Smart Meter Installation)

In November 2009, pursuant to the ARRA, DOE awarded KIUC and 26 other electric cooperatives from 10 states a \$33.9 million matching grant for the National Rural Electric Cooperative Association's Cooperative Research Network smart grid project. The total cost of the joint project is \$67 million; KIUC's portion is \$11 million, of which \$5.5 million is being covered by ARRA funds. The purpose of the project is to test and develop technologies that operate together to make the electrical power grid more efficient and reliable. The KIUC project involves replacing about 33,000 meters with smart meters, along with communications infrastructure that will allow two-way communication between the meter and KIUC (see <http://website.kiuc.coop/content/smart-grid>). The 5-year project includes 2 years to replace all 33,000 meters and 3 years to observe and access their functionality and collect energy usage data. Installation of smart meters is almost complete, and the project is expected to continue on time.

Project objectives are as follows ([KIUC 2011](#); [Cicotello 2012](#)):

- Enable KIUC to read meters remotely,
- Demonstrate the effectiveness of load control and demand response options within households,
- Manage and detect outages to the household level, and
- Evaluate different rate designs depending on usage.

Jump Start Maui Project

Japan's Hitachi, Cyber Defense Institute, and Mizuho Corporate Bank are working with HECO, the State of Hawai'i, the University of Hawai'i, and United States national laboratories on a smart grid demonstration project on the island of Maui (see <http://maui.com/?p=398>). The project is based on the [Japan-U.S. Clean Energy Technologies Action Plan of 2009](#) and has a projected budget of \$37 million. Hitachi, along with the other participants, conducted a feasibility study in 2011. Based on the results, the project is expected to begin in the winter of 2013 and conclude in the winter of 2015. Technologies that will be utilized include power distribution control, demand-side load control, control-information and communication technology platform, electric vehicles operation and charging control, multiple types of rapid chargers, and information and telecommunications technologies ([JUMPSmart Maui 2013](#)).

Project objectives are as follows ([Peeples 2011](#)):

- Implement advanced load shifting for optimum use of renewables,

- Increase the level of direct control of home appliances and solar generation output to manage quick changes in power supply and demand,
- Integrate electronic vehicle management systems with the grid management system to manage the impacts of high electronic vehicle concentrations,
- Introduce autonomous control architecture (intended to support scalability and rapid response energy control), and
- Increase cyber security.

U.S. Department of Defense SPIDERS Project (Wheeler Army Airfield)

SPIDERS, or Smart Power Infrastructure Demonstration for Energy Reliability and Security, represents the latest Joint Capability Technology Demonstration project involving the DOE, DoD, and DHS. The SPIDERS project demonstrates energy secure micro grids and transitions them as real property improvements at three DoD locations. Phase I was a circuit-sized demonstration at Joint Base Pearl Harbor Hickam followed by a larger Phase II effort at Fort Carson, Colorado. The largest project, an installation-sized micro grid at Camp H.M. Smith in Honolulu, will incorporate the entire base into the micro grid and is still in the initial planning stages ([Sandia 2012b](#)). Project objectives are as follows:

- Protect defense-critical infrastructure from power loss due to physical disruptions or cyber attacks to the bulk electrical grid.
- Integrate renewable energy sources and other distributed generation to power defense-critical infrastructure in times of emergency.
- Sustain critical operations during prolonged utility power outages.
- Manage DoD installation electrical power and consumption efficiently to reduce petroleum demand, carbon footprint, and cost.

The Army's Aloha Micro Grid Project: Smart Charging Micro Grid

The Smart-Charging Micro Grid system at the Wheeler Army Airfield base consists of a 25-kilowatt solar array on a carport, 200 kilowatt-hours of battery storage capacity, and four plug-in electric vehicles. The system powers the four electric vehicles and also has the ability to provide instant backup power to support three buildings for 72 hours, including the Garrison headquarters ([U.S. Army 2011](#)).

Based on the examples above it is clear that the electrical grid is in the process of evolving to a much different system that supports more real-time optimization, more diverse sources of electricity, more actively managed customer loads, and more dramatic variability. Hawai'i will continue to invest in a smarter grid to meet all these demands, and while the environmental impact will not be zero, the net impact of integrating more clean-energy sources will have a positive benefit.

Hawai'i is somewhat unique compared to the rest of the United States because of the large military/government loads that are served. While infrastructure improvements are paid for by the U.S. government, the infrastructure often must integrate with the local electrical distribution system. While infrastructure improvements represent large opportunities for demand response and other operational strategies, they also represent a very major critical load that has unique reliability requirements.

2.3.5.3.3 Permitting Requirements

See [Section 2.2.5](#) for a discussion on general permitting and regulatory requirements for proposed clean energy projects in Hawai‘i. Before implementation, smart grid projects must first meet local technical codes and requirements. Furthermore, individual counties within the State may require island-specific permits for construction activities, such as laying new utility lines that may play a role in any smart grid development ([DBEDT 2013a](#), [2013n](#)).

In addition, before utilities accept and deploy smart meters, these devices must meet a number of national and industry standards and comply with State and local codes designed to ensure proper operation, functionality, and safety. Smart meters are designed and certified to comply with:

- ANSI [C12.1](#), [C12.10](#), and [C12.20](#): Standards for accuracy and performance;
- [NEMASG-AMI 1](#), “Requirements for Smart Meter Upgradability”; and
- Title 47 CFR [1.1307\(b\)](#), [1.1310](#), [2.1091](#), [2.1093](#), Federal Communications Commission standards for intentional and unintentional radio emissions and safety related RF exposure: Parts 1 and 2 of the Commission’s Rules and Regulations.

The Edison Electric Institute and other industry groups prepared *A Discussion of Smart Meters and RF Exposure Issues*, which provides a relevant summary of key requirements and observations related to potential radio frequency exposure ([EEI, AEIC and UTC 2011](#)).

2.3.5.3.4 Representative Project

A representative smart grid project is assumed to consist of the following:

- Two-way communicating digital meters for every customer with the ability to control a small number of in-home/in-business devices.
- A comprehensive, robust, secure communications infrastructure capable of near real-time communication to more than 100,000 remote devices. Existing communications infrastructure would be used, including fiber optic cables connecting to radio towers and take out points that receive the signals from the remote wireless devices.
- Digital power equipment throughout 50 percent of the grid capable of real-time monitoring and communication.
- A robust geographic information system-based grid operation platform capable of collecting all remote data, performing real time analysis, and making operational decisions for both normal and emergency operations (including the ability to manage significant variable sources).
- A customer data collection and management system capable of providing near real time feedback to customers and control signals for significant customer loads.

Impacts from construction and operation activities related to the deployment of these smart grid technologies (e.g., replacement of existing meters in the customer facilities, installation of new fiber optic cable using existing structures, and installation of new instrumentation at the utility) would be minimal. However, as technologies advance, the requirements of existing jobs will change. Gridwise Alliance’s study on smart grid workforce trends predicts that utility companies and other smart grid stakeholders will need to focus a considerable effort toward both retraining current employees and recruiting new ones as

the growing industry creates more jobs ([GridWise 2011](#)). Specific workforce classifications that would be affected by smart grid deployment include the following:

- Line technicians
- Meter readers
- Meter electricians
- Engineer (new construction)
- System operation/dispatch
- Administrative support
- Substation operations
- Engineering support (planning/reliability)
- Management/supervision
- Customer service representatives
- Supply chain
- Meter lab repair
- New hires
- Communications technicians
- Contract construction/engineering labor
- Other support (IT, staffing)

Smart meters are one of the more controversial elements of a representative project and have drawn some concerns from certain public groups primarily focused on wireless radio frequency exposure. Industry has played a role in research and development and has completed a number of reports and studies on the topic, available from the Maui Smart Grid Project website: <http://www.mauismartgrid.com/category/news/>.

Smart grid projects vary substantially from utility to utility. However, the benefits of a comprehensive smart grid deployment in Hawai'i are many relative to other places in the United States for several reasons including the high cost of energy, the high penetration of variable power sources, and the small size of the grid(s). Specific technology choices are not critical to assessing the environmental impact of a representative project. Implementing such a project is largely software- and telecommunications-based with minimal impact.

2.3.5.4 Energy Storage

Traditional utility models track electricity from generation to demand but demand variations can be large, resulting in underutilized electricity, as represented in [Figure 2-65](#), resulting in underutilized electric generation and unbalanced loading. Energy storage can take electricity that is generated at one point in time and store it for use at a different time. Incorporating energy storage in the electricity distribution chain allows utilities to decouple generation from demand which has several benefits, including improved use of generated energy. This would help to minimize costs to utilities that, ultimately, would benefit ratepayers. Another benefit is delaying (or eliminating) large capital projects, such as transmission expansion, by using stored energy to alleviate bottlenecks. A third benefit is further integration of electricity from renewable energy resources whose availability may not be aligned with demand ([Baxter and Makansi 2002](#)).

Figure 2-65. Typical Weekday Demand for Hawai'i

Energy storage systems are designed with different energy densities, response times, time of operation, and power depending on the target application. In the electricity distribution chain, the primary applications for energy storage systems are:

- Energy Management – To provide electricity for use during a period other than the one during which it was generated. This energy storage system comes on slowly and lasts several hours.
- Bridging Power – To provide uninterrupted service when the generation source is switched. This energy storage system comes on quickly and lasts just a few minutes.
- Power Quality and Reliability – To ensure that any changes or fluctuations in power quality upstream do not impact sensitive users or equipment downstream. This energy storage system at times operates less than a second in response to the upstream fluctuation providing an uninterrupted power supply (UPS) to the equipment downstream.

Energy storage systems are designed to operate effectively in one or more of these applications. [Figure 2-66](#) shows the different energy storage technologies available by discharge time, amount of power (power rating), and application.

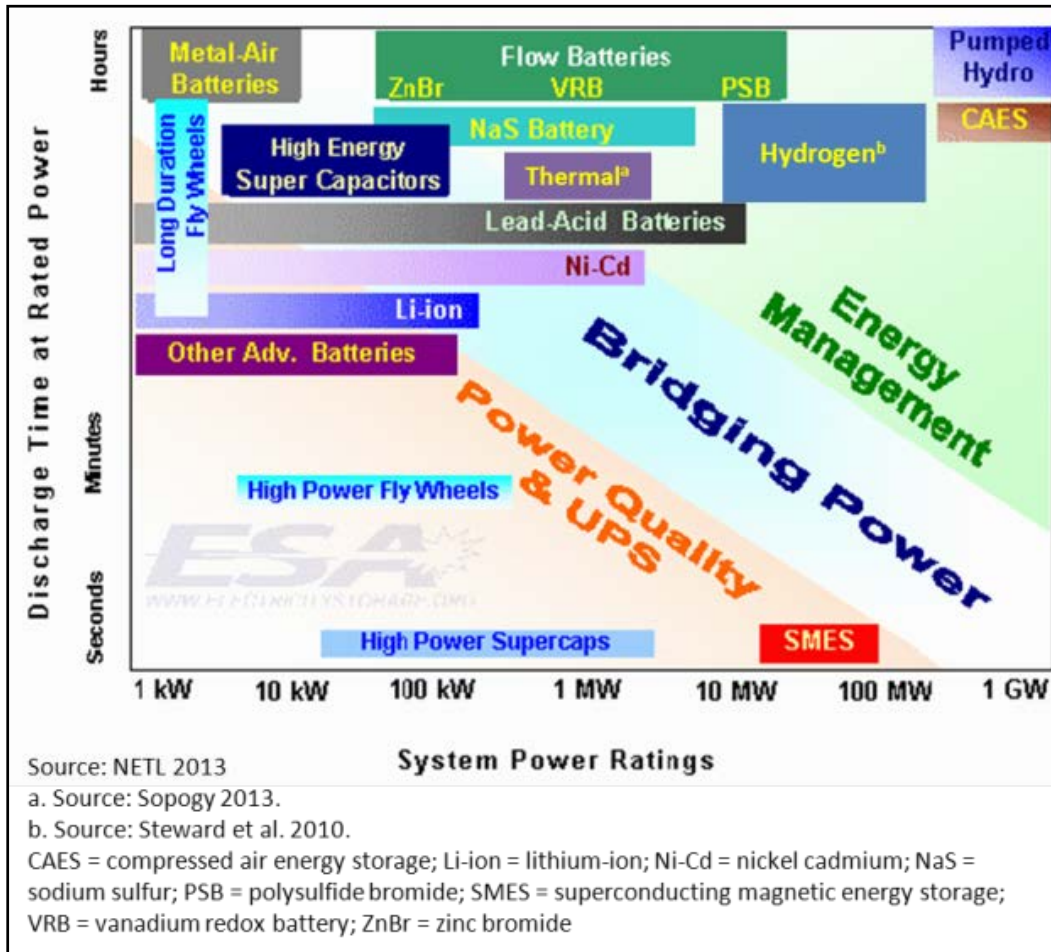

Figure 2-66. Power Rating vs. Discharge Time for Energy Storage Technologies

2.3.5.4.1 Technology Description

Energy storage can be achieved in a many ways, resulting in either long-term energy supply or short bursts of power depending on the application ([Baxter and Makansi 2002](#)). The text that follows briefly describes each of the technologies and their applications. The technologies are listed in alphabetical order. (See http://www.energyaccelerator.com/wp-content/uploads/2013/10/HawaiiEnergyStorageProjects_July2013_v3.pdf for a list of the Hawai'i energy storage projects.)

Capacitors

Capacitors store energy electrostatically. They contain two electrical conductors with an insulator, known as a dielectric, between them. When there is voltage across the conductors, an electric field develops with one side becoming positively charged and the other negatively charged. Capacitors can discharge rather quickly, making them ideal for power quality and bridging power applications ([Eyer and Corey 2010](#)). Ultra-capacitors essentially are two or more capacitors in series. [Figure 2-67](#) shows a 30-foot trailer housing 640 ultra-capacitors with a maximum power of 263 kilowatts ([Schneuwly 2009](#)).

Figure 2-67. Ultra Capacitor Installation

In a large system, the air can be stored in natural underground formations such as salt caverns, hard-rock mines, and aquifers ([Baxter and Makansi 2002](#); [Eyer and Corey 2010](#)). There are two plants using this technology; one in Alabama and one in Germany ([EPRI 2010](#)). For smaller quantities of compressed air, aboveground pressurized storage tanks or pipes can be used. Submerged systems are being considered by NELHA. Compressed air energy storage systems are used for energy management although the size of this storage is dependent on the turbine system that will use it and the amount of time in which it will operate; however, aboveground storage is typical for capacities on the order of 3 to 15 megawatts ([EPRI 2010](#)). [Figure 2-68](#) shows the process diagram for a generation facility with compressed air energy storage.

Compressed Air Energy Storage

A gas turbine uses air that is pressurized in the compressor section of the system. This pressurization typically uses two-thirds of the energy produced ([Baxter and Makansi 2002](#)). With compressed air energy storage, air is pressurized during low-demand times and stored for use during peak demand periods.

Flow Batteries

Batteries use electrochemical processes to convert chemical energy to electrical energy. They are composed of two or more electrochemical cells that include two electrodes and an electrolyte. Chemical reactions between the materials cause electrons to flow from one electrode to another, creating a current. Most batteries store the electrodes and electrolyte within a single container; however, with flow batteries the electrolyte is stored separately, outside of the battery container. The electrolyte flows into and out of the battery container during charging and discharging ([Eyer and Corey 2010](#)). Although the electrolyte is stored separately, this is still a closed loop system ([Baxter and Makansi 2002](#)). Some of the most common chemistries used in flow batteries are polysulfide bromide, vanadium redox battery, and zinc bromide ([Eyer and Corey 2010](#)). Flow batteries are used in energy management applications.

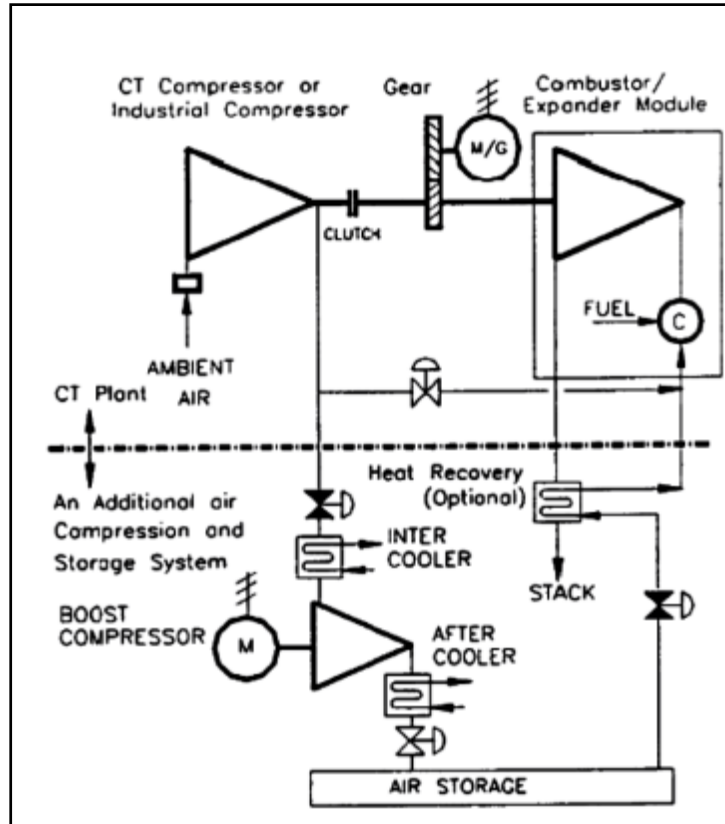

Figure 2-68. Process Diagram for a Turbine Generator System with Compressed Air Energy Storage (Source: NETL 2013)

The benefits of flow batteries are the separate storage of the electrolyte, which allows for more of the material to be added, thereby increasing the discharge duration. This configuration also allows for replacement of the electrolyte as it degrades without replacing the other components. Another benefit of flow batteries are their capacity to be customized based on the electrolytic tanks. As of June 2012, there was a 60-kilowatt zinc bromide project on O‘ahu serving as back-up power for an elevator ([DOE 2013u](#)).

Flywheels

Flywheels store energy in a spinning mass as inertial *kinetic energy*. The storage system consists of a cylinder with a rotor that is connected to a motor/generator, which accelerates the rotor to high speeds ([Figure 2-69](#)). Magnetic bearings limit friction losses and wear. When the energy is needed, the rotor is decelerated and the kinetic energy through the motor/generator is converted back to electrical energy. A robust enclosure surrounds all the components to protect anything on the

Figure 2-69. Flywheel Cross Section

exterior should there be a failure of the high-speed components ([Baxter and Makansi 2002](#); [Eyer and Corey 2010](#)).

Flywheels are designed for frequency regulation and reserve power. They have a fast response time, making them more effective than a conventional generator in stabilizing a system ([Akhil 2013](#)). For these reasons, flywheels are used in power quality and uninterruptible power supply applications.

Hydrogen

The production of hydrogen involves the conversion of electricity into a gas that can be used in a variety of applications, including [fuel cells](#), internal combustion engines, or in the production of liquids such as hydrogen-treated renewable jet fuel. Although the round-trip efficiency of electricity-to-hydrogen-to-electricity is less than other energy storage options, potential revenue from the sale of hydrogen for other

uses, including transportation and biofuel production, could influence specific project size, location, and feasibility ([Steward et al. 2010](#)). Hydrogen-related technologies are further discussed in [Sections 2.3.2.3](#) and [2.3.4.4](#).

Production of hydrogen through electrolysis (use of electricity to separate water into hydrogen and oxygen) could also be accomplished through electrolysis of sea water using excess renewable energy. For instance, excess wind energy could be used (instead of curtailing) to generate hydrogen, which could be stored until needed for energy generation.

Lead-Acid Batteries

Lead-acid batteries have the oldest chemistry of the batteries described here ([BCI 2013](#)). Lead-acid batteries are made in the traditional battery configuration of two electrodes and an electrolyte within a single container. Lead-acid batteries are reliable but have a limited operating range, which have kept them from being widely used in the electricity business ([Baxter and Makansi 2002](#)). Advanced lead-acid batteries are modern versions of lead-acid batteries that have addressed some of the limitations of traditional lead-acid batteries. These systems have additives like carbon and other additional components for improved performance, high power, or better cycle life ([Akhil 2013](#)). Lead-acid batteries are the most commonly used in energy management and bridging power applications.

Advanced lead-acid batteries that operate more efficiently and have an increased cycle life³² have been paired with solar and wind installations on Maui, Lānaʻi, Oʻahu, and Kauaʻi with some success ([DOE 2013u](#); [HNEI 2013c](#)). The sites vary in storage size from 1.5 to 15 megawatts. For example, the battery installation on Lānaʻi is paired with a 1.2-megawatt solar farm. The 1.125-megawatt battery system mitigates the solar generation's variability and allows the facility to sell its full capacity of 1.2 megawatts to MECO's Lānaʻi grid ([DOE 2013u](#)).

Lithium-ion Batteries

Like lead-acid and flow batteries, lithium-ion batteries use chemical reactions to store and release energy. There are a variety of slightly different chemistries in this group although all are generally referred to as lithium-ion ([Oberhofer 2012](#)). The electrodes of a lithium-ion battery are made of lightweight lithium and carbon. Within lithium-ion batteries there can be various cathode materials such as lithium iron phosphate (LiFePO₄) and lithium titanate (Li₄Ti₅O₁₂). The chemistry can store several times more watt-hours per kilogram compared with lead-acid batteries, making these batteries popular for portable consumer electronic products ([HNEI 2013c](#)). Within the electricity distribution chain, lithium-ion battery systems are still small, making them useful in power quality and uninterrupted power supply applications.

³² Cycle life is the life of a facility or unit based on the number of times it is used ([Baxter 2002](#)).

There are several projects in Hawai‘i where lithium-ion batteries are being used. The Ke Alahele Center, which is part of the Maui Economic Development Board Building, has a 16-kilowatt LiFePO₄ battery system in a power quality and grid stabilization application ([HNEI 2013c](#)). In addition, the MECO has selected lithium-ion batteries to provide energy storage capabilities to the Maui Smart Grid Project. The 1-megawatt system will deliver power for a full hour to reduce the peak energy load on the substation’s transformers thereby increasing grid stability and power quality ([MECO 2012](#)).

Pumped Storage Hydroelectric

Pumped storage hydroelectric consists of a lower and upper water reservoir, pumps, and a hydraulic turbine. When power is plentiful and cheap, water is pumped using a non-hydroelectric energy source from a lower elevation to a reservoir at a higher elevation. When energy is needed, water is released from the upper reservoir and passed through the turbine to generate power. Pumped storage units are generally utilized in energy management applications as back-up power generation during times of peak load, to stabilize the power grid, and provide clean, reliable, baseload power. These systems are the most commercially viable energy storage available today for large energy storage in the hundreds of megawatts ([ORNL 2010](#)). The large capacity comes with a large footprint. In an island application, seawater can be used as the lower water reservoir, thereby reducing the construction time and area. However, the upper reservoir can still be quite large, as is the case with the Okinawa Seawater Pumped Storage Plant upper reservoir, which covers a 14-acre area, has a total storage capacity of 156 million gallons, and provide 30-megawatts of power ([IEA 2000](#)). Pumped storage is a proven form of energy storage for electric utilities with over 150 plants in United States. Several natural geological features are needed for this technology, including close land areas divided by adequate elevation, and an adequate water supply. Smaller scale pumped storage is possible requiring less land disturbance but size will vary depending on the power needs, geological features and water available ([HECO 2013j](#)).

Sodium-Sulfur Batteries

Like the other previously mentioned batteries, sodium sulfur batteries work based on electrochemical processes. The sodium sulfur battery chemistry consists of molten sulfur on the positive electrode (anode) and molten sodium on the negative electrode (cathode). The electrolyte is a beta-aluminum tube ([Baxter and Makansi 2002](#)). The technology requires elevated temperatures (300° to 350°C), which poses a few challenges; however, the battery modules and the sites with sodium sulfur batteries maintain safety systems, such as fire suppression systems, in the event the elevated temperatures or chemistry result in a fire ([Akhil 2013](#)). These batteries have been used in commercial applications at the megawatt scale for more than 10 years, and enhancements continue to be made. Most large installations consist of modular units capable of storing 1 or 2 megawatts each. Sodium sulfur batteries are capable of long discharge time, up to 6 hours ([Akhil 2013](#)), so they are used in energy management applications.

There are more than 300 megawatts of sodium sulfur battery systems installed globally. Japan is planning to install an 80-megawatt system consisting of 40 sets of 2-megawatt sodium sulfur battery systems at the Noshiro thermal power station to supply energy during peak demand ([Hatta 2011](#)). Sodium sulfur batteries currently are manufactured by only one company, with an annual production of 90 megawatts ([NEA 2008](#)). [Figure 2-70](#) shows a general battery diagram and a 2-megawatt sodium sulfur battery installation in Bluffton, Ohio ([AEP 2013](#)).

Figure 2-70. Sodium-Sulfur Battery Installation

Superconducting Magnetic Energy Storage

A superconducting magnetic energy storage system stores energy in a magnetic field. The system consists of a superconducting coil, power conditioning equipment, and a cryogenic cooling system, as shown in [Figure 2-71](#). The coil is cooled below the material's critical temperature, and DC is sent through the coil, generating a magnetic field. This method of storage is very efficient and the energy can be held as long as the refrigeration is available. The system provides high power over a short duration and is being designed specifically for grid applications ([Baxter and Makansi 2002](#); [Eyer and Corey 2010](#)). Currently, there are about 10 projects worldwide that have implemented this technology. DOE's Advanced Research Project Agency – Energy is funding some supercomputing magnetic energy storage projects, suggesting the technology is still in the infancy stage of development.

Thermal Energy Storage

Thermal energy storage includes a number of different technologies. Thermal energy (hot and cold) can be stored at temperatures from -40°C to more than 400°C as sensible heat, latent heat, and chemical energy (thermochemical energy storage) using chemical reactions ([IEA 2012](#)). Thermal storage uses off-peak electricity to store cooling energy or heat energy, then during peak demand uses that energy for power needs.

There are two primary ways this can be implemented. The first is via ice-based systems, which are applicable to commercial, residential, and industrial cooling loads at the point of consumption. These systems are for bridging power applications and help shave peak demand. Ice-based thermal energy storage systems are well suited for warm regions like Hawai'i. There are three confirmed projects on O'ahu that use this technology: the Iolani School in Waikiki, the Nordstrom at the Ala Moana Center in Honolulu, and the Iwilei Costco in Honolulu ([Song 2008](#)). The second implementation is via a heat-based system using molten salt. The salt absorbs heat from a solar farm and uses that heat later to make steam for a turbine application. The molten salt systems are still in the development stage but may provide another means of capturing solar energy generation for use during peak demand hours ([Baxter and Makansi 2002](#)). The heat-based system can only operate in conjunction with a solar plant. The Holaniku facility at NELHA at Keahole Point is demonstrating a heat-based thermal system ([Sopogy 2013](#)). With any thermal storage, the duration of storage may be short, as the ability to insulate the material from the surrounding temperature drives how long the material remains in its useful hot or cold state.

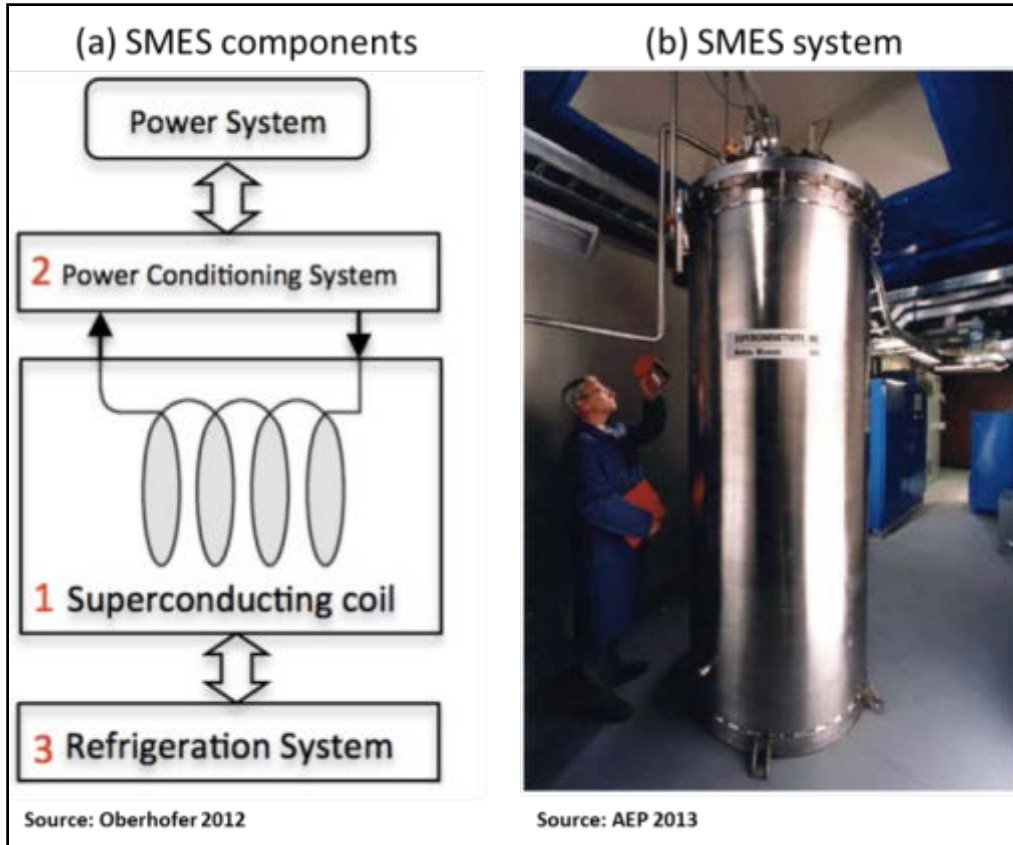

Figure 2-71. Superconducting Magnetic Energy Storage

2.3.5.4.2 Characterization of Technology Feasibility and Deployment

Energy storage systems are designed for different applications, making them useful in different parts of the electricity distribution chain. Some are designed to address short power quality issues while others are designed to support peak demand over a longer duration. [Table 2-32](#) summarizes the characteristics of the different technologies described in the previous section.

As shown in the table above, energy storage technologies vary by power, discharge duration, and response time, making them useful at many points along the electricity distribution chain. [Figure 2-72](#) illustrates where energy storage can be located and how the location addresses an electricity distribution issue. For example at location “A” energy storage pairs with renewable generation at the utility side to smooth out the variability associated with the wind resources. In location “E” energy storage is located after the distribution at the customer side to address any power quality issues associated with the electricity being delivered. The representative project refers to both of these examples (see [Section 2.3.5.4.4](#)).

Table 2-32. Energy Storage Technology Characteristics

Technology	Capacity (MWh)	Power (MW)	Discharge Duration (hrs)	% Efficiency (total cycles)	Response Time ^a	Lifetime (years) ^a
Capacitors ^b	0.5 kWh	200 kW	1–30 seconds	95	4 milliseconds	20 (or 106 cycles)
CAES (above ground)	250	50	5	70 ^c (>10,000)	Minutes	30
Flow Batteries	5–50	1–10	5	60–65 (>10,000)	< ¼ cycle	10
Flywheels	5	20	0.25	85–87 (>100,000)	< 1 cycle	20
Hydrogen ^d	300	50	6	35–45	Minutes	40 ^e
Lead-acid batteries	200	50	4	85–90 (2,200)	¼ cycle	5
Li-ion batteries	4–24	1–10	2–4	90–94 (4,500)	a few milliseconds ^f	20 ^g
Pumped Hydroelectric	1,680–5,300	280–530	6–10	80–82 (>13,000)	Minutes	30
NaS batteries	300	50	6	75 (4,500)	a few milliseconds ^f	5
SMES ^a	0.69 kWh ^h	20 kW ^h	1 second	>85 ^h	< ¼ cycle	30
Thermal (heat based system) ^a	4 ⁱ	100	12	50–90 ^j	Minutes	30 ⁱ

CAES = compressed air energy storage; hrs = hours; kWh = kilowatt-hour; Li-ion = lithium-ion; MW = megawatt; MWh = megawatt-hour; NaS = sodium sulfur; SMES = superconducting magnetic energy storage.

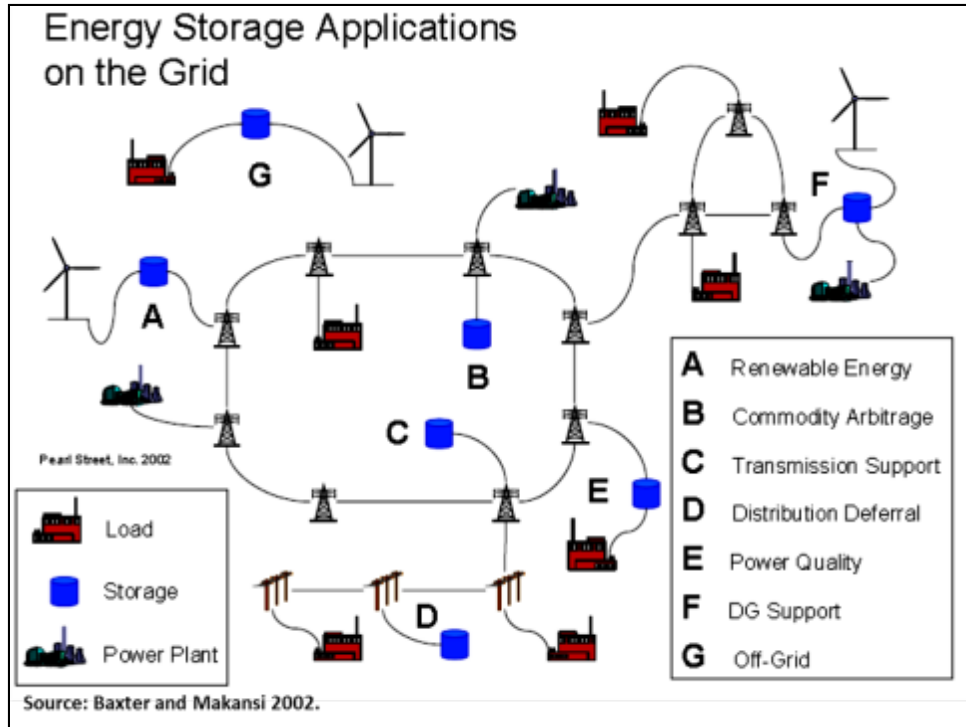

Figure 2-72. Potential Energy Storage Applications in the Electricity Delivery Chain

These technologies are rarely used in isolation, but rather in conjunction with other components in the electricity value chain. Co-location of storage generation, transmission, distribution, or load is typical and each of those locations has certain benefits and drawbacks. These benefits and drawbacks are also a matter of perspective. Many are example-specific, but some of the most common pros and cons of locating energy storage at different points in the value chain are shown in [Table 2-33](#). The table is devised from the perspective of the party maintaining the grid.

Because the storage feasibility needs to be evaluated with the generation or distribution technology that it helps enable, it is important to understand the advantages and disadvantages of each. [Table 2-34](#) lists some of those but there could be others based on the application.

While some technologies are commercially available today, others are still in the development stage. [Table 2-35](#) summarizes the stages of maturity for the energy storage technologies. Some technologies may be listed in multiple categories. As advancements are made, the technologies mature in more power regions and storage durations.

Table 2-33. Benefits and Drawbacks Associated with Energy Storage Locations

Image taken from Baxter and Makansi 2002.

Storage location	PRODUCTION:	TRANSMISSION:	DISTRIBUTION:	CUSTOMER/LOAD:
Site Description	Co-located with renewable generation on the developer's side of the meter	Located near renewable generation on the utility-side of the meter	Located within the distribution network in proximity to loads (commercial, residential, industrial)	Located at the customer side of the meter
Benefits	Dampen the effect of variability in production, higher generation dispatchability	Can provide additional services: regulation, spinning reserves, load leveling	Less Risk - Smaller expenditures over a longer time horizon, multiple vendors/solutions are possible, able to provide local voltage support	Increase customer reliability
	Cost absorbed by plant developer	Generally lower costs per kW for so larger systems are possible	More Reliability - Increase distribution system and customer reliability	Peak demand shaving
	Generally lower costs per kW for larger systems are possible		Flexible control - Off-load substation transformer during peak times, more discrete dispatching and optimization of resources, integration with Smart Grid communications	Cost absorbed by customer
Drawbacks	Generation takes precedence on the storage dispatch	Dual-use ownership and cost model would need to be defined and agreed upon	Safety hazards & additional equipment requirements associated with locating near population dense areas	Support only user loads
	More complicated business model for utility to access storage	Capital expenditures for distribution upgrades would still be needed.	Land availability & costs for placement	Additional controls needed to allow for backflow into the distribution chain
			Variation in local codes and jurisdictions may have an effect on technology selection or implementation	More complex ratepayer cost & revenue models
				Limited input and information about solutions implemented.

Table 2-34. Advantages and Disadvantages of Energy Storage Technologies

Storage Technology	Main Advantages	Disadvantages
Capacitors	Long cycle life, high efficiency	Low energy density
CAES	High capacity, low cost	Special site requirement, requires fuel
Flow batteries	High capacity, independent power and energy ratings	Low energy density
Flywheels	High power	Low energy density
Hydrogen ^a	High capacity, low cost	Low efficiency, safety concerns (addressed in design)
Lead-acid batteries	Low capital cost	Limited cycle life when deeply discharged
Li-ion batteries	High power and energy densities, high efficiency	High production cost, requires special charging circuit
Pumped Hydroelectric	High capacity, low cost	Special site requirement
NaS batteries	High power and energy densities, high efficiency	Production cost, safety concerns (addressed in design)
SMES	High power	Low energy density, high production cost
Thermal ^b	High capacity	Insulation requirements

b. Source: [IEA 2012](#).

CAES = compressed air energy storage; kW = kilowatt; MW = megawatt; NaS = sodium sulfur; SMES = superconducting magnetic energy storage.

HECO has demonstrated ultra-capacitors to mitigate short-term voltage and frequency deviations associated with wind power.

Deploying compressed air energy storage systems with aboveground tanks for small turbines is also feasible. Underground storage for compressed air energy storage systems is probably not suitable given the islands' geological characteristics. Due to the island's volcanic origins and active seismicity which create fissures, cracks and air bubbles in the basalt rock, Hawai'i's lands are highly permeable and not capable of containing pressurized air. The underground lava tube caves that exist are very long and shallow, which does not provide the lithostatic pressure needed for high pressure storage. In addition to the geological limitation, these caves are sometimes used by Native Hawaiians for burials ([Hon 2013](#)).

There are manufacturers of indoor and outdoor flywheel systems focused on power quality applications, but the devices are still fairly small and applications somewhat niche. They can be used for frequency regulation and output smoothing of solar and wind energy. Multiple units can be put in series to achieve the necessary storage capacity.

Batteries are appropriately sized for use at generation, distribution, or point of consumption sites on all of the islands. There are battery facilities in Hawai'i that are several megawatts in size, demonstrating the technology feasibility for Hawai'i.

While there are 31 megawatts of hydroelectric generation in the State of Hawai'i, there are no commercial pumped storage hydroelectric facilities ([DBEDT 2013g](#)). Studies have explored the possibilities of pumped storage hydroelectric facilities at Koko Crater and Ka'au Crater; on Hawai'i island at Puu Waawaa and Puu Anahulu in North Kona, Puu Enuhe in Ka'u and at Kaupulehu-Kūki'o. On Maui, pumped storage hydroelectric facilities have been considered at Ma'alaea, Napili-Honokōwai in the Ka'anapali area, Kohama near Lahaina and upcountry at Ulupalakua ([HECO 2013j](#)). There is a record of community opposition to hydroelectric and pumped storage hydroelectric projects on Kaua'i, Maui, Hawai'i and Molokai ([HREDV 2009b](#)). Even when the sea could be used as the lower reservoir, pumped storage hydroelectric systems require a large amount of land, which is one of an island's most precious resources. Thus, while seemingly a natural fit for Hawai'i, pumped storage hydroelectric may also be the most challenging to implement. Challenges include siting, permitting, water availability, cost and the long lead time for development ([HECO 2013j](#)).

Thermal energy storage systems are well suited for warm regions like Hawai'i. Ice-based systems have been in operation on O'ahu as previously mentioned and heat-based systems are still being demonstrated.

2.3.5.4.3 Permitting and Consultation Requirements

Energy storage systems vary by size, technology, and application. These technologies typically are co-located with other equipment such as a wind farm, substation, distribution line, or at the point of consumption. The storage systems can be introduced at the inception of the project or added at a later date. Permit requirements may vary depending on where the energy storage system is put in place and whether it is envisioned at the onset or brought in as an add on to an existing facility.

When the energy storage is considered at the onset of the project, the permit process would reflect the electricity chain that it supports. All components to make a project work, including transmission and storage infrastructure, are included in the original facility permit applications. When energy storage is added later, this may be considered an accessory use to the existing facility or may prompt the need to revisit all existing facility permits. The proper Federal, State, and county permitting authorities must be consulted. General Federal, State, and county permitting and regulatory requirements are discussed in [Section 2.2.5](#).

Because pumped storage hydroelectric would be constructed as a stand-alone facility, there are specific permits that may be required those Marine-based permits are applicable when the ocean serves as the lower reservoir. One or more of these permits may be required to connect the facility to the grid. On the mainland, FERC would have regulatory authority for these hydroelectric projects; however, in Hawai‘i, FERC’s authority is more limited. The following text is from FERC’s Order Dismissing Preliminary Permit Applications ([FERC 2011](#)):

“Given that Hawai‘i’s electrical generation and transmission system is not connected to the interstate electrical grid, Part I of the [Federal Power Act] applies in a different manner to State of Hawai‘i inland hydropower projects than to those located in the contiguous United States. Accordingly, as discussed below, many hydropower projects in Hawai‘i do not require a FERC license, and Hawai‘i has a long history of authorizing and regulating hydropower projects at the State level. There are no Commission-licensed hydropower projects in Hawai‘i.”

In addition, there are decommissioning activities associated with the dismantling of batteries and their disposal or the recycling of their chemicals ([Eyer and Corey 2010](#)). It is important to note that sodium sulfur battery components are disposed of or recycled by routine industrial processes and lead-acid battery procurement typically has contractual clauses requiring that the batteries be sent to a recycling center at the end of their operational life ([Akhil 2013](#)).

2.3.5.4.4 Representative Project

To illustrate a potential energy storage project that may be encountered on any of the islands, the analysis in this PEIS considers two representative projects that would include the energy storage for the following facilities:

- A hotel or resort facility. This project would have an energy storage system for any critical systems. The energy storage system would provide frequency regulation while connected to the grid and reserve power in the event of an outage until a generator could be put in place. It is assumed the hotel has approximately 400 rooms with a peak load of 10 megawatts and a 10 percent critical systems load of about 1 megawatt. Flywheel energy storage was selected because of its small footprint, fast response time, and life cycle.
- A [renewable energy](#) generation plant. This project would have an energy storage system that serves a bridging power function. The energy storage system would smooth out variability of the power sent from a renewable generation source to a transmission line. The [renewable energy](#) project may be a large (100-megawatt) solar farm or wind farm. The project assumes that one-third of the generation capacity is needed in storage and that the energy storage is co-located with the generation source that is already connected to the transmission line. Sodium sulfur battery storage was selected because of response time, discharge duration, and modularity allowing for more or less power depending on the generation capability.

The representative project is not intended to reflect any known or planned project and is developed for analytical purposes only. The characteristics of the representative projects are shown in [Table 2-36](#).

Table 2-36. Representative Project Characteristics

Line No.	Project Parameter	Hotel/Resort ^a	Renewable Power Plant ^b
	Technology Selected	Flywheels	NaS batteries
1	Infrastructure support Roads Water use Sewer	No No No	Yes (large, heavy, hazardous material loads) No No
2	Size of facility footprint height weight power generated number of modules	125 square feet 6.5 feet 22 tons 1.08 megawatts ^c 9 UPS150 units	26,000 square feet 17 feet 3580 tons 34 megawatt ^c (1/3 output) 34, 1,000-kilowatt NAS units
3	Cost of plant \$/MW or \$/kW	\$324,000 \$300 per kilowatt ^c	\$102M \$3M per megawatt ^d
4	Workforce Construction Operation	yes no	yes no
5	Noise generated	<70 dBA at 3 feet	Low noise
6	Air emissions	no	no
7	Waste generated Type Disposal	None Same as electronics	Battery chemicals Routine industrial process
8	Electrical Transmission lines	480VAC 3-phase 3-wire plus ground	Grid connections
9	Location	Building utility area	Near intermittent or curtailed renewable power plant

^a. Data included is based on the UPS150 unit from Active Power, Inc. ([Active Power 2012](#)).

^b. Data included is based on a 1,000-kilowatt NAS unit from NGK Insulators, Ltd. ([NGK 2013](#)). NAS is a registered trademark for NGK's sodium-sulfur battery system.

^c. Source: [Baxter and Makansi 2002](#).

^d. Source: [HECO 2013j](#).

^e. The flywheel system (providing power until a generator can be started) would provide its rated capacity for 27 seconds. The NaS battery system would provide its rated capacity for up to 7 hours.

dBA = A-weighted decibel; kW = kilowatt; MW = megawatt; NaS = sodium sulfur; VAC = volts alternating current.

2.4 No-Action Alternative

CEQ NEPA implementing regulations require that a PEIS analysis include a *no-action alternative*, which provides a baseline for comparison against the impacts of the proposed action. Under the no-action alternative, DOE would continue to support, through funding and other actions, the State of Hawai'i to meet its HCEI goals on a case-by-case basis, but without guidance to integrate and prioritize funding decisions and other actions.

Implementation of HCEI in Hawai'i will occur whether or not DOE develops guidance to assist in making decision or other actions related to clean energy in Hawai'i. Therefore, the potential environmental impacts associated with each of the renewable energy technologies would likely also occur under the no-action alternative; however, there may not be formal guidance in place that would assist DOE in taking actions that maximize the benefits of certain technologies while minimizing the potential environmental impacts in important resource areas. If the goals of the HCEI were not met, the State of Hawai'i would remain heavily dependent on fossil fuels and statutory greenhouse gas targets would probably not be met.

The State of Hawai‘i will continue taking the following steps to meet its goal of generating 40 percent clean energy by 2030:

- Align government regulations and policies with clean energy goals,
- Facilitate processes for developing renewable energy,
- Deploy renewable generation and grid infrastructure, and
- Explore next generation technologies and new applications of existing technologies.

2.5 Summary of Potential Environmental Impacts

Chapters 4 through 8 provide a characterization of the potential environmental impacts that could be expected from each of the analyzed energy efficiency activities and renewable energy technologies. As discussed throughout [Section 2.3](#), these impacts are based on a representative project and do not reflect any actual proposal. These activities and technologies represent potential future actions that could be used to implement HCEI.

The following tables present summaries of the potential environmental impacts and [best management practices](#) for the activities and technologies associated with each of the five clean energy categories. Each table presents the following:

- A reference to specific sections in Chapter 3 for those impacts that would be common among most construction or operation activities and are not technology-specific. The potential impacts are identified for each environmental resource area.
- Any potential environmental impacts that would be specific to that activity/technology.
- A reference to specific sections in Chapter 3 for those best management practices that would be common among most construction or operation activities and are not technology-specific. The best management practices are identified for each environmental resource area.
- Any potential best management practices that would be specific to that activity/technology.

Those resource areas with no impacts are shaded and were not carried forward for analysis specific to the activity/technology.

Best management practices and potential [mitigation measures](#) are identified in several places in the PEIS. For those impacts mentioned above that would be common among most construction or operation activities and are not technology-specific, best management practices are presented in Chapter 3 for each resource area. For the activity/technology-specific impacts, the best management practices and potential mitigation measures are presented in Chapters 4 through 8 with the impact analysis for that activity/technology. Implementation of these best management practices and potential mitigation measures are important to prevent or minimize the environmental impacts to that resource.

Accompanying each summary table is a tabular illustration of the potential impacts associated with each activity/technology for each resource area. The clear circles represent no potential impacts, the light-gray dots represent impacts that would be similar to those common among construction and operation activities, and the black dots represent those potential impacts specific to an activity or technology.

[Tables 2-37](#) and [2-38](#) provide the summary of potential environmental impacts and characterization for the activities and technologies in the energy efficiency clean energy category. [Tables 2-39](#) and [2-40](#) provide the summary of potential environmental impacts and characterization for the technologies in the

distributed renewables clean energy category. [Tables 2-41](#) and [2-42](#) provide the summary of potential environmental impacts and characterization for the technologies in the utility-scale renewables clean energy category. [Tables 2-43](#) and [2-44](#) provide the summary of potential environmental impacts and characterization for the technologies in the alternative transportation fuels and modes clean energy category. [Tables 2-45](#) and [2-46](#) provide the summary of potential environmental impacts and characterization for the technologies in the electrical transmission and distribution clean energy category.

Table 2-37. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Energy Efficiency

Resource Area	Energy Efficient Buildings	Sea Water Air Conditioning	Solar Water Heating
Geology and Soils			
	None; retrofitting buildings, would not cause any additional land disturbance that could result in impacts to geology and soils.	<p>Onshore Potential soil erosion and contamination during construction (short-term). See Section 3.1.3.</p> <p>Offshore Potential disturbance of marine sediments during construction (short-term) and operations.</p>	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to geology and soils.
Climate and Air Quality			
Air Quality	Minor impacts during construction. Reductions in criteria pollutants as a result of reduction of electricity generation using fossil fuels.	<p>General impacts during construction (short-term). See Section 3.2.4.</p> <p>The use of a SWAC system would require 75 percent less electricity than a standard cooling system; therefore, there would be a beneficial impact to air quality from a reduction of criteria pollutants resulting from electricity generated by fossil fuels.</p>	Minor impacts during construction. Reductions in criteria pollutants as a result of reduction of electricity generation using fossil fuels.
Climate Change	Minor impacts during construction. Reductions in GHG emissions as a result of reduction of electricity generation using fossil fuels.	Minor impacts during construction. Reductions in GHG emissions as a result of reduction of electricity generation using fossil fuels.	Minor impacts during construction. Reductions in GHG emissions as a result of reduction of electricity generation using fossil fuels.

Table 2-37. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Energy Efficiency (continued)

Resource Area	Energy Efficient Buildings	Sea Water Air Conditioning	Solar Water Heating
<p>Water Resources</p>	<p>None; retrofitting buildings would not cause any additional land disturbance or increased water demand that could result in impacts to water resources, including surface water, groundwater, floodplains, and wetlands.</p>	<p><u>Surface Water – Land Based</u> General impacts during construction (short-term). See Section 3.3.5.</p> <p>No operational impacts.</p> <p><u>Surface Water – Marine-Based</u> Sediment disturbance/ dispersal and increased turbidity.</p> <p>Potential site-specific impacts may occur to habitats or communities of concern.</p> <p>Potential increase in nutrient levels (nitrate and phosphates).</p> <p>Potential for sea water temperature variability impact.</p> <p><u>Groundwater</u> General construction impacts. See Section 3.3.5.</p> <p>No adverse operational impacts.</p> <p>Potential fresh water (groundwater) savings if wastewater is used as the cooling medium.</p> <p>Potentially beneficial; fresh water savings compared with a facility with an open cooling system.</p>	<p>None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to water resources.</p>

Table 2-37. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Energy Efficiency (continued)

Resource Area	Energy Efficient Buildings	Sea Water Air Conditioning	Solar Water Heating
		<p><u>Floodplains and Wetlands</u> Potential short-term impacts during construction. See Section 3.3.5.</p> <p>Potential effects during operations (site specific; i.e., if project were located in a floodplain/wetland).</p>	
Biological Resources			
	None; retrofitting buildings would not cause any additional land disturbance that could result in impacts to biological resources.	<p>General impacts to terrestrial and marine ecosystems during construction (short-term impacts to benthic communities and marine mammals if construction occurred in the Hawaiian Islands Humpback Whale National Marine Sanctuary).</p> <p>Minimal and localized impacts to marine organisms from water discharge temperature.</p> <p>Potential increase in nutrient levels resulting in increased marine productivity and possible creation of unusual algal blooms.</p> <p>Potential localized disturbance impacts to benthic communities at discharge point.</p> <p>Potential entrainment of smaller organisms at the intake pipe.</p>	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to biological resources.
Land and Submerged Land Use			
	None; retrofitting buildings would not cause any changes to land or submerged land use.	Short-term land disturbance impacts at the cooling station locations and along distribution line routes during construction.	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to land use.

Table 2-37. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Energy Efficiency (continued)

Resource Area	Energy Efficient Buildings	Sea Water Air Conditioning	Solar Water Heating
		Potential land use impacts related to expansions/maintenance of the cooling stations and/or distribution network.	
Cultural and Historic Resources			
	Potentially adverse visual or architectural context impact to historic properties.	Potential adverse impacts to cultural, historic, and related natural resources during construction and operation (both on and offshore).	Potentially adverse visual or architectural context impact to historic properties.
Coastal Zone Management			
	None; retrofitting buildings would not cause any changes that would have to be reviewed for coastal zone management.	Potential effects to special management areas established to protect specific coastline resources and limit shorefront access (project- and/or site-specific).	None; installation of solar water heating units would typically be done on rooftops and therefore would be required to comply with CZMA.
Scenic and Visual Resources			
	Potential short-term effects due to visibility of construction activities and personnel. Potential long-term visual impacts (project-specific).	Short-term impacts to visual resources during construction. See Section 3.8.3. Long-term visual impacts associated with the new cooling station.	Potential visual impacts due to visibility including to historic resources (site-specific).
Recreation Resources			
	None; retrofitting buildings, would not cause any additional land disturbance or impacts to recreation resources.	General impacts during construction. See Section 3.9.5. Potential short-term impacts to offshore recreation during installation of the subsurface piping. The short-term impacts could include: (1) restricted access to recreation areas near the area of installation of the underwater piping	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to recreation resources.

Table 2-37. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Energy Efficiency (continued)

Resource Area	Energy Efficient Buildings	Sea Water Air Conditioning	Solar Water Heating
		and on-shore facility, and (2) possible visual impairment from areas near the construction of the facilities that could have a negative effect on the ongoing recreational activities.	
Land and Marine Transportation			
	None; retrofitting buildings would not cause any changes or impacts to land or marine transportation.	<p>General impacts including localized short term traffic impacts during construction and/or if road crossings are needed.</p> <p>Potential short-term (temporary) impacts on harbor operation, local marine transportation, and military marine operations</p> <p>Potential impacts to military submarine operations.</p>	None; installation of solar water heating units would typically be done on rooftops and therefore would have no impacts to land and marine transportation.
Airspace Management			
	None; retrofitting buildings would not result in any tall structures or other potential impacts to airspace.	None; construction and operation of sea water air conditioning would not require any tall structures and therefore would not impact airspace management.	None; installation of solar water heating units would typically be done on rooftops but not result in any tall structures that could impact airspace.
Noise and Vibration			
	General construction and operation impacts. See Section 3.12.5.	<p>Short-term noise and vibration impacts during construction. Noise levels could temporarily exceed regulatory levels.</p> <p>Exposure to elevated noise and vibration levels may result in temporary impacts to marine & mammal behavior and marine mammal prey species.</p> <p>No long-term ambient noise or vibration impacts are expected during operation.</p>	General construction and operation impacts. See Section 3.12.5.

Table 2-37. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Energy Efficiency (continued)

Resource Area	Energy Efficient Buildings	Sea Water Air Conditioning	Solar Water Heating
		A positive benefit could be the elimination of noise currently generated from cooling towers as buildings convert to sea water air conditioning systems.	
Utilities and Infrastructure			
	Potential reduction in energy consumption. See Section 2.3.5 .	Potential reduction in energy consumption (may require modification of the utility structure to meet the RPS).	Decrease in energy consumption. No significant impacts to utilities or infrastructure.
Hazardous Materials and Waste Management			
Hazardous Materials	Potential impact from exposure to hazardous materials including: asbestos materials, lead-based paint, polychlorinated biphenyls, arsenic; and/or mercury (site-specific).	General impacts from exposure to hazardous materials during construction. See Section 3.14.4. No adverse operational impacts.	Potential impacts from exposure to hazardous materials encountered during installation including: asbestos materials, lead-based paint, polychlorinated biphenyls, and/or arsenic.
Waste Management	Potential impacts to waste management services could occur during project construction/retrofitting, as special handling and disposal of building materials and retrofits may be required. Retrofit work to bring buildings up to code with the 2009 IECC may result in the discovery of asbestos, lead-based paint, polychlorinated biphenyls, and arsenic. The replacement of incandescent light bulbs and/or compact fluorescent bulbs with LED lamps would require special handling and disposal requirements, as certain fluorescent bulbs contain a small amount of mercury. Potential landfill impacts.	General waste management impacts during construction. See Section 3.14.4. No adverse operational impacts.	Potential impacts to waste management services from hazardous demolition debris waste during installation. Potential landfill impacts.

Table 2-37. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Energy Efficiency (continued)

Resource Area	Energy Efficient Buildings	Sea Water Air Conditioning	Solar Water Heating
	After completion, building retrofits would not result in waste management impacts.		
Wastewater	Common impacts from typical construction activities are identified in Section 3.14.4.	<p>General wastewater impacts during construction.</p> <p>No adverse operational impacts.</p> <p>Potential beneficial impacts may occur if wastewater were utilized in place of sea water. This would minimize the amount of wastewater from other sources that would have to be treated by the local municipality.</p>	No wastewater impacts.
Socioeconomics			
	Beneficial – few jobs created.	Beneficial – few jobs created.	Beneficial – few jobs created.
Environmental Justice			
	No disproportionately high and adverse human health or environmental effects on minority and low-income populations.	Depending on siting, impacts to visual and scenic resources could have the potential to be disproportionately high and adverse with respect to environmental justice communities.	None; negligible adverse impacts to environmental resources. Therefore, no disproportionately high and adverse impacts to minority or low-income population.
Health and Safety			
	<p>General impacts during construction. See Section 3.17.3.</p> <p>During building retrofits, workers may encounter asbestos, lead-based paint, polychlorinated biphenyls, and arsenic. Exposure to such hazardous materials could result in harmful health effects, the severity of which would depend on the level of exposure.</p>	General waste management impacts during construction. See Section 3.17.3.	<p>General waste management impacts during construction. See Section 3.17.3</p> <p>Potential worker exposure to hazardous materials including: asbestos materials, lead-based paint, polychlorinated biphenyls, and/or arsenic.</p>

Resource Area	Biomass	Hydroelectric	Hydrogen Fuel Cells	Photovoltaic	Wind
Water Resources					
Surface Water	<p>General impacts during construction. See Section 3.3.5.</p> <p>Potential surface water impacts during operations (increased stormwater runoff).</p>	<p><u>Diversion System</u> Potentially adverse impacts to water quality (decreased dissolved oxygen content and increased temperature), water supply, and existing uses (e.g., irrigation fisheries, and recreation).</p> <p><u>Conduit System</u> None; the conduit system would be installed at an existing facility and not incrementally impact surface water.</p>	<p>General impacts during construction and operation. See Section 3.3.5.</p>	<p>None; Installation and use of rooftop solar modules would not involve land disturbance, would involve only minor water demand, and therefore would not impact water resources.</p>	<p>General impacts during construction. See Section 3.1.3.</p>
Groundwater	<p>General impacts during construction. See Section 3.3.5.</p> <p>Potential water resource impacts depending on design and use of groundwater.</p>	<p><u>Diversion System</u> General impacts during construction. See Section 3.3.5.</p> <p>No impacts during operation.</p> <p><u>Conduit System</u> None; the conduit system would be installed at an existing facility and not incrementally impact groundwater.</p>	<p>General impacts during construction and operation. See Section 3.3.5.</p>	<p>None; installation and use of rooftop solar modules would not involve land disturbance, would involve only minor water demand, and therefore would not impact ground water resources.</p>	<p>General impacts during construction. See Section 3.1.3.</p>

Table 2-39. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Distributed Renewables (continued)

Resource Area	Biomass	Hydroelectric	Hydrogen Fuel Cells	Photovoltaic	Wind
Floodplains and Wetlands	Minimal to no potential for common construction impacts. See Section 3.3.5.	<p><u>Diversion System</u> Potential impacts during construction (site-specific).</p> <p>No impacts during operation.</p> <p><u>Conduit System</u> Potential impacts during construction (site-specific)</p> <p>No impacts during operation.</p>	General impacts during construction and operation. See Section 3.3.5.	None; installation and use of rooftop solar modules would not involve land disturbance, would involve only minor water demand, and therefore would not impact floodplain and wetland resources.	General impacts during construction. See Section 3.3.5.
Biological Resources					
	<p>General impacts during construction. See Section 3.4.5.</p> <p>Potential impacts to terrestrial wildlife and protected plants and animals during construction of the boiler, turbine, and local infrastructure.</p> <p>Potential impacts to terrestrial plants and wildlife from biomass production.</p> <p>Potential lighting impacts on flights of marine birds, such as shearwaters and petrels (site-specific).</p>	<p><u>Diversion System</u> General construction impacts. See Section 3.4.5.1.</p> <p>Potential impacts from access roads during construction.</p> <p>Potentially adverse impacts to freshwater aquatic species.</p> <p><u>Conduit System</u> Impacts are unlikely due to the use of an existing conduit flow system.</p>	None; since there would be no land disturbance associated with hydrogen fuel cells, there would be no impacts to biological resources.	None; installation and use of rooftop solar modules would not involve land disturbance or sensitive habitat and therefore would not impact biological resources.	<p>General impacts during construction. See Section 3.4.5.</p> <p>Potential adverse impacts to protected avian and bat species</p>

Table 2-39. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Distributed Renewables (continued)

Resource Area	Biomass	Hydroelectric	Hydrogen Fuel Cells	Photovoltaic	Wind
Land and Submerged Land Use					
Land Use	General construction impacts. See Section 3.5.4 Potential change in land use.	<u>Diversion System:</u> Potential land disturbance during construction. Potential land use compatibility impacts. <u>Conduit System:</u> General construction impacts. See Section 3.5.4.	None; since there would be no land disturbance associated with hydrogen fuel cells, there would be no impacts to land use.	None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact land use.	General construction impacts. See Section 3.5.4 Potential change in land use.
Submerged Land use	None; biomass projects would not involve any off-shore elements.	None; the projects are for installations on the interior of the islands and make use of rivers and stream rather than the ocean.	None; hydrogen fuel cells would not involve any off-shore elements	None; installation and use of rooftop solar modules would not involve any off-shore elements.	None; the wind turbine would be installed on land and would not impact the marine environment.

Table 2-39. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Distributed Renewables (continued)

Resource Area	Biomass	Hydroelectric	Hydrogen Fuel Cells	Photovoltaic	Wind
Cultural and Historic Resources					
	General impacts during construction and operation. See Section 3.6.6.	<u>Diversion and Conduit Systems</u> General impacts during construction and operation. See Section 3.6.6.	None; since there would be no land disturbance associated with hydrogen fuel cells, there would be no impacts to cultural and historic resources.	Potential adverse visual or architectural context impact to a historic property/resource.	General impacts during construction and operation. See Section 3.6.6. The visual impact of wind turbines may be unacceptable near cultural and historic areas where the historic integrity (setting, feeling, association, viewsheds) plays an important role in the value of the resource.
Coastal Zone Management					
	Potential coastal zone impacts to special management areas, shorefront access, or shoreline erosion (project/site-specific).	None; the projects are for installations on the interior of the islands and would not affect the shoreline.	None; since there would be no land disturbance associated with hydrogen fuel cells, there would be no impacts to coastal zone management.	None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact coastal zone management.	Potential coastal zone impacts to special management areas, shorefront access, or shoreline erosion (project/site-specific).

Table 2-39. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Distributed Renewables (continued)

Resource Area	Biomass	Hydroelectric	Hydrogen Fuel Cells	Photovoltaic	Wind
Scenic and Visual Resources					
	<p>General impacts during construction See Section 3.8.3.</p> <p>Potential long-term visual impacts from outdoor and security lighting and visual character of project location (site-specific).</p>	<p><u>Diversion System</u> General impacts during construction See Section 3.8.3.</p> <p>Potential long-term visual impacts (site-specific).</p> <p><u>Conduit System</u> None.</p>	<p>None; since there would be no external facilities associated with hydrogen fuel cells, there would be no impacts to scenic and visual resources, the containers would be located either indoor or outdoor adjacent to existing facilities, negligible impacts to visual resources are expected.</p>	<p>Short-term visual resource impacts during installation.</p> <p>Potential long-term visual impacts (site-specific).</p> <p>Potential impacts to natural scenic and visual resources, or historic character of an area.</p>	<p>Short-term visual resource impacts during installation.</p> <p>Potential long-term visual impacts (site-specific).</p> <p>Potential impacts to natural scenic and visual resources, or historic character of an area.</p> <p>Potential lighting and shadow flicker impacts (site-specific)</p>

Table 2-39. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Distributed Renewables (continued)

Resource Area	Biomass	Hydroelectric	Hydrogen Fuel Cells	Photovoltaic	Wind
Recreation Resources					
	None; the biomass facility would be located near the commercial/industrial electricity users and would be compatible with existing land uses, which would not include recreation.	<p><u>Diversion System</u> General impacts during construction. See Section 3.9.4.</p> <p>Potential impacts to river-based recreation activities, such as fishing and kayaking.</p> <p><u>Conduit System</u> None.</p>	None; since the containers would be located either indoor or outdoor adjacent to existing facilities, no impacts to recreation resources are expected.	None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact recreation resources	Potential visual impacts to recreation resources (e.g., scenic lookouts and views).
Land and Marine Transportation					
Land Transportation	Potential localized roadway and traffic impacts from increased truck traffic associated with biomass feedstock.	<p><u>Diversion and Conduit Systems</u> None; construction and operation of hydroelectric facilities would be unlikely to have any impacts to land transportation.</p>	None; since there would be no land disturbance or external facilities associated with hydrogen fuel cells, there would be no impacts to land transportation.	None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact land transportation.	None; construction and operation of a small wind turbine would not impact land transportation.

Table 2-39. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Distributed Renewables (continued)

Resource Area	Biomass	Hydroelectric	Hydrogen Fuel Cells	Photovoltaic	Wind
Marine Transportation	None; a small distributed biomass energy power generation project would not be expected to require nor effect marine transportation. Biomass would be obtained locally.	<u>Diversion and Conduit Systems</u> None; construction and operation of hydroelectric facilities would be unlikely to have any impacts to marine transportation.	None; since there would be no land disturbance or external facilities associated with hydrogen fuel cells, there would be no impacts to marine transportation.	None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact marine transportation.	None; construction and operation of a small wind turbine would not impact marine transportation.
Airspace Management					
	None; a small distributed biomass energy power generation facility would not have an emission stack tall enough or produce a thermal plume large enough to cause an aviation hazard.	<u>Diversion and Conduit Systems</u> None; construction and operation of hydroelectric facilities would not affect airspace.	None; since there would be no external facilities associated with hydrogen fuel cells, there would be no impacts to airspace management.	None; although installation of rooftop solar modules could cause some glare and reflection, which could be seen by pilots, installations at a distributed scale would typically not require consultations on airspace management.	Potential impacts on airspace including military training airspace (site-specific).

Table 2-39. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Distributed Renewables (continued)

Resource Area	Biomass	Hydroelectric	Hydrogen Fuel Cells	Photovoltaic	Wind
Noise and Vibration					
	<p>Industrial noise would be produced from operation of the biomass handling facilities and removal of ash waste.</p> <p>Noise from the steam boilers and turbines mostly would be contained within the buildings.</p>	<p><u>Diversion System</u> General impacts during construction. See Section 3.12.5.</p> <p>Potential long-term noise and vibration impacts during operation (site-specific).</p> <p><u>Conduit System</u> General impacts during construction. See Section 3.12.5. No impacts during operation</p>	<p>None; since there would be no land disturbance or external facilities associated with hydrogen fuel cells and the fuel cells do not generate noise, there would be no impacts to noise and vibration.</p>	<p>None; installation and use of rooftop solar modules would not involve land disturbance or new facility construction and therefore would not impact noise and vibration.</p>	<p>Minimal noise and vibration impacts during construction.</p> <p>Potential long-term noise and vibration impacts (site-specific).</p>
Utilities and Infrastructure					
	<p>Minor impacts to electricity generating capacities.</p> <p>General impacts during construction and operation. See Section 3.13.3.</p>	<p><u>Diversion and Conduit Systems</u> General impacts during construction and operation. See Section 3.13.3.</p>	<p>Negligible impacts to electricity generating capacities.</p>	<p>Minor impacts to electricity generating capacities.</p> <p>General impacts during construction and operation. See Section 3.13.3.</p>	<p>Minor impacts to electricity generating capacities.</p> <p>General impacts during construction and operation. See Section 3.13.3.</p>

Table 2-39. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Distributed Renewables (continued)

Resource Area	Biomass	Hydroelectric	Hydrogen Fuel Cells	Photovoltaic	Wind
Hazardous Materials and Waste Management					
Hazardous Materials	General exposure impacts during construction and operation. See Section 3.14.4.	<u>Diversion and Conduit Systems</u> General exposure impacts during construction and operation. See Section 3.14.4.	No exposure impacts during construction. Minimal exposure impacts during operation.	General exposure construction impacts. See Section 3.14.4. Potential exposure impacts from end-of-life of the PV system and the battery energy storage.	General construction exposure impacts. See Section 3.14.4. Potential for hazardous material exposure resulting from handling and disposal of batteries (project-specific).
Waste Management	Potential waste management impacts related to ash disposal.	<u>Diversion and Conduit Systems</u> General impacts during construction and operation. See Section 3.14.4.	None; no waste management impacts from construction or operation of hydrogen fuel cells.	General construction impacts. See Section 3.14.4. Potential exposure to hazardous waste (i.e., potential for cadmium). Potential landfill impacts.	General construction impacts. See Section 3.14.4. Potential waste management impacts from toxic and hazardous waste contamination during disposal of batteries at their end-life (project specific)
Wastewater	Potential wastewater contamination from trace chemicals and elevated temperatures.	<u>Diversion and Conduit Systems</u> General impacts during construction. See Section 3.14.4.	None.	Potential impacts from the disposal of PV modules (i.e., potential for cadmium-contaminated wastewater).	General construction and operation impacts. See Section 3.14.4.

Table 2-39. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Distributed Renewables (continued)

Resource Area	Biomass	Hydroelectric	Hydrogen Fuel Cells	Photovoltaic	Wind
Socioeconomics					
	Few operation and construction jobs created and economic benefits.	<u>Diversion and Conduit Systems</u> A few operation and construction jobs created. No operational impacts.	None; installation and use of hydrogen fuel cells would result in few jobs and would not impact socioeconomics.	None; installation and use of PV modules would result in few jobs and would not impact socioeconomics.	None; Construction and operation of a small wind turbine would result in few jobs and would not impact socioeconomics.
Environmental Justice					
	Dependent on potentially adverse impacts to other resources in adjacent and nearby areas (site-specific).	<u>Diversion and Conduit Systems</u> Dependent on potentially adverse impacts to other resources in adjacent and nearby areas (site-specific).	None; there would be no measurable impacts to the human environment, and there would be no environmental justice impacts.	None; there would be no measurable impacts to the human environment, and there would be no environmental justice impacts.	None; there would be no measurable impacts to the human environment, and there would be no environmental justice impacts.
Health and Safety					
	General impacts during construction and operation. See Section 3.17.3.	<u>Diversion and Conduit Systems</u> General impacts during construction and operation. See Section 3.17.3.	Potential impacts related to hydrogen explosions are extremely unlikely.	General impacts during construction and operation. See Section 3.17.3.	General impacts during construction and operation. See Section 3.17.3.

○ = No potential impacts.

● = Potential impacts are common among most construction and operation activities.

● = Potential impacts are specific to an activity or technology.

Table 2-41a. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables

Resource Area	Biomass		Geothermal	Municipal Solid Waste (MSW) to Energy Facility	Marine Hydrokinetic Energy (MHK)
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
Geology and Soils					
	<p>General construction impacts. See Section 3.1.3.</p> <p>Potential soil erosion and degradation from agricultural activities.</p>	<p>General construction impacts. See Section 3.1.3.</p> <p>Potential soil erosion and degradation from agricultural activities.</p>	<p>General construction impacts including land disturbance. See Section 3.1.3.</p> <p>Potential well blowouts during drilling.</p> <p>Potential for increased risk to personnel and equipment from hot fluids and steam and geothermal gases such as hydrogen sulfide.</p> <p>Potential lava flow hazards and risks during operation associated with active volcanoes.</p>	<p>General construction impacts. See Section 3.1.3.</p> <p>No operational impacts.</p>	<p>General construction impacts including soil disturbance. See Section 3.1.3.</p> <p>Potential impacts associated with on-island electrical transmission lines; see Section 8.1.1.</p> <p>Potential impacts to marine sediments and marine communities; see Sections 8.2.1 and 6.4.4.</p> <p>No operational impacts.</p>
Climate and Air Quality					
Air Quality	<p>General construction impacts. See Section 3.2.4</p> <p>Potential increase in criteria pollutant emissions (including nitrogen dioxide, particulate matter, carbon monoxides, and sulfur dioxide, as well as carbon dioxide) during combustion.</p> <p>Potential increase in criteria pollutant emissions (including carbon dioxide) from biomass production (equipment, fertilizer/pesticide application, harvest, and transport).</p>	<p>General construction impacts. See Section 3.2.4.</p> <p>Additional criteria pollutant emissions during construction of the biodiesel plant.</p> <p>Increased criteria pollutant emissions (nitrogen dioxide, particulate matter, carbon monoxides, and sulfur dioxide, as well as carbon dioxide) from combustion.</p> <p>Increased criteria pollutant emissions (including carbon dioxide) from biomass production</p>	<p>General construction impacts. See Section 3.2.4.</p> <p>Potential emission of the non-condensable gases during operations.</p> <p>Potential for trace amounts of nitrogen oxides, negligible amounts of sulfur dioxide or particulate matter, and small amounts of carbon dioxide.</p> <p>Potential health impacts from naturally present hydrogen sulfide.</p>	<p>General construction impacts. See Section 3.2.4.</p> <p>Increased criteria pollutant emissions (nitrogen dioxide, particulate matter, carbon monoxide, and sulfur dioxide, as well as carbon dioxide) from combustion.</p> <p>Potential increase in pollutant emissions (including cadmium, carbon monoxide, dioxins/furans, hydrogen chloride, lead, mercury, nitrogen oxides, particulate matter, and sulfur dioxide) emissions during project ops.</p>	<p>General construction impacts. See Section 3.2.4.</p> <p>Potential land disturbance and associated fugitive dust at nearby onshore construction related areas.</p> <p>Potential short-term, minor increase in criteria pollutant emissions from construction equipment and marine vessels.</p> <p>Typically, no air quality impacts during operations</p>

Table 2-41a. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste (MSW) to Energy Facility	Marine Hydrokinetic Energy (MHK)
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
Climate Change	<p>Potential impacts from increased biogenic carbon dioxide emissions and increased greenhouse gas.</p> <p>Decreased greenhouse gas emissions from electricity production using fossil fuels.</p>	<p>Potential increase in carbon dioxide emissions would result in increased greenhouse gas.</p> <p>Decreased greenhouse gas from electricity production using fossil fuels.</p>	<p>Potential greenhouse gas emissions reduction from a mix of cleaner technologies used to produce electricity.</p>	<p>Decreased greenhouse gas from electricity production using fossil fuels.</p>	<p>Potential increase in greenhouse gas emissions from construction equipment and marine vessels.</p> <p>Potentially beneficial impacts from greenhouse gas reduction associated with less electricity production using fossil fuels.</p>
Water Resources					
Surface Water	<p>General construction impacts. See Section 3.3.5.</p> <p>Potential for increased stormwater runoff.</p> <p>Increased water demand for crop irrigation (ex: sugarcane crop – more water/acre).</p> <p>Potential adverse impacts from runoff contamination associated with fertilizer/pesticide applications.</p>	<p>General construction impacts. See Section 3.3.5.</p> <p>Potential for increased stormwater runoff.</p> <p>Increased water supply demand for crop irrigation.</p> <p>Potential adverse impacts from runoff contamination associated with fertilizer/pesticide applications.</p>	<p>General construction impacts. See Section 3.3.5.</p> <p>Potential for minor impacts to surface waters from runoff contaminated with geothermal fluids (“drift”) during operation.</p> <p>Potential impacts to surface waters from leaks or releases of low-boiling point organic working fluids (e.g., isobutene or isopentane) during operations.</p>	<p>General construction impacts. See Section 3.3.5.</p> <p>Potential water resource discharge impacts from blowdown chemicals.</p> <p>Potential stormwater contamination from solid waste activities, such as stockpiling, dumping, and moving.</p>	<p>Onshore General construction impacts. See Section 3.3.5.</p> <p>Potential for increased stormwater runoff from new building sites (site-specific).</p> <p>Offshore Potential ocean sediment disturbance. Potential increased turbidity to communities of concern (site-specific) in marine waters. See Section 8.2.3.</p>

					Potential alteration of shorefront access (site-specific) and alteration of ocean currents.
Scenic and Visual Resources					
	Short-term visual impacts during construction. See Section 3.8.3. Long-term visual impacts from introduction of a new facility. Potential impacts from harvest of biomass. Potential visual impacts from truck traffic during delivery.	Short-term visual impacts during construction. See Section 3.8.3. Long-term visual impacts from introduction of a new facility. Potential impacts during crop harvest. Potential visual impacts from truck traffic delivery.	Potential short-term construction impacts. See Section 3.8.3. Potential long-term visual impacts from the power plant, night lighting, visibility of the transmission line, and the presence of steam plumes at facilities using water-cooled systems.	General visual impacts during construction. See Section 3.8.3. Long-term visual impacts from the MSW combustion facility (site-specific). Long-term visual impacts from truck traffic delivery of MSW (site-specific).	General visual impacts during construction. See Section 3.8.3. Long-term visual impacts (i.e., onshore/ offshore—MHK technology and location specific). Long-term visual impacts from navigation lighting for devices.

Table 2-41a. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste (MSW) to Energy Facility	Marine Hydrokinetic Energy (MHK)
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
Recreation Resources					
	General construction impacts. See Section 3.9.4. Potential long-term recreation resource impacts from visual and noise effects. Potential recreational resource impacts from truck traffic.	General construction impacts. See Section 3.9.4. Potential long-term recreation resource impacts from visual and noise effects. Potential recreational resource impacts from truck traffic.	General construction impacts. See Section 3.9.4. Potential long-term recreational resource impacts including access restrictions, noise, and visual impacts from the new facilities. Potential permanent loss of recreational values (site-specific). Potential lighting impacts to nearby recreation resources such as campgrounds where dark night sky is valued.	General construction impacts. See Section 3.9.4. Potential long-term recreation resource impacts including from visual and noise impacts (site-specific). Potential recreational resource impacts from truck traffic. Potential impacts to recreation resources (i.e., nearby campgrounds or areas where a dark night sky is valued) from facility lighting.	General construction impacts. See Section 3.9.4. Potential long-term recreation resource impacts from visual impacts (site-specific). Potential effects to water-based recreation activities (i.e., swimming, surfing, boating, and fishing) resulting from access restrictions or use alterations to promote recreation user safety and prevent collisions or malfunctions to offshore technologies. Potential wave attenuation impacts at the shore (technology and site-specific; i.e., dependent on the array of devices and location).
Land and Marine Transportation					
Land Transportation	Potential increase in truck traffic for biomass delivery. Potential increased wear on paved roads and road maintenance.	Potential increase in truck traffic for biomass delivery. Potential increased wear on paved roads and road maintenance.	Potential short-term impacts on roadway traffic during project construction.	Potential for localized transportation impacts from transporting MSW.	None.

Table 2-41a. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste (MSW) to Energy Facility	Marine Hydrokinetic Energy (MHK)
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
Marine Transportation	None; it is unlikely that bulk biomass would be shipped between islands.	None; it is unlikely that bulk biomass would be shipped between islands.	None identified.	Because the MSW facility would be entirely land-based, there would be no impacts to marine transportation. Transfer of MSW between islands is not anticipated.	<p>Potential obstruction impacts to marine navigation including to tourist cruises, passenger ferries, fishing vessels (recreational and commercial), and large commercial cargo ships.</p> <p>Potential impacts to military marine operations, surface and subsurface navigation from both floating and submerged structures.</p>
Airspace Management					
	Potential hazards to aircrafts from emission stacks for those project locations nearby airports.	Minimal potential hazards to aircrafts from emission stacks for those project locations nearby airports.	None; the development and operation of a geothermal facility would not result in any tall structures or steam exhausts that would require further consultation on airspace management impacts.	Potential impacts if emission stacks are less than 200 feet.	None; MHK would not include any tall structures and therefore would not impact airspace management.
Noise and Vibration					
	<p>Short-term noise and vibration construction impacts.</p> <p>Potential long-term impacts to existing noise and vibration levels, depending on the location of facilities and compatibility with existing noise levels and land uses.</p> <p>Noise impacts from truck traffic delivery (site-specific).</p>	<p>Short-term noise and vibration construction impacts.</p> <p>Long-term noise and vibration operational impacts (site-specific).</p> <p>Noise impacts from truck traffic delivery (site-specific).</p>	Short-term and long-term noise and vibration impacts would result from exploration, construction, and operation. Potential impacts from noise and vibration would be wholly dependent on sound levels and the proximity of sensitive receptors to the source.	General impacts during construction and operation. See Section 3.12.5.	Short-term noise and vibration impacts to sensitive noise receptors, including potential impacts to marine mammals and sea turtles.

Table 2-41a. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste (MSW) to Energy Facility	Marine Hydrokinetic Energy (MHK)
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
Utilities and Infrastructure					
	General construction and operation impacts. See Section 3.13.3.1. Varying impacts to utilities (site/island-specific i.e., small effects to O'ahu, larger effects to Lāna'i), requiring potential adjustment/ management of power grids and overall power production.	General construction and operation impacts. See Section 3.13.3.1. Varying impacts to utilities (site/island-specific i.e., small effects to O'ahu, large effects to Lāna'i), requiring potential adjustment/ management of power grids and overall power production.	General construction impacts. See Section 3.13.3.1. Potential for minor to moderate impacts to electric utilities (site-specific, i.e., moderate effects to Maui and minor effects to Hawai'i's utilities).	General construction and operation impacts. See Section 3.13.3.1. Varying impacts to utilities (site/island-specific i.e., small effects to O'ahu, larger effects to Lāna'i), requiring potential adjustment/ management of power grids and overall power production.	General construction impacts. See Section 3.13.3.1.
Hazardous Materials and Waste					
Management Hazardous Materials	General construction impacts. See Section 3.14.4. Potential exposure to high quantities of fertilizers (primarily nitrogen), herbicides, and pesticides.	General construction impacts. See Section 3.14.4. Potential exposure to high quantities of fertilizers, herbicides, and pesticides. Potential hazardous materials exposure impacts from biodiesel leaks or accidents.	General construction impacts. See Section 3.14.4. Potential impact from exposure to hazardous materials if chemicals used during exploration/flow testing or from drilling fluids that were improperly handled or released into the environment. Potential impact from exposure to hazardous materials if an accidental spill or chemical release were to occur during operations from lubricating oils, hydraulic fluids, coolants, solvents, and/or cleaning agents. Potential impact from exposure associated with naturally occurring hydrogen sulfide.	General construction impacts. See Section 3.14.4. Potential exposure to hazardous materials from MSW delivered to the site. Potential impact from exposure to hazardous materials associated with the flammability of syngas production.	General construction impacts. See Section 3.14.4. Potential exposure to hazardous materials including fuels from boats, marine vessels, barges, lubricants and hydraulic fluids contained in the wave or tidal energy devices during operations and maintenance.

Table 2-41a. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste (MSW) to Energy Facility	Marine Hydrokinetic Energy (MHK)
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
Waste Management	General construction impacts. See Section 3.14.4.	General construction impacts. See Section 3.14.4. Potential increase in byproduct waste generated	General construction impacts. See Section 3.14.4. Potentially adverse impacts if additional waste were generated on the island of Hawai'i. Minor amounts of hazardous waste may be generated including paints, coatings, and spent solvents.	General construction impacts. See Section 3.14.4. Potential exposure to of hazardous waste (i.e., infectious waste, electronics, lead acid batteries, firearms, propane tanks, sludge, agricultural wastes, soil, and some noncombustible inorganic materials (such as concrete and stone). Potential waste management impacts from ash waste byproducts. Potentially beneficial impacts resulting from decreased MSW in landfills.	Potential landfill impacts to O'ahu and Hawai'i (pending the resolution of existing landfill capacity constraints) if non-recyclable materials add to existing landfill capacity constraints.
Wastewater	Potential impacts to wastewater services from trace amounts of chemicals and elevated temperatures during blowdown from the steam cycle and cooling system.	General construction impacts. See Section 3.14.4. Potential impacts to wastewater services from trace amounts of chemicals and elevated temperatures during blowdown from the steam cycle and cooling system.	General construction impacts. See Section 3.14.4. Potential wastewater impacts in the event of a leak containing geothermal waste fluids.	General construction impacts. See Section 3.14.4. Potential impacts to wastewater services from blowdown.	Potential impacts to wastewater services from vessel effluent during construction. No operational impacts.
Socioeconomics					
	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.

Table 2-41a. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Biomass		Geothermal	Municipal Solid Waste (MSW) to Energy Facility	Marine Hydrokinetic Energy (MHK)
	Direct Combustion Biomass-Fueled Steam Turbine Generating Project	Biodiesel Plant and Electric Power Plant Project			
Environmental Justice					
	Small potential impacts to the general population. Site-specific evaluation of impacted populations required.	Small potential impacts to the general population. Site-specific evaluation of impacted populations required.	Small environmental justice impacts. Site-specific evaluation of impacted populations required.	Small potential impacts to the general population. Site-specific evaluation of impacted populations required.	No effects identified. Because of the uncertainty of the MHK designs and the low potential for adverse impacts, there would be no disproportionate high and adverse impacts to minority or low-income populations, there would be no environmental justice impacts from MHK.
Health and Safety					
	General construction and operational impacts. See Section 3.17.3.	General construction and operational impacts. See Section 3.17.3. Health risks from the use of pesticides, herbicides, and fertilizers. Additional risks of traffic accidents associated with the transport of biomass materials.	General construction and operational impacts. See Section 3.17.3. Potential health and safety effects from drilling including hydrogen sulfide worker exposure. Potential health and safety impacts from physical, thermal, and chemical hazards such as hydrogen sulfide exposure.	General construction and operational impacts. See Section 3.17.3.	General construction and operational impacts. See Section 3.17.3. Potential for public health and safety effects including to boats, both civilian and military marine vessels, and to the public onshore in the event the device were destroyed, damaged or if the loss of mooring/ spatial stabilization were to occur.

Table 2-41b. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables

Resource Area	Ocean Thermal Energy Conversion (OTEC)	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
Geology and Soils					
	None; the only potential impacts to geology and soils would be the interface of the undersea cable to connect the OTEC facilities with the grid. These impacts are addressed in Section 8.1.	General construction impacts from land disturbance/soil erosion. See Section 3.1.3. No operational impacts.	General construction impacts from land disturbance. See Section 3.1.3. Potential for soil contamination in the event of a leak or accidental release of the heat transfer fluids (such as synthetic oil or even molten salt) used in the system.	General construction impacts from land disturbance/soil erosion. See Section 3.1.3. No operational impacts.	General onshore construction impacts from land disturbance/soil erosion. See Section 3.1.3. Potential impacts to marine sediments (e.g., natural migration of sand) from anchor/mooring devices, undersea cables, and land/sea transition zones. See Section 8.2.1. No operational impacts.
Climate and Air Quality					
Air Quality	General construction impacts. See Section 3.2.4.	General construction impacts. See Section 3.2.4 No operational impacts.	General construction impacts. See Section 3.2.4. No operational impacts.	General construction impacts. See Section 3.2.4. No operational impacts.	General construction impacts. See Section 3.2.4. No operational impacts.
	Potential increase in criteria pollutant emissions during construction from equipment or marine vessels powered by fossil fuels. Potential operational emissions from auxiliary diesel generators on the platform.				

Table 2-41b. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Ocean Thermal Energy Conversion (OTEC)	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
Climate Change	<p>Potential minor increase in greenhouse gas emissions from construction equipment and operation of diesel generators on the platform.</p> <p>Potential greenhouse gas emissions reduction from a mix of technologies used to produce electricity using fossil fuels.</p>	<p>Potential greenhouse gas emissions reduction from a mix of cleaner technologies used to produce electricity using fossil fuels.</p>	<p>Potential greenhouse gas emissions reduction from a mix of different technologies used to produce electricity using fossil fuels.</p>	<p>Potential greenhouse gas emissions reduction from a mix of cleaner technologies used to produce electricity using fossil fuels.</p>	<p>Potential greenhouse gas emissions reduction from a mix of cleaner technologies used to produce electricity using fossil fuels.</p>
Water Resources					
Surface Water	<p>Potential ocean sediment disturbance resulting in increased turbidity and impacts to coral or other bottom communities of concern.</p> <p>Potential water quality impacts from discharge not meeting water quality criteria for marine waters (e.g., nutrient levels such as nitrite plus nitrate, phosphate, and phosphorous).</p> <p>Potential increased algal bloom impacts from increased nutrient levels.</p> <p>Potential impacts from temperature variation and elevated chlorine levels of discharge. See Section 6.5.4 for impacts to biological resources.</p>	<p>General construction impacts. See Section 3.3.5.</p> <p>Potential stormwater runoff from the site (dependent on the amount of impermeable surface/nature of the preconstruction site).</p>	<p>General construction impacts. See Section 3.3.5.</p> <p>Potential stormwater runoff contamination in the event of leaks or accidental releases of the heat transfer fluids (such as synthetic oil or even molten salt) used in the system.</p>	<p>General construction impacts. See Section 3.3.5.</p> <p>Potential impacts from power pole installation to the nearest electrical grid are discussed in Section 8.1.3.</p> <p>Potential for increased stormwater runoff as a result of increased impermeable surfaces (wind turbine foundations, electrical support buildings, and paved roads or parking areas) – (site-specific).</p>	<p>General construction impacts including horizontal directional drilling for electrical cables and for the construction of a substation. See Section 3.3.5.</p> <p>No potential onshore effects during operations.</p> <p>Potential for increased turbidity at breakout point from drilling mud or slurries used during horizontal directional drilling.</p> <p>Potential impacts to coral or other bottom communities of concern from high turbidity (site-specific).</p>

Table 2-41b. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Ocean Thermal Energy Conversion (OTEC)	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
Groundwater	Minimal groundwater impacts during construction and operation.	General construction impacts. See Section 3.3.5 Potential changes in runoff to the site and potential associated change in groundwater recharge.	Minor groundwater impacts during construction. See Section 3.3.5. Potential changes in runoff to the site and potential associated change in groundwater recharge.	General construction impacts. See Section 3.3.5	General onshore construction impacts. See Section 3.3.5. No operational impacts.
Floodplains and Wetlands	None identified.	Potential impacts during construction and operation (site-specific). See Section 3.3.5.	Potential impacts during construction (site-specific). See Section 3.3.5.	Potential impacts during construction (site-specific). See Section 3.3.5.	Potential impacts during construction (site-specific). See Section 3.3.5.
Biological Resources					
	<p>Potential for short-term and small disturbances during placement of the cabling lines, moors, and anchors.</p> <p>Potential disturbance to deep and shallow marine habitats and shorelines (including marine pools, sandy and rocky beaches, seagrass habitat, shallow benthic communities, and coral reefs at multiple depths) during construction (site-specific).</p> <p>Potential impacts to the marine environment from introduction of an electromagnetic field along the undersea cable.</p>	<p>General construction impacts. See Section 3.4.5.</p> <p>Potential impacts to biological resources including migratory birds, threatened and endangered plants and animals, critical habitat, protected land areas, and wetlands from habitat loss during site development (site-specific).</p> <p>For locations near the ocean, potential impacts may occur to marine anchialine pools.</p>	<p>General construction impacts. See Section 3.4.5.</p> <p>Potential impacts to biological resources including migratory birds, threatened and endangered plants and animals, critical habitat, protected land areas, and wetlands) from habitat loss during site development (site-specific).</p> <p>For locations near the ocean, potential impacts may occur to marine anchialine pools.</p>	<p>General construction and operation impacts. See Section 3.4.5.</p> <p>Potential impacts to biological resources including loss of vegetation and wildlife (migratory birds, threatened and endangered plants and animals, critical habitat, and other high value areas such as wetlands and native plant communities) from site development (site-specific).</p> <p>Potential for mortality of avian species and bats (site-specific).</p> <p>Potential impacts to seabirds by attracting/disorienting them from onsite lighting.</p>	<p>General construction and operation impacts. See Section 3.4.5.</p> <p>Potential disturbance impacts to the ocean floor and marine communities/ habitats (i.e., coral reefs, shallow benthic communities, seagrasses, beaches, and possibly marine pools) during installation of anchors, undersea cables (site-specific).</p> <p>Potential impacts to marine animals from temporary construction noise impacts.</p> <p>Potential for increase in marine mammal collisions from ships and boats during construction.</p>

Table 2-41b. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Ocean Thermal Energy Conversion (OTEC)	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
	<p>Potential attraction of marine fish, mammals, and seabirds to structures and for biofouling organisms.</p> <p>Potential impacts to marine communities from nutrient rich discharge waters.</p> <p>Potential impacts to marine organisms due to intake pipes.</p> <p>Potential collision hazards to marine mammals from mooring lines.</p>				<p>Potential increase for hazards to marine mammals congregating in marine subsurface structures.</p> <p>Potential for increased collision hazard for large marine mammals (i.e., whales) from mooring cables. Potential hazards (increased risk for mortalities by rotor blade collision) to seabirds in areas surrounding wind turbines due to potential aggregation of forage fish near submarine structures, tower safety lighting, and potential use of aboveground platform structures as resting areas.</p> <p>Potential introduction of an electromagnetic field into the marine environment along the cable resulting in potential impacts to marine mammals with electrosensory systems.</p>
Land and Submerged Land Use					
Land Use	See Section 8.2.5 for typical land use impacts associated with the interface of an undersea cable and the electrical grid.	Potential land use impacts including land disturbance and possible conversion of undeveloped land and land in other current use to an energy generating facility.	Potential change in land ownership patterns through purchase and or land use leases for both the solar thermal project site and any linear corridors required to tie-in to the existing electrical grid.	Potential land use impacts including land disturbance during site preparation and turbine installation, as well as access road construction and support structures.	<p>Potential change in local landownership patterns.</p> <p>Potential land disturbance during construction of the tie-in to the existing transmission grid.</p>

Table 2-41b. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Ocean Thermal Energy Conversion (OTEC)	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
		<p>Potential change in land ownership patterns and/or easements required for the project (i.e., project site, access roads, corridors to the nearest electrical grid).</p> <p>Potential impacts to adjacent land uses (roads, residential/commercial areas, historic sites, scenic locations, and airports) from the glint and glare of the solar panels.</p>	<p>Potential impacts to undeveloped land or land currently used for other uses could be converted to energy uses.</p>	<p>Potential conversion of undeveloped land or land with other current land uses for energy use.</p> <p>Potential landownership changes and obtainment of land use easements.</p>	
Submerged Land Use	<p>Potential for large obstructions in the ocean floor from structures.</p>	<p>None; PV projects would be land-based and not impact submerged land uses.</p>	<p>None; solar thermal projects would be land-based and not impact submerged land uses.</p>	<p>None; land-based wind turbines would have no potential effects to submerged land use.</p>	<p>Potential impacts to sea floor requiring a submerged lands lease. See Section 8.2.5.</p>
Cultural and Historic Resources					
	<p>Common construction and operation impacts to cultural resources. See Section 3.6.6.</p> <p>Potential direct impacts from onshore and offshore construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p>	<p>Common construction and operation impacts to cultural resources. See Section 3.6.6.</p> <p>Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities.</p> <p>Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.</p>	<p>Common construction and operation impacts to cultural resources. Resource Area	Ocean Thermal Energy Conversion (OTEC)	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
Scenic and Visual Resources					
	<p>General visual impacts during construction. See Section 3.8.3.</p> <p>See Section 8.2.8 for potential visual impacts from land/ sea cable transition sites.</p> <p>Potential long-term visual impacts onshore from the introduction of a transition site.</p>	<p>General visual impacts during construction. See Section 3.8.3.</p> <p>Potential long-term visual impacts from solar panels, including in association with new facilities and associated buildings.</p> <p>Potential glinting, glare, and visual effects depending on the panel orientation, sun angle, viewing angle, viewer distance, and other visibility factors; may also be dependent on individual viewer sensitivity.</p> <p>Potential long term visual effects from routine maintenance activities.</p>	<p>General visual impacts during construction. See Section 3.8.3.</p> <p>Potential long-term dynamic visual impacts from parabolic troughs/mirrors (glare/ reflected light), thermal storage tanks, steam condenser, cooling towers (plumes) and generator as well as road access, parking, maintenance facilities, and transmission line tie-in.</p> <p>Potential for individual discomfort from glare effects, depending on viewer sensitivity, viewer location, viewer movement, and time of day.</p> <p>Potential increase in light pollution impacts (skyglow, light trespass, and glare) from security lighting and other exterior lighting around buildings, parking areas, work areas and during maintenance activities (vehicle-mounted lights).</p>	<p>General short-term visual impacts during construction including site preparation activities such as clearing, construction of access and onsite roads, equipment laydown areas, installation of turbine foundations, erection of turbines, and connection to the grid. See Section 3.8.3.</p> <p>Potential long-term visual impacts from wind turbine operations including the presence of the wind turbines, movement of the rotor blades, shadow flicker, blade glinting, flashing aviation warning lights (nighttime in particular), roads, vehicles, and workers conducting maintenance activities.</p> <p>Depending on viewer sensitivity, potential for long-term impacts to viewers nearby due to the strong vertical lines/ large sweep of turbines/ moving blades that can dominate views or command visual attention.</p>	<p>Potential long-term visual impacts from wind turbine operations including the presence of the wind turbines, the sweeping movement of the blades, lighting for the marine and aviation navigation, and the land/sea transition site.</p> <p>Depending on viewer sensitivity, potential for long-term impacts to viewers due to the strong vertical lines/large sweep of turbines/ moving blades that can dominate views or command visual attention.</p>

Table 2-41b. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Ocean Thermal Energy Conversion (OTEC)	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
				Depending on viewer sensitivity, potential for long-term shadow flicker impacts for viewers close enough to fall within the shadows cast by the turbines.	
Recreation Resources					
	<p>General construction impacts. See Section 3.9.4.</p> <p>Potential long-term recreation resource impacts in the vicinity of onshore and offshore facilities from access restrictions and potential visual impacts from the facilities.</p>	<p>General construction impacts. See Section 3.9.4.</p> <p>Potential long-term recreation resource impacts such as land cover required for the arrays and associated facilities required for the project resulting in access restrictions to area as well as visual impacts created by the presence of the facilities and maintenance activities.</p> <p>Potential impacts to nearby recreation areas from panels and other components that reflect and result in glinting, glare, and other visual effects.</p>	<p>General construction impacts. See Section 3.9.4.</p> <p>Potential long-term impacts to recreation resources from access restrictions to the site and visual impacts associated with the new facilities. See Section 6.7.8 regarding visual effects of solar thermal facilities.</p> <p>Potential impacts to recreation resources from light pollution, particularly those areas where a dark night sky is valued (i.e., campgrounds)</p>	<p>General construction impacts. See Section 3.9.4.</p> <p>Potential long-term recreational resource impacts such as access restrictions due to the presence of wind turbines, movement of the rotor blades, shadow flicker, blade glinting, aviation warning lights, roads, vehicles, and workers conducting maintenance activities.</p> <p>Potential impacts to nearby recreation areas from strong vertical lines of the turbines dominating views and large sweep of moving blades commanding visual attention.</p> <p>Potential intrusion to the natural scenery and viewshed depending on the viewer sensitivity.</p> <p>Potential impacts to the night sky for nearby recreation areas (i.e., campgrounds) from aviating warning lights.</p>	<p>General construction impacts. See Section 3.9.4.</p> <p>Potential long-term recreational resource impacts including access restrictions due to the presence of the wind turbines, the sweeping movement of the rotor blades, lighting for marine and aviation navigation, and the land/sea transition site.</p>

Table 2-41b. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Ocean Thermal Energy Conversion (OTEC)	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
Land and Marine Transportation					
Land Transportation	None.	Short-term transportation impacts associated with construction traffic.	Short-term transportation impacts associated with construction traffic.	Potential short-term impacts on roadway traffic during project development (i.e., transportation of wind turbine components such as the blades and turbines to the construction site).	Potential short-term impacts on roadway traffic during project development (i.e., transportation of wind turbine components such as the blades and turbines to the harbor for transport to the construction site).
Marine Transportation	Potential obstruction impacts to marine navigation including to tourist cruises, passenger ferries, fishing vessels (recreational and commercial), and large commercial cargo ships. Potential impacts to military marine operations, surface and subsurface navigation from both floating and submerged structures.	None; installation and operation of a utility-scale PV system would not impact marine transportation.	None; installation and operation of a solar thermal system would not have any marine transportation impacts as it would be totally land-based.	Minor impacts on marine transportation from shipment via marine cargo ship.	Potential navigation hazards to domestic and military marine transportation including to military submarine operations from undersea structures (mooring cables and power lines extending down to the ocean floor).
Airspace Management					
	Potential impacts to military transportation operations (marine surface and aviation operations). Potential impacts on approach paths to airports.	Potential hazards to aircraft and pilots from sunlight reflection; dependent on the magnitude of reflection (glint and glare) from solar power systems.	Potential hazards to both military and civilian aircraft from reflections of the concentrated solar power facility. Potential air turbulence hazards to both military and civilian aircraft (likely limited to low altitude aircraft; i.e., helicopters or during take-offs and landings) from concentrated solar power plants employing a dry cooling system.	Potential hazards to airspace navigation, both military (training and operations) and civilian (including tourist industry helicopters/ fix-winged). Potential impacts to aviation navigation and communication systems such as radar. Potential hazards to aircrafts downwind of rotor induced turbulence.	Potential hazards to airspace navigation, both military (training and operations) and civilian (including tourist industry helicopters/fix-winged aircraft). Potential impacts to aviation navigation and communication systems such as radar. Potential hazards to aircrafts downwind of rotor-induced turbulence.

Resource Area	Ocean Thermal Energy Conversion (OTEC)	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
Noise and Vibration					
	<p>Short-term noise and vibration impacts to sensitive noise receptors, including potential impacts to marine mammals and sea turtles.</p> <p>Long-term noise and vibration impacts from operation of an OTEC facility 3.5 miles off-shore would be minimal with implementation of best management practices.</p>	<p>General impacts during construction. See Section 3.12.5.</p>	<p>General impacts during construction. See Section 3.12.5.</p>	<p>General impacts during construction. See Section 3.12.5.</p> <p>Operational noise and vibration impacts from land-based wind turbines would occur when wind conditions are favorable, day or night.</p>	<p>Short-term noise and vibration impacts to sensitive noise receptors, including potential impacts to marine mammals and sea turtles.</p> <p>Long-term noise and vibration impacts from operation of wind turbines located 5 miles offshore would be minimal with implementation of best management practices.</p>
Utilities and Infrastructure					
	<p>General construction impacts. See Section 3.13.3.1.</p> <p>Potentially moderate effects to electric utilities (site-specific).</p>	<p>General construction impacts. See Section 3.13.3.1.</p> <p>Potential minimal impacts to electric utilities (site-specific).</p>	<p>General construction impacts. See Section 3.13.3.1.</p> <p>Potential minimal impacts to electric utilities (site-specific).</p>	<p>General construction impacts. See Section 3.13.3.1.</p> <p>Potential minor impacts to electric utilities (site-specific).</p>	<p>General construction impacts. See Section 3.13.3.1.</p> <p>Potential impacts to electric utilities (site-specific).</p>
Hazardous Materials and Waste Management					
Hazardous Materials	<p>General construction impacts. See Section 3.14.4.</p> <p>Potential exposure to hazardous materials during operations from large quantities of ammonia and/or chlorine gas/liquid, including through accidental releases or leaks.</p>	<p>General construction and operational impacts. See Section 3.14.4.</p> <p>Potential exposure to trace amounts of hazardous materials (i.e., cadmium, selenium, arsenic) if panels were broken.</p>	<p>General construction impacts. See Section 3.14.4.</p>	<p>General construction impacts. See Section 3.14.4.</p> <p>See Section 8.5.14 regarding potential hazardous material exposure impacts resulting from use of batteries for energy storage.</p>	<p>General construction impacts. See Section 3.14.4.</p> <p>Potential hazardous materials impacts associated with construction from munition response sites and the potential use of batteries for energy storage. See Section 8.2.14.</p>

Table 2-41b. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Utility-Scale Renewables (continued)

Resource Area	Ocean Thermal Energy Conversion (OTEC)	Photovoltaic Systems	Solar Thermal Systems	Wind (Land-Based)	Wind (Offshore)
	Potential for fires or explosions from chlorine and gaseous ammonia combinations.				
Waste Management	General construction impacts. See Section 3.14.4.	General construction and operational impacts. See Section 3.14.4. Potential of hazardous waste impacts resulting from trace amounts of cadmium, selenium, or arsenic if solar panels are broken and/or during solar panel decommissioning/disposal.	General construction impacts. See Section 3.14.4.	General construction impacts. See Section 3.14.4. See Section 8.5.14 regarding potential of hazardous waste impacts resulting from use of batteries for energy storage.	General construction impacts. See Section 3.14.4. Minimal construction and demolition waste. Potential impacts during the decommissioning and dismantling of the wind turbine as result of turbine removal.
Wastewater	Potential impacts to wastewater effluent from added chlorine. See Section 6.5.3 for additional discussion on impacts to water resources.	General construction impacts. See Section 3.14.4. Potential impacts from wastewater discharge resulting from disposal of PV modules at their end-life, particularly from potential leaching or contamination from cadmium containing materials.	General construction impacts. See Section 3.14.4.	General construction impacts. See Section 3.14.4.	Minor and limited wastewater impacts from construction and during operations/maintenance activities from personnel and machinery operations.
Socioeconomics					
	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.	Very small population and economic benefits (i.e., few net new jobs) during construction and operation.

- = No potential impacts.
- = Potential impacts are common among most construction and operation activities.
- = Potential impacts are specific to an activity or technology.

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Geology and Soils						
	<p>Construction impacts would be similar for any of the biofuel technologies and would be consistent with those expected for common construction actions as described in Section 3.1.3.</p> <p>During operation, potential impacts on geology and soils could vary greatly depending on the biofuel technology and feedstock: potential impacts include soil nutrient depletion; contamination from over-application of pesticides; and increased risk of erosion following crop harvest.</p>	<p>Soil disturbances would be limited to instances where minor trenching was required to install chargers at commercial or residential locations.</p>	<p>None; increasing the number of HEVs would not impact geology and soils.</p>	<p>General construction and operation impacts. See Section 3.1.3.</p>	<p>General construction and operation impacts. See Section 3.1.3.</p>	<p>General construction and operation impacts. See Section 3.1.3.</p>

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Climate and Air Quality						
Air Quality	<p>General construction and operation impacts. See Section 3.2.4.</p> <p>The production of the biomass required to produce the biofuels and the operation of facilities to produce biofuels would emit criteria pollutants during the production process. These emissions are addressed in Section 6.1.2 for utility-scale biomass projects.</p>	<p>Reduction in air emissions from lowering gasoline usage in passenger vehicles would be partially offset by the amount of air emissions produced from generating electricity.</p>	<p>Potential reduction in criteria pollutants emitted by internal combustion engine vehicles.</p>	<p>General construction impacts. See Section 3.2.4.</p> <p>Potential air emissions associated with distribution of hydrogen.</p>	<p>General construction impacts. See Section 3.2.4.</p> <p>Leaks and air emissions from the liquid natural gas import station would be possible.</p> <p>While greenhouse gas emissions would be produced, potentially beneficial operational air quality and climate change impacts due to replacement of 20 million gallons of gasoline.</p>	<p>General construction impacts. See Section 3.2.4.</p> <p>Using electricity to operate the rail transit would result in criteria pollutants from producing electricity from oil products, unless the generation used renewable sources.</p> <p>Although total transportation energy demand would decrease by 14.1 million gallons per year and reduce passenger vehicle emissions, criteria pollutant emissions still would occur from the operation and usage of diesel buses.</p>

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Climate Change	<p>The production of the biomass required to produce the biofuels and the operation of facilities to produce biofuels would emit greenhouse gases during the production process. These emissions are addressed in Section 6.1.2 for utility-scale biomass projects.</p> <p>Gasoline replacement would result in annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent.</p>	Reduction in greenhouse gas emissions from lowering gasoline usage in passenger vehicles would be partially offset by the amount of greenhouse gas emissions produced from generating electricity.	A reduction of 20 million gallons of gasoline would correspond with an annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent.	Potential beneficial impact; A reduction of 20 million gallons of gasoline would correspond with an annual reduction in greenhouse gas emissions of about 190,000 metric tons carbon dioxide equivalent.	<p>General construction impacts. See Section 3.2.4.</p> <p>Leaks and air emissions from the liquid natural gas import station would be possible.</p> <p>While greenhouse gas emissions would be produced, potential beneficial operational benefits due to replacement of 20 million gallons of gasoline.</p>	<p>General construction impacts. See Section 3.2.4.</p> <p>Using electricity to operate the rail transit would result in greenhouse gas emissions from producing electricity from oil products, unless the generation used renewable sources.</p> <p>Although total transportation energy demand would decrease by 14.1 million gallons per year and reduce passenger vehicle emissions, greenhouse gas emissions still would occur from the operation and usage of diesel buses.</p>

Water Resources						
Surface Water	<p>General construction impacts to surface water. See Section 3.3.5.</p> <p>Minimal operational impacts of a biofuel processing plant other than possibly increasing storm water runoff from the site.</p> <p>Potentially significant water use impacts associated with feedstock crops. See Section 6.1.</p> <p>Potential impacts from runoff contamination during feedstock/ agricultural production as a result of fertilizer or pesticide applications.</p> <p>No impacts to surface water resources from use of biofuel as a supplement to, or replacement for gasoline.</p>	None; increasing the number of electric vehicles in Hawai'i would not impact water resources.	None; increasing the number of HEVs would not impact water resources.	<p>General construction and operation impacts. See Section 3.3.5.</p> <p>Groundwater likely would be required for the generation of hydrogen.</p>	General construction and operation impacts. See Section 3.3.5.	<p>General construction impacts. See Section 3.3.5.</p> <p>Potential improvement to storm water runoff quality from fewer cars on the road (i.e., less contamination).</p>

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Groundwater	<p>General construction impacts. See Section 3.3.5.</p> <p>Long-term operational impacts of biofuel processing plant to groundwater would be limited primarily to the water needs to operate the facilities. Potential operational impact of biofuel agricultural activities due to contamination from fertilizer or pesticide applications reaching groundwater either via runoff or local recharge.</p> <p>Use of biofuel as a supplement to, or replacement for gasoline would not be expected to have any impact on groundwater resources.</p>	None; increasing the number of electric vehicles in Hawai'i would not impact groundwater resources.	None; increasing the number of HEVs would not impact groundwater resources.	General construction and operation impacts. See Section 3.3.5.	General construction and operation impacts. See Section 3.3.5.	<p>General construction impacts. See Section 3.3.5.</p> <p>Potential improvement to groundwater quality from cleaner runoff.</p>
Floodplains and Wetlands	Potential effects to floodplain and wetland areas during constr. if floodplains and wetlands were not avoided.	None; increasing the number of electric vehicles in Hawai'i would not impact floodplains and wetland resources.	None; increasing the number of HEVs would not impact floodplain and wetland resources.	General construction and operation impacts. See Section 3.3.5.	General construction and operation impacts. See Section 3.3.5.	General construction impacts. See Section 3.3.5.

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Biological Resources						
	<p>Impacts common to construction and operations activities are identified in Section 3.4.5.</p> <p>Impacts to terrestrial wildlife and protected plants and animals from construction of the biofuel production plant and local infrastructure (e.g., access roads, water lines, electrical lines) are expected to be relatively minor.</p> <p>Potentially significant impacts associated with agricultural production of some feedstocks posing invasive risk.</p> <p>Minimal potential impacts associated with conversion of land to feedstock production as there is readily available surplus of arable land previously used in</p>	None; increasing the number of electric vehicles in Hawai'i would not impact biological resources.	None; increasing the number of HEVs would not impact biological resources.	None; the generation of hydrogen and use of hydrogen as a vehicle fuel would not result in impacts to biological resources.	No biological resources impacts anticipated during upgrade and expansion of existing onshore infrastructure as these activities are expected to occur in existing developed areas.	General construction and operation impacts. See Section 3.4.5.

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
	agricultural production. Biomass crops may become habitat for protected species, which would restrict the ability to harvest, particularly during birthing seasons.					
Land and Submerged Land Use						
Land Use	<p>General construction and operation impacts. See Section 3.5.4.</p> <p>Land use impacts could occur from the construction and operation of new production facilities required to generate the biofuels and the infrastructure required to distribute it as an alternative transportation fuel source.</p>	Reduced gasoline demand could result in decreased number of conventional fueling stations; small parcels of land could be converted to other uses and ownership.	None; increasing the number of HEVs would not impact land use.	<p>Potential change in land use from the expansion geothermal facilities on Hawai'i and a future PV complex on O'ahu to produce hydrogen.</p> <p>Depending on the actual siting of the facility there could be change in landownership patterns.</p> <p>Potential change in land use in locations where distribution pipeline and storage tanks would be installed and fueling stations constructed.</p> <p>Operation impacts to land use would be</p>	General construction and operation impacts. See Section 3.5.4.	Potential change in land use designation and/or ownership in areas of railway. Reduced demand for gasoline and diesel fuel leading to a decrease in the number of conventional fueling stations, and small parcels of land could be converted to other uses and ownership.

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
				limited to facility maintenance activities.		
Submerged Land Use	Potential submerged land use impacts if feedstock used to produce the biofuels were harvested offshore (i.e., algae).	None; increasing the number of electric vehicles in Hawai'i would not impact submerged land use.	None; increasing the number of HEVs would not impact submerged land use.	None identified.	None; increased use of LNG and LPG would not impact submerged land use.	None identified.
Cultural and Historic Resources						
	General construction and operation impacts. Sections 3.6.6.	None; increasing the number of electric vehicles in Hawai'i would not impact cultural or historic resources.	None; increasing the number of HEVs would not impact cultural or historic resources.	General construction and operation impacts. See Section 3.6.6. Additional cultural perspectives and impacts regarding geothermal energy development are described in Section 6.2.6.	General construction and operation impacts. See Section 3.6.6.	General construction and operation impacts. See Section 3.6.6.
Coastal Zone Management						
	General, site-specific impacts dependent on the locations of additional fueling stations.	None; increasing the number of electric vehicles in Hawai'i would not impact coastal zone management.	None; increasing the number of HEVs would not impact coastal zone management.	Potential impacts to designated special management areas and affect shorefront access.	None; increasing the number of vehicles using LPG/LNG would not impact coastal zone management.	None; the representative project does not include locations near the coast.

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Scenic and Visual Resources						
	<p>Potential visual impacts from constructing and operating biofuel processing plant described in Section 6.1.8.</p> <p>Minimal long-term visual impacts typical of agricultural activity, including presence of workers and equipment; lands zoned for agricultural use.</p> <p>Minimal visual impacts associated with truck traffic delivering biomass to processing plant.</p>	<p>None; increasing the number of electric vehicles in Hawai'i would not impact scenic or visual resources.</p>	<p>None; increasing the number of HEVs would not impact scenic or visual resources.</p>	<p>General construction impacts. See Section 3.8.3.</p> <p>Long-term visual impacts would occur from the presence of the new production facilities and distribution infrastructure, including pipelines, storage tanks, and fueling stations, and exterior lighting.</p> <p>Visual impacts would be highly dependent on the location and compatibility with the existing viewshed and land uses.</p>	<p>General construction impacts. See Section 3.8.3.</p> <p>Potential long-term impacts due to new aboveground storage tanks and fueling facilities (site-specific).</p>	<p>General construction impacts. See Section 3.8.3.</p> <p>Long-term scenic and visual resource impacts from new infrastructure (site-specific).</p>

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Recreation Resources						
	<p>General construction impacts. See Section 3.9.4.</p> <p>Minimal long-term impacts of feedstock production due to existing agricultural character of the area potentially included in the growing of feedstock and likelihood of growing feedstock in land zoned for agricultural uses as opposed to recreation uses.</p>	<p>None; increasing the number of electric vehicles in Hawai'i would not impact recreation resources.</p>	<p>None; increasing the number of HEVs would not impact recreation resources.</p>	<p>General construction and operation impacts. See Section 3.9.4.</p>	<p>General construction and operation impacts. See Section 3.9.4.</p>	<p>Potential long-term impacts if new infrastructure intersected an area currently used or with potential for future use for recreational purposes.</p>
Land and Marine Transportation						
Land Transportation	<p>Increased truck and employee traffic around processing facilities.</p> <p>Minor increase in truck traffic near biomass collection points.</p>	<p>Land transportation infrastructure could be affected through decreases in HDOT revenue from reductions in petroleum fuel taxes as the number of plug-in electric vehicles increased.</p>	<p>Land transportation infrastructure could be affected through decreases in HDOT revenue from reductions in petroleum fuel taxes as the number of hybrid electric vehicles increases.</p>	<p>General construction impacts. See Section 3.10.3.</p> <p>Potential long-term land transportation impacts from tanker trucks transporting the produced hydrogen if tankers are used with or in place of pipelines.</p>	<p>Land transportation would be required to distribute gas to local fueling stations.</p> <p>Natural gas would likely replace other petroleum-based products; therefore the amount of truck transportation would not increase but change to a different type of vehicle.</p>	<p>Beneficial impacts to traffic congestion by reducing number of cars on the road.</p> <p>Potential for an expanded and/or new maintenance and heavy maintenance facility for increased fleet of diesel buses.</p>

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
	Repeated truck traffic could increase wear and tear on road pavement and increase the frequency of road maintenance.					Potential local traffic impacts during construction of infrastructure to support increased fleet of diesel buses and to expand light rail service.
Marine Transportation	Potential impacts on operation of the harbor systems, harbor infrastructure, primary shipping routes between islands, general marine transportation around the islands (tourism, fishing), and military marine surface and subsurface operations. Potential impact to harbor system if new liquid bulk handling facilities are required.	None; increasing the number of electric vehicles in Hawai'i would not impact marine transportation.	None; increasing the number of HEVs would not impact marine transportation.	Potential long-term marine transportation impacts if produced hydrogen is transported to other islands; would require additional handling facilities at harbors as well as ships with the appropriate storage capability.	Fueling facilities would be constructed consistent with existing traffic patterns	None; while an increase in multi-modal transportation could affect inter- and intra-island ferry use, the representative project addresses bus and rail transportation only.

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Airspace Management						
	None; interference with safe air traffic would not occur as a result of the development or use of biofuels.	None; increasing the number of electric vehicles in Hawai'i would not impact airspace management.	None; increasing the number of HEVs would not impact airspace management.	None; the generation of hydrogen or the use of hydrogen as a vehicle fuel would not result in any tall structures or other impacts to regional airspace.	None; the use of LNG/LPG or the additional fueling stations would not impacts airspace.	None; no impacts to airspace management would be expected from the increased use of multi-modal transportation.
Noise and Vibration						
	<p>General impacts during construction. See Section 3.12.5.</p> <p>Potential long-term impacts to existing noise and vibration levels, depending on the location of facilities and compatibility with existing noise levels and land uses.</p>	<p>General impacts during construction and operation. See Section 3.12.5.</p>	<p>None; there are no HEVs manufactured in Hawai'i. Therefore, noise and vibration impacts associated with construction would occur elsewhere.</p>	<p>General impacts during construction. See Section 3.12.5.</p> <p>Potential long-term impacts to existing noise and vibration levels, depending on the location of facilities and compatibility with existing noise levels and land uses.</p> <p>Increase in marine vessel transport operations would increase noise levels at the harbors.</p>	<p>General impacts during construction associated with construction of fueling facilities. See Section 3.12.5.</p>	<p>General impacts during construction. See Section 3.12.5.</p> <p>Operation of expanded bus and rail systems could potentially result in long-term impacts compared to existing noise and vibration levels, depending on the location of transit corridors and compatibility with the existing noise levels and land uses.</p>

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Utilities and Infrastructure						
	Potential impact to local energy utilities by bringing large production facilities online which could affect their load capacity.	Potential impacts on the islands electric utilities would primarily be an increased power demand of 292 gigawatt-hours per year (equivalent to about 33megawatts if operated continuously) to operate charging stations for the required number of vehicles to support the reduction of 20 million gallons of gasoline. This increase would need to be met either by offsetting renewable power generators or continued use of existing power facilities. This additional load would ramp up slowly as the penetration of PEVs increased on the islands.	None; increasing the number of HEVs would not impact utilities and infrastructure.	Impacts from increased hydrogen production would be similar to those in Section 6.2.3 for the geothermal technology and Section 6.7.3 for PV technology. No impacts from hydrogen-operated vehicles because it would not result in a change to electricity demand.	Infrastructure of LNG and LPG fueling stations would need to be expanded to support demand.	None; no impacts to utilities and infrastructure would be expected from increased use of multi-modal transportation.

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Hazardous Materials and Waste Management						
Hazardous Materials	<p>Potential impacts from exposure to hazardous materials could result from chemical application (herbicides, pesticides, soil amendments) related to feedstock production.</p> <p>Potential impacts from exposure to hazardous materials associated with biofuel processing. See Section 6.1.14.</p> <p>Potential impacts from exposure to hazardous materials from accidents and spills during handling, storage, and transport of biofuels to fuel stations.</p>	<p>Minimal hazardous material impacts from plug-in electric vehicles during operations.</p> <p>Hazardous material impacts may result at the end-life of the vehicle use from batteries. See Section 7.2.14.1.2.</p>	<p>Potential hazardous material exposure impacts resulting from hybrid electric vehicles at its end-life or during its disposal.</p>	<p>Minimal hazardous material exposure impacts anticipated from increased hydrogen production at the geothermal facility.</p> <p>No hazardous material exposure impacts anticipated from hydrogen production via a 50-megawatt utility-scale solar PV system.</p> <p>Minimal hazardous waste exposure impacts during distribution of fuel via tankers or pipelines.</p> <p>Minimal impacts from exposure to hazardous materials during construction and development of hydrogen pipelines and fueling stations.</p> <p>Minimal hazardous material exposure impacts during operation of hydrogen fuel-celled vehicles.</p>	<p>Potential exposure to hazardous material impacts during import, storage, and distribution of natural gas if accidental spills or releases occur.</p> <p>Potential short-term construction impacts from exposure to hazardous materials during modifications and/or expansions of natural gas distribution system. See Section 3.14.</p> <p>Minimal impacts from exposure to hazardous materials from increased propane production, distribution and use on O'ahu.</p> <p>The operation of compressed natural gas vehicles and propane-powered vehicles is not anticipated to result in hazardous material exposure impacts.</p>	<p>Potential impact from exposure. Increased fleet size leads to an increased potential for leaks and spills of lubricating oils, hydraulic fluids, coolants, solvents, and cleaning agents. Ultimately, a well-designed multi-modal transportation system should result in fewer vehicles on the road and a decrease in gas use, leaks, and spills.</p> <p>Increased fleet size leads to an increased potential for leaks and spills of lubricating oils, hydraulic fluids, coolants, solvents, and cleaning agents. Ultimately, a well - designed multi-modal transportation system should result in fewer vehicles on the road, and a decrease in gas use, as well as leaks and spills.</p>

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Waste Management	<p>Minimal waste management impacts from feedstock production and processing.</p> <p>Potential impacts would occur during the construction and operation of the processing facilities to produce biofuels. See Section 6.1.14.</p>	<p>Potential waste management impacts at the end-life of electric vehicles or during its disposal.</p> <p>Potential impacts would result from the import and use of plug-in electric vehicles; replacement of existing internal combustion engine vehicles result in an increase in the amount of waste vehicles.</p>	<p>Potential waste management impacts resulting from the use of hybrid electric vehicles would occur at the end-life of the vehicles or during their disposal.</p>	<p>No new solid waste to be generated by the geothermal facility for hydrogen production.</p> <p>Minimal waste management impacts would occur during construction of utility-scale PV system for hydrogen production and associated distribution pipelines and fueling stations; See Section 3.14.4.</p> <p>Minimal impacts would occur during the end life of the PV system; discarded solar panels may need to be managed and disposed of as hazardous waste; it is anticipated that primary waste management impacts resulting from the project would be minimal.</p>	<p>Potential waste management impacts during construction and development of additional natural gas fueling stations. See Section 3.14.</p> <p>Minimal impacts associated with modification and expansion of LPG fueling stations.</p> <p>Minimal impacts associated with retrofitting existing vehicle fleet for natural gas/LPG use.</p>	<p>General construction and operation impacts. See Section 3.14.4.</p> <p>Operational impacts include a decline in single vehicle ownership and increased car waste, as well as an increase in the amount of auto shredder residue to landfills.</p> <p>Potential increase in car waste, including increase in auto shredder residue disposal in landfills.</p>

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
				Other potential impacts may result from displacement of existing internal combustion.		
Wastewater	Refer to surface water impacts.	None; transitioning to a fleet of electric and hybrid electric vehicles would not impact wastewater.	None; increasing the number of HEVs would not impact wastewater.	<p>Potential wastewater impacts associated with hydrogen production from the representative geothermal project would be similar to those impacts discussed in Section 6.2.</p> <p>Potential beneficial impacts to water resources and wastewater services if the project produced hydrogen using wastewater.</p> <p>Wastewater impacts resulting from solar energy produced hydrogen would likely occur during the manufacturing process. These impacts are discussed in Section 5.4.</p>	None; increasing the number of LNG and LPG vehicles in Hawai'i would not impact wastewater.	General construction and operation impacts. See Section 3.14.4.

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Socioeconomics						
	The impact to population and employment variables would be very small.	The impact to population and employment variables would be very small.	None; increasing the number of HEVs would not impact socioeconomics.	The impact to population and employment variables would be small.	The impact to population and employment variables would be very small.	The impact to population and employers could be significant including cost savings and health benefits. A well-designed multi-modal transportation system would likely result in a decline of personal vehicles resulting in costs savings and health benefits.
Environmental Justice						
	Small environmental justice impacts. Site-specific evaluation of impacted populations required.	None; transitioning to a fleet of electric and hybrid electric vehicles would not have environmental justice impacts.	None; increasing the number of HEVs would not have environmental justice impacts.	Small environmental justice impacts. Site-specific evaluation of impacted populations required.	Small environmental justice impacts.	Positive impacts to residents as a result of cost savings and health benefits associated with greater access to active transit options, healthier food options, as well as education, and jobs.

Table 2-43. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Alternative Fuels and Transportation Modes (continued)

Resource Area	Biofuels	Plug-In Electric Vehicles	Hybrid Electric Vehicles	Hydrogen	CNG, LNG, and LPG	Multi-Modal Transportation
Health and Safety						
	<p>The use of biofuels would not introduce any unique health hazard beyond that already addressed as a function of air quality or standard industrial hazards.</p> <p>Health risks from the use of pesticides, herbicides, and fertilizers in the growth of biomass.</p> <p>Additional risks of traffic accidents associated with the transport of biomass materials.</p>	<p>None; transitioning to a fleet of electric and hybrid electric vehicles in Hawai'i would not introduce any new significant hazards compared with gasoline- or diesel-powered vehicles.</p>	<p>None; increasing the number of HEVs in Hawai'i would not introduce any new significant hazards as compared to gasoline- or diesel-powered vehicles</p>	<p>No significant accident consequences are anticipated as a result of increased use of hydrogen as a vehicle fuel.</p> <p>Storage, handling, and distribution of hydrogen has risks of fire and explosions.</p> <p>Effects on island public safety services would be small; workers needed to construct and operate facilities expected to come from the State's existing workforce. Police, fire, and medical services would not be adversely affected with this small change.</p>	<p>General construction and operation impacts. See Section 3.17.3.</p> <p>Facilities for storing, handling, and distributing compressed or liquefied natural gas or liquefied petroleum gas have potential hazards related to toxic (fumes), combustion (flammable), and overpressure (explosions) that could extend into the surrounding area.</p>	<p>Potential impacts include improved health from active transit options and accessibility to healthier food options.</p>

				Flywheel	Sodium-Sulfur Battery
Climate and Air Quality					
Air Quality	General impacts during construction See Section 3.2.4.	General impacts during construction. See Section 3.2.4. No impacts from operations.	None; installing electronic equipment and upgrading software for the representative smart grid project would not involve land disturbance and therefore would not impact climate or air quality.	General construction impacts. See Section 3.2.4. No long-term impacts from operation; the flywheel energy storage system would not produce measureable amounts of criteria pollutants. No fossil fuel would be burned and no fugitive dust would be generated.	General construction impacts. See Section 3.2.4. Negligible increase in criteria pollutants during operations. No fugitive dust generated during operation.
Climate Change	General impacts during construction See Section 3.2.4.	General impacts during construction. See Section 3.2.4.	None; installing electronic equipment and upgrading software for the representative smart grid project would not involve land disturbance and therefore would not impact climate or air quality.	General construction impacts. See Section 3.2.4. Negligible increase in greenhouse gas emissions during operation of the flywheel energy storage system.	Negligible increase in greenhouse gas emissions during operation, since fossil fuels would not be burned.
Water Resources					
Surface Water	General impacts during construction. See Section 3.3.5. Operational impacts include possible alteration of stormwater runoff along transmission corridor as vegetation is reestablished. Any single drainage path expected to experience minimal alteration.3	Onshore General impacts during construction. See Section 3.3.5. Potential impacts if increase in impermeable surfaces at built up land-sea transition sites.	None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and therefore would not impact water resources.	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	General construction impacts. See Section 3.3.5. Potential increase in storm water runoff during operation.

Biological Resources					
	<p>General impacts to terrestrial ecosystems during construction, including potential access roads. See Section 3.4.5.</p> <p>Operational maintenance of cleared areas around towers and vegetation height along transmission corridor.</p> <p>Potential bird and bat collisions with towers and lines, especially nocturnal flying species.</p>	<p>General impacts to terrestrial and marine ecosystems during construction (short-term impacts to benthic communities and marine mammals if construction occurred in the Hawaiian Islands Humpback Whale National Marine Sanctuary).</p> <p>Potential localized disturbance impacts to benthic communities at HDD breakout point and along cable route during construction due to direct displacement or indirect sedimentation.</p> <p>Potential operational impacts on sensitive species by EMF fields along undersea cable route.</p>	<p>None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and therefore would not impact biological resources.</p>	<p>None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.</p>	<p>None; the battery energy storage system would involve minor land disturbance in previously developed locations.</p>
Land and Submerged Land Use					
Land Use	<p>Transmission line corridors and location of substations and switching yards could result in changes of land ownership patterns and land use.</p>	<p>General impacts during construction and operation. See Section 3.5.4</p>	<p>None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and would not impact land use.</p>	<p>None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.</p>	<p>None; the battery energy storage system would involve minor land disturbance in previously developed locations.</p>

Table 2-45. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Electrical Transmission and Distribution (continued)

Resource Area	On-Island Transmission	Undersea Cables	Smart Grid	Energy Storage	
				Flywheel	Sodium-Sulfur Battery
Submerged Land Use	None; the on-island transmission project would not extend offshore.	Short-term submerged land disturbance impacts along the undersea cable corridor during construction; Potential temporary impacts during maintenance/expansion activities. Potential land use impacts along undersea cable corridor.	None; installing electronic equipment and upgrading software for the representative project would not impact submerged land use.	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	None; the battery energy storage system would involve minor land disturbance in previously developed locations.
Cultural and Historic Resources					
	Common impacts to cultural resources during construction and operation. See Section 3.6.6. Potential direct impacts from construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities. Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.	Common construction and operation impacts to cultural resources (see Section 3.6.6). Potential direct impacts from onshore and offshore construction activities to archaeological and historic properties, including burial sites and protected traditional and customary activities. Increased likelihood of unauthorized access to culturally sensitive areas by worker presence during operations.	None; installing electronic equipment and upgrading software for the representative project would not involve land disturbance and therefore would not impact cultural or historic resources.	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	General impacts during construction and operation. See Section 3.6.6.

Resource Area	On-Island Transmission	Undersea Cables	Smart Grid	Energy Storage	
				Flywheel	Sodium-Sulfur Battery
Hazardous Materials and Waste Management					
Hazardous Materials	<p>General impacts from exposure to hazardous materials during construction. See Section 3.14.4.</p> <p>Potential impacts from exposure to hazardous materials during operation and maintenance from use of herbicides to maintain transmission corridor</p>	<p>General impacts during construction and operation, particularly during development of converter stations. See Section 3.14.4.</p>	<p>Potential impact from exposure to hazardous materials that may be present in old utility meters that are replaced by smart meters.</p>	<p>None; no hazardous materials would be required for the construction or installation of a flywheel energy storage system.</p>	<p>Potential hazardous material exposure impacts during construction and operation due to presence of hazardous chemicals inside the battery.</p>
Waste Management	<p>None; any vegetation cleared likely would be composted or reused.</p>	<p>Any waste generated onboard the construction vessels and barges would be disposed of at the appropriate landfill.</p>	<p>Potential impacts from exposure related to disposal of old utility meters.</p>	<p>General construction and operation impacts. See Section 3.14.4.</p>	<p>General construction and operation impacts. See Section 3.14.4.</p> <p>Potential impacts may occur during disposal of battery at its end of life.</p>

Table 2-45. Summary of the Potential Environmental Impacts, including Resource Areas with No Potential for Impacts – Electrical Transmission and Distribution (continued)

Resource Area	On-Island Transmission	Undersea Cables	Smart Grid	Energy Storage	
				Flywheel	Sodium-Sulfur Battery
Wastewater	General impacts during construction. See Section 3.14.4.	General impacts during construction and operation, particularly during development of converter stations. See Section 3.14.4.	None; installing electronic equipment and upgrading software for the representative project would not involve wastewater services.	None; the flywheel energy storage system would involve minor land disturbance in a previously developed location and then be installed inside the hotel.	None; the battery energy storage system would involve minor land disturbance in previously developed locations.
Socioeconomics					
	Minimal beneficial impacts during construction and operation.	Minimal beneficial impacts during construction and operation.	As technologies advance, job requirements will evolve.	Very small impact to population and employment variables.	Very small impacts to population and employment variables.
Environmental Justice					
	Small environmental justice impacts. Site-specific evaluation of impacted populations required.	Small environmental justice impacts. Site-specific evaluation of impacted populations required.	None; installing electronic equipment and upgrading software for the representative project would not result in environmental justice impacts.	None; installation of a flywheel for energy storage would not result in environmental justice impacts.	None; installation of a sodium-sulfur battery for energy storage would not result in environmental justice impacts.

Health and Safety					
	<p>Potential health and safety impacts to workers during installation, maintenance, and repairs of the transmission lines. Typical industrial hazards.</p> <p>Additional health and safety risks specific to electrical generation, transmission, and distribution industry.</p> <p>Potential minor health and safety impacts to the public during operation of the transmission lines as a result of electromagnetic fields generated. Limited to areas immediately adjacent to transmission lines.</p>	<p>General construction and operation impacts. See Section 3.17.3.</p> <p>Potential health and safety impacts to workers during installation, maintenance, and repairs of the undersea cables and transition sites, including increased safety risks associated with the marine environment.</p> <p>Additional health and safety risks specific to electrical generation, transmission, and distribution industry.</p>	<p>General construction and operation impacts. See Section 3.17.3.</p> <p>Minimal potential for health and safety impacts to the public associated with electromagnetic fields and radiofrequency.</p>	<p>General construction and operation impacts. See Section 3.17.3.</p>	<p>General impacts during construction and operation. See Section 3.17.3.</p>

Table 2-46. Characterization of the Potential for Environmental Impacts – Electrical Transmission and Distribution

Activity/Technology	Resource Areas																
	Geology and Soils	Climate and Air Quality	Water Resources	Biological Resources	Land and Submerged Land Use	Cultural and Historic Resources	Coastal Zone Management	Scenic and Visual Resources	Recreation Resources	Land and Marine Transportation	Airspace Management	Noise and Vibration	Utilities and Infrastructure	Hazardous Materials and Waste Management	Socioeconomics	Environmental Justice	Health and Safety
On-Island Transmission	●	●	●	●	●	●	●	●	●	●	●	●	●	●	●	○	●
Undersea Cables	●	●	●	●	●	●	●	●	●	○	○	●	●	●	●	○	●
Smart Grid	○	○	○	○	○	○	○	○	○	○	○	○	●	●	●	○	●
Energy Storage	○	○	●	○	○	●	●	○	○	○	○	○	●	●	●	○	●

○ = No potential impacts.

● = Potential impacts are common among most construction and operation activities.

● = Potential impacts are specific to an activity or technology.

2.5.1 CUMULATIVE IMPACTS

The treatment of cumulative impacts in this PEIS is qualitative in nature. DOE is not proposing any specific project or technology to be implemented as a result of this PEIS; therefore, the proposed action (development of guidance that can be used in making decisions to support the State of Hawai‘i in achieving the goals established in the HCEI) would not cause any additional, incremental impacts beyond those that are currently part of the affected environment baseline. However, evaluating the potential cumulative effects resulting from future development of activities and technologies to satisfy the HCEI goals would be dependent on a combination of two primary factors: (1) existing deployment and (2) other future development. The identification of the existing deployment or penetration of each of the activities and technologies is presented throughout [Section 2.3](#). Future development would depend on the degree of implementation of each of the activities and technologies evaluated for environmental impacts in Chapters 4 through 8. Thus, although a detailed discussion of cumulative impacts is not feasible at this stage, information about existing deployment and about environmental impacts presented in this PEIS will likely help analyze cumulative impacts in project-specific environmental reviews.

2.5.2 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

As required under CEQ regulations ([40 CFR 1502.16](#)), this PEIS evaluates the irreversible and irretrievable commitment of resources from implementation of the proposed action. Because the proposed action is to develop guidance and not any specific activity or technology, the only commitment of resources that DOE is making as a result of this PEIS is the financial commitment of funding necessary to prepare the PEIS. Any future Federal involvement in a specific renewable energy project (such as through permitting or funding) would involve additional environmental review under NEPA.

2.5.3 RELATIONSHIP BETWEEN SHORT-TERM USES AND LONG-TERM PRODUCTIVITY

As required under CEQ regulations ([40 CFR 1502.16](#)), this PEIS evaluates the relationship between short-term uses of man’s environment and the maintenance and enhancement of long-term productivity from implementation of the proposed action. Because the proposed action is to develop guidance and not any specific activity or technology, DOE is not altering any current uses of the environment in Hawai‘i. Any future Federal involvement in a specific renewable energy project (such as through permitting or funding) would involve additional environmental review under NEPA. At that point, each specifically identified project would need to evaluate and disclose the potential long-term effects on productivity of each environmental resource area and discuss potential trade-offs that may be necessary to achieve the goals established by HCEI.

2.5.4 UNAVOIDABLE ADVERSE IMPACTS

As required under CEQ regulations ([40 CFR 1502.16](#)), this PEIS evaluates the unavoidable adverse impacts from implementation of the proposed action. Because the proposed action is to develop guidance and not any specific activity or technology, there would be no unavoidable adverse impacts resulting from DOE’s current proposal. Any future Federal involvement in a specific renewable energy project (such as through permitting or funding) would involve additional environmental review under NEPA.

2.5.5 PREFERRED ALTERNATIVE

Title [40 CFR 1502.14\(e\)](#) requires DOE to identify its preferred alternative, if one exists, in the Draft PEIS. DOE plans to incorporate the information presented in this PEIS into draft guidance that could build upon the permitting requirements, best management practices, and potential mitigation measures

identified to minimize potential environmental impacts for future development of renewable energy projects and energy efficiency activities. Therefore, DOE's proposed action is also the preferred alternative.

2.7 Glossary

Affected Environment: In accordance with CEQ NEPA regulations, the affected environment is “interpreted comprehensively to include the natural and physical environment and the relationship of people with the environment.” The descriptions of the affected environment serve as a baseline – or description of existing environmental conditions – against which the impacts of potential future actions may be evaluated and compared.

Air Pollutant: Generally an airborne substance that could, in high enough concentrations, harm living things or cause damage to materials. From a regulatory perspective, an air pollutant is a substance for which emissions or atmospheric concentrations are regulated or for which maximum guideline levels have been established due to potential harmful effects on human health and welfare. In Hawai‘i, under HRS Chapter 342B, the term “air pollutant” has the same meaning as under the Clean Air Act. *Related terms: air pollution, air quality, ambient air.*

Air Pollution: Under Hawaii law ([HRS Chapter 342B](#)), refers to the presence in the outdoor air of substances in quantities and for durations which may endanger human health or welfare, plant or animal life, or property or which may unreasonably interfere with the comfortable enjoyment of life and property throughout the State and in such areas of the State as are affected thereby, but excludes all aspects of employer-employee relationships as to health and safety hazards. *Related terms: air pollutant, air quality, ambient air.*

Air Quality: The cleanliness of the air as measured by the levels of air pollutants relative to standards or guideline levels established to protect human health and welfare. Air quality is often expressed in terms of the pollutant for which concentrations are the highest percentage of a standard (e.g., air quality may be unacceptable if the level of one pollutant is 150 percent of its standard, even if levels of other pollutants are well below their respective standards). *Related terms: air pollutant, air pollution.*

Alternative Transportation Fuels and Modes: Encompass those fuel types and methods of transportation that are different than conventional gasoline-powered automobiles.

Ambient Air: The surrounding atmosphere, usually the outside air, as it exists around people, plants, and structures. It is not the air in immediate proximity to an emission source. Under Hawaii Administrative Rules (HAR) Title 11 Chapter 59, ambient air is defined as the general outdoor atmosphere to which the public has access. *Related terms: air pollutant, air pollution, criteria pollutant, National Ambient Air Quality Standards.*

Best Management Practices (BMPs): Policies, practices, and measures that reduce the environmental impacts of designated activities, functions, or processes. BMPs are distinguished from mitigation measures because mitigation measures are required as a result of the NEPA/HEPA environmental review process.

Carbon Dioxide Equivalent (CO₂Eq): A metric measure used to compare the emissions from various greenhouse gases based upon their global warming potential (GWP). Carbon dioxide equivalents are commonly expressed as “million metric tons of carbon dioxide equivalents (MMT_{CO₂Eq).” The carbon dioxide equivalent for a greenhouse gas is derived by multiplying the tons of the gas by the associated global warming potential (GWP):}

$$\text{MMT}_{\text{CO}_2\text{Eq}} = (\text{million metric tons of a gas}) * (\text{GWP of the greenhouse gas})$$

Related terms: climate change, global warming potential, greenhouse gases.

Clean Diesel: Otherwise known as ultra-low sulfur diesel fuel, clean diesel is diesel fuel that has been refined so that its sulfur content is 15 parts per million (ppm) or less. This is 97 percent cleaner than the standard highway-use diesel fuel sold in the United States, which contains an average of 500 ppm of sulfur. Sulfur, a natural part of the crude oil from which diesel fuel is derived, is one of the key causes of particulates or soot in diesel.

Climate Change: (1) Climate change refers to any significant change in the measures of climate lasting for an extended period of time. In other words, climate change includes major changes in temperature, precipitation, or wind patterns, among others, that occur over several decades or longer. (2) A change of climate which is attributed directly or indirectly to human activity that alters the composition of the global atmosphere and which is in addition to natural climate variability observed over comparable time periods. Among these human activities are burning fossil fuels as oil, coal, and natural gas (for electricity and transportation); farming (agriculture); deforestation; and other land use changes that result in the release of substantial amounts of greenhouse gases into the atmosphere that most climate scientists believe is contributing to human-induced climate change. The term “global warming” is often used in public discourse when referring to this human-induced climate change. *Related terms: carbon dioxide equivalent, greenhouse gases, global warming potential.*

Council on Environmental Quality (CEQ): A division within the Executive Office of the President that coordinates Federal environmental efforts and works closely with agencies and other White House offices in the development of environmental policies and initiatives. Established under the National Environmental Policy Act (NEPA) of 1969, CEQ is tasked with ensuring that Federal agencies meet their obligations under NEPA by overseeing Federal agency implementation of the environmental impact assessment process and to act as a referee during agency disagreements.

Criteria Pollutant: An air pollutant that is regulated by the Environmental Protection Agency (EPA) under the Clean Air Act through the National Ambient Air Quality Standards on the basis of specific criteria of human health-based and/or environmentally based criteria. EPA has set Standards for six criteria air pollutants: sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and two size classes of particulate matter, less than 10 micrometers (0.0004 inch) in diameter, and less than 2.5 micrometers (0.0001 inch) in diameter. *Related terms: air pollutant, air pollution, ambient air, National Ambient Air Quality Standards.*

Critical Habitat: Areas deemed necessary to a species’ conservation and officially designated under the Endangered Species Act; provided that the species is legally protected. *Related terms: Endangered species, threatened species*

Demand-Side Management (DSM): A utility action that reduces or curtails end-use equipment or processes. DSM is often used in order to reduce customer load during peak demand and/or in times of supply constraint. DSM includes programs that are focused, deep, and immediate such as the brief curtailment of energy-intensive processes used by a utility's most demanding industrial customers, and programs that are broad, shallow, and less immediate such as the promotion of energy-efficient equipment in residential and commercial sectors.

Distributed Generation: Electricity generation by a generator that is located close to the particular load that it is intended to serve. *Related term: Utility-scale generation.*

Distributed Renewables: refer to the use of renewable energy resources for an electricity generator that is located close to the end user or even onsite. The generating capacity of a distributed generation source can range from generation at a single residence to larger installations for commercial or multi-unit housing applications.

District Cooling/Heating: A system that uses chilled or heated fluid to provide cooling or heat, respectively, to a wide group (a “district”) of users.

Effect: A change that is the result or consequence of an action or other cause. As defined in 40 CFR 1508.8, effects include direct effects, which are caused by the action and occur at the same time and place, and indirect effects, which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems. Effects include ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative. Effects may also include those resulting from actions which may have both beneficial and detrimental (adverse) effects, even if on balance the agency believes that the effect will be beneficial.

Electrical Transmission and Distribution: Refers to the transmission of electrical power from a point of generation and the means by which it is stored and distributed to electricity users. Electricity transmission and distribution systems form an electrical grid or network that is used to manage and distribute electricity in a geographic region. While electrical transmission and distribution is not specifically addressed in the HCEI, implementation of new renewable energy technologies and/or improving the existing electrical network in Hawai‘i would directly affect transmission of such electricity and is therefore analyzed in this PEIS.

Endangered Species: Any species in danger of extinction throughout all or a significant portion of its range. *Related terms: Listed species, threatened species.*

Energy Efficiency: Refers to reducing the energy used for a given purpose or service while maintaining the same results; for example, replacing an incandescent light bulb with a different type of lighting technology that uses less energy to produce the same amount of light. Energy efficient technologies reduce the need for energy while energy efficient activities require less energy or save energy. *Related terms: Hawai‘i Energy Efficiency Portfolio Standard, Renewable Energy.*

Energy Literacy: Refers to an understanding of the nature and role of energy in the world and daily lives accompanied by the ability to apply this understanding to answer questions and solve problems

Environmental Consequences: Refers to the environmental impacts (effects) of alternatives, including the proposed action, any adverse environmental effects which cannot be avoided, the relationship between short-term uses of the human environment, and any irreversible or irretrievable commitments of resources which would be involved if the proposal should be implemented. *Related term: Affected environment, effect, proposed action.*

Essential Fish Habitat (EFH): Those waters and substrate necessary to fish for spawning, breeding, or growth to maturity.

Feedstock: Any renewable, biological material that can be used directly as a fuel, or converted to another form of fuel or energy product. Biomass feedstocks are the plant and algal materials used to derive fuels like ethanol, butanol, biodiesel, and other hydrocarbon fuels. Examples of biomass feedstocks include corn starch, sugarcane juice, crop residues such as corn stover and sugarcane bagasse, purpose-grown grass crops, and woody plants. *Related terms: Biofuel, biomass, biomass energy.*

Floodplain: The lowlands and relatively flat areas adjoining inland and coastal waters and the flood prone areas of offshore islands. Floodplains include, at a minimum, that area with at least a 1.0 percent

chance of being inundated by a flood in any given year (that is, experiencing a 100-year flood). Floodplains include the base floodplain (those areas subject to 100-year floods) and the critical action floodplain (those areas with at least a 0.2 percent chance of being flooded in any given year, also known as a 500-year flood).

Flow: As used in relation to hydroelectric power, “flow” is a measure of the quantity of water (typically given in cubic feet per second) flowing through a system. Together with head, flow provides information on the potential extractable energy in the water. *Related terms: Head, hydroelectric power.*

Fuel Cell: A device that converts the chemical energy from a fuel into electricity through a chemical reaction with oxygen or another oxidizing agent. A hydrogen fuel cell is thus a specific kind of fuel cell that utilizes hydrogen as its fuel. Fuel cells can be used to for almost any application typically powered by batteries or internal combustion engine, and they can be scaled to provide energy for anything from a laptop computer to a utility-scale power station. A fuel cell produces no criteria air pollutants or greenhouse gas emissions at the point of operation, although there are associated byproducts from manufacturing and decommissioning.

Geothermal Energy: Earth’s interior heat made available by extracting it from hot water or rocks for use in generating electricity. Geothermal energy is one of the utility-scale renewable energy technologies analyzed in this PEIS. *Related term: Utility-scale renewables.*

Global Warming Potential (GWP): A measure of the total energy that a gas absorbs over a particular period of time (usually 100 years), compared to carbon dioxide. In this way, GWP of a gas provides a relative basis for calculating the equivalent warming it produces as carbon dioxide. For reference carbon dioxide has a GWP of 1, and is therefore the standard by which all other greenhouse gases are measured. The term “global warming” is synonymous with climate change. *Related terms: Carbon dioxide equivalent, climate change, greenhouse gases.*

Greenhouse Gases: Those natural or manmade gaseous constituents of the atmosphere that absorb and re-emit infrared radiation. Such gases allow sunlight to enter the atmosphere freely but absorb the resulting infrared or thermal radiation (heat) that is reradiated by the ground, objects on it, or even the air itself. In this way, such gases “trap” the heat in the atmosphere, causing the air warm. There are many greenhouse gases in nature including water vapor, carbon dioxide, methane, and nitrous oxide, as well certain manmade ones such as aerosols and chlorofluorocarbons (CFCs). Each gas had a specific ability to warm the air that is measured versus the warming potential of carbon dioxide. *Related term: air pollutant, air pollution, climate change.*

Groundwater: Water below the ground surface in a zone of saturation. *Related terms: Watershed, wetlands.*

Hawai‘i Clean Energy Initiative (HCEI): The partnership established through the 2008 Memorandum of Understanding (MOU) between the State of Hawai‘i and the U.S. Department of Energy in furtherance of the provisions of Section 355 of the *Energy Policy Act of 2005* (EPAct 2005) in order to transform the way in which energy efficiency and renewable energy resources are planned and used in the Hawaiian Islands. The overarching goal of HCEI is to meet 70 percent of Hawai‘i’s energy needs by 2030 through energy efficiency and conservation measures and renewable energy generation, collectively referred to as clean energy. The 70 percent goal includes 30 percent from energy efficiency measures and 40 percent from locally generated renewable sources. This commitment to the HCEI was reaffirmed in a 2014 MOU. *Related terms: Energy efficiency, Hawai‘i Energy Efficiency Portfolio Standard, renewable energy, Hawai‘i Renewable Portfolio Standard.*

Hawai‘i Energy Efficiency Portfolio Standard (EEPS): A policy that sets usage levels as legally mandated targets for the reduction of electricity usage to be achieved through efficiency measures and technologies. Programs and technologies include improvements in energy efficiency of public buildings and creating incentives to achieve electricity use reductions. *Related terms: Energy efficiency, Hawai‘i Renewable Portfolio Standard.*

Hawai‘i Renewable Portfolio Standard (RPS): A policy that requires electricity retailers to provide a minimum percentage or quantity of their electricity supplies from designated or defined renewable energy sources. *Related terms: Renewable Energy, Hawai‘i Energy Efficiency Portfolio Standard.*

Hazardous Material: Any item or agent (biological, chemical, physical) that has the potential to cause harm to humans, animals, or the environment, either by itself or through interaction with other factors. *Related terms: Hazardous waste, solid waste.*

Hazardous Waste: (1) As defined in this PEIS, a hazardous waste refers to any *hazardous material* that can be characterized by ignitability, corrosiveness, reactivity, and toxicity. Those solid wastes that exhibit one or more of these characteristics is are classified as a hazardous wastes, and/or as a hazardous substances, including discarded military munitions. (2) As defined by EPA, a hazardous waste is any waste that is dangerous or potentially harmful to our health or the environment. Hazardous wastes can be liquids, solids, gases, or sludges. *Related terms: Hazardous material, solid waste.*

Head: As used in relation to hydroelectric power, “head” refers to the vertical distance that water drops, and in the case of a conduit system, is a characteristic of the channel or pipe through which water flows before it interacts with the turbine. Head is measured in feet or in units of pressure. Together with flow, head provides information on the potential extractable energy in the water. *Related terms: Flow, potential energy.*

Heating Value: As applied to biomass fuel, a measure of the amount of heat energy released during combustion of a unit mass of material. The heating value is often expressed as energy per unit mass such as mega-joules per kilogram.

Joule: The International System of Units (SI) unit of work or energy equal to the work done by a force of one newton (N) acting through a distance of one meter (m). The joule is abbreviated J.

Kinetic Energy: The energy of motion of an object. That is, the kinetic energy of an object is the energy it possesses because of its motion. Kinetic energy is an expression of the fact that a moving object can do work on anything it hits; it quantifies the amount of work the object could do as a result of its motion. The total mechanical energy of an object is the sum of its kinetic energy and potential energy. *Related term: Potential energy.*

LEED (Leadership in Energy and Environmental Design): A national voluntary program developed by the U.S. Green Building Council that promotes a whole-building approach to sustainability by recognizing performance in five key areas of human and environmental health: sustainable site development, water savings, materials selection, indoor environmental quality, and overall energy efficiency. The program provides performance ratings that range from the lowest, LEED certified, to the highest, LEED Platinum Refer to <http://www.usgbc.org/leed> for more information and to get the latest certification requirements.

Listed Species: Any species of fish, wildlife, or plant determined to be endangered or threatened under Section 4 of the Endangered Species Act. *Related terms: Critical habitat, endangered species, threatened species.*

Low-Income: Individuals who fall below the poverty line are categorized as low-income. The poverty line takes into account family size and the age of individuals in the family. For any given family below the poverty line, all family members are considered to be below the poverty line for analysis. *Related term: Minority.*

Marine Hydrokinetic Energy: The kinetic energy of moving water such as waves, tides, and ocean currents. *Related term: Kinetic energy.*

Minority: Persons are included in the minority category if they identify themselves as belonging to any of the following groups (1) Hispanic or Latino, (2) Black (not of Hispanic origin) or African American, (3) American Indian or Alaska Native, (4) Asian, or (5) Native Hawaiian or other Pacific Islander. In addition, individuals who categorize themselves as being of multiple racial or ethnic origins are minorities. *Related term: Low-income.*

Mitigation Measures: Refers to any required plan or course of action (i.e., a measure) for purposes of mitigation. Such measures are required as a result of the National Environmental Policy Act / Hawai'i Environmental Policy Act (NEPA/HEPA) environmental review process for future proposed actions to support the State of Hawai'i in achieving the goals established in the HCEI.

National Ambient Air Quality Standards (NAAQS): Refers to the standards established under the Clean Air Act (42 U.S.C. § 7401 *et seq.*) and implementing Environmental Protection Agency (EPA) regulations (40 CFR Part 50) defining the highest allowable levels of certain pollutants in the ambient air (i.e., the outdoor air to which the public has access). Primary standards are established to protect public health; secondary standards are established to protect public welfare (for example, visibility, crops, animals, buildings). EPA is required to establish the criteria for setting these standards, and therefore the regulated pollutants are called criteria pollutants. EPA has set standards for six principal criteria pollutants include sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and two size classes of particulate matter, less than 10 micrometers (0.0004 inch) in diameter, and less than 2.5 micrometers (0.0001 inch) in diameter. *Related terms: air pollutant, air pollution, ambient air, criteria pollutant.*

National Pollutant Discharge Elimination System (NPDES): A provision of the Clean Water Act which prohibits discharge of pollutants into waters of the United States unless a special permit is issued by the Environmental Protection Agency, a state, or, where delegated, a tribal government on an Indian reservation. The NPDES permit lists either permissible discharges, the level of cleanup technology required for wastewater, or both.

National Register of Historic Places (NRHP): The official list of the Nation's cultural resources that are worthy of preservation. The National Park Service maintains the list under direction of the Secretary of the Interior. Buildings, structures, objects, sites, and districts are included in the National Register for their importance in American history, architecture, archeology, culture, or engineering. Properties included on the National Register range from large-scale, monumentally proportioned buildings to smaller scale, regionally distinctive buildings. The listed properties are not just of nationwide importance; most are significant primarily at the state or local level. Procedures for listing properties on the National Register are found in 36 CFR Part 60.

Navigable Waters (of the United States): As defined in section 502(7) of the Clean Water Act (1972 amendments) and 33 CFR 329.4, refers to those waters that are subject to the ebb and flow of the tide and/or are presently used, or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce.

Net Zero Energy: A condition when the total amount of energy used by a building on an annual basis is roughly equal to the amount of renewable energy created on the site.

No-Action Alternative: The alternative where current conditions and trends are projected into the future without another proposed action [refer to 40 CFR 1502.14(d)]. CEQ NEPA implementing regulations require that a PEIS analysis include a no action alternative, which provides a baseline for comparison against the impacts of the Proposed Action or other action alternatives. *Related term: Action alternative, proposed action.*

Potential Energy: The energy of an object that results from position or configuration. An object may have the capacity for doing work as a result of its position in a gravitational field (gravitational potential energy), an electric field (electric potential energy), or a magnetic field (magnetic potential energy). The total mechanical energy of an object is the sum of its kinetic energy and potential energy. *Related term: Kinetic energy*

Renewable Energy: For the purposes of this PEIS, renewable energy includes energy derived from renewable sources such as the sun, wind, falling water, the ocean, geothermal, biomass, waste-to-energy, as well as hydrogen produced from renewable energy sources. *Related terms: Energy efficiency, Hawai‘i Renewable Portfolio Standard.*

Solid Waste: As defined by the U.S. Environmental Protection Agency (EPA), any garbage or refuse, sludge from a wastewater treatment plant, water supply treatment plant, or air pollution control facility and other discarded material, including solid, liquid, semi-solid, or contained gaseous material resulting from industrial, commercial, mining, and agricultural operations, and from community activities. Solid waste includes both hazardous waste and non-hazardous waste. EPA regulations at 40 CFR 261.2 provide the conditions for whether the discarded material meets the “Definition of Solid Waste” (DSW) under RCRA Subtitle C Hazardous Waste. *Related term: Hazardous waste.*

Take (Taking): As defined under the Endangered Species Act in relation to threatened or endangered species, to “take” means to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect or attempt to engage in any such contact. *Related terms: Endangered species, listed species, threatened species.*

Threatened Species: Any species likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range. *Related terms: Listed species, endangered species.*

Utility-Scale Renewable: Refers to the use of renewable energy resources from a centrally located regional power plant. Utility-scale renewable technologies include the same kinds of renewable energy resources as distributed renewables, as well as other resources whose use at the distributed scale is impractical. The generating capacities for utility-scale technologies are typically at least an order of magnitude larger than for distributed applications.

Watershed: An area that drains into a body of water, such as a river, lake, reservoir, estuary, sea, or ocean. It includes the rivers, streams, and lakes that convey the water, as well as the land surfaces from which water runs off. In the Hawaiian Islands, the primary inland surface water features are streams that drain watersheds. By contrast, there are very few natural lakes in the Hawaiian Islands. *Related terms: Groundwater, watershed.*

Wave Power: The amount of power between wave crests. It is measured in units of kilowatts of power per meter. There exist different categories of wave power technology that utilize distinct designs to capture energy based on the kinetic properties of the water. *Related term: Kinetic energy.*

Wetlands: For regulatory purposes under the Clean Water Act, the term wetlands means “those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs and similar areas” [40 CFR 230.3(t)]. In the case of Hawai‘i, there are four distinct types of wetlands:

Riverine wetlands – These are the surface water systems found along the edges of rivers and streams.

Palustrine wetlands – These include marshes and bogs and generally are found in depressions where rain and groundwater collect. Hawai‘i’s rare montane bogs, which take millions of years to form, are in this group.

Estuarine wetlands – These include swamps and mudflats that occur on coasts where streams empty to the ocean. These areas typically are influenced by tides, are brackish, and provide habitat for fish, shellfish, and water birds.

Marine wetlands – These include intertidal shorelines, seagrass beds, and tide pools. They are saltwater systems that often provide habitat for many species harvested by humans for food.

Related terms: Groundwater, watershed.

Wind curtailment: Refers to the required reduction in electric generation output by a wind energy facility. This typically occurs when there is excess electric production in an area and there is insufficient transmission capacity to move that electricity to where it is needed.

CHAPTER 3

Affected Environment

3 AFFECTED ENVIRONMENT

In accordance with [Council on Environmental Quality](#) (CEQ) NEPA regulations (40 CFR Parts 1500 through 1508) for preparing an EIS, the [affected environment](#) is “interpreted comprehensively to include the natural and physical environment and the relationship of people with the environment.” This chapter describes the affected environment to provide the context for understanding the environmental impacts of implementing the renewable energy technologies presented in Chapter 2. Chapters 4 through 8 present the potential impacts of each technology in perspective to the environmental resource areas described herein. The descriptions in this chapter serve as a baseline—or description of existing environmental conditions—against which the impacts of potential future actions may be evaluated and compared. The description of the affected environment is of sufficient detail to support the programmatic nature of the Hawai‘i Clean Energy PEIS.

This chapter also includes a discussion about the construction and operation impacts that would be expected to typically occur for each environmental resource area for common construction projects, regardless of the renewable energy technology or activity employed. Finally, each section concludes by reviewing the [best management practices](#) (BMPs) and/or [mitigation measure](#) that would minimize or avoid the common construction and operation impacts of the resource area. These lists are not all inclusive, but, rather, meant to provide the standard BMPs for purposes of analysis. Additional BMPs may be developed for individual projects and would be outlined during that planning and compliance process. Construction and operation impacts and BMPs specific to the renewable energy technologies are analyzed in Chapters 4 through 8. Because of the interconnectedness of the information presented, DOE has published this EIS as an electronic document with bookmarks within and across chapters. The information presented is complete and progresses logically; however, for best results, it is recommended that the document be read via electronic copy—CD or website.

The study area for the affected environment analysis encompasses the State of Hawai‘i and the six principal Hawaiian Islands of Kaua‘i, O‘ahu, Molokai, Lāna‘i, Maui, and Hawai‘i. This chapter provides much of the basic resource information that will be used in shaping the decisions regarding potential development within the study area, including a general description of current conditions and trends for resources and resource uses within the study area that may be affected.

The level of detail presented for the affected environment varies depending on the potential for impacts on a particular resource as a result of implementation of the energy efficiency activities and renewable energy technologies. In addition, the region of influence within the study area varies by resource depending upon the scope of potential impacts on respective resources. For example, [air quality](#) would have a broader region of influence because air emissions travel many miles, while soils would have a more restrictive region of influence because impacts are more localized to the areas of physical disturbance. Relevant island-specific information is provided where applicable. During the preparation of this PEIS, analysts used accurate information available to describe existing environments, facilities, activities, and projects. The analysts used recent research, studies, and relevant laws and regulations in describing the existing environment and cite such as appropriate. A listing of reference sources is provided in the back of each chapter where the citation occurs.

This chapter is organized by 17 resource areas, as listed below:

- [Geology and Soils](#) – The geologic characteristics of the area at and below the ground surface, the frequency and severity of seismic activity, and the kinds and quality of soils.
- [Climate and Air Quality](#) – Climatic conditions such as temperature and precipitation, the quality of the air, and [greenhouse gas](#) emissions.

- Water Resources – Marine, surface-water, and groundwater features, water quality and availability, floodplains, and wetlands.
- Biological Resources – Plants and animals that live in the area and the occurrence of special-status species.
- Land and Submerged Land Use – Land and submerged land use practices and land ownership information.
- Cultural and Historic Resources – Cultural, historic, and archaeological resources and the importance of those resources.
- Coastal Zone Management – The existing regulatory process for consistency with coastal zone management plans, special management areas, and shoreline setbacks.
- Scenic and Visual Resources – Scenic and visual resources in terms of land formations, vegetation, and color, and the occurrence of unique natural views.
- Recreation Resources – Existing recreational areas and uses; both on land and in the marine environment.
- Land and Marine Transportation – The existing transportation systems in the area.
- Airspace Management – Existing airport systems and military air bases and operation as well as the processes for managing the safe utilization of the airspace for intended uses.
- Noise and Vibration – Ambient noise and vibration levels, analytical techniques, and the identification of sensitive receptors.
- Utilities and Infrastructure – Existing electric utilities and electrical transmission and distribution services.
- Hazardous Materials and Waste Management – Solid and hazardous waste generation and management practices, wastewater services, the types of waste from current activities, the means by which waste is disposed, and pollution prevention practices.
- Socioeconomics – The labor market, population, housing, public services, and personal income.
- Environmental Justice – The identification of low-income and minority populations that could be subject to disproportionate and adverse environmental impacts.
- Health and Safety (including Accidents and Intentional Destructive Acts) – The existing public and occupational safety conditions, including information on health and safety regulations, , and worker safety and injury data. The impacts chapters will also provide a perspective of potential impacts from accidents and intentional destructive acts.

3.1 Geology and Soils

The *affected environment* for geological resources is presented in two areas: (1) general geology and physiology (including soils), and (2) geological hazards. As applicable, discussions start with a State overview then move to the individual islands, ordered according to age.

3.1.1 GENERAL GEOLOGY AND PHYSIOLOGY

3.1.1.1 State Overview

The State of Hawai‘i is part of a chain of 129 volcanoes stretching about 3,800 miles from central to northern Pacific (almost to the Aleutian Islands). The northern, older portion consists of the *Emperor Seamounts* (mountains rising from the sea floor, but not reaching the water surface) and the southern, younger portion is the *Hawaiian Ridge or Archipelago*. Collectively, this chain is known as the Emperor Seamounts – Hawaiian Archipelago. As shown in [Figure 3-1](#), this chain of volcanoes changes direction about midway along its path. It is this change that marks the end of the Emperor Seamounts and the beginning of the Hawaiian Ridge or Archipelago. The oldest seamount near the north end of the chain formed about 80 million years ago; the oldest features of the Hawaiian portion, at its northwest end, formed about 30 million years ago ([UH Hilo 1998](#)).

GEOLOGY TERMS

Lithosphere: Outer layer of the earth, consisting of the outer crust and the rigid, upper part of the mantle. It is 25 to 125 miles thick under the continents and 30 to 60 miles thick under the oceans.

Hotspots: Locations where massive plumes of hot rock have risen through the mantle toward the lithosphere, causing melting along the upper margin as lower pressures are reached at the lithosphere’s base. The molten rock, known as magma, can rise into the crust and generate active volcanism.

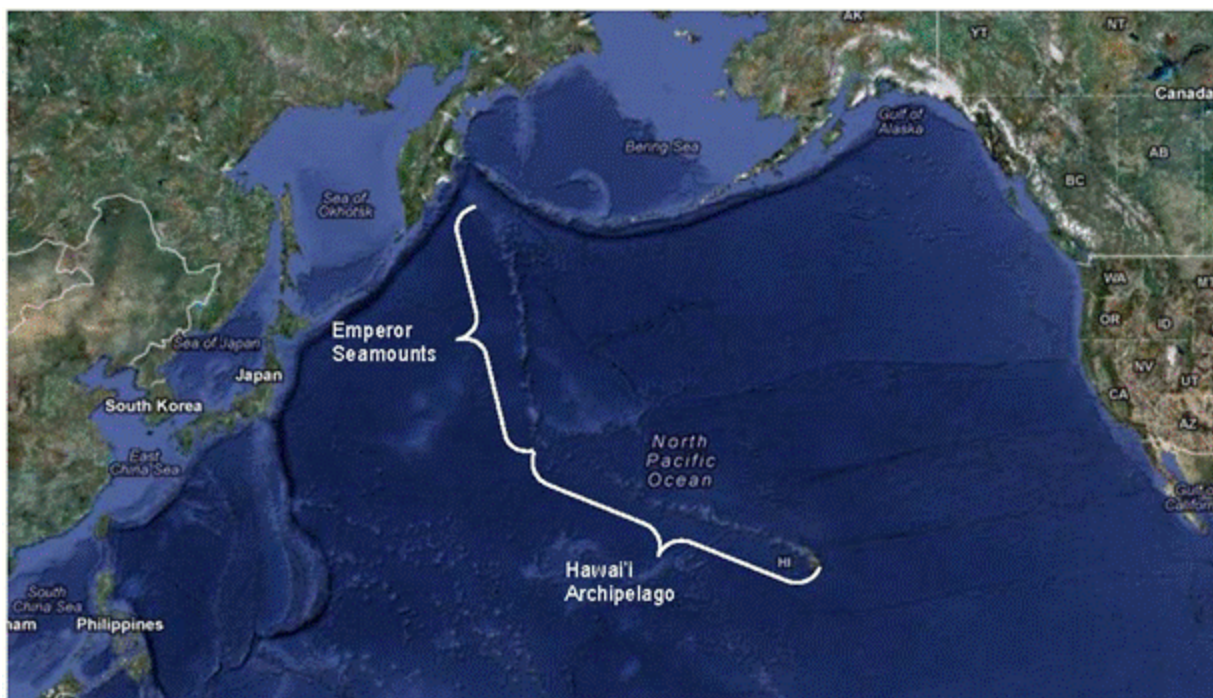

Figure 3-1. The Chain of Volcanoes Making up the Emperor Seamounts – Hawaiian Archipelago

At the southeastern end of the chain are the youngest and currently active volcanoes. These volcanoes formed as the Pacific Plate, one of the moving tectonic plates that make up the earth's *lithosphere*, passed over a *hotspot* that has remained in a relatively fixed position over the last 40 million years ([UH Hilo 1998](#)). That is, what appears to be a chain of volcanoes moving toward the east-southeast is actually the result of the Pacific Plate moving to the west-northwest over a relatively stationary hotspot.

Each of the volcanoes in the chain has evolved, or is evolving, through a similar sequence of stages ([UH Hilo 1998](#)) that together can last several million years. The stages range from the volcano's birth deep underwater, followed by erupting great volumes during the shield stage to reach the surface and to grow thousands of feet above the water, then to go through less active periods, eventually becoming extinct (or near extinct), and go through a phase of erosion and subsidence, slowly retreating back into the ocean. In its last phases the extinct volcano is reduced to sea level and transformed first into a coral atoll and then, with further subsidence, into a *guyot*, a below-sea level, flat-topped, and coral-capped volcano. As indicated in subsequent discussions, some of the volcanoes go through a late eruptive or rejuvenated stage after significant erosion and subsidence has occurred. The volcanoes that make up the Hawaiian Islands are in various positions in this general sequence of stages.

Geologic maps of the islands presented and addressed in the discussions that follow identify materials in terms of the stage during which they were ejected in volcanic eruptions. Assignment of volcanic materials to the stages is based primarily on the chemical variations that are typical of each and also takes into account their position in the rock layering, or stratigraphy, and their relative ages.

Of the eight large Hawaiian Islands, Ni'ihau and Kaua'i (the northernmost) have undergone a long duration of the rejuvenation stage. The long duration of this stage for these older islands suggests that eruptions of this stage could still occur on each of the younger volcanoes on islands to the southeast, including on the extinct Kohala volcano on Hawai'i island. *Lō'ihī*, located about 3,200 feet below sea level and 18 miles off the southeastern coast of Hawai'i island, is the newest volcano of the *Hawaiian Ridge* and is in transition between the preshield and shield stages. It is estimated that this volcano will emerge as an island within the next 200,000 years ([UH Hilo 1998](#)).

Although the islands are of volcanic origin, the thousands and in some cases millions of years involved in their evolution have allowed a constant reworking of the volcanic rocks. This is particularly true of the erosion stage described above during which time the volcanically active island moves off the hotspot and there ensues long periods of time between eruptions. Weathering, gravity, rainwater, and waves erode the volcanic slopes; rock and vegetation decay to form soil; and water, air, and animals contribute to the chemistry that forms organic debris across the volcanic landscape. These processes combined to produce islands with dense forests, streams, *watersheds*, and broad fringing reefs ([Fletcher et al. 2010](#)).

Soils across the islands, although derived from a common source of basalt lavas and volcanic ash, vary based on conditions such as local climate (particularly the amount of precipitation and/or flooding), slope and drainage, and exposures to organic materials and other chemistry-altering factors as well as the amount of time they have been subjected to these conditions. The modern system of soil classification groups soils into 12 Orders at the top of its hierarchy that then includes (in descending order and increasing number of groupings) Suborders, Great Groups, Subgroups, Families, and Series. At the lowest level of the hierarchy—the Series—more than 19,000 have been recognized in the United States ([NRCS 1999](#)). Soil surveys of the Hawaiian Islands have identified 11 of the 12 soil Orders. (The only soil Order not identified in the figure is Gelisols, which are soils underlain by permafrost.)

[Figure 3-2](#) shows a general relationship between the soil Orders and the amount of weathering to which they have been subjected. The figure identifies the 11 soil Orders found on the Hawaiian Islands. Consistent with the relationships shown in [Figure 3-2](#), soil maps show the relatively young Hawai'i island with large areas of Histosols but no Oxisols. Conversely, soil maps of the older islands of Kaua'i and O'ahu show large areas of Oxisols and other soil Orders.

Figure 3-2. General Relationship between Soil Orders and Weathering (Source: [UH Hilo 1998](#))

The island-by-island discussions that follow include summaries of soil data maintained by the Natural Resources Conservation Service (NRCS) of the U.S. Department of Agriculture

(USDA). The data identify soil series and the amount of land area occupied by each, along with land areas for portions of the islands not classified as soil (for example, water, rock outcrops, and rough mountain land). Where soil series are present, the data characterize the soil by its textural classification based on the amounts of clay, silt, and sand that are present. In this system, a loam soil is a mixture of the three that is within specific percentage bounds. The data for soil series often provide additional breakouts on the amount of soil area at different slope intervals or whether certain soil areas have high amounts of stones or gravel. The high-level summaries of the NRCS soil survey data provided for the islands are based on the textural characteristics of the various soil series, which are then grouped together. When the information was available, the tables provide a breakout for soils with slopes of less than (and greater than) about 15 percent. This slope breakout was done because the NRCS data also identify soil that qualifies as prime farmland, and soils with slopes greater than 15 percent generally do not qualify as prime farmland.

It should be noted that the State of Hawai'i incorporates a land resource evaluation system into its Land Use Commission statutes that rates agricultural productivity of land based, in part, on soil characteristics. The rating system, employed in the 1960s and 1970s by the Land Study Bureau of the University of Hawai'i, considered soil characteristics such as texture (that is, proportions of sand, silt, and clay), structure, depth, drainage, parent material, and stoniness. These soil characteristics, along with location descriptors, including topography and climate, were used to establish a five-class productivity rating system (A, B, C, D, and E) for agricultural lands. Land rated with the highest agricultural productivity potential is assigned a classification of "A" and the lowest an "E." The applicable State legal statute [Hawai'i Revised Statute Chapter 13, Section 205 (HRS 13-205)] sets acceptable uses for agricultural lands, with a primary goal of protecting (for agricultural uses) lands with high agricultural productivity, particularly those with A and B ratings. This rating system is not addressed further in this section, but its land use implications are noted in [Section 3.5](#).

3.1.1.2 Kaua'i

3.1.1.2.1 Geology

Kaua'i, the northernmost and geologically oldest of the main Hawaiian Islands, is roughly circular in shape and formed from one or possibly two shield volcanoes about 5 million years ago. The single shield

volcano is the best-known interpretation of Kaua‘i’s volcanic history, but there is some evidence suggesting there may have been two systems erupting. This alternate hypothesis is considered one that is yet to be resolved ([Sherrod et al. 2007](#)).

[Figure 3-3](#) is a generalized geologic map of Kaua‘i. The large central caldera, is mapped by the Olokele Member of the Waimea Canyon Basalt in the figure. The Olokele Member consists primarily of thick lava flows that ponded within the caldera about 4 million years ago. The Nāpali Member consists of thin flows apparently formed from spill-over from the caldera. The Hā‘upu Member is believed to have originated in a small caldera on the southeastern flank of the volcano complex. Late in the period of the Olokele Member, a structural trough, termed the Makaweli graben, developed on the southern side of the caldera. Lava flows into this trough are assigned to the Makaweli Member, which was emplaced from about 4 to 3.5 million years ago. The Kōloa Volcanics were erupted long after the main stage of shield growth ended. They represent rejuvenated-stage lava flows that were emplaced mainly between 2.6 and 0.15 million years ago ([Sherrod et al. 2007](#)).

Kaua‘i is generally considered the most structurally complex of the Hawaiian Islands ([Sherrod et al. 2007](#)). This is largely due to the deep erosion and weathering that has occurred over time plus the large amount of rejuvenated-stage lavas that covered much of the island. These more recent lavas covered much of the eastern half of the island and included eruptions on the submarine east and southeastern flanks. These flows also filled canyons and diverted rivers and were subsequently carved into new river beds ([UH Hilo 1998](#)).

3.1.1.2.2 Soils

NRCS data for Kaua‘i identify more than 40 soil series. [Table 3-1](#) provides a high-level summary of the NRCS soil survey data based on the textural characteristics of the various soil series. As can be seen in the table, classified soil series represent about half of the island’s area, with silty clays and silty clay loams representing the largest land areas. The table also shows that about 20 percent of the island qualifies as prime farmland. It should be noted, however, that many of the NRCS prime farmland classifications are identified with an “if irrigated” caveat, and a few are identified with “if protected from flooding” or “if drained” notes.

3.1.1.3 O‘ahu

3.1.1.3.1 Geology

O‘ahu was formed by two volcanoes: Wai‘anae on the west and Ko‘olau on the east. Wai‘anae is the older of the two and consists of shield-stage lavas, erupted between 3.9 and 3.5 million years ago, and a thick sequence of postshield-stage basalt, erupted from about 3.2 to 2.5 million years ago. Ko‘olau consists of shield-stage lavas, erupted between 2.5 and 1.7 million years ago, and younger rejuvenated lavas; no postshield lavas have been identified for this volcano. Both volcanoes experienced giant submarine landslides. Figure 3-4 is a geologic map of O‘ahu. The Wai‘anae caldera is centered near

Lualualei Valley, shown on the west side of the island. The caldera complex that developed for the Ko‘olau volcano is referred to as the Kailua caldera and its location is shown in the figure near the southeastern corner of the island.

Wai‘anae Volcano

The oldest exposed lava flows on O‘ahu are those of the Lualualei Member of the Wai‘anae Volcanics, which formed from about 3.9 to 3.5 million years ago. A subsequent sequence, also of the shield-building stage, the Kamaile‘unu Member, involved eruptions lasting from 3.5 to 3.1 million years ago. The Pālehua and Kolekole Members form the postshield cap of the volcano. The postshield volcanism started with the Pālehua about 3.1 million years ago and continued with the Kolekole, which formed about 3 to 2.9 million years ago. A massive submarine slumping on the western side of the Wai‘anae Volcano or a related event may have been the separation between the two Members. The huge landsliding event, designated the Wai‘anae Slump (see the bathymetric (or underwater topography) map at the top of [Figure 3-4](#)), is one of the larger submarine landslides associated with the Hawaiian Islands, covering roughly 2,100 square miles. It initiated a major erosional episode that preceded the Kolekole time ([Sherrod et al. 2007](#)).

Ko‘olau Volcano

The Ko‘olau Range that extends along the northeastern side of O‘ahu is the western slope of the Ko‘olau volcano. Shield-stage lavas erupted from this volcano from about 3 to 1.8 million years ago and are designated the Ko‘olau Basalt shown in [Figure 3-4](#). The Kailua Member of the Ko‘olau Basalt provides the demarcation for the Kailua caldera. A northwest-trending rift zone on the eastern side of the range is characterized by a dike complex containing over 7,400 dikes ([Sherrod et al. 2007](#)). It is shown in [Figure 3-4](#) as the line of scattered red markings all along the eastern-northeastern side of the island. [Section 3.3](#) of this PEIS describes how these dikes (and similar ones on other islands) cause infiltrating rainwater to be caught in subsurface storage areas or compartments, well above the lens of fresh water that underlies the island. These [groundwater](#) storage areas often feed springs located at lower elevations.

During Ko‘olau’s building stage, a giant debris avalanche or landslide, designated the Nu‘uanu Slide (see the bathymetric map at the top of [Figure 3-4](#)), tore away a large portion of the volcano’s eastern half. The resulting submarine landslide material extends more than 100 miles to the northeast and involves an estimated debris volume of up to 1,000 cubic miles ([Sherrod et al. 2007](#)). Nu‘uanu Pali, the northeast-facing cliffs that extend 25 miles along the crest of the volcano, as well as the steep slopes along the northeastern side of the Ko‘olau Range, are exposed features due to the Nu‘uanu Slide and the subsequent erosion.

The final element of the Ko‘olau geology described here is the rejuvenated-stage volcanism that involved lava flows and vent deposits scattered above the Ko‘olau Basalt. These eruptions, which occurred from about 0.8 to 0.1 million years ago, and possibly as recently as about 40,000 years ago ([Sherrod et al. 2007](#)), are designated the Honolulu Volcanics because they erupted mainly in the Honolulu area. Many of the vents associated with this stage erupted through a coral reef along O‘ahu’s southern side, tended to be explosive, and often produced tuff cones ([UH Hilo 1998](#)). Some of Hawai‘i’s best known vents, including Diamond Head, Punchbowl Crater, Salt Lake Crater, and Koko Head, formed during this stage ([Sherrod et al. 2007](#)).

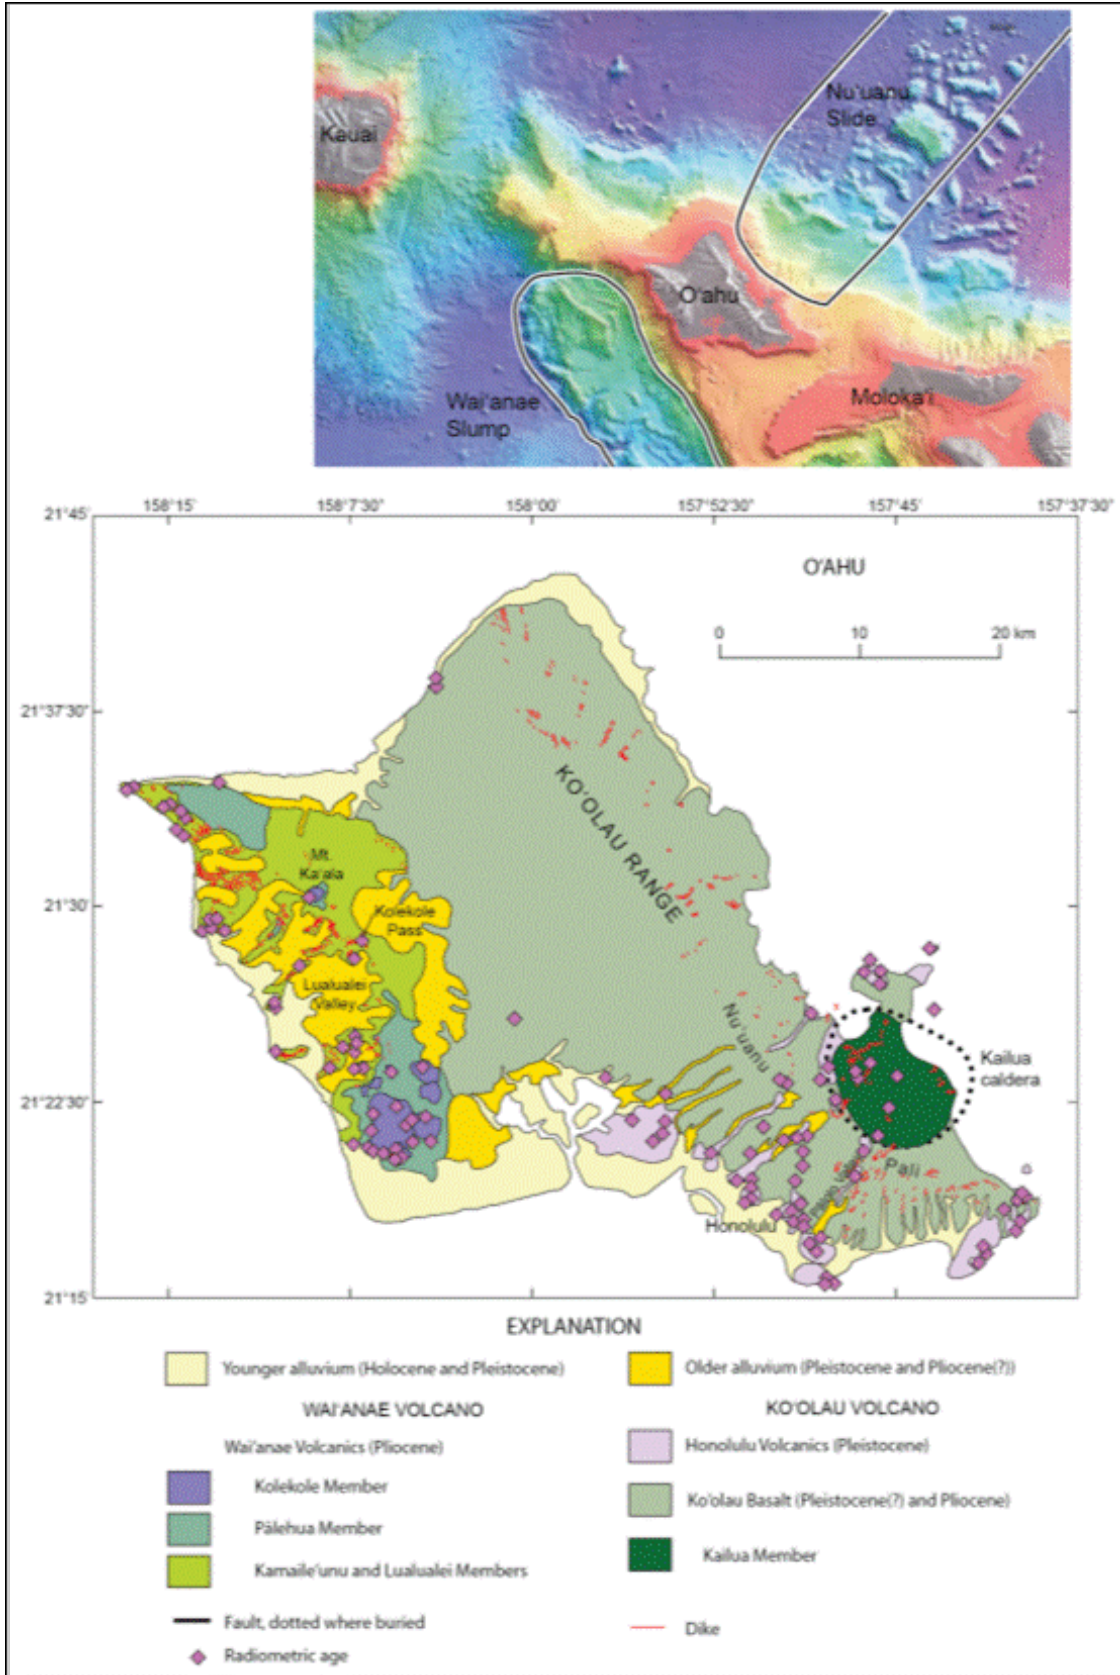

Figure 3-4. Generalized Geologic Map of O'ahu (Source: [Sherrod et al. 2007](#))

3.1.1.3.2 Soils

NRCS data for O‘ahu identify about 50 soil series. [Table 3-2](#) provides a high-level summary of the NRCS soil survey data based on the textural characteristics of the various soil series. As can be seen in the table, classified soil series represent more than half of the island’s area, with silty clays the most common soil type, followed by clay and silty clay loam. The table also shows that more than 25 percent of the island qualifies as prime farmland. It should be noted, however, that many of the NRCS prime farmland classifications are identified with an “if irrigated” caveat.

< = less than; > = greater than; NA = not applicable.

3.1.1.4 Molokai

3.1.1.4.1 Geology

Molokai was formed by two volcanoes: West Molokai and East Molokai. West Molokai is the older of the two; East Molokai, the larger of the two. East Molokai experienced a giant submarine landslide that resulted in the northern half of the volcano dropping away into the ocean. [Figure 3-5](#) is a geologic map of Molokai. A buried fault (dashed line) roughly separates flows from the West and East volcanoes. This fault has a displacement of at least 490 feet. This displacement was subsequently filled with flows from East Molokai. West Molokai has no exposed caldera, while the location of the East Molokai caldera is shown in [Figure 3-5](#).

West Molokai

It is speculated that West Molokai experienced a landslide to the east that dropped the summit and the eastern half of the volcano. If this occurred, it would have happened before East Molokai had expanded to the west and up against the eastern flank of the older volcano ([UH Hilo 1998](#)) at the fault line described above. In the last 100 years, soil eroded from this portion of the island appears to have expanded the southern coastline and buried a portion of the fringing reef along the southern coast. This high rate of erosion is attributed to historic overgrazing ([Sherrod et al. 2007](#)).

East Molokai

Lava from East Molokai covers about two-thirds of the island. The volcano's last eruptions were from vents along the northern side of the island that formed the Kalaupapa Peninsula ([Sherrod et al. 2007](#)).

The northern side of the East Molokai volcano was removed by the Wailau landslide that resulted in blocks and debris falling away to the north and traveling as far as 100 miles ([UH Hilo 1998](#)). As can be seen in the bathymetric maps at the tops of Figures 3-4 and 3-5, debris from the Wailau landslide extends into the same area of debris created by the Nu'uaniu slide that occurred off the northeastern side of O'ahu. The steep cliffs on the northern side of the island represent the slide's headwall and expose about 4,900 feet of shield and postshield lava flows ([UH Hilo 1998](#)).

3.1.1.4.2 Soils

NRCS data for Molokai identify about 30 soil series. [Table 3-3](#) provides a high-level summary of the NRCS soil survey data based on the textural characteristics of the various soil series. As can be seen in the table, classified soil series represent slightly less than half of the island's area, with silty clays and silty clay loams the most common soil types. The table also shows that about 18 percent of the island qualifies as prime farmland, but all of these land classifications are identified with an "if irrigated" caveat. More than 20 percent of the island's land is characterized as rough mountainous land.

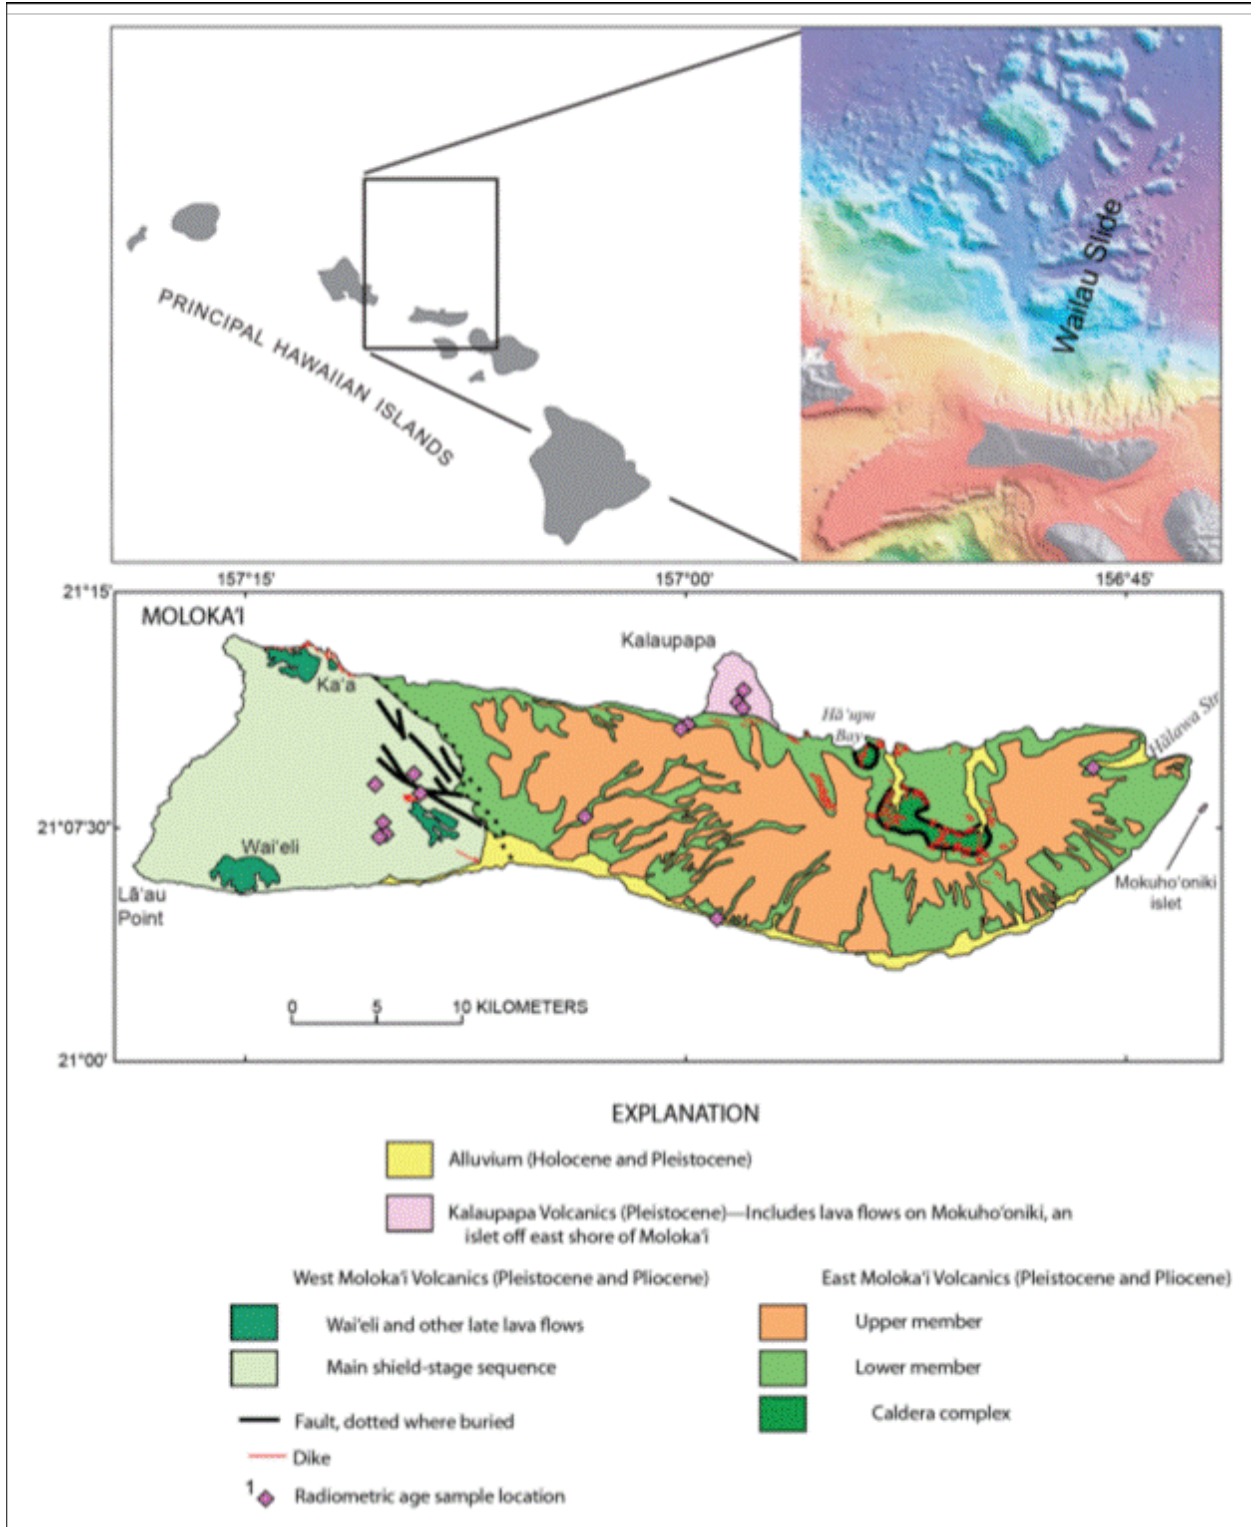

Figure 3-5. Generalized Geologic Map of Molokai (Source: [Sherrod et al. 2007](#))

< = less than; > = greater than; NA = not applicable.

3.1.1.5 Lāna‘i

3.1.1.5.1 Geology

Lāna‘i is a one-volcano island that was built up by shield-stage eruptions. A large deposit on the seafloor on the southern side of the island is attributed to a landslide, designated the Clark debris avalanche (see the bathymetric map at the top of [Figure 3-6](#)), that came from the outer slopes of Lāna‘i. It is thought to have occurred about 0.65 million years ago ([Sherrod et al. 2007](#)).

Coral cobbles and fine material found on the southeastern flank of the island at elevations up to 1,000 feet above sea level are thought by some to be deposits from a tsunami triggered by the Alika landslide on Mauna Loa’s western side ([UH Hilo 1998](#)). Other interpretations of these materials are deposit locations that represent storm beaches or uplifted shorelines ([Sherrod et al. 2007](#)).

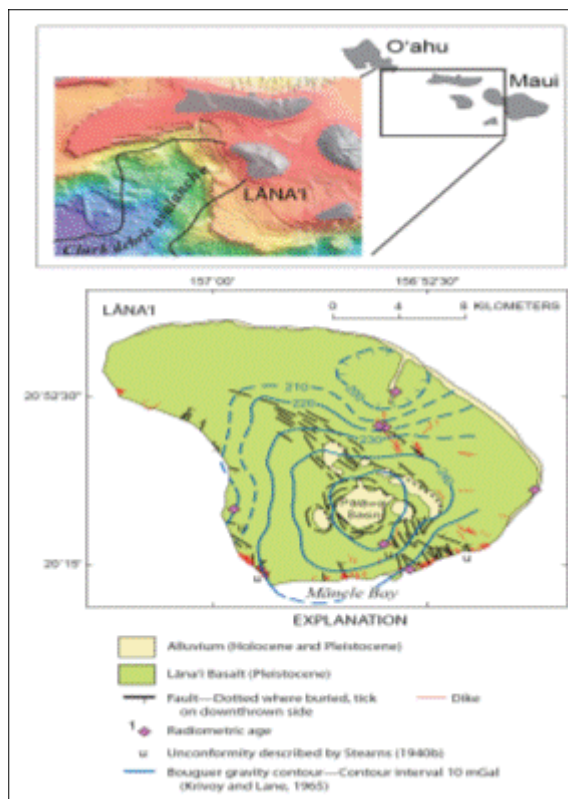

Figure 3-6. Generalized Geologic Map of Lānaʻi (Source: [Sherrod et al. 2007](#))

3.1.1.5.2 Soils

NRCS data for Lānaʻi identify fewer than 20 soil series. [Table 3-4](#) provides a high-level summary of the NRCS soil survey data based on the textural characteristics of the various soil series. As can be seen in the table, classified soil series represent less than half of the island’s area, with silty clays and silty clay loams the most common soil types. The table also shows that slightly more than 20 percent of the island qualifies as prime farmland, but all of these land classifications are identified with an “if irrigated” caveat. More than 50 percent of the island’s land can be characterized as rock outcrops or very rocky land.

3.1.1.6 Maui

3.1.1.6.1 Geology

Maui is a two-volcano island with a broad, low plain between the two. West Maui, the older of the two volcanoes, is extinct, but experienced a rejuvenated stage. The younger East Maui volcano, or Haleakalā, is still active (or potentially still active). This volcano has erupted frequently in the last 10,000 years and as recently as about 1600 based on recent radiocarbon dating ([Sherrod et al. 2007](#)). Previously it was thought to have erupted as recently as about 1790. [Figure 3-7](#) is a geologic map of Maui.

West Maui

The oldest exposed strata on West Maui volcano, the shield-stage lavas, are designated the Wailuku Basalt. The caldera-filling sequence and the dike complex shown in [Figure 3-7](#) are separately mapped flows within the Wailuku. The Honolulu Volcanics are the postshield eruptions that overlie the Wailuku

Basalt ([Sherrod et al. 2007](#)). The postshield stage is well represented by cones, domes, dikes, flows, and pyroclastic deposits ([UH Hilo 1998](#)). Although the dates for the Wailuku and Honolulu overlap, there is no known evidence of interfingering, so it appears the shield stage ended fairly abruptly, at least in geologic terms ([Sherrod et al. 2007](#)).

Four cinder and spatter cones represent the rejuvenated stage of West Maui. Deposits from these features are designated the Lahaina Volcanics for the town where the most extensive of the flows is exposed ([Sherrod et al. 2007](#)). In [Figure 3-7](#), the town of Lahaina is located on the southeastern coast of the West Maui portion, within the mapped segment of younger alluvium deposits just south of the largest area of Lahaina Volcanics.

Deep gulches have been eroded and radiate outward from the high caldera area of West Maui. Nearly 4,900 vertical feet of volcanic layers have been exposed by erosion in places on this portion of the island ([UH Hilo 1998](#)).

East Maui (Haleakalā)

The oldest exposed flows on the East Maui volcano are the Honomanū Basalt, which erupted 1.1 to 0.97 million years ago. As can be seen in [Figure 3-7](#), the areas of exposed Honomanū Basalt are very limited, as it was almost completely buried by the subsequent postshield flows designated the Kula and Hāna Volcanics. The Kula Volcanics formed a thick mantle over most of the volcano’s volume; at the summit, it is more than 3,200 feet thick. As noted previously, the last eruption was about 400 years ago. Previous

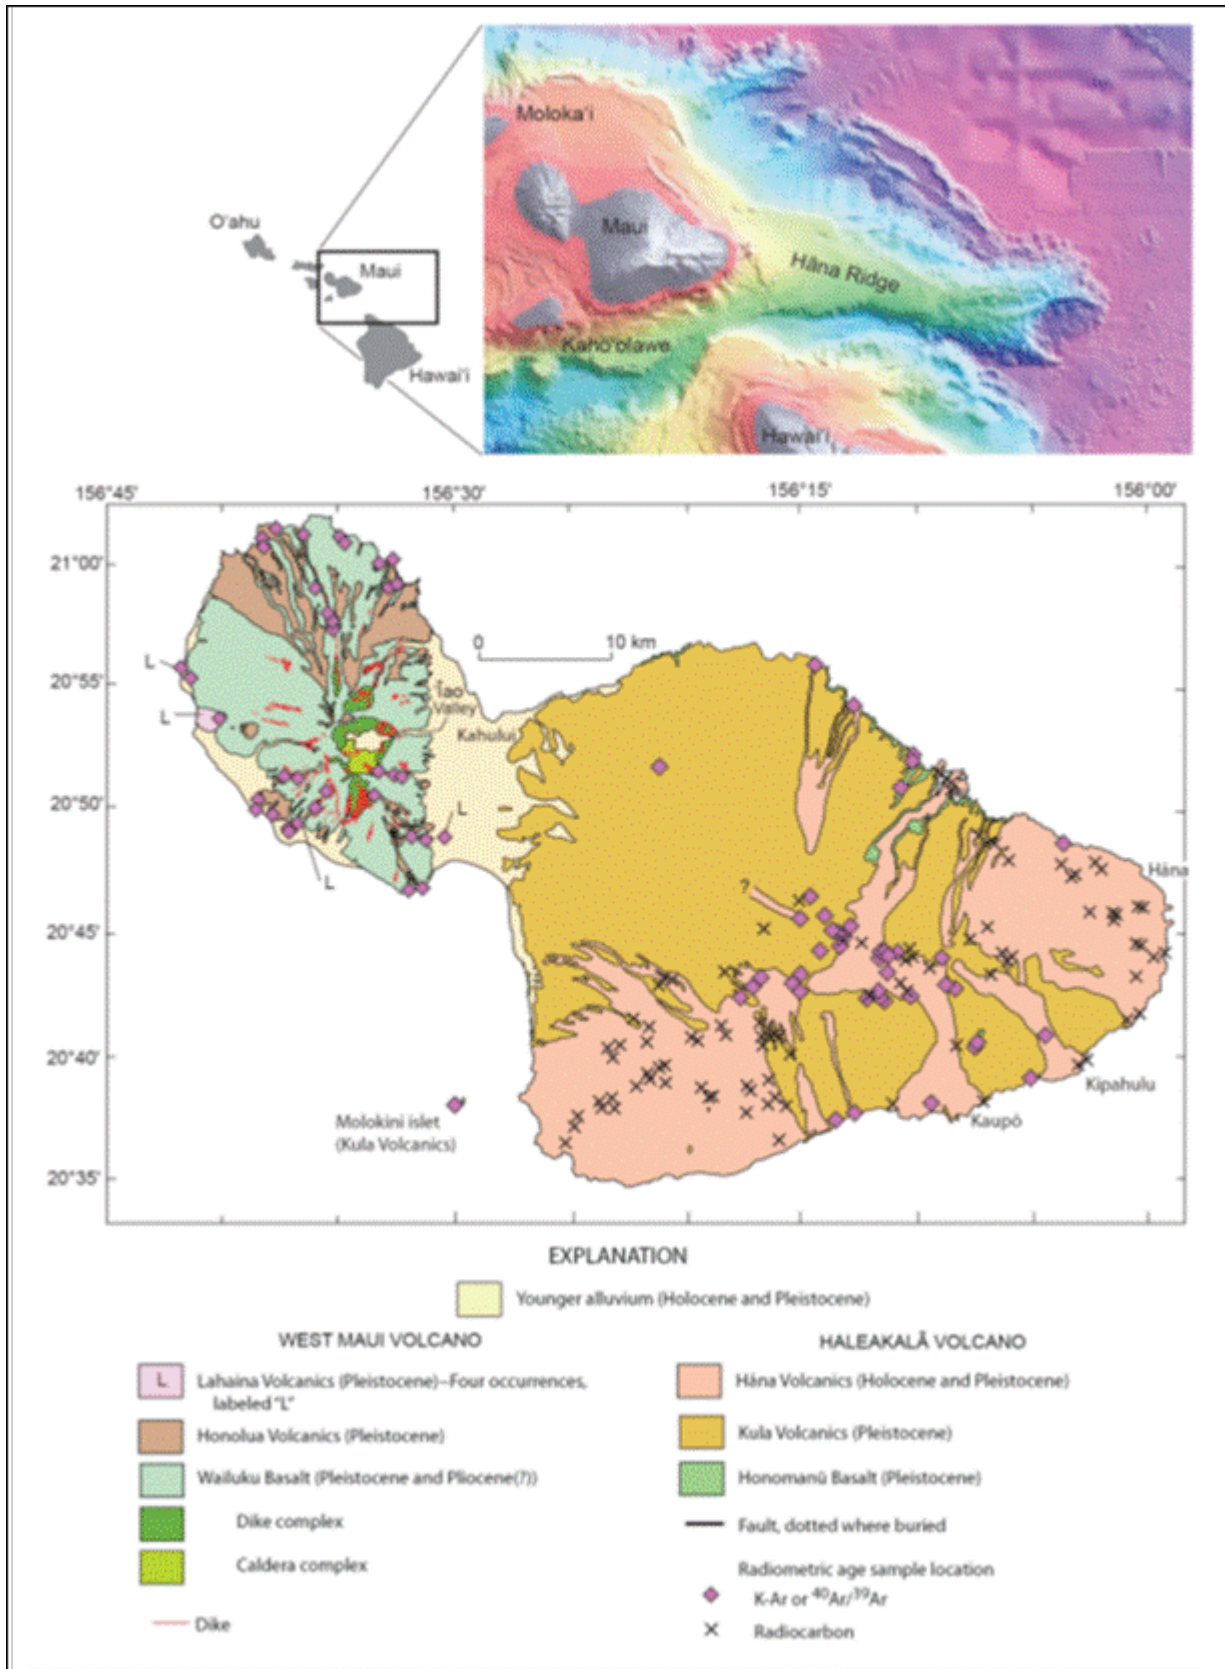

Figure 3-7. Generalized Geologic Map of Maui (Source: [Sherrod et al. 2007](#))

interpretations of the Hāna were that it represented a rejuvenated-stage deposit. However, more recent data indicate only a small gap in ages between it and the Kula and similarity in the geochemistry, which indicates it, too, is part of the postshield stage. Evaluations of the postshield volcanics indicate that Haleakalā has continued to erupt every 200 to 500 years ([Sherrod et al. 2007](#)).

No specific caldera is identified for Haleakalā. A large summit depression, once believed to be a caldera, is now interpreted to be an erosional feature generated by landslides that merged two river canyons. The rift zones along which the Kula and Hāna Volcanics erupted extend along an east-to-southwest line through the summit area with a branch to the north-northwest.

Maui Nui

Descriptions of the Hawaiian Islands geology sometimes address Maui Nui, the ancient island believed to include what are now the islands of Maui, Kaho‘olawe, Lāna‘i, and Molokai. At its maximum size, this island would have been roughly 50 percent larger than the present-day Hawai‘i island. As Maui Nui subsided, the area evolved into the current island configuration. About 300,000 to 400,000 years ago, the area probably consisted of two islands: the Molokai, and Lāna‘i group to the northwest, and the Maui and Kaho‘olawe group to the southeast. The current configuration probably came into being within the last 100,000 to 200,000 years ([UH Hilo 1998](#)).

3.1.1.6.2 Soils

NRCS data for Maui identify more than 50 soil series. [Table 3-5](#) provides a high-level summary of the NRCS soil survey data based on the textural characteristics of the various soil series. As can be seen in the table, classified soil series represent more than 60 percent of the island’s area, with silty clay loams and silty clays the most common soil types. The table also shows that about 17 percent of the island qualifies as prime farmland, but many of these land classifications are identified with an “if irrigated” caveat. More than 20 percent of the island’s land can be characterized as rough broken or mountainous land.

3.1.1.7 Hawai‘i

3.1.1.7.1 Geology

Hawai‘i island encompasses five major shield volcanoes and a sixth submerged off the northwestern shore. A seventh volcano, *Lō‘ihi* is the newest in the chain, lying about 3,200 feet beneath the sea off the island’s southeastern shore. [Figure 3-8](#) is a geologic map of Hawai‘i. [Figure 3-9](#) is a bathymetric map of the island such as has been presented for the other islands.

Table 3-5. High-Level Summary of the NRCS Soil Survey Data for Maui

Description	Slopes	Acres	Portion of Island	Prime Farmland

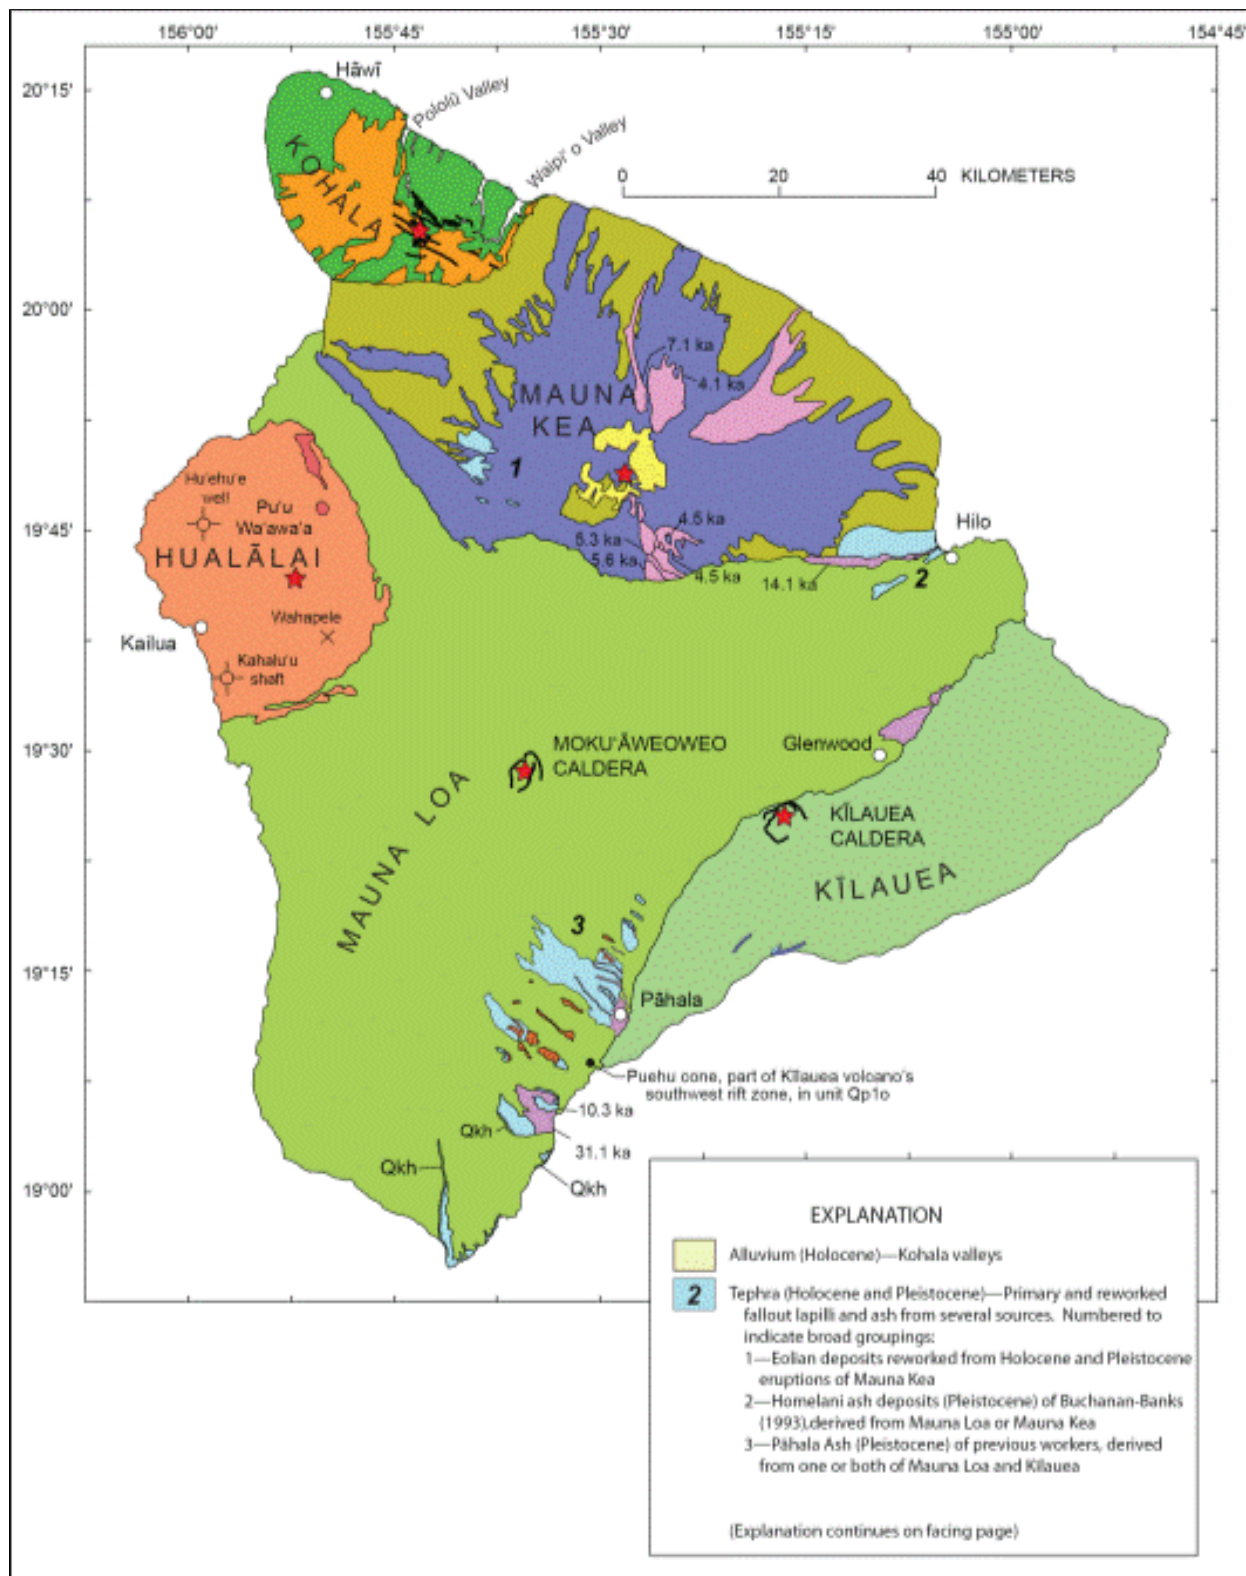

Figure 3-8. Generalized Geologic Map of Hawai'i island (Source: [Sherrod et al. 2007](#))

Figure 3-8. Continued

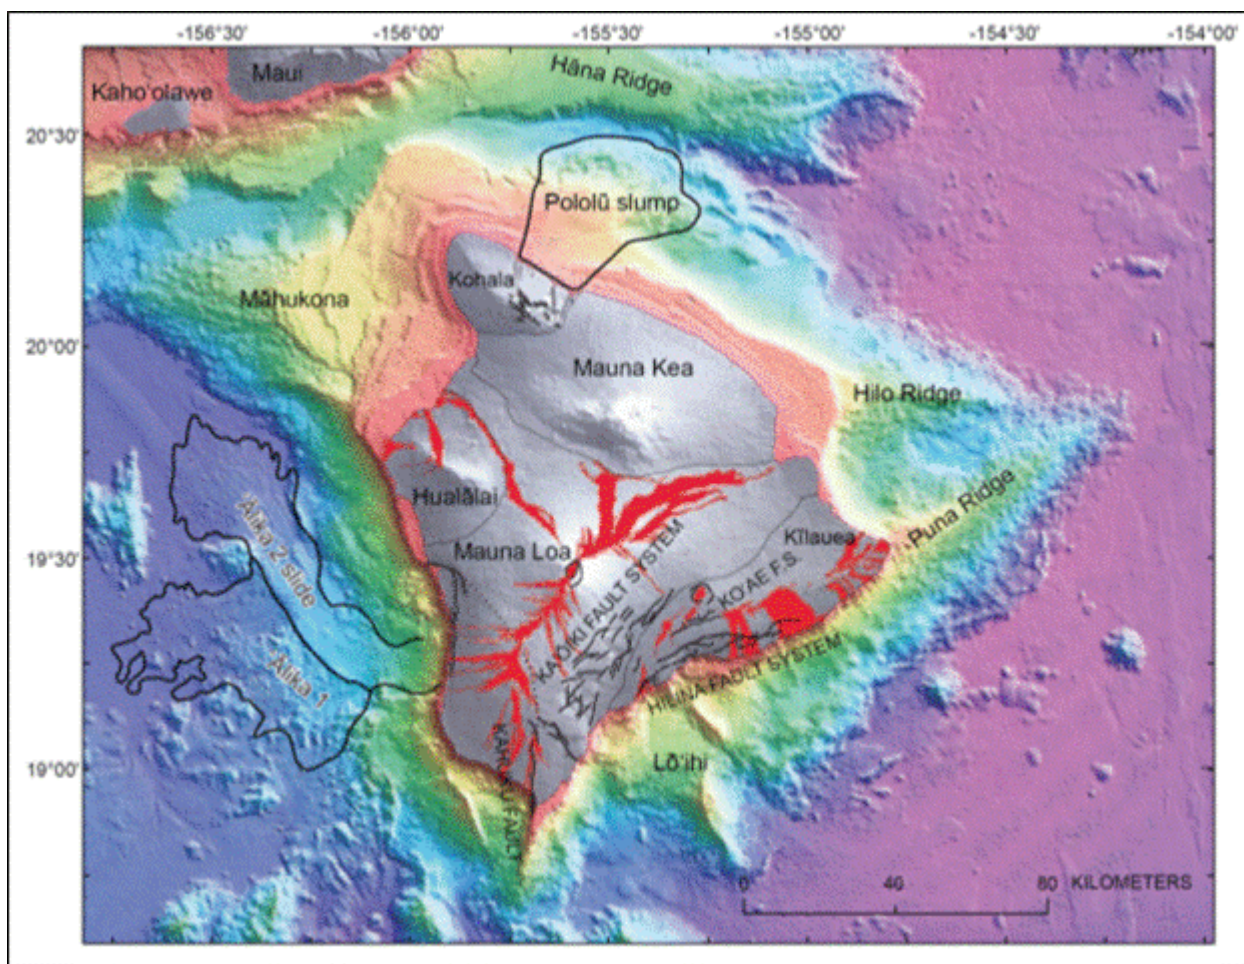

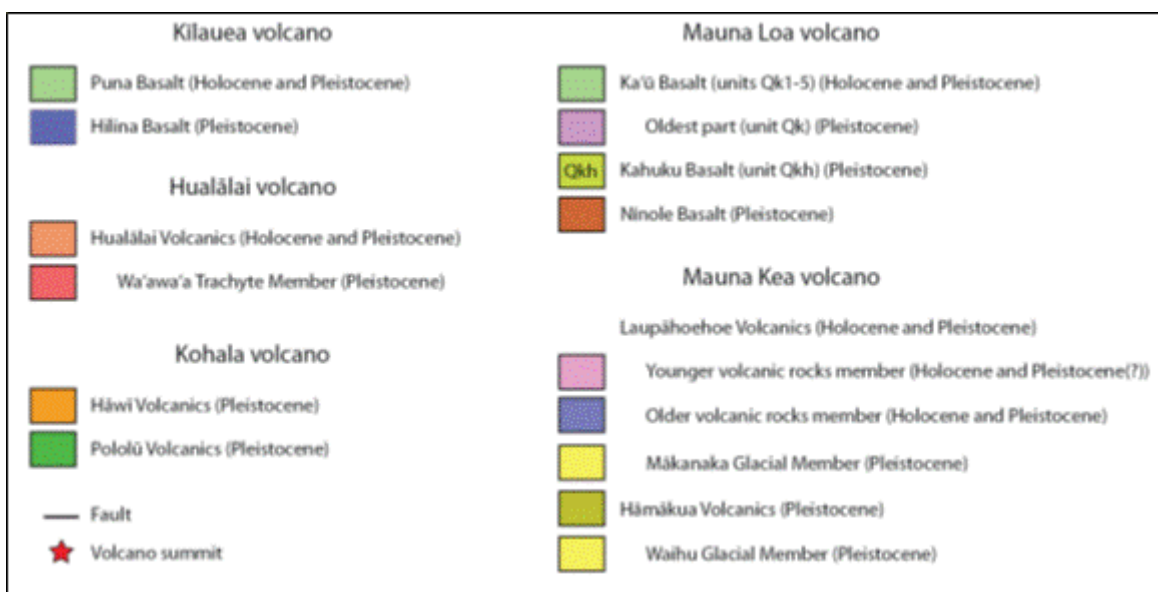

Figure 3-9. Bathymetric Map of Hawai'i island (Source: [Sherrod et al. 2007](#))

The following discussion of the Hawai‘i volcanoes starts with the oldest and moves to the youngest.

Mahukona

This was the first volcano to form part of the island. It rose only about 820 feet above sea level and submerged off the northwestern shore ([Figure 3-9](#)) ([UH Hilo 1998](#)).

Kohala

This is the oldest of the island’s surface volcanoes and forms the protrusion that is the north-northwest extent of the island ([Figure 3-8](#)) ([Sherrod et al. 2007](#)). Late in the time of the Pololū Volcanics there was a large landslide or slump off the northeastern side of Kohala (see the Pololu slump in [Figure 3-9](#)). Large stream valleys were cut into the resulting indentation along the shoreline. The subsequent Hāwī flows draped the valley walls and flowed down into Pololū Valley ([Sherrod et al. 2007](#)). Most of the thick ash cover on Kohala is believed to have come from Mauna Kea eruptions ([UH Hilo 1998](#)).

Mauna Kea

This is a dormant volcano that forms much of the northern section of the island ([Figure 3-8](#)) and last erupted about 4,600 years ago. Mauna Kea forms the highest summit in the State and is the only volcano in the chain known to have been glaciated. Many of Mauna Kea’s eruptions were explosive, possibly triggered by interaction of lava with glacial water, and produced widespread ash deposits ([UH Hilo 1998](#)). Mauna Kea is more symmetrical than other volcanoes on the island and lacks well-defined rift zones.

The oldest exposed volcanic layers are designated the Hāmākua Volcanics. These materials are found on all flanks of the volcano, are of postshield stage origin (that is, no shield-stage lavas are exposed). Two glacial sequences are interbedded with the Hāmākua on the upper flanks of Mauna Kea and are designated the Pōhakuloa Glacial (the older) and the Waihū Glacia (the younger) Members. The latest stages of Mauna Kea volcanism (still of the postshield stage) are designated the Laupāhoehoe Volcanics. The younger member of the Laupāhoehoe formed from 7,100 to 4,600 years ago.

Hualālai

Hualālai is an active volcano on the central-west portion of the island ([Figure 3-8](#)). Its most recent eruption was about 200 years ago, before that was about 700 years ago, and it erupted three times from about 900 to 1,200 years ago ([UH Hilo 1998](#)). The volcano’s summit caldera is buried, but vents, including spatter and cinder cones, define the rift zones that extend northwest and southeast from the summit. This volcano is one of several Hawaiian volcanoes known to have phreatic explosions ([Sherrod et al. 2007](#)), which are explosive eruptions of steam and rock fragments resulting from magma very rapidly heating ground or surface water into steam.

Hualālai is completely covered by postshield lavas. The earlier, shield-stage lava flows have been identified offshore and in wells, some as shallow as about 250 feet below the surface. The shield-stage eruptions stopped about 130,000 years ago. The overlying postshield lavas, designated the Hualālai Volcanics, started about 114,000 years ago. The oldest, or lowest, member of the Hualālai Volcanics is the Wa‘awa’a Trachyte Member and it erupted from about 114,000 to 92,000 years ago ([Sherrod et al. 2007](#)).

Mauna Loa

Mauna Loa comprises the central and southern parts of the island ([Figure 3-8](#)). It is the world’s largest volcano with an above-ocean-floor edifice that ranges in volume from 16,000 to 19,000 cubic miles, which includes a load-induced subsidence of 5 to 6 miles in the Pacific Plate ([Sherrod et al. 2007](#)). This growth was accompanied by several landslides to the west, the latest (and most recent in the Hawaiian Islands) being the Alika slide that occurred about 110,000 years ago ([UH Hilo 1998](#)). The Kahuku and Kealakekua faults on Mauna Loa’s west flank likely had exposures of more than 4,900 to 6,600 feet

during the volcano's history as a result of these landslides, although now they are hidden by subsequent flows ([Sherrod et al. 2007](#)). Mauna Loa is in the late shield stage, with a declining eruption rate: 36 eruptions in the 170 years since 1843 and 3 eruptions in the 60-plus years since 1950, with the last eruption in 1984. Eruptions have been primarily along two prominent rift zones with repeated fissure eruptions on the northern and northwestern flanks ([UH Hilo 1998](#)).

The oldest exposed rocks on Mauna Loa are the lava flows of the Nīnole Basalt, dated at 0.2 to 0.1 million years ago. Younger lava flows are divided into two formations: the older Kahuku Basalt and the younger, far more widespread, Ka'ū Basalt. These two basalts are generally separated by an intervening ash that has been dated at 30,000 to 13,000 years ago. The summit caldera, Moku'āweoweo, has younger, thin deposits of explosive debris on its northwest and southeast rims. These deposits are interpreted as being phreatic in origin and are dated at less than 1,000 years ago ([Sherrod et al. 2007](#)).

Kīlauea

Kīlauea forms the southeastern flank of the island ([Figure 3-8](#)) and is the youngest of Hawai'i's emergent volcanoes. It is also perhaps the most active volcano in the world, having erupted 60 times since 1840 and almost continually since 1983. Eruptions occur anywhere at the summit or along two rift zones. Kīlauea is currently in the explosive phase of its shield stage. It primarily discharges lava, but past lava flows are interbedded with ash deposits from infrequent explosive eruptions ([UH Hilo 1998](#)). The summit is mantled with a thick ash, or tephra, designated the Keanakāko'i Ash Member, that accumulated during a series of explosive eruptions over the time from about 1500 to 1790. A system of faults along Kīlauea's southern flank have offsets in the range of 1,600 to 2,200 feet and are highly active. This fault system has been associated with large earthquakes; a magnitude 7.2 earthquake occurred on the southern flank in November 1975 ([Sherrod et al. 2007](#)).

Kīlauea's surface materials are divided into three major units (starting with the oldest): (1) the Hilina Basalt, (2) an overlying accumulation of basaltic ash, and (3) the capping Puna Basalt ([Sherrod et al. 2007](#)).

3.1.1.7.2 Soils

NRCS presents data for the island of Hawai'i in two groups: one group for Hawai'i Volcanoes National Park and one group for the rest of the island. In combination, the data identify more than 150 soil series. [Table 3-6](#) provides a high-level summary of the NRCS soil survey data based on the textural characteristics of the various soil series. The NRCS data for most of the island did not contain the same level of detail as was available for the islands addressed above. For example, there was no information for the major portion of the island on which soil series qualified as prime farmland. Because of this, no attempt was made to sort soils by slopes as was done for the previous island soils. As can be seen in the table, classified soil series represent slightly less than 60 percent of the island's area, with silty clay loams and silt loams the most common soil types. The table also shows that 40 percent of the island qualifies as lava flows or lava flow-soil complexes.

Table 3-6. High-Level Summary of the NRCS Soil Survey Data for Hawai'i island

Description	Volcanoes National Park		Rest of Island		Island Total	
	Acres	Portion	Acres	Portion	Acres	Portion
Soils						
Silty clays – including silty clays that are cobbly, stony, or ashy			15,201	0.7%	15,201	0.6%
Loam – including loam that is cobbly, stony, or ashy, or that contains organic material	5,914	1.6%	120,526	5.5%	126,440	4.9%
Ashy or Sandy loam – including sandy loam that is cobbly or stony	6,598	1.6%	242,068	10.7%	248,666	9.6%

3.1.2 GEOLOGIC HAZARDS

3.1.2.1 Earthquakes

3.1.2.1.1 Earthquake Occurrences and Magnitudes

The process that is building the Hawaiian Islands is also responsible for the State's seismic activity. Unlike most areas where seismic activity is associated with movement along tectonic plate boundaries, Hawai'i's earthquakes primarily are the direct result of volcanic activity, occurring before or after eruptions, or as a result of magma moving underground without erupting ([UH Hilo 1998](#)). Another type of earthquake affecting the State involves flexing of the *lithosphere* under the weight of the islands rather than active volcanism ([USGS 2011](#)). Thousands of earthquakes occur each year in Hawai'i, but most are only detectable by highly sensitive instruments. Throughout recorded time, the State's seismic activity has been concentrated beneath Hawai'i island and the surrounding ocean floor. The type of earthquake

involving flexing of the lithosphere, however, could occur beneath the older Hawaiian Islands ([USGS 2011](#)).

[Table 3-7](#) lists Hawai‘i earthquakes with magnitudes 6.0 or greater occurring since 1868 based on recorded measurements or eye witness accounts. The size of an earthquake typically is expressed in terms of its magnitude, which is an instrument’s measurement of the amount of energy released at the source of the earthquake. The magnitude is a measure of the size or amplitude of the seismic wave that is created and is based on a logarithmic scale such that an increase in one whole number represents a tenfold increase in the size of the seismic wave. Earthquake magnitudes of 3 or less are generally not felt; magnitudes greater than 6 can cause widespread damage.

Table 3-7. Destructive Earthquakes in Hawai‘i since 1868

Year-Mon-Day	Magnitude	Maximum Intensity	Source Description
1868-03-28	7.0	IX	Southern Hawai‘i Island
1868-04-02	7.9	XII	Southern Hawai‘i Island
1918-11-02	6.2	VII	Ka’ōiki, between Mauna Loa and Kīlauea
1919-09-14	6.1	VII	Ka’u District, Mauna Loa south flank
1926-03-19	>6.0		Northwest of Hawai‘i Island
1927-03-20	6.0	VII	Northeast of Hawai‘i Island
1929-09-25	6.1	VII	Hualālai
1929-10-05	6.5	VIII	Hualālai
1938-01-22	6.9	VIII	North of Maui
1940-06-16	6.0	VII	North of Hawai‘i Island
1941-09-25	6.0	VII	Ka’ōiki
1950-05-29	6.4	VIII	Kona
1951-04-22	6.3	VIII	Lithospheric
1951-08-21	6.9	VIII	Kona
1952-05-23	6.0	VII	Kona
1954-03-30	6.5	VIII	Kīlauea south flank
1955-08-14	6.0	VII	Lithospheric
1962-06-27	6.1	VII	Ka’ōiki
1973-04-26	6.3	VIII	Lithospheric, north of Hilo
1975-11-29	7.2	VIII	Kīlauea south flank
1983-11-16	6.6	VIII	Ka’ōiki
1989-06-25	6.1	VII	Kīlauea south flank
2006-10-15	6.1	VII	Northwest of Hawai‘i Island, north of Kīholo Bay
2006-10-15	6.7	VIII	Northwest of Hawai‘i Island, near Kīholo Bay

Sources: [UH Hilo 1998](#); [USGS 2006, 2013a](#).

Intensity = Modified Mercalli Intensity Scale measure.

Another measuring approach for earthquakes is the Modified Mercalli Intensity Scale, which ranks on a scale from I to XII based on the shaking severity of the earthquake and its effects on people, human structures, and the natural environment. An intensity of I is “not felt except by a very few under especially favorable conditions” and a XII indicates “Damage total - lines of sight and level are distorted - objects thrown into the air” ([USGS 2013b](#)). [Table 3-7](#) shows the intensity values for each of the magnitude 6.0 or greater earthquakes since 1868. Earthquake magnitudes of less than 3 correspond to a level I on the Intensity Scale. A level II earthquake generally is felt by only a few people, particularly on upper floors of buildings; a level III generally is felt by people indoors, but is often not recognized as an earthquake because the vibrations are similar to those a passing truck might cause. Although there might be superficial damage to some structures at intensity levels V and VI, it generally takes a level of VII before there is considerable damage in poorly constructed structures and a level of VIII before there is

widespread damage in other buildings except those specially designed to withstand earthquakes ([USGS 2013b](#)). Modified Mercalli Intensity Scale levels of VII and greater are associated with earthquakes of magnitude 6.0 and greater.

As a better indication of where earthquakes take place, [Figure 3-10](#) shows locations of earthquakes occurring since 1973. This figure shows more earthquakes than [Table 3-7](#) lists for this timespan because it shows events down to a magnitude 5. As can be seen in the figure, very few of the depicted earthquakes occurred outside of the immediate area of Hawai'i island, and all of those occurring in outer areas were in the smallest category shown; that is, they were all of a magnitude from 5.0 to 6.0.

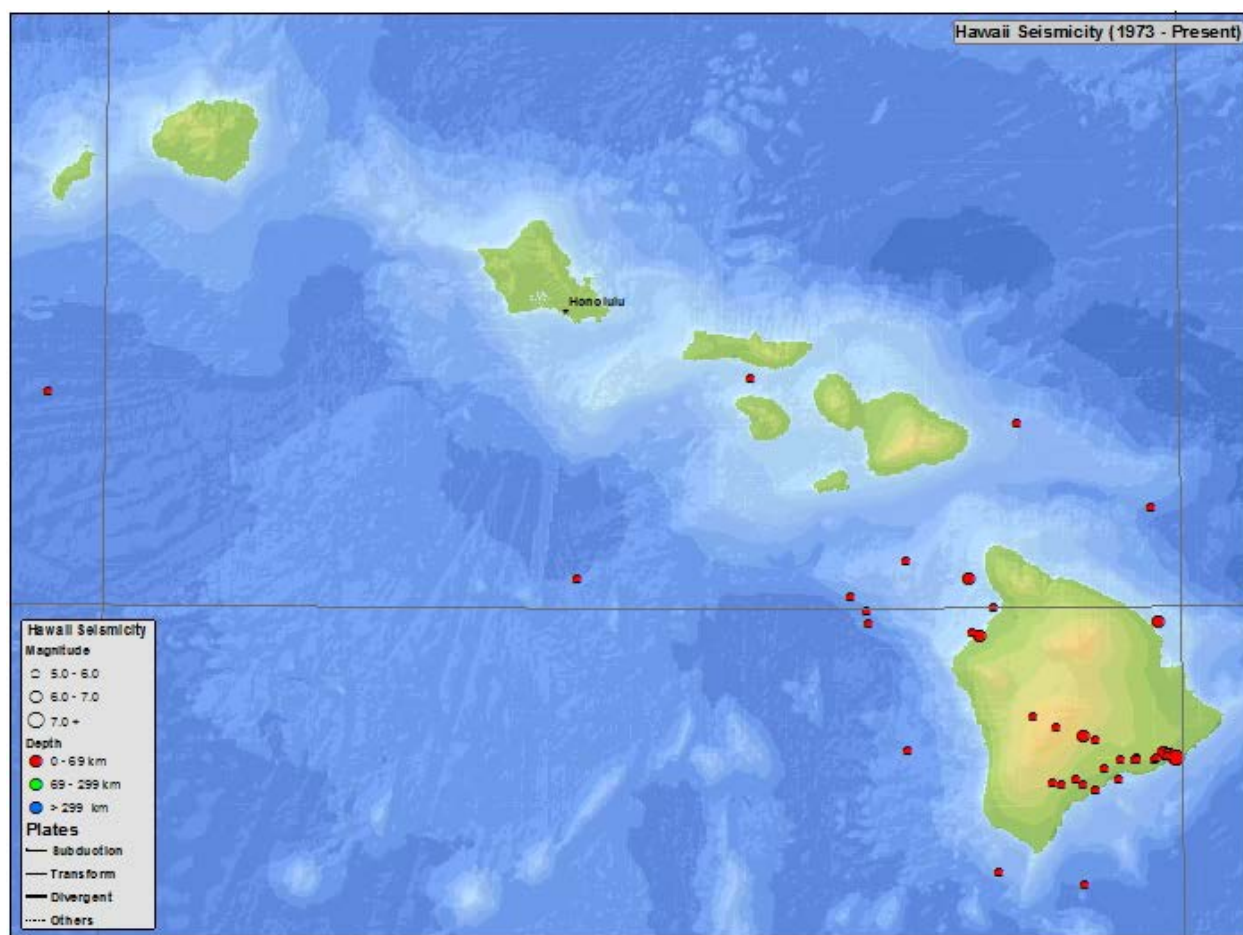

Figure 3-10. Hawaiian Earthquake Locations from 1973 to Present (Source: [USGS 2013c](#))

3.1.2.1.2 Earthquake Hazards

The U.S. Geological Survey (USGS) has developed probabilistic seismic hazard maps for the entire United States that depict the magnitude of an earthquake with a specific probability of occurring. For example, a typical seismic hazard map generated by the USGS shows how the earthquake magnitude varies over a region for an earthquake with a 10 percent probability of occurring in 50 years. This is equivalent to a 100 percent probability in 500 years (or 1 percent in 5 years). Restated, it is the magnitude of an earthquake that would be expected to occur, on average, once every 500 years. Another earthquake frequency typically shown in another set of maps is one with a 2-percent probability of occurring in 50 years. This would be an earthquake that would be expected to occur, on average, once every 2,500 years. This latter earthquake would have less probability of occurring in any year and, accordingly, would be a

larger earthquake. These seismic hazard maps show earthquake magnitude in terms of the peak ground motion they would generate and, specifically, the peak acceleration. The maps show the peak acceleration in terms of a percentage of acceleration due to gravity or “g.”

[Figure 3-11](#) is a three-part figure presenting different seismic hazard map information. At the top of the figure is the official USGS seismic hazard map for the Hawaiian Islands that shows the peak acceleration for an earthquake with a 10-percent chance of occurring in 50 years. The middle figure presents the same information from a different source that generally provides a clearer distinction of where peak acceleration values change. For comparison purposes, the bottom of the figure provides a map of the conterminous United States that shows peak acceleration for an earthquake of the same probability of occurrence. Note that the scale in the bottom map is slightly different, in that it presents peak acceleration as a factor of “g,” whereas the top two present peak acceleration as a percentage of “g” (that is, a peak acceleration of 100 percent g on the top two maps is equivalent to a value of 1 g on the bottom).

As can be seen in [Figure 3-11](#), the southeastern side of Hawai‘i island shows that an earthquake with a 10-percent chance of occurring in 50 years would produce a peak acceleration of up to about 120 percent g (or 1.2 g). This is equivalent to an earthquake with a magnitude of about 6.9 and a Modified Mercalli Intensity of IX for violent shaking with heavy damage ([USGS 2013b](#)). For this earthquake recurrence frequency, only a few areas along the very westernmost coast of the conterminous United States would reach similar peak acceleration values. Beyond the island of Hawai‘i (and even the northwestern side of it), however, peak acceleration drops to about 30 percent g or less (see also [USGS 2013d](#)). At a peak acceleration of about 30 percent g, the equivalent magnitude is below 6.0 and the Modified Mercalli Intensity is about VII or less. As noted above, an intensity of VII would result in considerable damage in poorly built structures, but negligible damage in buildings of good design and construction.

From about midway on Maui and for the rest of the islands to the west, peak acceleration drops to about 20 percent of g and less. The respective magnitude and intensity would be about 5.5 and VI and less. At an intensity of VI, damage to structures would be expected to be superficial at most.

3.1.2.2 Volcanic Eruptions and Lava Flows

The Hawaiian Islands have six volcanoes classified as active: Kīlauea, Mauna Loa, Hualālai, and Mauna Kea on Hawai‘i island; Haleakalā on Maui; and the submarine volcano Lō‘ihi to the southwest of Hawai‘i island. The following points summarize eruption characteristics on these six (from youngest to oldest):

- Lō‘ihi is the newest volcano of the Hawaiian Ridge, and it has small and infrequent eruptions. Still about 3,200 feet below sea level, this volcano is not expected to surface for approximately 200,000 years ([UH Hilo 1998](#)).
- Kīlauea has been erupting almost continuously since 1983 ([Sherrod et al. 2007](#)).
- Mauna Loa last erupted in 1984 ([Sherrod et al. 2007](#)) and is expected to erupt frequently throughout the foreseeable future ([UH Hilo 1998](#)).
- Hualālai last erupted in 1801, and it is believed to be on an eruption cycle of about 250 years ([UH Hilo 1998](#)).
- Mauna Kea last erupted about 4,600 years ago ([Sherrod et al. 2007](#)) and, though active, is considered dormant.
- Haleakalā last erupted in about 1600, and it is believed to be on an eruption interval of every 200 to 500 years ([Sherrod et al. 2007](#)).

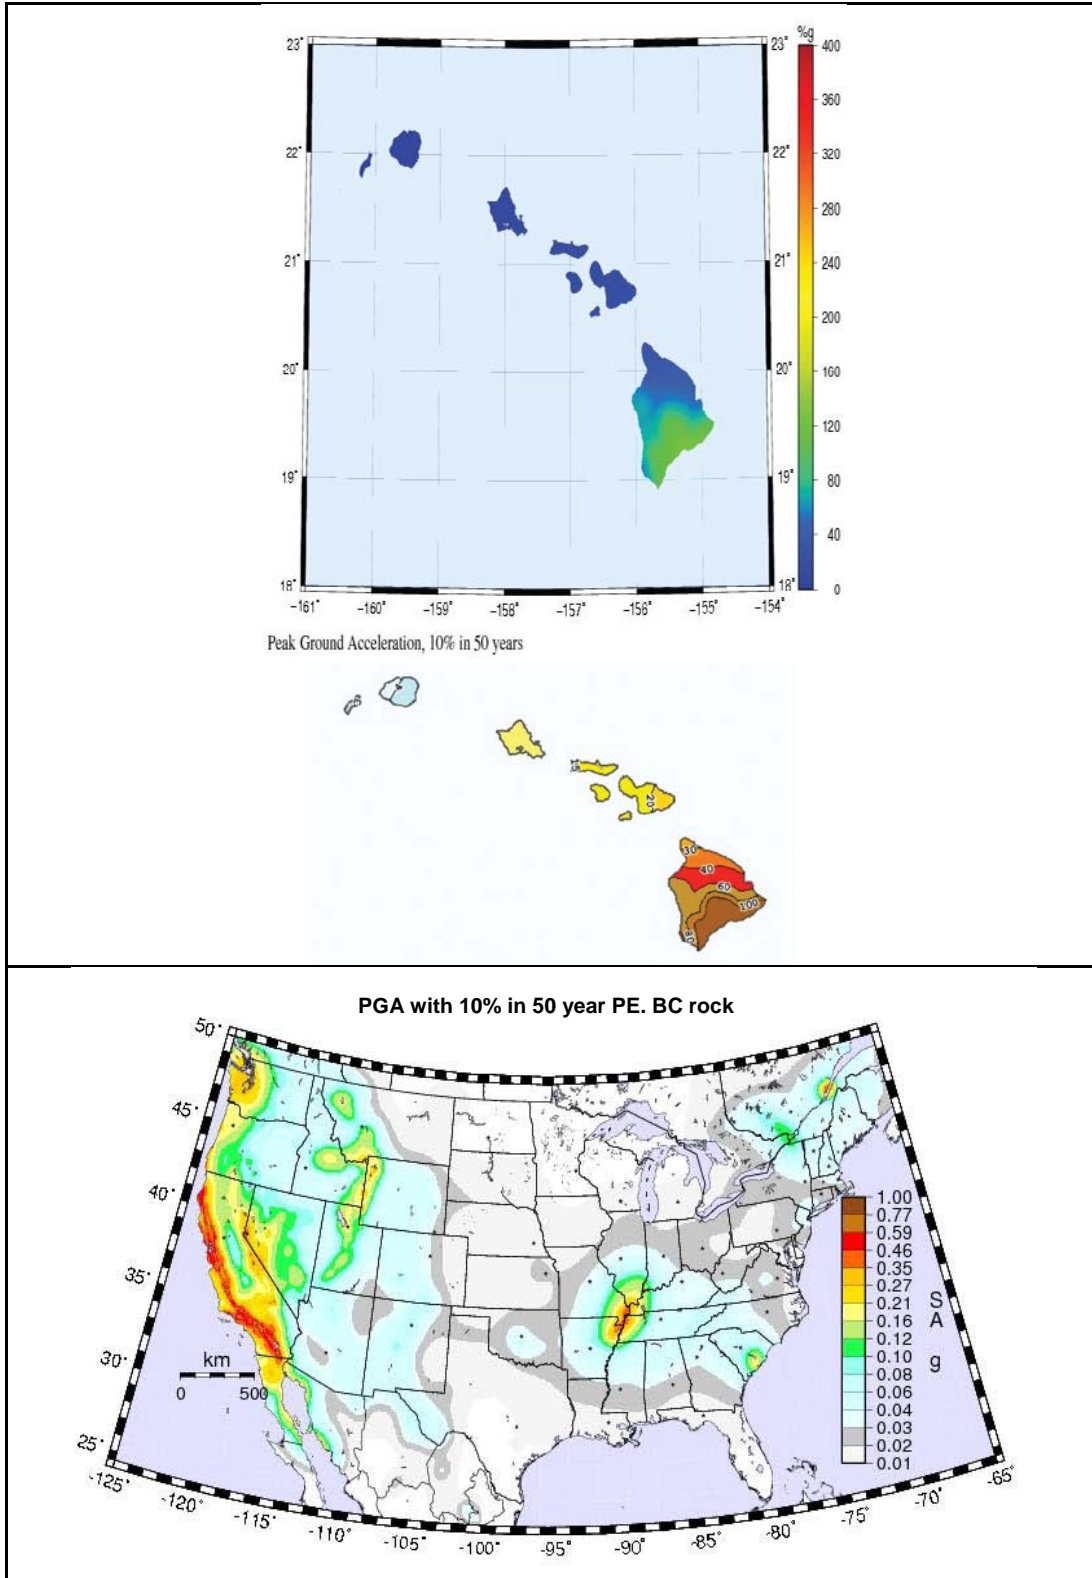

Figure 3-11. Seismic Hazard Maps for the Hawaiian Islands and the Conterminous United States for an Earthquake with a 10-percent Chance of Occurring in 50 Years (Sources: [USGS 1998](#), [2008](#), [2011](#))

Kohala, the fifth volcano on Hawai‘i island, is considered extinct, but as noted in the geology discussion, some believe that the extensive rejuvenated stage that occurred on some of the older islands is an indication that some of the younger volcanoes could go through additional eruptions. Kohala was specifically identified as a case in point.

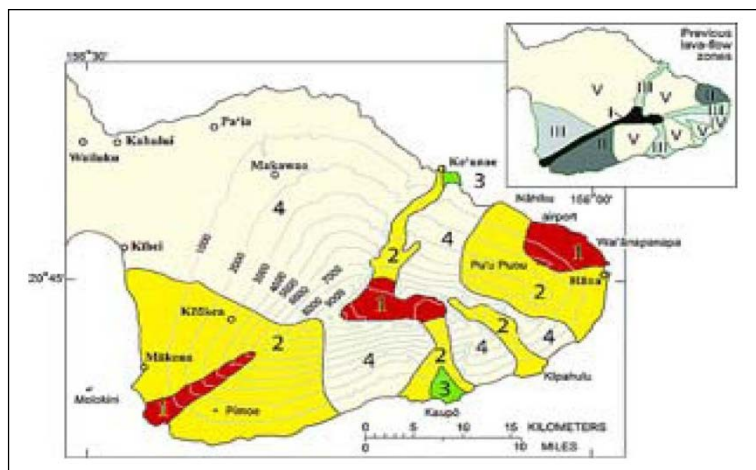

Since most Hawaiian volcano eruptions produce fluid lava flows that can travel for miles, these lava flows represent the primary volcanic hazard to island residents and property (UH Hilo 1998). [Figure 3-12](#) is a hazard map the USGS developed to depict the relative risk presented by lava flows on Hawai‘i island.

Legend			
Zone	Percentage of area covered by lava since 1800	Percentage of area covered by lava in last 750 years	Explanation
1	Greater than 25	Greater than 65	Includes the summits and rift zones of Kīlauea and Mauna Loa where vents have been repeatedly active in historic time.
2	15 to 25	25 to 75	Areas adjacent to and downslope of active rift zones.
3	1 to 5	15 to 75	Areas gradationally less hazardous than Zone 2 because of greater distance from recently active vents and/or because the topography makes it less likely that flows will cover these areas.
4	About 5	Less than 15	Includes all of Hualālai, where the frequency of eruptions is lower than on Kīlauea and Mauna Loa. Flows typically cover large areas.
5	None	About 50	Areas currently protected from lava flows by the topography of the volcano.
6	None	Very little	Same as Zone 5.
7	None	None	20 percent of this area covered by lava in the last 10,000 years.
8	None	None	Only a few percent of this area covered in the past 10,000 years.
9	None	None	No eruption in this area for the past 60,000 years.

Figure 3-12. Lava Flow Hazard Map for the Island of Hawai‘i (Source: [USGS 1997](#))

The information in the map is based on past coverage of lava flows, the location of vents, and the larger topographic features of the volcanoes that would affect distribution of the flows. The USGS generated this map for general planning purposes only and notes that the boundaries are approximate, with

transitions from one zone to another being gradual and likely occurring over a distance of a mile or more (USGS 1997).

A similar lava flow hazard map has also been developed for the eastern portion of Maui, where eruptions from Haleakalā are expected to occur at some time in the future. This map is shown in Figure 3-13, which includes, as an inset, an older version. No legend is available for the Maui map, but the USGS suggests that Zone 1 on the Maui map is roughly equivalent to the Zone 3 on the Hawai‘i island map; the Maui Zone 2 is roughly equivalent to Hawai‘i island Zone 4; and Maui Zone

Figure 3-13. Lava Flow Hazard Map for Maui (Source: USGS 2012)

3 is roughly equivalent to Hawai‘i island Zone 6. The implication in these approximate equivalencies is that there are no locations on Maui with volcanic hazards comparable to those of Zones 1 and 2 on Hawai‘i island (USGS 2012).

3.1.2.3 Tsunami Hazards

Tsunami are caused by sea floor disturbances that displace water. They typically are caused by earthquakes, but they can also be the result of underwater slides or volcanic eruptions. The Hawaiian Islands are susceptible to tsunami generated along the “Ring of Fire” fault zone that borders the Pacific Ocean, and Pacific-wide tsunami are only moderately weakened as they travel across the ocean. For example, the massive earthquake that occurred in Chile in May 1960 generated a tsunami that not only impacted and caused severe damage to the bayfront of Hilo, it caused considerable damage to coastal areas in Japan. Over the open ocean, tsunami waves are basically imperceptible, but as the water gets shallower, the waves slow down and the tremendous energy they carry transforms their height. These wave heights can reach up to 30 feet, and when they hit shore, the “sloshing” action or runup can be even greater. As the tsunami waves encounter the varying depths and ocean floor topographies that are often around islands, their directions can change such that coasts not facing the source of the tsunami can also be impacted (UH Hilo 1998).

Since 1819 when the first tsunami was recorded in Hawai‘i, there have been 87 observed tsunami, 15 of which resulted in significant damage. Figure 3-14 provides a graphical representation of the major tsunami runups that have been observed in the Hawaiian Islands from 1819 through 1994 from sources outside of Hawai‘i. Major is defined as a runup of 3 feet or greater. As noted in the figure, the tsunami database the National Oceanic and Atmospheric Administration (NOAA) developed (NOAA 2013a) shows one additional event since 1994. In March of 2011, a magnitude 9 earthquake in Japan caused a tsunami that impacted the Hawaiian Islands with runups recorded in several locations, the largest almost 7 feet on O‘ahu. The database did not specify significant injuries or property losses for this event.

Note: Since 1994, there has been one additional major tsunami of record ([NOAA 2013a](#)):
 Year: 2011
 Runup: 6.6 feet on Maui
 Origin: Japan

Figure 3-14. Observed Major Tsunami Runups in Hawai‘i, 1819 to 1994, from Outside Sources (Source: [UH Hilo 1998](#))

Of the tsunamis depicted in [Figure 3-14](#), two are worth specific note. The most destructive tsunami to hit Hawai‘i was one that occurred in April 1946 as a result of an earthquake in the Aleutian Islands. Waves 55 feet high struck the northeastern coast of Hawai‘i island. At Hilo, 173 people were killed and a similar number were injured, 488 buildings were demolished, and railroads were destroyed. During the same event, railroads on the north shore of O‘ahu also were destroyed ([USGS 1972](#)). [Figure 3-15](#) shows runups reported throughout the State from this tsunami and provides an indication of how extensive the effects were. As shown in the figure, runups were reported on all sides of all islands. The northern sides of the islands generally had the higher waves, as might be expected since the wave source was the Aleutian Islands to the north. The highest runup, as shown on the map, was 54 feet on the north shore of Molokai. However, there also were several instances where runups of about 30 feet occurred on the western and even southwestern sides of the islands ([UH Hilo 1998](#)). The other notable event shown in [Figure 3-14](#) was the previously mentioned May 1960 tsunami resulting from the Chilean earthquake. This one hit Hilo very hard, killing 61 people ([USGS 2011](#)).

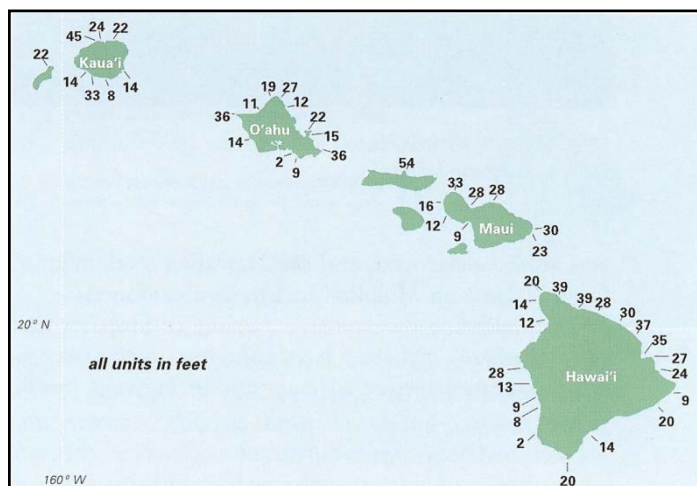

Figure 3-15. Wave Runups from 1946 Tsunami (Source: [UH Hilo 1998](#))

Two additional significant tsunamis are not included in [Figure 3-14](#) because they were generated from local events. Specifically, they were the result of two of the earthquakes identified in [Table 3-7](#). The great earthquake of 1868 generated a 45-foot tsunami wave on the southeastern coast of Hawai‘i island that killed 46 people. The November 1975 earthquake on the southern flank of Kīlauea also generated a tsunami wave with a maximum height of 45 feet. Two people were killed by this wave. During the twentieth century, tsunami of all sources were responsible for taking 234 lives in Hawai‘i ([UH Hilo 1998](#)).

NOAA operates the Pacific Tsunami Warning Center, a tsunami warning and evacuation system developed after World War II, out of O‘ahu. This operation supports Hawai‘i and 25 countries around the Pacific Rim in tracking potential tsunami based on earthquake events. When an earthquake occurs that could potentially trigger a tsunami, wave paths or directions are projected and wave speeds are calculated that allow tsunami warnings to be issued. Local civil defense agencies, police, and fire departments can then oversee evacuations. These type of tsunami warnings can be very effective for locations distant from the source. For example, the May 1960 tsunami that originated off Chile took about 14 hours to reach Hawai‘i ([UH Hilo 1998](#)). However, in the case of local events, the short time available to react makes warnings difficult if not impossible.

3.1.3 COMMON CONSTRUCTION AND OPERATION IMPACTS

Effects on geology and soils from common construction actions would be limited primarily to: (1) the potential for disturbed soils in construction areas to be eroded as a result of being carried away by storm water runoff or wind, and (2) the potential for contaminants to be present that could be imparted to soils. This second issue would also include pollutants that could be transported with runoff to other soil areas. Contaminants in soils have the potential to be transported in normal runoff flows to receiving waters, be leached into groundwater, or pose a direct health risk to people living, working, or playing in or near the soil area.

As described in Hawai‘i Administrative Rules Title 11, Chapter 55, “Water Pollution Control” ([HAR 11-55](#)), any construction activity that would disturb one or more acres of land is required to obtain a [National Pollutant Discharge Elimination System](#) (NPDES) permit for the discharge of storm water before beginning construction. The common construction actions addressed here are assumed to involve land disturbance of one or more acres, which would be applicable to most of the utility-scale renewable energy projects analyzed in this PEIS.

In order to obtain this storm water NPDES permit, the action proponent must develop a construction site BMP plan that (as specified in Appendix C of [HAR 11-55](#)) includes:

- A county-approved erosion and sediment control plan.
- A site-specific plan to minimize erosion of soil and discharge of other pollutants into State waters.
- Descriptions of measures that will minimize the discharge of pollutants via storm water after construction operations have been finished.

These would be considered the minimum requirements because, depending on the project location, the proponent may also be subject to county permitting requirements. In general, the construction activities associated with renewable energy projects would not be expected to involve unusual activities or sources of potential contamination, so common BMPs would be implemented and would be expected to provide appropriate protection against soil erosion or contamination. The primary concern with regard to pollutants for common construction actions would be spills or leaks of fuel and lubricants from vehicles and equipment, and the types of precautions normally implemented (such as response plans, cleanup equipment, and secondary containment) would keep the potential for soil contamination at a minimum.

Areas with highly erodible soils and high slopes would, of course, present sensitive locations for any soil disturbing activities and represent areas where erosion and contamination control measures could be more difficult to implement. Such obstacles would also increase project costs and make such areas less attractive.

Areas of high earthquake activity (primarily on Hawai‘i island), areas with lava flow hazards (areas on the Islands of Hawai‘i and Maui), and coastal areas with tsunami risks (all islands) represent locations with higher-than-average (though still small) risks of damage due to the islands’ geological settings. Because these types of risks involve events with a low probability of occurrence in any short period of time, they would be unlikely to affect construction activities, but would pose a higher threat to long-term operations of a project. These risks are typically addressed by land use regulations (zoning) and building codes that limit construction in areas with unacceptably high risks and/or set design standards that reduce risks to widely acceptable levels.

3.1.4 COMMON BEST MANAGEMENT PRACTICES

Typical or common BMPs to reduce impacts to geology and soils are generally associated with construction but can often be extended into subsequent project phases. BMPs described in this section are grouped in categories of those intended to reduce soil erosion and those intended to reduce the potential for soil contamination. BMPs that would be considered during construction actions to control soil erosion include the following (from Appendix C of [HAR 11-55](#), unless referenced otherwise):

- Construction management techniques:
 - Hold clearing and grubbing to the minimum necessary for grading and equipment operations.
 - Sequence construction actions to minimize the exposure time for any cleared surface area. For large projects, phase construction actions so that areas disturbed in one phase can be stabilized (that is, protecting disturbed soil from rainfall impacts and runoff) before another phase is initiated.
 - Have erosion and sediment control measures in place and functional before beginning earth moving operations and ensure their proper monitoring and maintenance throughout the construction period. This includes establishing a monitoring schedule that is consistent with the use of the control measures; for example monitor the control measures weekly during dry periods, within 24-hours of rainfall, and daily during prolonged rainfall. Maintain records of monitoring checks and repairs.
 - Consider constructing during summer when rainfall potential is lower ([Tetra Tech 2011](#)).
 - Assign a specific individual to be responsible for erosion and sediment controls at each project site.
- Vegetation controls:
 - Avoid disturbance of existing vegetation more than 20 days prior to land disturbance.
 - If disturbed areas are to remain unfinished for more than 30 days, apply temporary soil stabilization using appropriate vegetation.
 - Apply permanent soil stabilization, with perennial vegetation or pavement, as soon as practical after final grading. If perennial vegetation is used, provide irrigation and maintenance for 30 days or until the vegetation takes root.
 - Use fertilizers in areas of poor, nutrient deficient soils to promote faster growth and better erosion control, but use only if needed ([Keller and Sherar 2003](#)).

- Develop local plant sources and nurseries for vegetative erosion control materials. Use local [*native species*](#) whenever possible, selecting species appropriate for the use, the site, and the bioregion ([Keller and Sherar 2003](#)).
- Structural and operational controls:
 - Divert storm water flows away from the construction area using appropriate control measures, as practical. Control measures may include ditches, berms, check structures, live grass barriers, or rock ([Keller and Sherar 2003](#)).
 - Design erosion control measures according to the size of the disturbed or drainage areas to detain runoff and trap sediment. Sediment control structures can include rock berms, sediment catchment basins, straw bales, brush fences, and silt fencing ([Keller and Sherar 2003](#)).
 - Reduce wind erosion by using common dust suppression techniques, such as regularly watering exposed soils and soil stockpiles and by stabilizing soil.
 - Maintain and reapply erosion control measures until vegetation is successfully established ([Keller and Sherar 2003](#)).

BMPs that would be considered during construction actions to minimize the potential for releasing contaminants to soil include the following (from [EPA 2007](#)):

- Design and implement waste management procedures and practices that address actions such as trash disposal, recycling, proper material handling, and cleanup measures. Provide toilet facilities that are regularly inspected and serviced and located away from storm drain inlets and waterways.
- Establish comprehensive procedures for the handling and management of building materials, particularly those that may be hazardous or toxic (such as paints, solvents, pesticides, fuels and oils, etc.) and store such materials indoors or under cover whenever possible or in areas with secondary containment. Designate staging areas for activities such as fueling vehicles/equipment, mixing paints, mixing mortar, and so on.
- Designate washout areas for concrete operations as well as for operations such as painting or stucco use and keep such areas at least 50 yards from storm drains and watercourses whenever possible.
- If equipment/vehicle fueling and maintenance actions must be performed on-site, create a clean and dry site, covered if possible, with a spill kit present and staff that know how to use it.
- Establish procedures and practices for equipment/vehicle washing that include use of off-site facilities; washing in designated, contained areas only; eliminating discharges to storm drain by using infiltration systems or routing to the sanitary sewer; and training staff in proper washing procedures.
- Develop a spill prevention and response plan that identifies ways to reduce the chance of spills, stop the source of spills, contain and clean up spills, dispose of spill residues, and train appropriate personnel.

Although the above measures are designated BMPs, it should be noted that the intent of the storm water NPDES permit described in [Section 3.1.3](#) is for the proponent to develop plans that identify the control measures they intend to implement. Those plans and the control measures then become requirements under the permit, unless there are more stringent requirements in the permit's standard conditions.

3.2 Climate and Air Quality

3.2.1 REGIONAL CLIMATE

The climate of the Hawaiian Islands is characterized by mild temperatures throughout the year, moderate humidity, persistence of trade winds from the northeast, significant differences in rainfall within short distances, and infrequent severe storms ([NWS 2007](#)). The mountainous topography creates one of the most spatially diverse climates in the world and significantly influences every aspect of weather and climate. Rainfall, solar radiation, temperature, humidity, and wind often have large changes over short distances ([UH Hilo 1998](#)). Changes in climate are especially noticeable along mountain slopes, where the mountains obstruct, deflect, and accelerate the flow of air. When warm, moist air rises over windward coasts and slopes, clouds and rainfall are much greater than over open sea. Air descending over leeward areas causes those areas to be more sunny and dry. Air temperature decreases with increasing elevation gain by about 3 degrees Fahrenheit (°F) per thousand feet, so Hawai'i's mountains, which range from sea level to nearly 14,000 feet, contain a climatic range from tropical to sub-Arctic ([NWS 2007](#)).

Most of Hawai'i experiences only two noticeable seasons: "summer" (dry season) between May and September and "winter" (wet season) between October and April. Summer is the warm season with the sun almost directly overhead and winds reliably from the northeast. Winter has cooler temperatures, a lower sun, more variable winds, and extensive rains ([UH Hilo 1998](#)). Hawai'i does not have extremes of cold winters and hot summers and does not normally have associated storms such as hail storms or hurricanes. However, the tallest mountains can get winter season blizzards, ice, and snow. The highest temperature ever recorded in the State of Hawai'i was 100°F at Pahala (elevation 870 feet) on the island of Hawai'i on April 27, 1931, and the lowest temperature was 12°F on Mauna Kea (elevation 13,770 feet) also on the island of Hawai'i on May 17, 1979 ([NWS 2007](#)).

The Hawaiian Islands are located at the edge of the tropics and inside a belt of steady trade winds and accompanying downwelling of upper-level air. The length of the day and the monthly temperatures in Hawai'i are relatively uniform throughout the year due to its location. The uniform day lengths result in small seasonal variations in incoming solar radiation, and therefore, produce only small variations in seasonal temperature. The annual variation in mean monthly temperatures is only about 9°F for areas at sea level ([UH Hilo 1998](#)).

The ocean temperature varies about 6°F during the year, which also contributes to the small variation in seasonal air temperature. The ocean temperature ranges from a low of 73° or 74°F during the winter to a high of near 80°F during the summer. The warmest months in Hawai'i are August and September, and the coolest months are February and March, reflecting the seasonal lag in the ocean's temperature.

The ocean near Hawai'i averages between 25 and 30 inches of rainfall per year. The islands can receive as much as 15 times that amount of rain or as little as one-third of it, depending on the mountain rains that form when the moist trade winds move from the ocean to the mountain slopes of the islands. Over the lower islands, the average rainfall distribution closely resembles the topographic contours, with greater amounts over the upper slopes. On the higher mountains, the belt of maximum rainfall lies between 2,000 and 3,000 feet, and rainfall amounts decrease rapidly with further elevation. As a result, the highest slopes are relatively dry ([NWS 2007](#)). Another source of rainfall are the cumulus clouds that build up over the

mountains and interiors on sunny afternoons due to [convection](#). These rainfalls may be intense, but they are usually brief and localized.

Hawai'i's heaviest rains usually come from winter storms between October and April. While the effects of terrain are not as great on winter storm rainfall as they are on trade wind showers, large differences in rainfall still can occur over small distances. These differences in rainfall amount vary with each storm. The leeward and other dry areas receive precipitation mainly from winter storms, so summers are relatively dry. [Climate change](#) appears to be impacting the timing, intensity, and duration of rains across the islands.

Drought can occur when there are no winter storms or trade winds. In the absence of winter storms, the normally dry leeward areas are hardest hit. The absence of trade winds affects mostly the windward and upland regions, which receive a smaller percentage of their rain from winter storms ([NWS 2007](#)) than from trade winds.

Scientists at the University of Hawai'i at Manoa have observed a decrease in the frequency of northeast trade winds and an increase in eastern trade winds over the past four decades. Northeast trade winds occurred 291 days per year 37 years ago at the Honolulu International Airport and now occur only 210 days per year. A dramatic reduction in trade wind frequencies could affect Hawai'i's future overall climate and reduce the amount of precipitation on the islands ([UH Manoa 2012](#)).

Although the regional climate applies to all the islands, each island has localized characteristics.

3.2.1.1 Kaua'i

Trade winds from the northeast affect the climate of the island of Kaua'i. The range in normal temperature between February, the coolest month, and August, the warmest month, is less than 8°F. The daily range in temperature is less than 15°F. Trade wind showers are relatively common and most are light and of short duration. Normal annual rainfall is over 40 inches at Lihue Airport (100 feet above sea level on the eastern coast), with most rain falling during the seven-month wet season from October through April. Normal precipitation in January, the wettest month, is more than 6 inches. The frequency and intensity of showers increase in the western mountains, with Mt. Wai'ale'ale receiving 486 inches of rain annually, which historically has been considered the highest recorded average in the world ([NWS 2005a](#)). However, recent studies indicate that eastern Maui receives more rainfall per year ([Giambelluca 2013](#)).

Hurricanes and other severe windstorms are rare. Although strong winds can occur in connection with storm systems, they seldom cause extensive damage. Relative humidity, moderate to high all year, is slightly higher during the wet season. However, even during periods of high temperature and humidity, the trade winds provide a system of natural ventilation that keeps the weather from seeming oppressive ([NWS 2005a](#)).

3.2.1.2 O'ahu

The northeasterly trade winds are the prevailing wind, although the average frequency of the wind varies from 90 percent during the summer to only 50 percent in January. The temperature range is moderate due to the small seasonal variation in the energy received from the sun and the tempering effect of the surrounding ocean. Honolulu Airport has recorded temperatures as high as the mid-90s and as low as the lower 50s (°F) ([NWS 2005b](#)). Rainfall is heaviest in the mountains (over 100 inches per year) and lowest along the coast west of the Wai'anae Mountains, where rainfall drops to about 20 inches per year. Rains

during the wet season, October through April, can sometimes cause serious flash flooding. Hail seldom occurs, but small tornadoes or waterspouts are known to do damage.

3.2.1.3 Molokai

As with the other Hawaiian Islands, topography has a large effect on the climate of Molokai. West Molokai is hilly with little rainfall while east Molokai is mountainous with significantly greater rainfall ([UH Hilo 1998](#)). Southwestern portions of the island receive less than 15 inches of rain per year, and the eastern mountains can receive greater than 160 inches of rain per year. The central plains, which include the island's airport, receive less than 30 inches of rain per year ([UH Hilo 1998](#)). The weather on Molokai shows little variation between the seasons. Average February high temperatures at Molokai Airport (elevation 450 feet) are 77°F, while average September temperatures are 85°F. The highest and lowest recorded temperatures are 96° and 46 °F, respectively ([WRCC 2012](#)).

3.2.1.4 Lānaʻi

Lānaʻi falls in the rain shadow of Maui, which greatly affects its weather conditions. Lānaʻi is one of the driest of the Hawaiian Islands and rarely receives continuous showers because most of the rain associated with the trade winds falls on Maui to the east. The center of the island receives about 30 to 40 inches of rain per year while the rest of the island receives only about 10 to 20 inches of rain per year ([UH Hilo 1998](#)). Temperatures in Lānaʻi City (near the center of the island) are cooler than at sea level. The average high temperature in Lānaʻi City in January is 72°F, while the average low temperature is 60°F. By contrast, the average high and low temperatures in September are 79° and 65°F, respectively ([WRCC 2006](#)).

3.2.1.5 Maui

As with the other islands, the northeasterly trade winds affect the climate of the island of Maui. The normal temperature between February, the coolest month, and August, the warmest month, ranges less than 7.2°F. The lack of temperature differences is associated with the tempering effect of the Pacific Ocean and the small seasonal variation in the amount of energy received from the sun. At Kahului Airport (in a central valley near the northern coast), rainfall is relatively light, although the contrasts between the wet season, November through April, and the dry season, May through October, are quite pronounced. Approximately 50 percent of the normal annual rainfall occurs in the three months of December through February, and over 80 percent during the six months of the wet season ([NWS 2005c](#)). As with the other Hawaiian Islands, the amount of rainfall across the island varies greatly as the result of influences from the mountainous terrain. Whereas Kahului Airport receives less than 30 inches of rain per year due to its location in a broad valley, the northeastern coast can receive more than 100 inches, and the mountain peak of Puʻu Kukui can receive more than 360 inches of rain per year ([UH Hilo 1998](#)). Recent studies indicate that Big Bog on eastern Maui receives the highest average annual rainfall in the State ([Giambelluca 2013](#)).

The trade wind flow is most prevalent during the dry season (May through October). Wind is more variable during the wet season although the trade winds still occur more than 50 percent of the time during the wetter months. Hurricanes rarely affect the Kahului area, but tropical storms may pass close enough to produce heavy rain and strong winds ([NWS 2005c](#)).

3.2.1.6 Hawaiʻi

Similar to the other islands, the island of Hawaiʻi lies within the belt of northeasterly trade winds generated by the semi-permanent Pacific high-pressure cell to the north and east. In Hilo (located near the

midpoint of the eastern coast), July and August are the warmest months with average daily highs and lows of 83° and 68°F, respectively. January and February are the coolest months with highs and lows of 80° and 63°F. Greater variations can occur in areas with less rain and clouds, but temperatures in the mid-90s or low 50s (°F) are uncommon anywhere on the island near sea level ([NWS 2005d](#)). Mean annual rainfall on the windward slopes of the island, with the exception of the semi-sheltered Hāmākua area, increases from 100 inches along the coasts to a maximum of over 300 inches at elevations of 2,000 to 3,000 feet, and then drops to about 15 inches at the summits of the Mauna Kea and Mauna Loa volcanoes. The leeward areas are topographically sheltered from the trade winds and are drier. The driest area receives an annual rainfall of less than 10 inches ([NWS 2005d](#)).

The trade winds can occur throughout the year and greatly affect the climate. Severe weather seldom occurs except for periods of heavy rain. During the winter, cold front or subtropical storms may bring blizzards to the upper slopes of Mauna Loa and Mauna Kea, with snow extending down to 9,000 feet or below ([NWS 2005d](#)).

3.2.2 EXISTING AIR QUALITY

3.2.2.1 Ambient Air Quality Standards

The *Clean Air Act* ([42 U.S.C. § 7401 et seq.](#); CAA) requires the U.S. Environmental Protection Agency (EPA) to set standards for pollutants considered harmful to public health and the environment. National primary [ambient air quality](#) standards define levels of air quality that EPA has determined necessary to provide an adequate margin of safety to protect public health, including the health of sensitive populations such as children and the elderly. National secondary ambient air quality standards define levels necessary

AMBIENT AIR

The surrounding atmosphere, usually the outside air, as it exists around people, plants, and structures. It is not the air in immediate proximity to an emission source.

to protect the public welfare, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings. EPA has established primary standards for six [criteria pollutants](#): carbon monoxide, lead, nitrogen dioxide, ozone, particulate matter [which includes particulate matter with an aerodynamic diameter less than or equal to 10 micrometers (PM₁₀) and less than or equal to 2.5

micrometers (PM_{2.5})], and sulfur dioxide. The State of Hawai‘i also has established ambient air quality standards that apply throughout the State including an ambient standard for hydrogen sulfide. [Table 3-8](#) presents applicable [National Ambient Air Quality Standards \(NAAQS\)](#) and Hawai‘i ambient air quality standards.

The State of Hawai‘i Department of Health (HDOH) Clean Air Branch monitors ambient air in Hawai‘i to determine compliance with the NAAQS. The air monitoring system includes 14 air monitoring stations on 4 islands. The State reviews the number and locations of the stations annually and can relocate, add, or discontinue stations as needed. The monitoring stations on O‘ahu measure air quality impacts from commercial, industrial, and transportation activities; the station on Maui measures impacts from agriculture activities; the station on Kaua‘i measures impacts from cruise ships; and the stations on Hawai‘i measure air quality impacts from volcanoes and geothermal energy production ([HDOH 2012a](#)).

The State of Hawai‘i has set an ambient air standard for hydrogen sulfide even though no such standard exists within the NAAQS. While hydrogen sulfide is a naturally occurring gas related to volcanic eruptions, HDOH is concerned about hydrogen sulfide emissions related to geothermal energy production. Consequently, an air monitoring station is located approximately 1 mile southwest of the geothermal energy facility on the island of Hawai‘i ([HDOH 2012a](#)). The HDOH operates this ambient air

Table 3-8. National and State of Hawai‘i Ambient Air Quality Standards

Pollutant	National Primary Standards^a	National Secondary Standards^a	Form (national standards)	State of Hawai‘i Standards^b
Carbon monoxide				
8-hour average	9 ppm	None	Not to be exceeded more than once per year	4.4 ppm
1-hour average	35 ppm	None		9 ppm
Lead				
Rolling 3-month average	0.15 µg/m ³	Same as primary	Not to be exceeded	None specified
Calendar quarter average	None	None	None	1.5 µg/m ³
Nitrogen dioxide				
Annual arithmetic mean	0.053 ppm	Same as primary	Annual Mean	0.04 ppm
1-hour	0.10 ppm	None	98 th percentile, averaged over 3 years	None specified
Ozone				
8-hour average (2008 standard)	0.075 ppm	Same as primary	Annual fourth-highest daily maximum 8-hr concentration, averaged over 3 years	0.08
PM₁₀				
Annual (arithmetic mean)	None	None		50 µg/m ³
24-hour average	150 µg/m ³	Same as primary	Not to be exceeded more than once per year on average over 3 years	Same as national
PM_{2.5}				
Annual arithmetic mean	12.0 µg/m ³	15.0 µg/m ³	Annual mean, averaged over 3 years	None specified
24-hour average	35 µg/m ³	Same as primary	98 th percentile, averaged over 3 years	None specified
Sulfur dioxide				
Annual average	None	None		0.03 ppm
24-hour average	None	None		0.14 ppm
3-hour average	None	0.5 ppm	Not to be exceeded more than once per year	0.5 ppm
1-hour average	0.075 ppm	None	99 th percentile of 1-hour daily maximum concentrations, averaged over 3 years	None specified
Hydrogen Sulfide				
1-hour average	None	None		0.025 ppm

ppm = parts per million; µg/m³ = micrograms per cubic meter.

quality monitoring station located downwind of the facility and reviews monthly data from three continuous hydrogen sulfide monitoring stations operated by the geothermal facility ([HDOH 2013a](#)).

The Kīlauea volcano on Hawai‘i island emits sulfur dioxide, which is considered a natural volcanic event. Therefore, EPA may exclude the NAAQS exceedances of sulfur dioxide and sulfate particles (measured as PM_{2.5}) from attainment determinations ([HDOH 2012a](#)).

3.2.2.2 Air Quality Control Regions and Attainment Status

The Hawaiian Islands are within the State of Hawai‘i Air Quality Control Region. As defined by 40 CFR 81.76, the region consists of the territorial area encompassed by the outermost boundaries of Hawai‘i including the territorial area of all municipalities geographically located within the outmost boundaries of the area.

Ambient air quality in an area is characterized by whether it complies with the primary and secondary NAAQS. All counties of Hawai‘i meet the NAAQS and are designated as attainment areas for all criteria air pollutants ([40 CFR 81.312](#)).

3.2.2.3 General Conformity

Promulgated under the CAA [Section 176(c)(4)], the [General Conformity Rule](#) requires Federal agencies to ensure their actions conform to applicable implementation plans for the achievement and maintenance of the NAAQS for criteria pollutants. To achieve conformity, a Federal action must not contribute to new violations of standards for ambient air quality, increase the frequency or severity of existing violations, or delay timely attainment of standards in the area of concern (for example, a state or a smaller air quality region). Federal agencies prepare written Conformity Determinations for Federal actions that are in or affect NAAQS nonattainment areas or maintenance areas when the total direct or indirect emissions of nonattainment pollutants (or their precursors in the case of ozone) exceed specified thresholds. Because all counties in Hawai‘i are in attainment, the general conformity requirements do not apply to projects proposed on any of the Hawaiian Islands.

3.2.3 EXISTING FACILITY EMISSIONS AND AIR PERMITS

3.2.3.1 Existing Air Quality and Emissions for Hawai‘i Counties

Emissions of criteria pollutants are recorded by Hawai‘i counties rather than by island (that is, Maui County reports for the islands of Molokai, Lāna‘i, and Maui). [Table 3-9](#) lists regional air pollutant emissions for the counties. The emissions are for the year 2008, the most recent year with available data.

In addition to the emissions shown in the table, the Kīlauea volcano on the island of Hawai‘i emitted about 1,100 tons of sulfur dioxide from its summit and 550 tons of sulfur dioxide from its rift zone vents per day in April 2013 ([USGS 2013e](#)). Sulfur dioxide emissions from the volcano vary over time, but the April 2013 emission rate would account for annual sulfur dioxide emissions of about 600,000 tons per year. Volcanic eruptions are considered natural events. Further, the sulfur dioxide emitted from the Kīlauea volcano can mix and react with oxygen, moisture in the air, dust, and sunlight to create a phenomenon called [vog](#).

Table 3-9. Air Emissions Reported for Counties within the State of Hawai‘i for Calendar Year 2008

Pollutant	Hawai‘i County Emissions (tpy)	City and County of Honolulu Emissions (tpy)	Kaua‘i County Emissions (tpy)	Maui County Emissions ^a (tpy)
Particulate matter less than 2.5 microns (PM _{2.5})	1,600	4,800	1,000	2,600
Particulate matter less than 10 microns (PM ₁₀)	9,300	17,000	4,400	9,900
Carbon monoxide (CO)	31,000	136,000	19,000	40,000
Nitrogen oxides (NO _x)	6,500	33,000	3,900	10,000
Sulfur dioxides (SO ₂)	6,100	21,000	360	5,300
Volatile organic compounds (VOC)	6,000	30,000	3,500	6,000

Source: [EPA 2013a](#).

a. Includes Kalawao County emissions.

Tpy = tons per year.

Geothermal wells located at a geothermal power plant on Hawai‘i island can possibly release hydrogen sulfide into the atmosphere. Island residents have much concern about potential hydrogen sulfide emissions, and the Puna Geothermal Venture has made available five-minute averages for hydrogen sulfide concentrations ([http://www.ormat.com/case-studies/puna-geothermal-venture-Hawai‘i](http://www.ormat.com/case-studies/puna-geothermal-venture-Hawai'i)). In addition, the State of Hawai‘i has installed an air monitoring station near the Puna facility to measure hydrogen sulfide and sulfur dioxide concentrations. The highest 1-hour hydrogen sulfide concentration in 2011 (the most recent year with published data) was 0.004 ppm, which was well below the State attainment standard of 0.025 ppm ([HDOH 2012a](#)). Near-time concentration measurements from the State’s Puna E monitoring station can be accessed via the HDOH website (http://emdweb.doh.hawaii.gov/air-quality/StationInfo.aspx?ST_ID=42). In addition to possible hydrogen sulfide emissions from Puna, the volcanic system on Hawai‘i island naturally releases hydrogen sulfide.

3.2.3.2 Prevention of Significant Deterioration Class I Areas

Prevention of Significant Deterioration (PSD) applies to new or major modifications at existing sources where the source is located in attainment or unclassifiable areas of the NAAQS. The PSD portion of the CAA is an important authority for protecting the resources of national parks and wilderness areas that are designated as Class 1 air quality areas. Class 1 areas include national wilderness areas and national memorial parks larger than 5,000 acres, and national parks larger than 6,000 acres. A Class I area is one in which very little increase in pollution is allowed due to the pristine nature of the area. The PSD Class I areas within the Hawaiian Islands are Haleakalā National Park on Maui and Hawai‘i Volcanoes National Park on Hawai‘i island. The remaining portions of the State of Hawai‘i are classified as Class II. A Class II area is one in which more moderate increases in pollution are allowed.

3.2.3.3 Greenhouse Gases

The burning of fossil fuels such as coal, diesel, and gasoline emits carbon dioxide, which is a *greenhouse gas*. Greenhouse gases can trap heat in the atmosphere, similar to the glass walls of a greenhouse, and have been associated with global climate change. Climate change refers to any significant change in measures of climate (such as temperature, precipitation, or wind) that lasts for an extended period (decades or longer). The *Intergovernmental Panel on Climate Change*, in its Fourth Assessment Report, stated that warming of the earth’s climate system is unequivocal, and that most of the observed increase in globally averaged temperatures since the mid-twentieth century is very likely due to the observed increase in concentrations of greenhouse gases from human activities ([IPCC 2007](#)). These gases are well mixed

throughout the lower atmosphere, so emissions add to cumulative regional and global concentrations of carbon dioxide. The effects from an individual source, therefore, cannot be determined quantitatively.

Greenhouse gases include carbon dioxide, methane, nitrous oxide, ozone, water vapor, and several hydrocarbons and chlorofluorocarbons. Each greenhouse gas has an estimated [global warming potential](#), which is a function of its atmospheric lifetime and its ability to absorb and radiate infrared energy emitted from the earth's surface. The global warming potential for a greenhouse gas provides a relative basis for calculating its [carbon dioxide equivalent](#). This is a measure for comparing emissions from various greenhouse gases to carbon dioxide based on their global warming potential. Carbon dioxide has a global warming potential of 1 and is, therefore, the standard by which all other greenhouse gases are measured.

In June 2014, the EPA proposed a plan to cut greenhouse gas emissions from power plants. EPA's [Clean Power Plan proposed rule](#) builds on state, city, and business actions to address the risks of climate change. The plan is flexible and reflects that different states have a variety of sources and opportunities in partnering with the Federal Government in cutting pollution. The EPA proposed state-specific, rate-based goals for carbon dioxide emissions from the power sector, as well as guidelines for states to follow in developing plans to achieve the state-specific goals. The State of Hawai'i supports EPA's proposed Clean Power Plan and developed a strategy of reducing greenhouse gas emissions to below 1990 levels by the year 2020. The Clean Power Plan aligns with Hawai'i's agenda and provides flexibility for cost-effective, technically viable, and meaningful greenhouse gas reductions ([Hawai'i 2014](#)).

The total greenhouse gas emissions for the State of Hawai'i for the year 2007 were 24.3 million metric tons of carbon dioxide equivalent. Carbon dioxide accounted for 91 percent of that total ([ICF 2008](#)). [Table 3-10](#) shows the greenhouse gas emissions for the different islands for that period.

Table 3-10. Greenhouse Gas Emission Summary by Island, for Calendar Year 2007 (in MMTCO₂Eq)

Pollutant	Hawai'i	Kaua'i	Lāna'i	Maui	Molokai	O'ahu
Greenhouse gas	2.81	1.10	0.08	2.69	0.17	17.4

Source: [ICF 2008](#).

MMTCO₂Eq = million metric tons of carbon dioxide equivalent.

EPA is responsible for characterizing greenhouse gas emissions using two complementary programs designed to help the public and policymakers understand both the sources and magnitude of these emissions: the National Greenhouse Gas Inventory and the Greenhouse Gas Reporting Program. The EPA develops the national greenhouse gas inventory each year to track trends in total greenhouse gas emissions and removals across all sectors of the economy. The Greenhouse Gas Reporting Program (<http://www.epa.gov/ghgreporting/>) is a relatively new EPA program that collects detailed emissions data from the largest greenhouse gas-emitting facilities in the United States ([EPA 2015](#)). Greenhouse gas emissions for existing facilities in Hawai'i, as reported through these EPA programs, have been declining since 2007 through the latest reporting year of 2013 ([EPA 2014](#)).

3.2.3.4 Air Quality Permits

Air quality in the Hawai'i is subject to a variety of Federal and State regulations pertaining to the construction and operation of air emission sources. The EPA and HDOH regulate air quality on the various islands throughout the State.

The State of Hawai'i requires [air pollution](#) control permits prior to constructing, reconstructing, modifying, or operating a [stationary air pollution source](#) ([HDOH 2011a](#)). The State issues two types of air pollution control permits: [covered source](#) and [noncovered source](#). A covered source is any major

source, any source subject to a standard or other requirements under Section 111, “Standards of performance for new stationary sources,” of the CAA, or any source subject to an emissions standard or other requirements for *hazardous air pollutants* under Section 112, “Hazardous air pollutants,” of the CAA (with specified exceptions). A covered source permit generally is synonymous with a Title V or operating permit as referred to in Federal regulations. A noncovered source is any stationary source constructed, modified, or relocated after March 20, 1972, that is not a covered source (HDOH 2011a).

Section 165 of the CAA requires a *major stationary source* in an attainment area to obtain a PSD permit before beginning construction. The EPA has two largely identical sets of regulations implementing the PSD program. Hawai‘i’s State Implementation Plan lacks an approved PSD program, so the applicable requirements governing the issuance of PSD permits in Hawai‘i are the Federal PSD regulations at [40 CFR 52.21](#). Although EPA Region 9 delegated administration of the PSD program to Hawai‘i, PSD permits issued by HDOH are Federal permits.

Permit applicability requirements for noncovered and covered sources are specified in [HAR 11-60.1-62](#) and [HAR 11-60.1-82](#), respectively. An applicant for an air quality permit should contact the Engineering Section of the HDOH Clean Air Branch as soon as questions arise as to applicability of regulations and any application data requirements. Applicants are encouraged to consider seeking professional assistance, consisting of qualified engineering and consulting firms.

<p><u>MAJOR SOURCE</u></p> <p>“A source or a group of <i>stationary sources</i> located on one or more contiguous or adjacent properties that is under common control of the same person or persons and that emits or has the potential to emit:</p> <ul style="list-style-type: none"> • 10 tons or more per year of any single <i>hazardous air pollutant</i> or 25 tons or more per year of any combination of hazardous air pollutants. • 100 tons or more per year of any other <i>air pollutant</i>.”
--

3.2.4 COMMON CONSTRUCTION AND OPERATION IMPACTS

Air quality impacts associated with construction would be short-term, intermittent, and limited to the duration of the construction project. Construction-related impacts to air quality would include emissions of fugitive dust (airborne particulate matter generated from a source other than a stack or chimney) and emissions from fossil-fueled construction equipment, temporary fuel transfer systems, and associated fuel storage tanks. Construction equipment, such as earth-moving equipment, cranes, and trucks, would be powered by diesel or gasoline engines and the burning of fossil fuels in these engines would result in the emission of criteria pollutants, small amounts of hazardous air pollutants, and greenhouse gas emissions.

Estimating exact emissions for any construction project depends on a number of variable factors, including the type of construction, the number and types of construction vehicles and equipment, the length of the construction period, the area encompassed by the construction, and the number of workers.

For any large construction project, criteria pollutants would be emitted from a variety of sources that could operate during construction. These sources could include:

- Grading and clearing of the land;
- Earth-moving equipment;
- Generators, bulldozers, cranes, and trucks; and
- Vehicles of commuting workers.

Clearing and grading the land would cause fugitive dust emissions. The amount of fugitive dust generated during construction would be affected by specific construction activities, silt content in the soil, soil

moisture, wind speed, frequency of precipitation, vehicle traffic, and roadway characteristics. The EPA's [Compilation of Air Pollutant Emission Factors](#) (AP-42) Section 13.2.3, "Heavy Construction Operations," estimates that 1.2 tons of total suspended particulates are emitted per acre per month of construction. Based on experiments on dust emission during construction, approximately 30 percent of that amount would be PM₁₀ and that the remainder would be larger particles ([EPA 1988](#)). In addition, fugitive dust from off-road travel would be expected, but would be mitigated by BMPs.

Criteria pollutants and carbon dioxide would be emitted by the engines of construction equipment. For example, a generic construction project that would include two cranes, two short-haul trucks, one backhoe, and two front-end loaders would emit an estimated 0.38 ton of carbon monoxide, 0.84 ton of nitrogen oxides, 0.0011 ton of sulfur oxides, 0.041 ton of particulate matter, and 100 tons of carbon dioxide from the engines of the construction equipment during each month of construction. These estimates are based on generic construction equipment emission factors and assuming 21 work days per month. In addition, the vehicles of workers commuting to the work site would emit criteria pollutants. A workforce of an estimated 100 workers, with a 20-mile daily roundtrip would travel an estimated 42,000 miles per month. The estimated monthly emissions would be about 0.15 ton of carbon monoxide, 0.015 ton of nitrogen oxide, 0.00022 ton of sulfur oxides, 0.043 ton of particulate matter, and 23 tons of carbon dioxide. The actual amount of criteria pollutants emitted for a specific construction project would be dependent on the construction equipment and number of workers for that project.

3.2.5 COMMON BEST MANAGEMENT PRACTICES

Developers of clean energy facilities need to be aware of potential issues due to global climate change. For instance, coastal areas could be impacted by sea level rise due to rising global temperatures. Consequently, initial planning of the facilities should develop adaptive management strategies to protect clean energy facilities from the impacts of climate change. Initial planning should insure that major modifications to clean energy facilities and operations are not required due to sea level rise and other impacts of climate change.

General BMPs that can be used to minimize air emissions include:

- Identify applicable Federal, State, and county air quality management agencies and follow requirements and application procedures;
- Identify all emission sources associated with the proposed technology and/or use information from existing facilities with similar characteristics; and
- Consider dust abatement procedures that will minimize particulate matter emissions while reducing the use of extensive amounts of water.

Specific BMPs that can be used to reduce criteria pollutants from fuel-burning equipment include:

- Minimize idling time;
- Maintain all construction equipment in proper working condition according to the manufacturer's specifications;
- Use late model/low emission engines; and
- Comply with EPA regulations for on-road and non-road engines (40 CFR Parts 86 and 89).

Specific BMPs that can be used to reduce fugitive dust and particulate matter emissions include:

- Limit vehicle speed to less than 25 miles per hour on non-paved roads,
- Water non-paved roads and disturbed land,
- Apply mulch to reduce wind erosion, and
- Install fences to reduce wind velocities to non-erosive levels.

3.3 Water Resources

This section describes Hawai‘i’s water resources in terms of surface water and [groundwater](#). It also discusses the State’s [floodplains](#), [wetlands](#), and oceans. Each of the topical areas is addressed first in terms of a State overview then, as applicable, on an island-by-island basis.

3.3.1 SURFACE WATER

3.3.1.1 State Overview

The primary inland surface water features in Hawai‘i are the streams that drain the [watersheds](#). There are very few natural lakes in Hawai‘i ([CWRM 2008a](#)).

Most streams in Hawai‘i originate in the mountainous interiors, within the rainfall belts, and terminate at the coast ([Oki 2003](#)). Trade winds from the northeast dominate Hawai‘i’s weather pattern and carry moisture-rich air over the islands. As the air masses are lifted over or

WATERSHED

An area that drains into a body of water, such as a river, lake, reservoir, estuary, sea, or ocean. It includes the rivers, streams, and lakes that convey the water, as well as the land surfaces from which water runs off.

around the mountainous areas, they cool and create local rain and fog drip. Because of this predominant weather pattern, the windward sides of the islands (that is, the east to northeast sides) generally receive more rainfall than the leeward areas and contain most of the perennial streams ([CWRM and NPS 1990](#)). The islands of Ni‘ihau, Kaho‘olawe, and Lāna‘i are affected by both of these rainfall trends in that their maximum elevations are the lowest of any of the primary islands and they are located on the leeward side of larger islands. As a result, Ni‘ihau, Kaho‘olawe, and Lāna‘i are dry in comparison to the other islands and have no [perennial streams](#) ([CWRM 2008a](#)).

STREAM CLASSIFICATIONS

Perennial Stream: A stream that flows continuously throughout the year over at least a portion of its course. In Hawai‘i, perennial streams are continuous if they normally flow all the way to the sea, but often they are termed interrupted because they flow year-round in upper portions and intermittently at lower elevation under normal conditions. Interruptions may be natural or manmade.

Intermittent Stream: A stream, or part of a stream, that flows only at certain times of year, generally for several weeks or months in response to seasonal precipitation and subsequent groundwater discharge.

Ephemeral Stream: A stream with little or no groundwater influence that flows only a few hours or days in direct response to rainfall. These streams typically are manifest by dry gulches and in Hawai‘i are generally found on the leeward side of mountainous areas.

The *1990 Hawai‘i Stream Assessment: A Preliminary Appraisal of Hawai‘i’s Stream Resources* ([CWRM and NPS 1990](#)), which is still a key reference for Hawaiian stream

information and cited often in this document, identifies 376 perennial streams within the State. By island, 61 of the perennial streams are on Kaua‘i, 57 are on O‘ahu, 36 are on Molokai, 90 are on Maui, and 132

are on Hawai‘i. Approximately two-thirds of the perennial streams are continuous, with the others classified as interrupted streams (see text box definitions).

The U.S. Army Corps of Engineers (USACE) recently completed its *Hydroelectric Power Assessment – State of Hawai‘i* ([USACE 2011](#)) to determine if there was Federal interest for the USACE to participate in further cost-share feasibility studies to identify, evaluate, and recommend solutions to address the potential hydroelectric power needs in Hawai‘i. While the USACE identified several candidate hydroelectric facilities, to date no further USACE study has been approved.

The topography of the islands typically results in drainage patterns that radiate out from the central high areas such that streams flow away from one another. Since distances to the streams’ mouths (that is, the ocean) are relatively short, this leads to many small streams draining relatively small watersheds rather than having many streams combine over long flow paths as is common in continental drainages. This is particularly true on the geologically younger islands, such as the island of Hawai‘i, where watersheds tend to be short with narrow channels and streams have few tributaries. On the older islands, such as Kaua‘i, watersheds have more eroded features, including deeper channels and more complex networks of tributary branches. The older islands also tend to have more developed estuaries at the river-ocean interface compared to the island of Hawai‘i where streams sometimes end in a waterfall at the ocean ([CWRM 2008a](#)).

3.3.1.1.1 Stream Flow and Length Characteristics

Stream flow in Hawai‘i is dominated by runoff and, as a result, flow rates are highly variable ([CWRM and NPS 1990](#)). It is estimated that about 30 percent of annual Statewide precipitation goes to runoff and stream flow. Within smaller areas and over shorter timeframes, this number can easily vary up or down by 20 percent or more depending on the nature of the specific drainage basin, the intensity of the precipitation, and the existing moisture content of the ground ([Oki 2003](#)). Even with the relatively small size of most watersheds, these runoff rates can produce large quantities of water given the high precipitation rates in some areas, particularly in the mountains. However, perennial streams and even intermittent streams or segments are augmented with a base flow from groundwater or through bog areas; that is, some water storage mechanism that acts to even out the variable, sporadic nature of precipitation. [Section 3.3.2](#) discusses the occurrence of groundwater in Hawai‘i and its contribution to surface water flows.

MEDIAN VERSUS AVERAGE FLOW RATES

Median flow rate is the rate that is equaled or exceeded 50 percent of the time. Average (that is, mean) flow rate is the total water volume passing a point in the stream over a period of time, typically a year, divided by the total time units (such as seconds) during that same period.

Because of the high contributions of runoff and the associated high variability in flow, it is typical for a Hawaiian stream to have an average flow rate that is notably higher than its median flow rate. In most continental drainage systems, the average and median flow rates would be expected to be close together. However, in Hawai‘i, the very high flows for relatively short periods of time effectively push the average flow rate higher than the median; high enough that the average may only be exceeded 10 percent of the time ([CWRM and NPS 1990](#)).

The 1990 Hawai‘i Stream Assessment ([CWRM and NPS 1990](#)) evaluated flow data from 110 streams with continuous gauging records. The evaluation grouped the streams in the following size categories based on their median or average flow rate:

- Large streams – Streams with median flow rates greater or equal to 50 cubic feet per second, or average flow rates greater or equal to 80 cubic feet per second.
- Medium streams – Streams with median flow rates between 10 and 50 cubic feet per second, or average flow rates between 20 and 80 cubic feet per second.
- Small streams – Streams with median flow rates less than or equal to 10 cubic feet per second, or average flow rates less than or equal to 20 cubic feet per second.

The evaluation indicated that a majority of the gauged streams fit into the category of small streams. Of the 110 streams, 11 were considered large, 36 medium, and 63 small. [Table 3-11](#) lists the streams that were characterized as large. The list includes several on Hawai‘i island that are suspected to meet the above definition of a large stream, but which do not have gauging stations. The table also includes two

Table 3-11. Large Streams in Hawai‘i

Stream	Code ^a	Flow in cfs	
		Average	Median
Kaua‘i			
Wainiha River	2-1-14	138	79
Lumahai River	2-1-15	117	67
Hanalei River	2-1-19	212	130
Wailua Stream	2-2-08s	239	110
Hanapepe	2-3-07	85	32
Koula River	Tributary to Hanapepe	85	34
Waimea Stream	2-4-04s	253	63
Makaweli River	Tributary to Waimea	100	23
Maui

‘Iao	6-2-09	65	43
Hawai‘i			
Wailoa/Waipio	8-1-44	75	51
Honoli‘i	8-2-56	125	38
Wailuku River	8-2-60	84	59
Others suspected to qualify as large, all on Hawai‘i island			
Kaula	8-1-90	NA	NA
Kapehu	8-2-12	NA	NA
Pohakupuka	8-2-16	NA	NA
Kolekole	8-2-23	NA	NA
Umauma	8-2-30	NA	NA
Hakalau	8-2-32	NA	NA
Kawainiu	8-2-43	NA	NA
Maile	8-2-57	NA	NA

Sources: Information on the tributaries, the Koula and Makaweli rivers, come from [USGS 2007](#). All other information comes from [CWRM and NPS 1990](#).

a. The State’s coding system includes a first digit that identifies the island, a second that identifies the hydrographic unit within the island, and a third that identifies the stream mouth where it enters the ocean (originally assigned in a clockwise order within the hydrographic unit). The “s” designation indicates this is a stream system in which tributaries drain separate valleys and merge close to the mouth.

cfs = cubic feet per second; NA = not available.

tributaries that were not identified in the 1990 evaluation but are included here because they appear to qualify on their own before joining the subsequent stream. As can be seen in the table, the islands of Kaua‘i and Hawai‘i have the greatest number of large streams. This is consistent with the fact that the peaks of Kaua‘i receive some of the largest annual precipitation of any of the islands ([UH Hilo 1998](#)) and, because it is an older island, there are more networks of tributaries contributing to the large streams. With regard to Hawai‘i, it has the highest peaks of the State and its large size supports a wide band of land with high precipitation and a high number of large streams in spite of not having significant networks of tributaries. The individual island discussions identify the number of streams characterized as medium and small, but it should be noted that this information is more likely an indication of where the gauging stations were located than how medium and small streams are distributed among the islands.

The 1990 Hawai‘i Stream Assessment ([CWRM and NPS 1990](#)) describes an evaluation of stream lengths. The evaluation measured map lengths for all streams thought to have an average flow of at least 5 cubic feet per second. The evaluation concluded that there were only 28 streams in the State at least 10 miles long. The longest, at almost 60 miles each, are the Wailua River on Kaua‘i and the Kiiiki (Kaukonahua Stream) on O‘ahu.

The Hawai‘i Commission on Water Resource Management (CWRM) administers the State Water Code ([HRS 174C](#)), which was created by the 1987 Hawai‘i State Legislature. The Commission’s general mission is to protect and enhance the water resources of the State of Hawai‘i through wise and responsible management, including determining the allowable use of Hawai‘i’s water resources. Water resource management is so critical to Hawai‘i that Article XI, Section 7 of the State Constitution states:

“The legislature shall provide for a water resources agency which, as provided by law, shall set overall water conservation, quality and use policies; define beneficial and reasonable uses; protect ground and surface water resources, watersheds and natural stream environments; establish criteria for water use priorities while assuring appurtenant rights and existing correlative and riparian uses and establish procedures for regulating all uses of Hawai‘i’s water resources.”

3.3.1.1.2 Diversions and Dams

Diversions and dams are common surface water modifications. The major ditch systems of the islands are significant physical and historical features. Traditional Hawaiian civilization included elaborate hydraulic works to support taro irrigation, which requires large volumes of cool, running water. The primary sources of water used for this purpose were the perennial streams originating in the mountains and springs ([UH Hilo 1998](#)). Irrigation systems became much more extensive in the late 1800s when they were developed to support the sugar cane industry. Although commonly referred to as ditches, these irrigation systems included concrete-lined and unlined channels, tunnels, and flumes, often designed to move water from wet, windward areas to the drier leeward areas ([CWRM 2008a](#)).

Developers built the first great ditch, the Hāmākua, on Maui in 1878, and since then, over a dozen major systems have been developed on the four largest islands. These systems usually divert water from higher elevations, but some move water out of the watershed in which it originated. In some instances, water traveled through tunnels cut in the mountains to go from windward to leeward sides of the island ([CWRM and NPS 1990](#)). By 1920, the sugar industry likely used about 800 million gallons of surface water and about 400 million gallons of groundwater each day ([CWRM 2008a](#)).

Since the demise of the sugar industry toward the end of the twentieth century, most of the diversion systems are not maintained as they once were and are not as efficient. As a result of their planned

drainage paths and because of leakage, these diversion systems continue to affect surface water and groundwater hydrology ([CWRM 2008a](#)).

Although there are few natural lakes in Hawai‘i, numerous reservoirs have been constructed to serve the sugar and pineapple industries, for flood control, or as impoundments to feed drinking water treatment plants ([CWRM 2008a](#)). Many of these reservoirs also support recreational boating and fishing.

Roughly one-third of the streams on O‘ahu and Hawai‘i and over one-half of Maui’s streams support notable diversions. There is little diversion of streams on Molokai, the eastern part of East Maui, or the north shore of Kaua‘i ([CWRM and NPS 1990](#)). Because Lāna‘i does not have perennial streams, there are no notable diversions. Some of the more significant diversion systems and dams are described further in the individual island discussions below.

3.3.1.1.3 Water Quality

The *Clean Water Act* ([33 U.S.C. § 1251 et seq.](#); CWA) establishes a framework for regulating quality standards for surface waters and discharges into those waters. Under that framework, the states evaluate their surface waters, determine applicable beneficial uses, set water quality criteria to support those uses, and implement rules and regulations to achieve or maintain water quality criteria. In Hawai‘i, HDOH established [HAR 11-54](#), “Water Quality Standards,” which sets beneficial uses for inland and marine waters of the State and establishes water quality criteria applicable to beneficial uses. Section 305(b) of the CWA requires states to develop and periodically update an inventory of the water quality of all water bodies in the state. These inventories, provided to EPA, and released to the public, indicate if the water quality supports the designated uses. Section 303(d) of the CWA requires states to develop and periodically update an inventory of water bodies that do not meet water quality standards, which the states also provide to EPA and release to the public.

The State’s inland waters are assigned to a Class 1 or 2 category to identify their beneficial uses that are to be protected. These water uses are set in [HAR 11-54](#) as follows:

- Class 1 – “It is the objective of Class 1 waters that these waters remain in their natural state as nearly as possible with an absolute minimum of pollution from any human-caused source. To the extent possible, the wilderness character of these areas shall be protected. Waste discharge into these waters is prohibited.” Uses to be protected in this class include “protection of native breeding stock, baseline references from which human-caused changes can be measured, compatible recreation, aesthetic enjoyment, and other nondegrading uses.” Class 1.a waters are also to be protected for scientific and educational purposes and class 1.b waters are to be protected for domestic water supplies and food processing.
- Class 2 – “The objective of Class 2 waters is to protect their use for recreational purposes, the support and propagation of aquatic life, agricultural and industrial water supplies, shipping, and navigation. The uses to be protected in this class of waters are all uses compatible with the protection and propagation of fish, shellfish, and wildlife, and with recreation in and on these waters.”

The State’s marine waters are assigned to a Class AA or A category to identify the beneficial uses that are to be protected. These water uses are set in [HAR 11-54](#) as follows:

- Class AA – “It is the objective of Class AA waters that these waters remain in their natural pristine state as nearly as possible with an absolute minimum of pollution or alteration of water

quality from any human-caused source or actions. To the extent practicable, the wilderness character of these areas shall be protected.”

- Class A – “It is the objective of Class A waters that their use for recreational purposes and aesthetic enjoyment be protected. Any other use shall be permitted as long as it is compatible with the protection and propagation of fish, shellfish, and wildlife, and with recreation in and on these waters.”

[Table 3-12](#) summarizes criteria set by the State in [HAR 11-54](#) for Class 1 and 2 inland waters and Class AA and A marine waters.

Table 3-12. Inland and Marine Water Classification Criteria from HAR Chapter 11-54

Water Quality Classification Criteria for Inland and Marine Waters		
Inland Waters		
Fresh waters Flowing waters - A Standing waters - B Elevated and low wetlands - C Brackish or saline waters - D	Class 1.a <ul style="list-style-type: none"> • All A, B, C, or D within the natural reserves, preserves, sanctuaries, and refuges established by DLNR under HRS 195 or similar reserves for the protection of aquatic life established under HRS 195. • All A, B, C, or D in national and State parks. • All A, B, C, or D in State or Federal fish and wildlife refuges. • All A, B, C, or D that have been identified as a unique or critical habitat for threatened or endangered species by the USFWS. • All A, B, C, or D in Wai-manu National Estuarine Research Reserve (Hawaii). • All D in the Lumahai and Kīlauea estuaries (Kaua‘i). Class 1.b <ul style="list-style-type: none"> • All A, B, C, or D in protective subzones designated under Chapter 13-5 of the State Board of Land Natural Resources. 	Class 2 <ul style="list-style-type: none"> • All A, B, C, or D in areas not otherwise classified.
Marine Waters		
Embayments - E Open coastal waters - F Oceanic waters - G	Class AA <ul style="list-style-type: none"> • Specific E or F by island (see discussions of individual islands in this PEIS) • All E or F in preserves, reserves, sanctuaries, and refuges established by DLNR under HRS 195 or 190 or similar reserves for the protection of marine life established under HRS 190. • All E or F in State or Federal fish and wildlife refuges and marine sanctuaries. • All E which have been officially identified as a unique or critical habitat for threatened or endangered species by the USFWS • All F surrounding the islands not otherwise classified in this section. 	Class A <ul style="list-style-type: none"> • Specific E by island • All F not otherwise specified. • All G.

DLNR = Department of Land and Natural Resources; HRS = Hawai‘i Revised Statutes; USFWS = U.S. Fish and Wildlife Service.

The most recent Section 303(d) and Section 305(b) reports the State developed are in the form of an integrated report (covering both CWA requirements) for the 2008 to 2010 timeframe ([HDOH 2012b](#)). Water quality conditions the State’s report describes are addressed on an island-by-island basis later in this section. [Table 3-13](#) summarizes the report findings for inland waters of the entire State. The table shows 177 specific inland waters (streams, estuaries, wetlands, lakes, and reservoirs) identified, and the results of assessments for 116 of those waters. There was insufficient characterization data on the other 61 waters to support a water quality assessment. Of the 116 assessed, 101 were identified as impaired for not meeting one or more applicable water quality standards and 15 were identified as meeting some but not

all standards. The 101 impaired waters include 7 that do not require the development of *total maximum daily loads (TMDLs)*, which are the maximum amount of a pollutant that a water body can receive and still meet water quality standards. Once TMDLs have been determined, discharge requirements can be developed that will bring a water body back into compliance. If a TMDL is not required, it generally means that stage of the process is already complete. The most common water quality standard exceeded by inland waters was turbidity, the second most common was nitrate-plus-nitrite nitrogen.

Table 3-13. Summary of State of Hawai‘i Inland Waters Considered Impaired

Number of Impaired Inland Waters ^a	Reason(s) for Impairments

Source: [HDOH 2012b](#).

- a. Inland waters identified in the source document consist of 168 streams, 6 estuaries, 1 lake, 1 reservoir, and 1 wetlands area; of which, 116 were assessed with the following results: 94 impaired, 7 impaired but need no TMDL, and 15 meet some, but not all standards. The last category is for instances where there are data sufficient to show certain standards are met, but not sufficient to make a determination with regard to other standards. In the case of waters identified but not assessed, available data are insufficient to determine whether standards are met (or if the water is impaired).
 - b. This group consists of 33 streams, two estuaries, and one lake.
 - c. This group consists of 26 streams, three estuaries, and one reservoir.
 - d. This group consists of one stream, one estuary, and one wetlands area.
- Total N = total nitrogen; NO₃+NO₂ = nitrate + nitrite nitrogen; Total P = total phosphorus; TMDL = Total Maximum Daily Load.

Table 3-14 summarizes HDOH (2012b) findings for marine waters of the entire State, which identifies 522 specific marine waters and the results of assessments for 279 of those waters. There was insufficient characterization data on the other 243 waters to support a water quality assessment. Of the 279 assessed, 207 were identified as impaired for not meeting one or more applicable water quality standard and 72 were identified as meeting some but not all standards. Again, this latter designation indicates the characterization data available were in compliance with applicable standards, but there were insufficient data to evaluate against all applicable standards. The most common water quality standard exceeded by marine waters was turbidity; the second most common was total nitrogen. HDOH provides current water quality data on many discharge points at <http://emdweb.doh.hawaii.gov/CleanWaterBranch/WaterQualityData/default.aspx>.

Table 3-14. Summary of State of Hawai'i Marine Waters Considered Impaired

Source: [HDOH 2012b](#).

a. The source document identifies 522 marine waters; of which, 279 were assessed with the following results: 204 impaired, 3 impaired but need no TMDL, and 72 meet some, but not all standards. The last category is for instances where there are data sufficient to show certain standards are met, but data are not sufficient to make a determination with regard to other standards. In the case of waters identified but not assessed, available data are insufficient to determine whether standards are met (or if the water is impaired).

Total N = total nitrogen; NO₃+NO₂ = nitrate + nitrite nitrogen; Total P = total phosphorus; PCB = polychlorinated biphenyl; TMDL = Total Maximum Daily Load.

3.3.1.1.4 Water Use

[Table 3-15](#) summarizes water use in the State of Hawai‘i for the year 2010. It includes both surface water and groundwater (both fresh and saline) uses to provide a more complete picture. About half of the State’s water usage is for thermoelectric purposes. The thermoelectric designation is for water, most of which is saline, used in generating electricity. If water used in production of electricity is excluded, municipal water supplies and irrigation represent by far the greatest water uses in the State, at about 42 and 50 percent, respectively. Without the thermoelectric category, groundwater is the primary source of the water used in Hawai‘i. The USGS compiles water use data every five years and has published 2010 data since issuance of the Draft PEIS. Table 3-15 reflects these new data.

Table 3-15. 2010 Water Use (in million gallons per day) by Category and Source for the State of Hawai‘i

Water Use Category	State (Five County Totals)					Percent of State Water Use	
	Groundwater		Surface Water		Totals ^a	With Thermoelectric	Without Thermoelectric
	Fresh	Saline	Fresh	Saline

Sources: CWRM 2008a for military water value; USGS 2014 for all other water values.

a. Values may not add up to totals because of independent rounding, here and in the referenced source.

b. Self-supplied domestic water, as opposed to domestic water from a municipal source.

3.3.1.2 Kaua‘i

Sixty-one of the State’s 376 perennial streams are located on Kaua‘i. [Figure 3-16](#) is a simple map of Kaua‘i showing approximate locations of some of the island’s more prominent perennial streams. The figure also shows how the State of Hawai‘i divided the island into five hydrologic regions that were used in the numeric designation of the island’s streams. The State assigned the number “2” to the island, itself, and assigned numbers to each stream mouth (where they drain to the ocean) within each of the hydrologic regions. These three numbers provide the basis for coding the streams. For example, the Hanalei River, which drains to the north shore of the island and is one of its largest streams ([Table 3-11](#)), is assigned a numeric designation of “2-1-19” because it is on Kaua‘i, in hydrologic region 1, and its mouth is numbered “19” on [Figure 3-16](#).

Since publication of the 1990 Hawai‘i Stream Assessment ([CWRM and NPS 1990](#)), which is the source for [Figure 3-16](#), the State has divided Kaua‘i into a more refined, smaller set of hydrologic units, or watershed areas. The island now comprises 74 hydrologic units, each with an average size of about 7.6 square miles. The largest unit is about 86 square miles and the smallest is less than 0.3 square mile ([CWRM 2008a](#)). Boundaries of the five regions shown in the figure match well with boundaries of the 74 hydrologic units such that:

- Region 1 of the map contains 34 hydrologic units designated 2001 through 2034,
- Region 2 of the map contains 12 hydrologic units designated 2035 through 2046,
- Region 3 of the map contains 8 hydrologic units designated 2047 through 2054,
- Region 4 of the map contains 6 hydrologic units designated 2055 through 2060, and
- Region 5 of the map contains 14 hydrologic units designated 2061 through 2074.

3.3.1.2.1 Stream Flow and Length Characteristics

Most streams shown in [Figure 3-16](#) originate in the mountainous area in the central part of the island. The exception is region 5, where the streams drain the portion of island to the west of Waimea Canyon. [Section 3.3.1.1.1](#) above presents criteria used to rate Hawaiian streams as large, medium, or small. As shown in [Table 3-11](#), of the 21 streams in the State that qualify or are believed to qualify as large, 8 are on Kaua'i and, based on their identifying codes, they are found in each of the regions shown in the map except region 5. Region 1, with three large streams, has the most. Of the streams evaluated for flow characteristics in the 1990 Hawai'i Stream Assessment ([CWRM and NPS 1990](#)), 5 of the 36 medium-sized streams and 6 of the 63 small-sized streams are on Kaua'i.

The CWRM and NPS (1990) evaluation of stream lengths concluded there are only 28 streams or stream systems in the State that were at least 10 miles long, and 10 of those are on Kaua'i. This includes one of the longest rivers, the Wailua River (2-2-08), and the third longest, the Waimea River system (2-4-04s).

3.3.1.2.2 Diversions and Dams

The State of Hawai'i has inventoried stream diversions by hydrologic unit and shows a total of 289 for Kaua'i ([CWRM 2008a](#)), with the majority occurring in regions 1 and 2 in [Figure 3-16](#). The elaborate irrigation diversion systems (see [Section 3.3.1.1.2](#)) are also well represented on Kaua'i. These typically are systems that include concrete weirs in the main stream channels that divert flow to ditches. Within the region 1 area shown in [Figure 3-16](#), the Hanalei River (2-1-19) and the Kalihiwai Stream (2-1-25) both had multiple diversions feeding ditch systems. There was even a tunnel that carried water from the Hanalei to the North Fork of the Wailua River in region 2. In region 2, the Anahola Stream (2-2-01), Wailua River system (2-02-08s), and Huleia (2-2-15) drainage all had multiple diversions, including two designated as aqueducts and one tunnel. In region 3, there was a ditch diversion and a pump station out of the Hanapepe River (2-3-07). Finally, in region 4 there were multiple diversions out of the Waimea River system (2-4-04s) ([CWRM and NPS 1990](#)).

The Hawai'i DLNR is responsible for inspection and regulation of dams or reservoirs that are 25 feet or taller and that have a capacity of at least 50 acre-feet (about 17 million gallons) ([DLNR 2013a](#)). DLNR maintains a database of qualifying dams or reservoirs, and shows 55 dams on Kaua'i. These dams are found primarily in regions 2 and 3 in [Figure 3-16](#), with 20 and 22 dams, respectively. Region 1 has five qualifying dams and regions 4 and 5 each have four dams ([DLNR 2013b](#)).

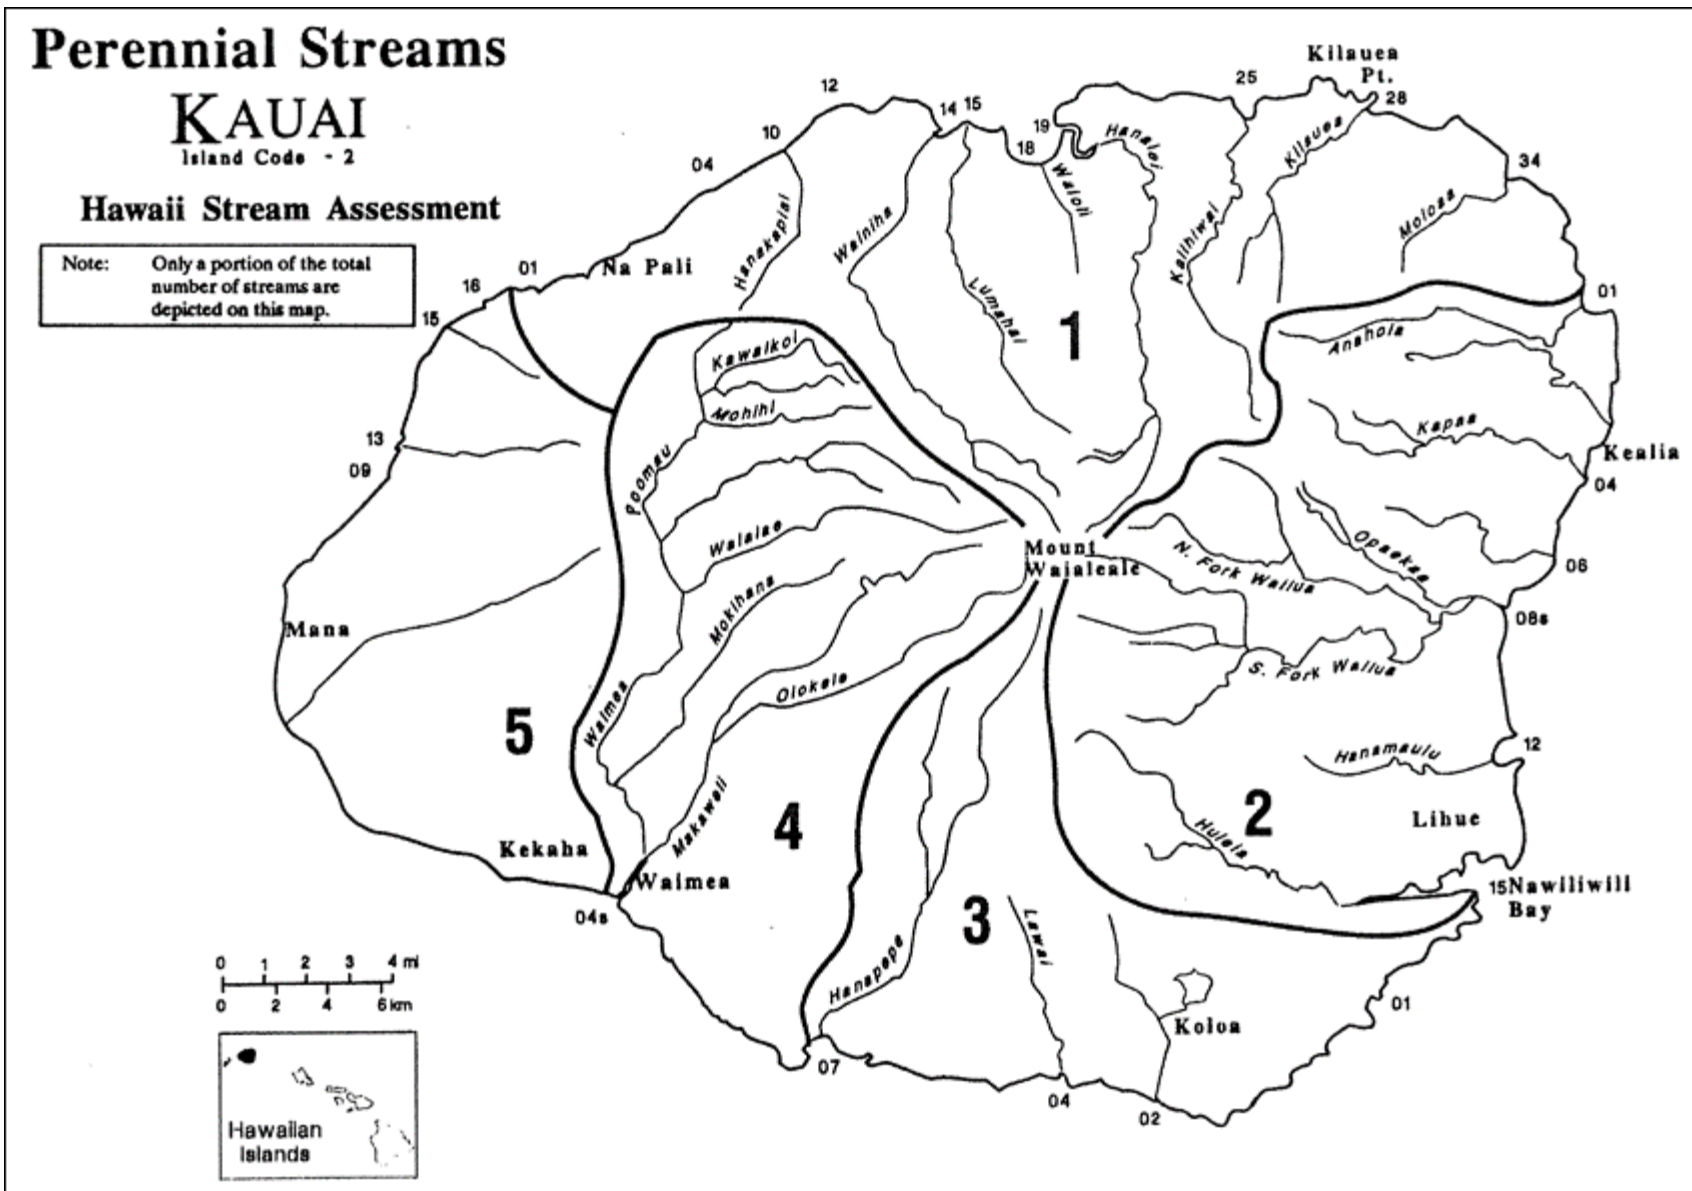

Figure 3-16. Map of Kaua'i Showing Some of the Island's More Prominent Perennial Streams (Source: [CWRM and NPS 1990](#))

3.3.1.2.3 Water Quality

[Figure 3-17](#) shows the inland and marine waters of Kaua‘i that are designated Class 1 and Class AA waters, respectively. These are the most protected waters in the State (see [Section 3.3.1.1.3](#)). Class 1 inland waters are those waters or segments of waters located within the dark-brown shaded areas. For marine waters, [HAR 11-54](#) specifically identifies the following as Class AA waters:

- Embayments – Hanalei Bay (north, central side of the island, [Figure 3-17](#)); and
- Open Coastal Waters – (1) between Hikimoe Valley and Makahoe Point (the long band on the northwestern side of the island) and (2) between Makahuena Point and the westerly boundary of Hoai Bay (the short band on the south-central side of the island).

[Table 3-16](#) summarizes information on impaired inland and marine waters on Kaua‘i from Hawai‘i’s Section 303(d) and Section 305(b) integrated report for the 2008 to 2010 timeframe ([HDOH 2012b](#)). The table identifies the number of impaired waters and the constituent that caused the impairments. With regard to inland waters, the table shows that out of the 24 waters assessed, 21 were considered impaired. As with the Statewide summary ([Table 3-13](#)), the most common reason for impairment of inland waters was high turbidity levels.

In the case of marine waters, the table shows that of the 36 waters assessed, 26 were considered impaired. As identified in the Statewide summary ([Table 3-14](#)), the most common reason for impairment of marine waters was high turbidity levels, but in Kaua‘i the second most frequently encountered issue was unacceptable enterococci levels. Enterococci are indicator bacteria used to identify the possible presence of contamination such as might occur from a sewage leak.

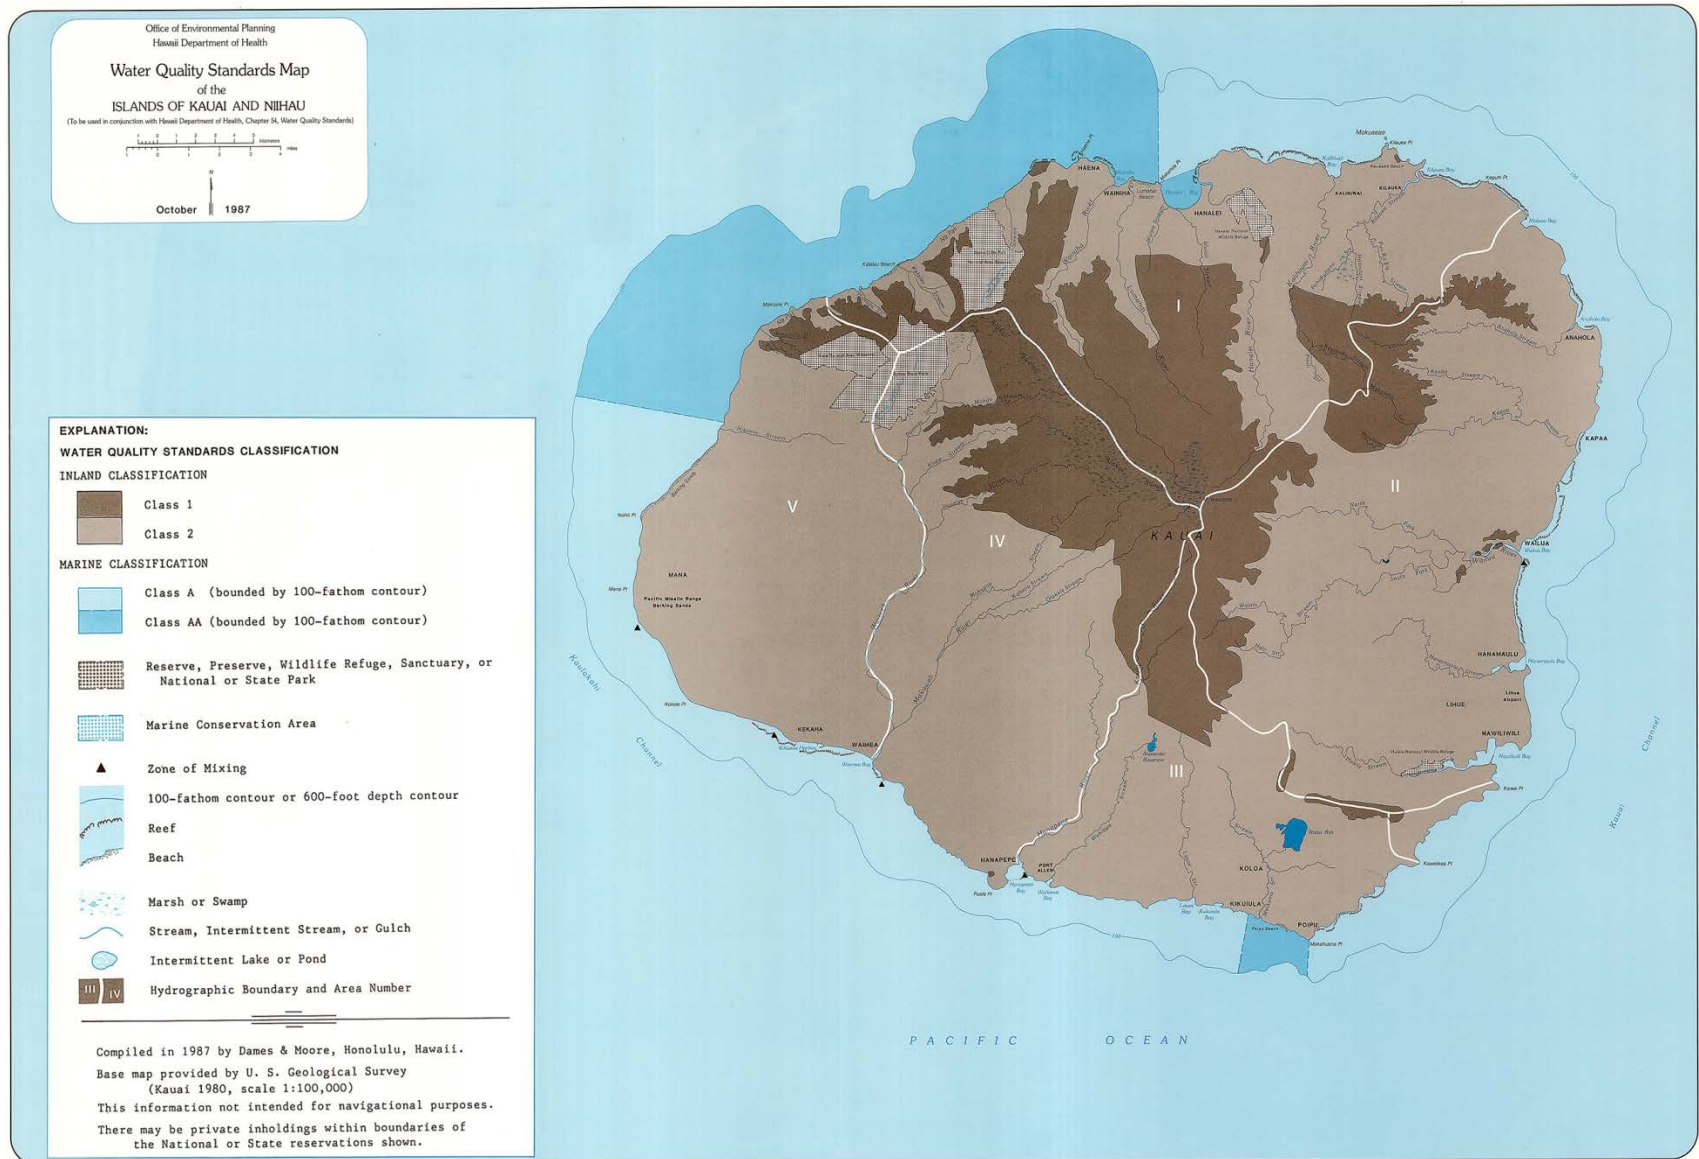

Figure 3-17. Water Quality Designations for the Island of Kaua'i (Source: Modified from [HDOH 1987](#))

Table 3-16. Summary of Kaua‘i Inland and Marine Waters Considered Impaired

Source: [HDOH 2012b](#).

- a. Inland waters identified in the source document consist of 29 streams and 1 estuary; of which, 24 were assessed with the following results: 16 impaired, 5 impaired but need no TMDL, and 3 meet some, but not all standards. The last category is for instances where there are data sufficient to show certain standards are met, but not sufficient to make a determination with regard to other standards. In the case of waters identified but not assessed, available data are insufficient to determine whether standards are met (or if the water is impaired).
- b. The source document identifies 81 marine waters; of which, 36 were assessed with the following results: 23 impaired, 3 impaired but need no TMDL, and 10 meet some, but not all standards.

Total N = total nitrogen; NO₃+NO₂ = nitrate + nitrite nitrogen; Total P = total phosphorus; TMDL = Total Maximum Daily Load.

3.3.1.2.4 Water Use

[Table 3-17](#) summarizes water use in the County of Kaua‘i for the year 2010. For comparison purposes, the table also shows Statewide water usage for the same period. Surface water values are for Kaua‘i County, which includes the island of Ni‘ihau, but surface water use on Ni‘ihau, if any, would be very minor. As can be seen in the table, a majority of the water used on Kaua‘i is for irrigation and it comes from surface water sources. The table also shows that the total amount of water used on Kaua‘i is less than 5 percent of the water used in the State. If the thermoelectric category were to be excluded from the totals, Kaua‘i’s percentage would double to just under 10 percent of the State’s value.

Table 3-17. 2010 Water Use (in million gallons per day) by Category and Source on Kaua'i and for the State of Hawai'i

Water Use Category	Kaua'i					State					Island % of State
	Groundwater		Surface		Totals ^a	Groundwater		Surface		Totals ^a

Sources: CWRM 2008a for military water value; USGS 2014 for all other water values.

Water Sources: Fr = Fresh water; Sa = Saline water; Surface = surface water.

a. Values may not add up to totals because of independent rounding, here and in the referenced source.

b. Self-supplied domestic water, as opposed to domestic water from a municipal source.

3.3.1.3 O'ahu

Fifty-seven of the State's 376 perennial streams are located on O'ahu. [Figure 3-18](#) is a simple map of O'ahu showing approximate locations of some of the island's more prominent perennial streams. The figure also shows how the State of Hawai'i divided the island into six hydrologic regions that were used in the numeric designation of the island's streams. The State assigned the number "3" to the island, itself, and assigned each stream mouth within each of the hydrologic regions a number. These three numbers provide the basis for coding the streams. For example, the Kahana Stream, which drains to the northeast of the island and is one of its largest streams, by flow, is assigned a numeric designation of "3-1-18" because it is on O'ahu, in hydrologic region 1, and its mouth is numbered "18" on [Figure 3-18](#).

Since publication of the 1990 Hawai'i Stream Assessment ([CWRM and NPS 1990](#)), which is the source for [Figure 3-18](#), the State has divided O'ahu into a more refined, smaller set of hydrologic units or watershed areas. The island now comprises 87 hydrologic units with an average size of about 6.8 square miles each. The largest unit is about 59 square miles and the smallest is less than 0.3 square mile ([CWRM 2008a](#)). Boundaries of the six regions shown in the figure match well with boundaries of the 87 hydrologic such that:

- Region 1 of the map contains 19 hydrologic units designated 3001 through 3019,
- Region 2 of the map contains 18 hydrologic units designated 3020 through 3037,
- Region 3 of the map contains 18 hydrologic units designated 3038 through 3055,
- Region 4 of the map contains 12 hydrologic units designated 3056 through 3067,
- Region 5 of the map contains 9 hydrologic units designated 3068 through 3076, and
- Region 6 of the map contains 11 hydrologic units designated 3077 through 3087.

3.3.1.3.1 Stream Flow and Length Characteristics

Most streams shown in [Figure 3-18](#) originate either in the Ko‘olau Range that runs northwest-southeast along the eastern side of the island or the Wai‘anae Range that curves through the western side. [Section 3.3.1.1.1](#) above presents criteria used to rate Hawaiian streams as large, medium, or small. As shown in [Table 3-11](#), none of the 21 streams in the State that qualify or are believed to qualify as large are located on O‘ahu. Of the streams evaluated for flow characteristics in the 1990 Hawai‘i Stream Assessment ([CWRM and NPS 1990](#)), 10 of the 36 medium-sized streams and 16 of the 63 small-sized streams are on O‘ahu.

The [CWRM and NPS \(1990\)](#) evaluation of stream lengths concluded there are only 28 streams in the State that were at least 10 miles long, and 5 of those are on O‘ahu. This includes the longest system in Hawai‘i, the Kiikii River system (3-6-06s), which includes the Kaukonahua Stream.

3.3.1.3.2 Diversions and Dams

The State of Hawai‘i has inventoried stream diversions by hydrologic unit and shows a total of 198 for O‘ahu ([CWRM 2008a](#)), with almost half occurring in region 2 (see [Figure 3-18](#)). The elaborate irrigation diversion systems (see [Section 3.3.1.1.2](#)) are also represented on O‘ahu, primarily by the Waiahole tunnel and ditch system. This system was constructed in the early 1900s to collect surface water and high groundwater from the windward side of the Ko‘olau Range and deliver it to sugar cane fields on the leeward side of the range. Flow through this system was typically on the order of 25 to 30 million gallons per day ([CWRM and NPS 1990](#)).

The Hawai‘i DLNR’s database of dams and reservoirs (see [Section 3.3.1.2.2](#)) shows 16 dams on O‘ahu. These dams are found primarily in region 6 in [Figure 3-18](#), which has nine dams. Region 4 has four dams, region 2 has two dams, and region 3 has one dam ([DLNR 2013b](#)).

3.3.1.3.3 Water Quality

[Figure 3-19](#) shows the inland and marine waters of O‘ahu that are designated Class 1 and Class AA, respectively. These are the most protected waters in the State (see [Section 3.3.1.1.3](#)). Class 1 inland waters are those waters or segments of waters located within the dark-brown shaded areas. For marine waters, [HAR 11-54](#) specifically identifies the following as Class AA waters:

- Embayments – Kahana Bay in the southeast of region 1 ([Figure 3-19](#)), Kāne‘ohe Bay in the northeast of region 2, Hanauma Bay in the southeast of region 3, and Waialua Bay in the north-central area of region 6.
- Open Coastal Waters – (1) Waimanalo Bay from the southerly boundary of Kaiona Beach Park to Makapu‘u Point (the southeastern tip of region 2 in [Figure 3-19](#)), and (2) along Pua‘ena Point, about 3.5 miles from Ka‘ena Point toward Mākua and 3.5 miles from Ka‘ena Point toward Mokulē‘ia (along the northwestern tips of regions 5 and 6).

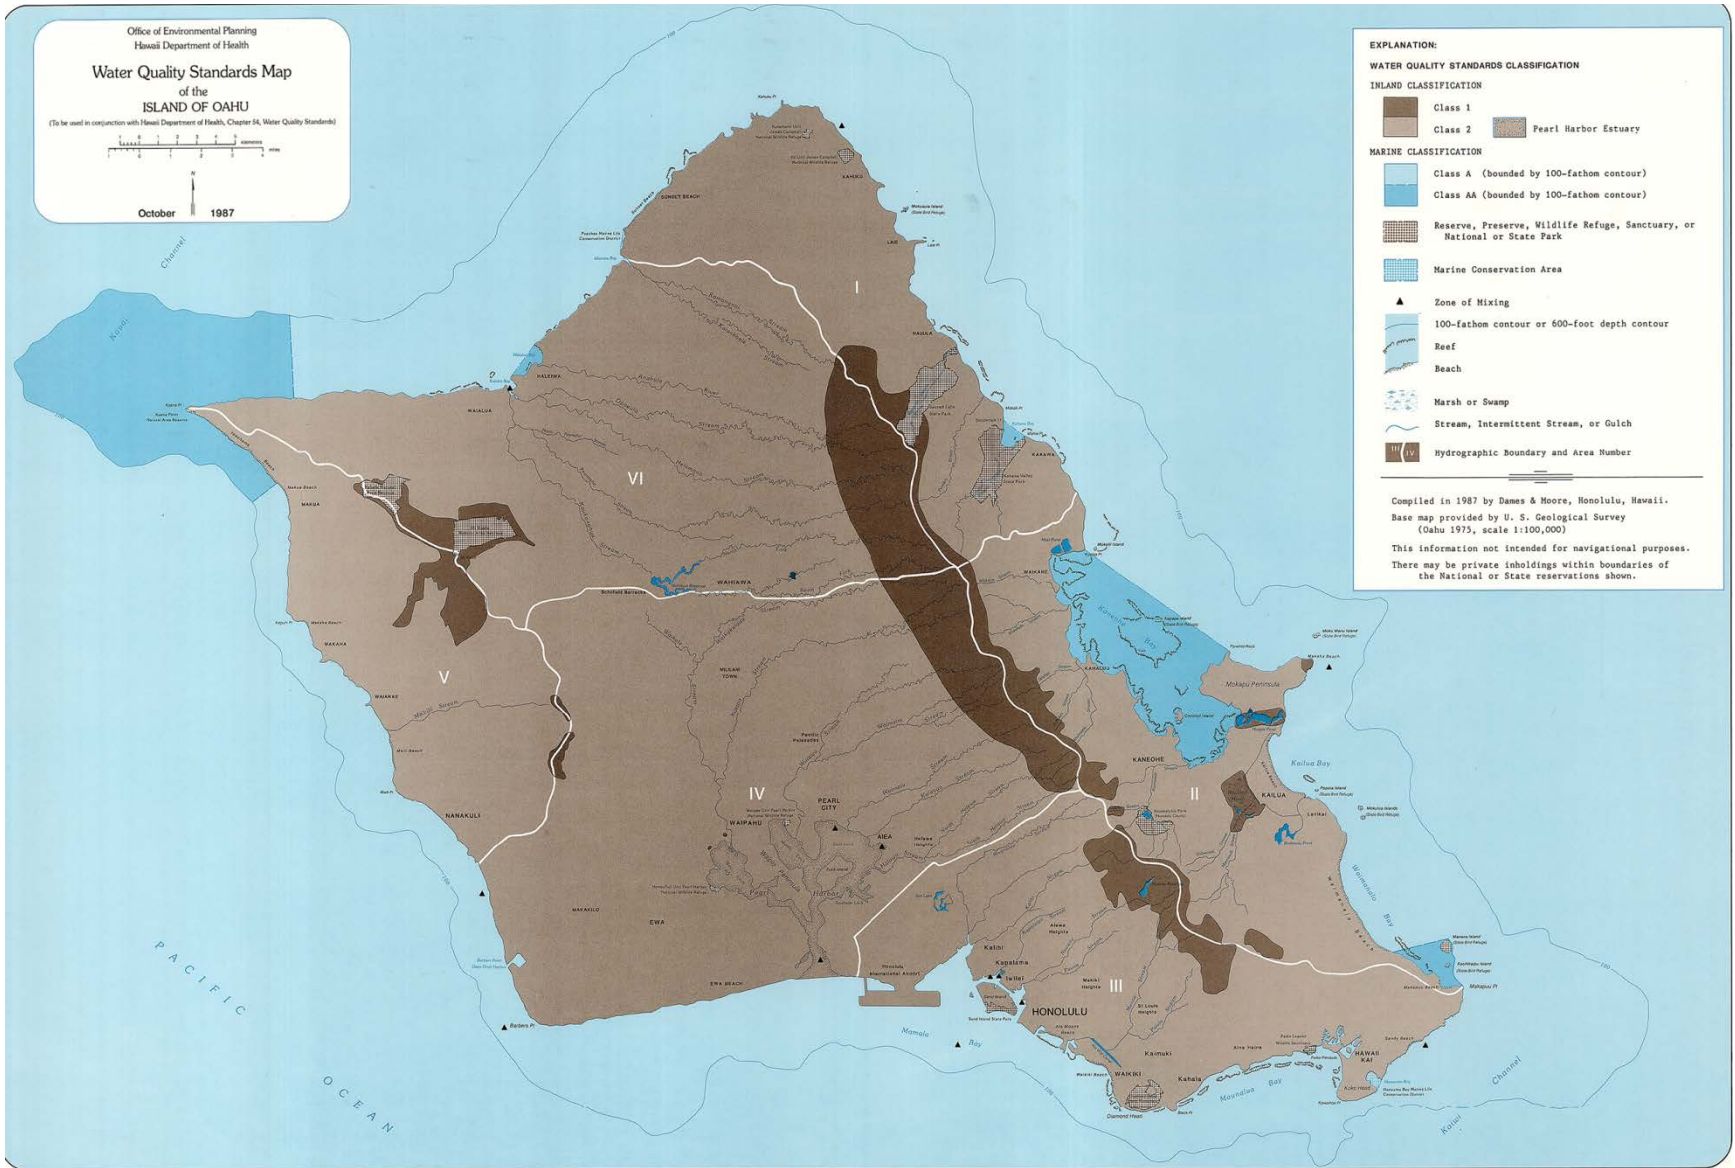

Figure 3-19. Water Quality Designations for the Island of O'ahu (Source: modified from [HDOH 1987](#))

Table 3-18 summarizes information on impaired inland and marine waters on O‘ahu from Hawai‘i’s Section 303(d) and Section 305(b) integrated report for the 2008 to 2010 timeframe (HDOH 2012b). The table identifies the number of impaired waters and the constituent that caused the impairments. With regard to inland waters, the table shows that out of the 52 waters assessed, 51 were considered impaired. As the Statewide summary (Table 3-13), the most common reason for impairment of inland waters was high turbidity levels, but nitrogen constituents, both total and as nitrate-plus-nitrite, were close behind.

Table 3-18. Summary of O‘ahu Inland and Marine Waters Considered Impaired

Number of Impaired Waters	Reason(s) for Impairments

Source: [HDOH 2012b](#).

- a. Inland waters identified in the source document consist of 50 streams, 4 estuaries, 1 wetland, 1 lake, and 1 reservoir; of which, 52 were assessed with the following results: 49 impaired, 2 impaired but needing no TMDL, and 1 meets some, but not all standards. The last category is for instances where there are data sufficient to show certain standards are met, but not sufficient to make a determination with regard to other standards. In the case of waters identified but not assessed, available data are insufficient to determine whether standards are met (or if the water is impaired).
- b. This group consists of 24 streams, two estuaries, and one reservoir.
- c. This group consists of five streams, one estuary, and one lake.
- d. This group consists of one stream, one estuary, and one wetlands area.
- e. The source document identifies 176 marine waters; of which, 112 were assessed with the following results: 65 impaired and 47 meet some, but not all standards.

Total N = total nitrogen; NO₃+NO₂ = nitrate + nitrite nitrogen; Total P = total phosphorus; PCB = polychlorinated biphenyl; TMDL = Total Maximum Daily Load.

In the case of marine waters, the table shows that out of the 112 waters assessed, 65 were considered impaired. As identified in the Statewide summary ([Table 3-14](#)), a common reason for impairment of marine waters was high turbidity levels, but in O‘ahu the most frequently encountered issue was unacceptable total nitrogen levels.

3.3.1.3.4 Water Use

[Table 3-19](#) summarizes water use on O‘ahu for the year 2010. For comparison purposes, the table also shows Statewide water usage for the same period. As can be seen in the table, with the exception of that used for thermoelectric uses, a great majority of the water used on O‘ahu is from groundwater, and other than thermoelectric, the largest use category is municipal water supplies. The table also shows that the total amount of water used on O‘ahu is almost 64 percent of the water used in the State. If the thermoelectric category were to be excluded from the totals, O‘ahu’s percentage would decrease to about 42 percent of the State’s value.

Table 3-19. 2010 Water Use (in million gallons per day) by Category and Source on O‘ahu and for the State of Hawai‘i

Water Use Category	O‘ahu					State					Island % of State
	Groundwater		Surface		Totals ^a	Groundwater		Surface		Totals ^a

Totals^a (% of county or state total)	211.4 (25.6)	3.0 (0.4)	59.2 (7.2)	552.0 (66.9)	825.7	449.1 (34.5)	50.8 (3.9)	248.2 (19.1)	552.0 (42.5)	1300.1	63.5

Sources: CWRM 2008a for military water value; USGS 2014 for all other water values.

Water Sources: Fr = Fresh water; Sa = Saline water; Surface = surface water

a. Values may not add up to totals because of independent rounding, here and in the referenced source.

b. Self-supplied domestic water, as opposed to domestic water from a municipal source.

3.3.1.4 Molokai

Thirty-six of the State’s 376 perennial streams are located on Molokai. [Figure 3-20](#) is a simple map of Molokai showing approximate locations of some of the island’s more prominent perennial streams. The figure also shows how the State of Hawai‘i divided the island into four hydrologic regions that were used in the numeric designation of the island’s streams. The State assigned the number “4” to the island, itself, and assigned each stream mouth within each of the hydrologic regions a number. These three numbers provide the basis for coding the streams. For example, the Wailau Stream, which drains to the north shore of the island and is one of its larger streams, is assigned a numeric designation of “4-1-15” because it is on Molokai, in hydrologic region 1, and its mouth is numbered “15” on [Figure 3-20](#).

Since publication of the 1990 Hawai‘i Stream Assessment ([CWRM and NPS 1990](#)), which is the source for [Figure 3-20](#), the State has divided Molokai into a more refined, smaller set of hydrologic units or watershed areas. The island now comprises 50 hydrologic units with an average size of about 5.3 square miles each. The largest unit is about 25 square miles and the smallest is less than 0.2 square mile ([CWRM 2008a](#)). Boundaries of the five regions shown in the figure match well with boundaries of the 50 hydrologic such that:

- Region 1 of the map contains 21 hydrologic units designated 4001 through 4021,
- Region 2 of the map contains 16 hydrologic units designated 4022 through 4037,
- Region 3 of the map contains nine hydrologic units designated 4038 through 4043 and 4048 through 4050, and
- Region 4 of the map contains four hydrologic units designated 4044 through 4047.

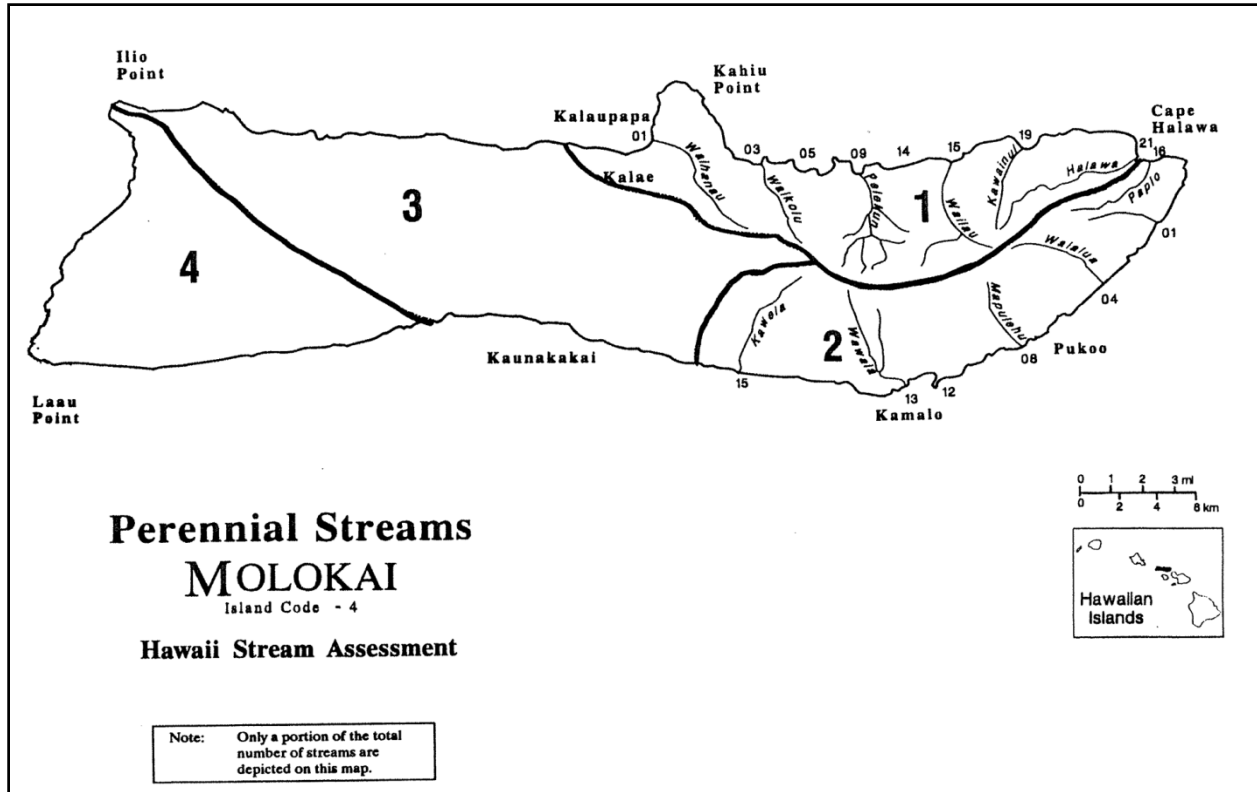

Figure 3-20. Map of Molokai Showing Some of the Island’s More Prominent Perennial Streams (Source: [CWRM and NPS 1990](#))

3.3.1.4.1 Stream Flow and Length Characteristics

Most streams shown in [Figure 3-20](#) originate in the mountainous area on the eastern half of the island. There are also numerous gulches draining the hilly area on the southern half of region 4 in the figure. [Section 3.3.1.1](#) above presents criteria used to rate Hawaiian streams as large, medium, or small. As shown in [Table 3-11](#), none of the 21 streams in the State that qualify or are believed to qualify as large is located on Molokai. Of the streams evaluated for flow characteristics in the 1990 Hawai’i Stream Assessment ([CWRM and NPS 1990](#)), 5 of the 36 medium-sized streams and 4 of the 63 small-sized streams are on Molokai.

The CWRM and NPS (1990) evaluation of stream lengths described previously concluded there are only 28 streams in the State that are at least 10 miles long and none of those is on Molokai.

3.3.1.4.2 Diversions and Dams

The State of Hawai’i has inventoried stream diversions by hydrologic unit and shows a total of 47 for Molokai ([CWRM 2008a](#)), with all but one in regions 1 and 2 and the majority occurring in region 2 (see [Figure 3-20](#)). The most elaborate of the diversions systems is the Molokai Tunnel, which is about 5 miles long and was completed in 1968 ([Molokai Dispatch 2007](#)). This tunnel diverts water, at an average rate of 4 to 5 million gallons per day, from Waikolu Stream (4-1-03) and two tributaries in the Waikolu Valley to west-central Molokai (region 3 in [Figure 3-20](#)).

The Hawai’i DLNR’s database of dams and reservoirs (see [Section 3.3.1.2.2](#)) shows just one dam on Molokai (a reservoir at Kualapu’u). This dam is located within region 3 in [Figure 3-20](#) ([DLNR 2013b](#)).

3.3.1.4.3 Water Quality

[Table 3-20](#) summarizes information on impaired inland and marine waters on Molokai from Hawai‘i’s Section 303(d) and Section 305(b) integrated report for the 2008 to 2010 timeframe ([HDOH 2012b](#)). The table identifies the number of impaired waters and the constituent that caused the impairments. With regard to inland waters, the table shows that out of the three waters assessed, just one was considered impaired. High turbidity levels were the only parameter identified as the cause of the impairment.

[Figure 3-21](#) shows the inland and marine waters of Molokai that are designated Class 1 and Class AA waters, respectively. These are the most protected waters in the State (see [Section 3.3.1.1.3](#)). Class 1 inland waters are those waters or segments of waters located within the dark-brown shaded areas. For marine waters, [HAR 11-54](#) specifically identifies the following as Class AA waters:

- Embayments – No specific Molokai embayments are named; and
- Open Coastal Waters – (1) from the westerly boundary of Hale‘o‘Lono Harbor to Lamaloa Head Point (the long band starting on the southwestern side of the island and extending around the northern side, all the way to the eastern end of the island in [Figure 3-21](#)) and (2) from Cape Hālawā to the easterly boundary of Kaunakakai Harbor (the band starting at the eastern end and extending along the southeastern side of the island).

In the case of marine waters, the table shows that three waters were assessed and all were considered impaired. Consistent with the Statewide summary ([Table 3-14](#)), the most common reason for impairment of marine waters was high turbidity levels, and for two of the Molokai marine waters it was the only identified cause for impairment. The third marine water also indicated nitrogen and phosphate levels.

Table 3-20. Summary of Molokai Inland and Marine Waters Considered Impaired

Number of Impaired Waters	Reason(s) for Impairments					
	Enterococci	Total N	NO ₃ +NO ₂	Total P	Turbidity	Other Pollutants (number of waters)
Molokai Inland Waters^a						
1					X

1	0	0	0	0	1	
Molokai Marine Waters^b						
2					X	
1		X	X	X	X	Suspended solids (1); nutrients (1)
TOTALS						
3	0	1	1	1	3	Suspended solids (1); nutrients (1)

Source: [HDOH 2012b](#).

a. Inland waters identified in the source document consist of 6 streams; of which, 3 were assessed with the following results: 1 impaired and 2 meet some, but not all standards. The last category is for instances where there are data sufficient to show certain standards are met, but not sufficient to make a determination with regard to other standards. In the case of waters identified but not assessed, available data are insufficient to determine whether standards are met (or if the water is impaired).

b. The source document identifies 37 marine waters; of which, 3 were assessed with the following results: 3 impaired. Total N = total nitrogen; NO₃+NO₂ = nitrate + nitrite nitrogen; Total P = total phosphorus; TMDL = Total Maximum Daily Load.

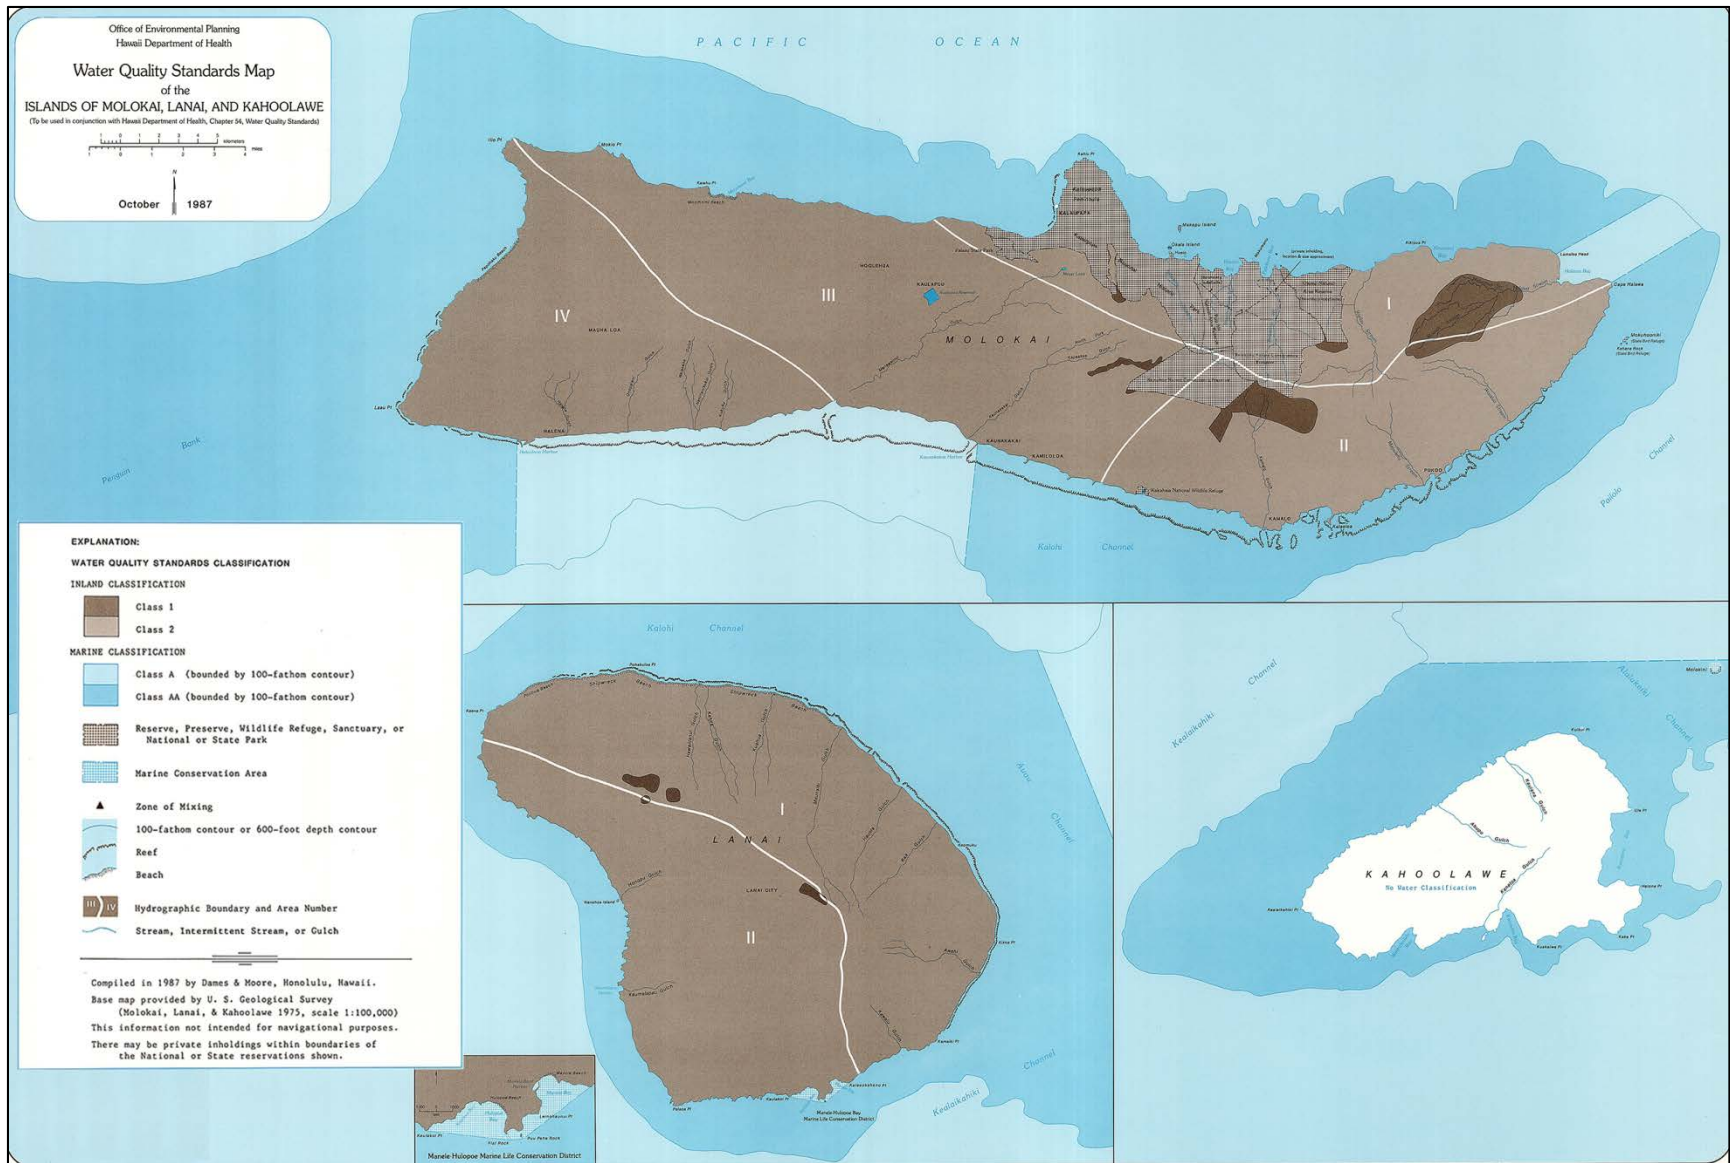

Figure 3-21. Water Quality Designations for the Islands of Molokai and Lāna‘i (Source: modified from [HDOH 1987](#))

3.3.1.4.4 Water Use

[Table 3-21](#) summarizes water use on Molokai for the year 2010. For comparison purposes, the table also shows Statewide water usage for the same period. As can be seen in the table, municipal water supply and irrigation represent the primary water uses on Molokai and it comes from groundwater. The table also shows that the total amount of water used on Molokai is about 0.2 percent of the water used in the State. If the thermoelectric category were to be excluded from the totals, Molokai’s percentage would increase to about 0.4 percent of the State’s value.

3.3.1.5 Lāna‘i

None of the State’s 376 perennial streams is located on Lāna‘i. However, the State of Hawai‘i divided Lāna‘i into a set of hydrologic units or watershed areas, based on drainages and the presence of intermittent or ephemeral streams. Lāna‘i comprises the 32 hydrologic units, as shown in [Figure 3-22](#).

3.3.1.5.1 Stream Flow and Length Characteristics

Consistent with the layout of hydrologic areas in [Figure 3-22](#), Lāna‘i has a large number of eroded gulches that radiate out from the higher interiors portions of the island and drain toward the ocean. Based on aerial views of the island, these gulches typically run 1 to 3 miles, but in places they can be up to 5 miles or more.

Table 3-21. 2010 Water Use (in million gallons per day) by Category and Source on Molokai and for the State of Hawai‘i

Water Use Category	Molokai					State					Island % of State
	Groundwater		Surface		Totals ^a	Groundwater		Surface		Totals ^a	
	Fr	Sa	Fr	Sa		Fr	Sa	Fr	Sa

Domestic (self) ^c	0	0	N/A ^b	N/A ^b	0	1.8	0	6.2	0	8.0	0
Industrial	0	0	N/A ^b	N/A ^b	0	4.6	0	0	0	4.6	0
Irrigation	0.9	0	N/A ^b	N/A ^b	0.9	100.9	0	222.5	0	323.5	0.3
Livestock	0.1	0	N/A ^b	N/A ^b	0.1	0.6	0	1.2	0	1.8	5.6
Aquaculture	0	0	N/A ^b	N/A ^b	0	2.1	0	2.4	0	4.5	0
Mining	0	0	N/A ^b	N/A ^b	0	1.4	0	0.1	0	1.5	0
Thermoelectric	0	0	N/A ^b	N/A ^b	0	53.2	50.8	0	552.0	655.9	0
Military	0	0	N/A ^b	N/A ^b	0	26.4	0	0	0	26.4	0
Totals^a (% of county or state total)	2.8 (100)	0 (0)	N/A ^b (0)	N/A ^b (0)	2.8	449.1 (34.5)	50.8 (3.9)	248.2 (19.1)	552.0 (42.5)	1300.1	0.2

Sources: CWRM 2008a for Molokai groundwater and military water values; USGS 2014 for all other water values.

Water Sources: Fr = Fresh water; Sa = Saline water; Surface = surface water

a. Values may not add up to totals because of independent rounding, here and in the referenced source.

b. N/A = Not available. CWRM 2008 provides only groundwater use data; USGS 2014 provides water use only at the county level. As a result, any surface water use on Molokai is included in the surface water use shown for Maui and the Molokai groundwater use may be double counted in the Maui values.

c. Self-supplied domestic water, as opposed to domestic water from a municipal source.

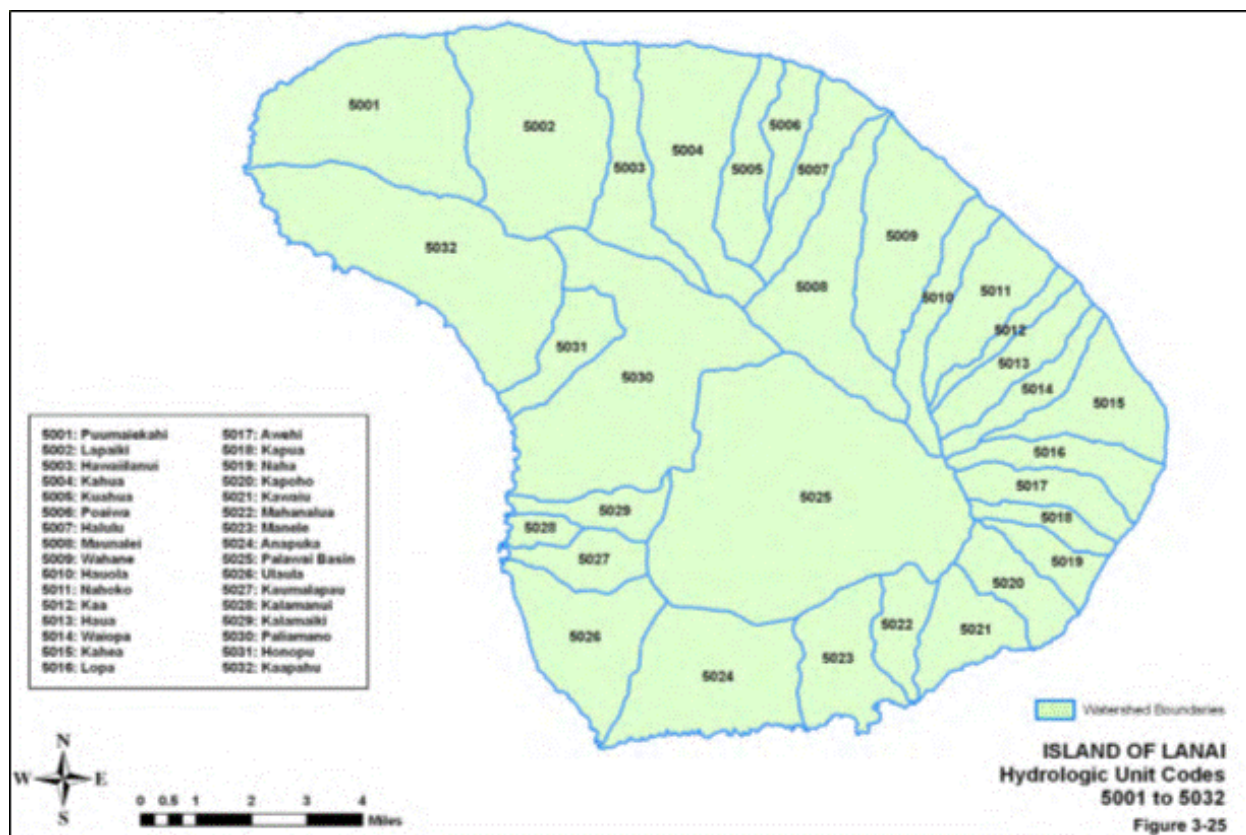

Figure 3-22. Map of Lānaʻi Showing Areas Designated as Hydrologic Units (Source: [CWRM 2008a](#))

3.3.1.5.2 Diversions and Dams

The State’s inventory of stream diversions has no entries for the island of Lānaʻi ([CWRM 2008a](#)). The Hawaiʻi DLNR’s database of dams and reservoirs indicates there are no regulated dams on Lānaʻi ([DLNR 2013b](#)).

3.3.1.5.3 Water Quality

[Figure 3-22](#) shows the marine waters of Lānaʻi that are designated Class AA waters. These are the most protected waters in the State (see [Section 3.3.1.1.3](#)). [HAR 11-54](#) specifically identifies the following as Lānaʻi’s Class AA waters:

- Embayments – No specific Lānaʻi embayments are named, and
- Open Coastal Waters – All open coastal waters surrounding the island.

[Table 3-22](#) summarizes information on impaired marine waters on Lānaʻi from Hawaiʻi’s Section 303(d) and Section 305(b) integrated report for the 2008 to 2010 timeframe ([HDOH 2012b](#)). The table identifies the number of impaired waters and the constituent that caused the impairments. The table shows that out of the eight waters that were assessed, all were considered impaired. As opposed to the Statewide summary ([Table 3-14](#)), which shows turbidity as the most common reason for impairment of marine waters, the most frequent cause of impairment in the Lānaʻi waters was total nitrogen. Turbidity, however, was an issue in about half of the assessed waters.

Table 3-22. Summary of Lāna‘i Marine Waters Considered Impaired

Number of Impaired Waters	Reason(s) for Impairments					
	Enterococci	Total N	NO ₃ +NO ₂	Total P	Turbidity	Other Pollutants (number of waters)
Lāna‘i Inland Waters – None identified						
Lāna‘i Marine Waters^a						
4		X				Chlorophyll a (1)
2		X			X	Chlorophyll a (2)
2					X	Chlorophyll a (1); ammonia nitrogen (1)
TOTALS						
8	0	6	0	0	4	Chlorophyll a (4); ammonia nitrogen (1)

Source: [HDOH 2012b](#).

a. The source document identifies 17 marine waters; of which, 8 were assessed with the following results: 8 impaired. In the case of waters identified but not assessed, data are insufficient to determine whether standards are met (or if the water is impaired).

Total N = total nitrogen; NO₃+NO₂ = nitrate + nitrite nitrogen; Total P = total phosphorus.

3.3.1.5.4 Water Use

[Table 3-23](#) summarizes water use on Lāna‘i for the year 2010. For comparison purposes, the table also shows Statewide water usage for the same period. As can be seen in the table, municipal water supply and irrigation represent the only water uses on Lāna‘i and it comes from groundwater. The table also shows that the total amount of water used on Lāna‘i is about 0.1 percent of the water used in the State. If the thermoelectric category were to be excluded from the totals, Lāna‘i’s percentage would increase to about 0.2 percent of the State’s value.

Table 3-23. 2010 Water Use (in million gallons per day) by Category and Source on Lāna‘i and for the State of Hawai‘i

Water Use Category	Lāna‘i					State					Island % of State
	Groundwater		Surface		Totals ^a	Groundwater		Surface		Totals ^a	
	Fr	Sa	Fr	Sa		Fr	Sa	Fr	Sa		
Municipal	1.1	0	N/A ^b	N/A ^b	1.1	258.1	0	15.8	0	273.9	0.4
Domestic (self) ^c	0	0	N/A ^b	N/A ^b	0	1.8	0	6.2	0	8.0	0
Industrial	0	0	N/A ^b	N/A ^b	0	4.6	0	0	0	4.6	0
Irrigation	0.7	0	N/A ^b	N/A ^b	0.7	100.9	0	222.5	0	323.5	0.2

Thermoelectric	0	0	N/A ^b	N/A ^b	0	53.2	50.8	0	552.0	655.9	0
Military	0	0	N/A ^b	N/A ^b	0	26.4	0	0	0	26.4	0
Totals^a (% of county or state total)	1.8 (100)	0 (0)	N/A ^b (0)	N/A ^b (0)	1.8	449.1 (34.5)	50.8 (3.9)	248.2 (19.1)	552.0 (42.5)	1300.1	0.1

Sources: CWRM 2008a for Lāna‘i groundwater and military values; USGS 2014 for all other water values.

Water Sources: Fr = Fresh water; Sa = Saline water; Surface = surface water

a. Values may not add up to totals because of independent rounding, here and in the referenced source.

b. N/A = Not available. CWRM 2008 provides only groundwater use data; USGS 2014 provides water use only at the county level. As a result, any surface water use on Lāna‘i is included in the surface water use shown for Maui and the Lāna‘i groundwater use may be double counted in the Maui values.

c. Self-supplied domestic water, as opposed to domestic water from a municipal source.

3.3.1.6 Maui

Ninety of the State's 376 perennial streams are located on Maui. [Figure 3-23](#) is a simple map of Maui showing approximate locations of some of the island's more prominent perennial streams. The figure also shows how the State of Hawai'i divided the island into five hydrologic regions that were used in the numeric designation of the island's streams. The State assigned the number "6" to the island, itself, and assigned each stream mouth within each of the hydrologic regions a number. These three numbers provide the basis for coding the streams. For example, the Waihe'e River, which drains to the north-central portion of the island and is one of its largest streams, by flow, was assigned a numeric designation of "6-2-07" because it is on Maui, in hydrologic region 2, and its mouth is numbered "07" on [Figure 3-23](#).

Since publication of the 1990 Hawai'i Stream Assessment ([CWRM and NPS 1990](#)), which is the source for [Figure 3-23](#), the State has divided Maui into a more refined, smaller set of hydrologic units or watershed areas. The island now comprises 112 hydrologic units with an average size of about 6.6 square miles. The largest unit is about 56 square miles and the smallest is less than 0.2 square mile ([CWRM 2008a](#)). Boundaries of the five regions shown in the figure match well with boundaries of the 112 hydrologic such that:

- Region 1 of the map contains 13 hydrologic units designated 6003 through 6015;
- Region 2 of the map contains 11 hydrologic units designated 6001, 6002, and 6016 through 6024;
- Region 3 of the map contains 24 hydrologic units designated 6025 through 6043 and 6108 through 6112;
- Region 4 of the map contains 33 hydrologic units designated 6044 through 6076; and
- Region 5 of the map contains 31 hydrologic units designated 6077 through 6107.

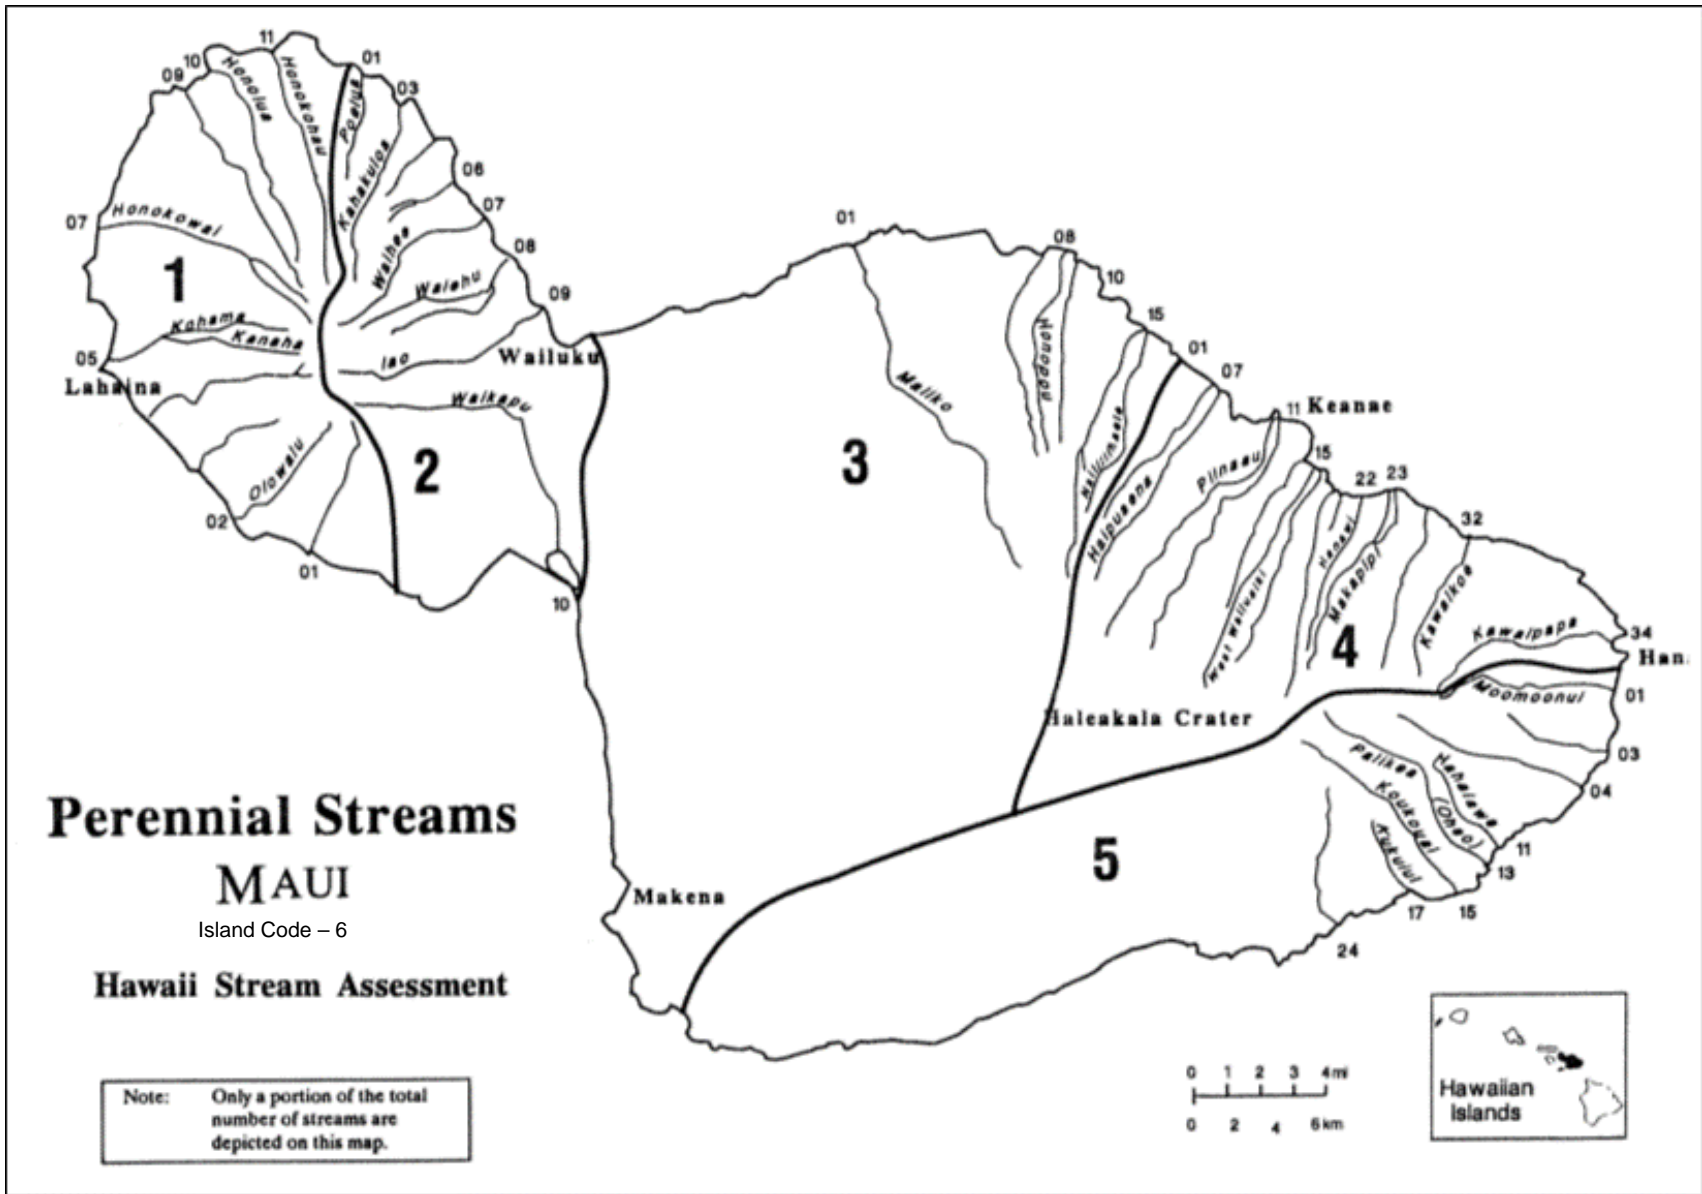

3.3.1.6.1 Stream Flow and Length Characteristics

Most streams shown in [Figure 3-23](#) originate either in the West Maui Mountains or in the area of the Haleakalā Crater. [Section 3.3.1.1](#) above presents criteria used to rate Hawaiian streams as large, medium, or small. As shown in [Table 3-11](#), 2 of the 21 streams in the State that qualify or are believed to qualify as large are located on Maui. Of the streams evaluated for flow characteristics in the 1990 Hawai'i Stream Assessment ([CWRM and NPS 1990](#)), 12 of the 36 medium-sized streams and 23 of the 63 small-sized streams are on Maui.

The [CWRM and NPS \(1990\)](#) evaluation of stream lengths described previously concluded there are only 28 streams in the State that are at least 10 miles long, and two of those are on Maui. These are the Kakipi (6-3-07) and the Piinau (6-4-11), (the latter is shown in [Figure 3-23](#)).

3.3.1.6.2 Diversions and Dams

The State of Hawai'i has inventoried stream diversions by hydrologic unit and shows a total of 489 for Maui ([CWRM 2008a](#)), with almost half occurring in region 3 (see [Figure 3-23](#)). Region 4 has the next largest number of diversions. The elaborate irrigation diversion systems (see [Section 3.3.1.1.2](#)) are well represented on Maui. Several east Maui streams are used to feed a system of ditches that move more than 160 million gallons per day. In region 1 in [Figure 3-23](#), the Honokohau Stream (6-1-11) is the primary source for the Honokohau Tunnel, which carries more than 20 million gallons per day to several northwestern coast communities. In region 2, the Waihe'e (6-2-07), Waiehu (6-2-08), 'Iao (6-2-09), and Waikapū (6-2-10) streams all include diversions to multiple ditches that, in combination, carry in excess of 80 million gallons per day ([CWRM and NPS 1990](#)).

Affected Environment

Figure 3-23. Map of Maui Showing Some of the Island's More Prominent Perennial Streams (Source: [CWRM and NPS 1990](#))

The Hawai'i DLNR's database of dams and reservoirs (see [Section 3.3.1.2.2](#)) shows 53 dams on Maui. These dams are found primarily in region 3 in ([Figure 3-23](#)), which has 33 dams. Region 1 is next with 14 dams, region 2 has four dams, and region 4 has two dams ([DLNR 2013b](#)).

3.3.1.6.3 Water Quality

[Figure 3-24](#) shows the inland and marine waters of Maui that are designated Class 1 and Class AA, respectively. These are the most protected waters in the State (see [Section 3.3.1.1.3](#)). Class 1 inland waters are those waters or segments of waters located within the dark-brown shaded areas. For marine waters, [HAR 11-54](#) specifically identifies the following as Class AA waters:

- Embayments – No specific Maui embayments are named; and
- Open Coastal Waters – (1) between Nākālele Point and Waihe'e Point (the northern shore dark-blue band off region 2 in [Figure 3-24](#)), and (2) between Huelo Point and Pu'uōla'i (the long band along the eastern and southern shores).

[Table 3-24](#) summarizes information on impaired inland and marine waters on Maui from Hawai'i's Section 303(d) and Section 305(b) integrated report for the 2008 to 2010 timeframe ([HDOH 2012b](#)). The table identifies the number of impaired waters and the constituent that caused the impairments. The table shows that out of the 16 inland waters assessed, 11 are considered impaired. As identified in the Statewide summary ([Table 3-13](#)), the most common reason for impairment of inland waters was high turbidity levels.

In the case of marine waters, the table shows that of the 73 waters assessed, 72 of those were considered impaired. As identified in the Statewide summary ([Table 3-14](#)), the most common reason for impairment of marine waters was high turbidity levels, high nitrogen (both total and nitrate-plus-nitrite) were the next most common issues.

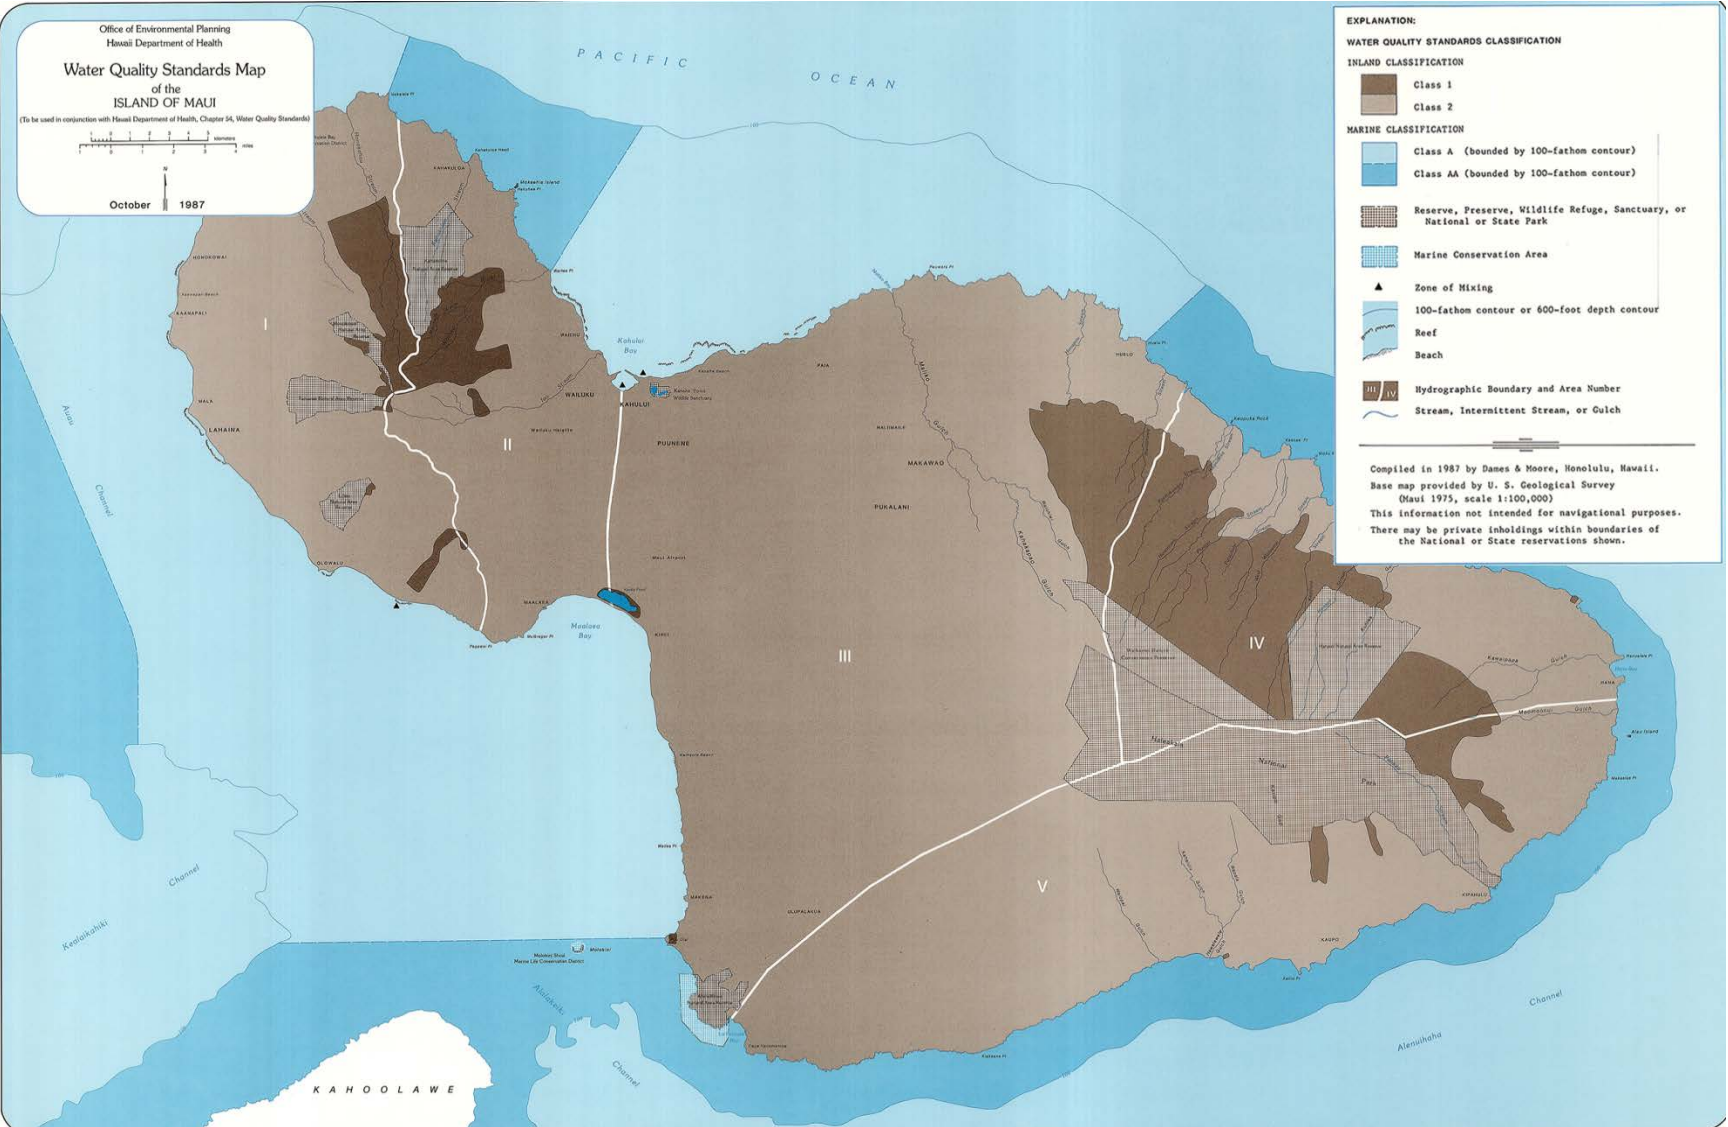

Figure 3-24. Water Quality Designations for the Island of Maui (Source: modified from [HDOH 1987](#))

Table 3-24. Summary of Maui Inland and Marine Waters Considered Impaired

- a. Inland waters identified in the source document consist of 48 streams; of which, 16 were assessed with the following results: 11 impaired and 5 meet some, but not all standards. The last category is for instances where there are data sufficient to show certain standards are met, but not sufficient to make a determination with regard to other standards. In the case of waters identified but not assessed, available data are insufficient to determine whether standards are met (or if the water is impaired).
- b. The source document identifies 122 marine waters; of which, 73 were assessed with the following results: 72 impaired and 1 meets some, but not all standards.

Total N = total nitrogen; NO₃+NO₂ = nitrate + nitrite nitrogen; Total P = total phosphorus; PCB = polychlorinated biphenyl; TMDL = Total Maximum Daily Load.

3.3.1.6.4 Water Use

[Table 3-25](#) summarizes water use on Maui for the year 2010. For comparison purposes, the table also shows Statewide water usage for the same period. As can be seen in the table, a majority of the water used on Maui is from groundwater and the largest use category is irrigation, with municipal uses the next largest. The table also shows that the total amount of water used on Maui is about 21 percent of the water used in the State. If the thermoelectric category were to be excluded from the totals, Maui's percentage increases to about 37 percent of the State's value.

Table 3-25. 2010 Water Use (in million gallons per day) by Category and Source on Maui and for the State of Hawai‘i

Sources: CWRM 2008a for military water value; USGS 2014 for all other water values.

Water Sources: Fr = Fresh water; Sa = Saline water; Surface = surface water

- USGS 2014 provides water use data only at the county level. As a result, these values include the relatively small water use values, as applicable, for Lāna‘i and Molokai.
- Values may not add up to totals because of independent rounding, here and in the referenced source.
- Self-supplied domestic water, as opposed to domestic water from a municipal source.

3.3.1.7 Hawai‘i

One hundred and thirty-two of the State’s 376 perennial streams are located on Hawai‘i island. [Figure 3-25](#) is a simple map of Hawai‘i showing approximate locations of some of the island’s more prominent perennial streams. The figure also shows how the State of Hawai‘i divided the island into five hydrologic regions that were used in the numeric designation of the island’s streams. The State assigned the number “8” to the island, itself, and assigned each stream mouth within each of the hydrologic regions a number. These three numbers provide the basis for coding the streams. For example, the Honoli‘i Stream, which drains to the eastern side of the island, near Hilo, and is one of its largest streams, by flow, was assigned a numeric designation of “8-2-56” because it is on Hawai‘i, in hydrologic region 2, and its mouth is numbered “56” on [Figure 3-25](#). As indicated in the figure, nearly all of Hawai‘i’s perennial streams are in regions 1 and 2; the only exceptions are one in region 4 and three in region 5 ([CWRM and NPS 1990](#)).

Since publication of the 1990 Hawai‘i Stream Assessment ([CWRM and NPS 1990](#)), which is the source for [Figure 3-25](#), the State has divided Hawai‘i into a more refined, smaller set of hydrologic units or watershed areas. The island now comprises 166 hydrologic units with an average size of about 24 square miles. The largest unit is about 389 square miles and the smallest is less than 0.2 square mile ([CWRM 2008a](#)). In region 1, which is the smallest region and which has been divided into the greatest number of units, the average unit size is 4.7 square miles, the largest unit is about 31 square miles, and it is the site of the smallest unit. Boundaries of the five regions shown in the figure match fairly well with boundaries of the 112 hydrologic such that:

- Region 1 of the map contains 82 hydrologic units designated 8001 through 8082;
- Region 2 of the map contains 58 hydrologic units designated 8083 through 8140;
- Region 3 of the map contains 9 hydrologic units designated 8141 through 8149;
- Region 4 of the map contains 6 hydrologic units designated 8150 through 8155; and
- Region 5 of the map contains 11 hydrologic units designated 8156 through 8166.

3.3.1.7.1 Stream Flow and Length Characteristics

Streams shown in [Figure 3-25](#) originate on the windward sides of the Kohala Mountains and Mauna Kea. [Section 3.3.1.1](#) above presents criteria used to rate Hawaiian streams as large, medium, or small. As shown in [Table 3-11](#), 11 of the 21 streams in the State that qualify or are believed to qualify as large are located on Hawai'i. Of the streams evaluated for flow characteristics in the 1990 Hawai'i Stream Assessment ([CWRM and NPS 1990](#)), 4 of the 36 medium-sized streams and 14 of the 63 small-sized streams are on Hawai'i.

The [CWRM and NPS \(1990\)](#) evaluation of stream lengths described previously concluded there are only 28 streams in the State that are at least 10 miles long, and 11 of those are on Hawai'i. These include the Wailoa/Waipio (8-1-44) and the Wailuku (8-2-60), which are both shown in [Figure 3-25](#).

3.3.1.7.2 Diversions and Dams

The State of Hawai'i has inventoried stream diversions by hydrologic unit and shows a total of 206 for Hawai'i ([CWRM 2008a](#)), with three-quarters of those occurring in regions 1 and 2 (see [Figure 3-25](#)). The elaborate irrigation diversion systems (see [Section 3.3.1.1.2](#)) are well represented on Hawai'i. The large ditch systems, many in the Kohala area, carried more than 70 million gallons of water per day for irrigation ([CWRM and NPS 1990](#)).

The Hawai'i DLNR's database of dams and reservoirs (see [Section 3.3.1.2.2](#)) shows 13 dams on Hawai'i. These dams are found predominantly in region 1 in [Figure 3-25](#), which has 12 dams. The only other dam is in region 3 ([DLNR 2013b](#)).

3.3.1.7.3 Water Quality

[Figure 3-26](#) shows the inland and marine waters of Hawai'i that are designated Class 1 and Class AA, respectively. These are the most protected waters in the State (see [Section 3.3.1.1.3](#)). Class 1 inland waters are those waters or segments of waters located within the dark-brown shaded areas. For marine waters, [HAR 11-54](#) specifically identifies the following as Class AA waters:

- Embayments – Puakō Bay, Waiulua Bay, Anaeho'omalua Bay, Kīholo Bay, Kailua Harbor, Kealakekua Bay, and Hōnaunau Bay; and
- Open Coastal Waters – from Leleiwi Point to Waiulaula Point (the dark-blue band around the southern shore and most of the east and west shores of the island in [Figure 3-26](#)).

[Table 3-26](#) summarizes information on impaired inland and marine waters on Hawai'i from the State's Section 303(d) and Section 305(b) integrated report for the 2008 to 2010 timeframe ([HDOH 2012b](#)). The table identifies the number of impaired waters and the constituent that caused the impairments. The table shows that out of the 21 inland waters assessed, 17 were considered impaired. As identified in the Statewide summary ([Table 3-14](#)), the most common reason for impairment of inland waters was high turbidity levels.

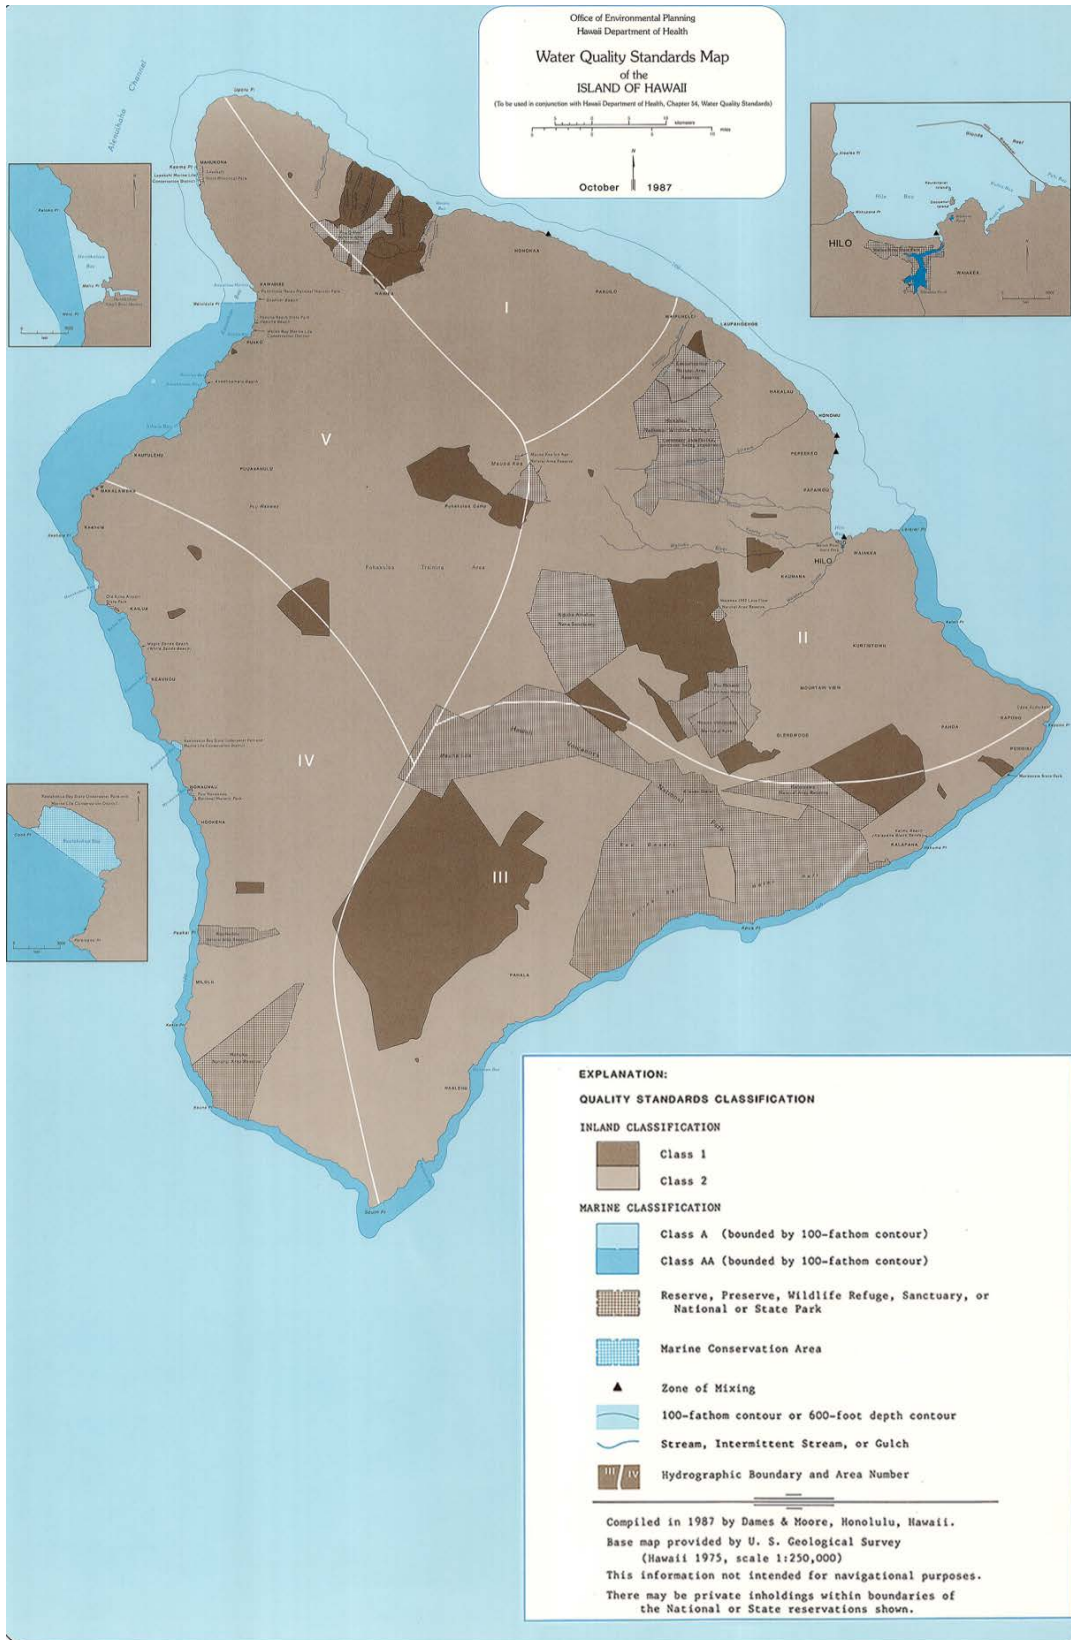

Figure 3-26. Water Quality Designations for the Island of Hawai'i (Source: modified from [HDOH 1987](#))

- a. Inland waters identified in the source document consist of 35 streams and 1 estuary; of which, 21 were assessed with the following results: 17 impaired and 4 meet some, but not all standards. The last category is for instances where there are data sufficient to show certain standards are met, but not sufficient to make a determination with regard to other standards. In the case of waters identified but not assessed, available data are insufficient to determine whether standards are met (or if the water is impaired).
- b. The source document identifies 89 marine waters; of which, 47 were assessed with the following results: 33 impaired and 14 meet some, but not all standards.

Total N = total nitrogen; NO₃+NO₂ = nitrate + nitrite nitrogen; Total P = total phosphorus; TMDL = Total Maximum Daily Load.

In the case of marine waters, the table shows that out of the 47 waters assessed, 33 were considered impaired. As identified in the Statewide summary ([Table 3-14](#)), the most common reason for impairment of marine waters was high turbidity levels, high total nitrogen was the next most common issue.

3.3.1.7.4 Water Use

[Table 3-27](#) summarizes water use on the island of Hawai‘i for the year 2010. For comparison purposes, the table also shows Statewide water usage for the same period. As can be seen in the table, a majority of the water used on Hawai‘i island is from groundwater, and the largest use categories are thermoelectric and municipal water supplies. The table also shows that the total amount of water used on Hawai‘i is about 10 percent of the water used in the State. If the thermoelectric category were to be excluded from the totals, the island of Hawai‘i’s percentage would increase to about 12 percent of the State’s value.

3.3.2 GROUNDWATER

3.3.2.1 State Overview

3.3.2.1.1 Hydrogeology

In any groundwater system, the geology of the area dictates how groundwater moves and where it can move at rates and quantities that support an [aquifer](#) designation. In very general terms, rocks of the

AQUIFER

Water-bearing geologic formation(s) with sufficient saturated, permeable material to yield significant quantities of water to wells or springs.

islands can be grouped into two hydrogeologic categories: the older volcanic rocks and the younger deposits ([Oki et al. 1999](#)). The volcanic materials are found throughout the islands. The younger deposits include alluvium derived from erosion of volcanic rock, coralline limestone, and cemented beach or dune sand. These materials are scattered about the islands, mostly in

coastal areas, and, where present, generally overlay volcanic rock. The following text describes the two hydrogeologic materials to provide a basis for subsequent groundwater discussions.

The flanks of each volcano, which represent the largest area of the island, were formed by thousands of lava flow eruptions from the caldera or associated rift zones. These lava flows were either pāhoehoe or ‘a‘ā lavas. The pāhoehoe is the predominant type of flow and is characterized by its undulating surface and ropy appearance that is consistent with its thinner, more fluid flows. The ‘a‘ā flows have a coarse rubble (clinker) surface and a massive rock interior ([Gingerich and Oki 2000](#)). The clinker sections, voids between flows, shrinkage joints, fractures, lava tubes, and other such features in these materials provide porosity and, generally, permeability, so they are very good aquifers ([UH Hilo 1998](#)). The interior of the thicker flows, particularly the ‘a‘ā, can have very low permeability, so groundwater movement can be hindered by some layers. Also, deposits of pyroclastic rock, consisting of ash, cinder, spatter, and large blocks, can be present as occasional layers within the lava flows. Where present, compaction and weathering of these pyroclastic rock layers generally resulted in thin confining layers; that is, layers with low permeability that can confine overlying groundwater. The most productive aquifers in the islands are

in thick sequences of numerous thin lava flows, and these are also the most widespread aquifers ([Gingerich and Oki 2000](#)).

One other volcanic formation is important to the distribution of groundwater. In the center area of the volcano and along rift zones, the molten lava intruded into fissures and hardened as sheets of basalt rock, or dikes, which are dense and generally of low permeability ([UH Hilo 1998](#)). These dikes can extend vertically and laterally for long distances ([Gingerich and Oki 2000](#)). Where present, they restrict and often trap groundwater flows within intervening permeable lava flows. At high elevations in the rift zones, these dikes can occur in great numbers and are called dike complexes. In such areas, percolating rainwater can be caught in the compartments formed by the dikes. In places where these compartments overflow or are cut into by erosion, the water can discharge as springs and feed streams or feed streams directly ([UH Hilo 1998](#)). Water spilling from the diked areas can also continue to move downward in the ground to deeper aquifers.

As noted previous, the younger consolidated sedimentary deposits are found mostly in the coastal areas. The limestone can be quite permeable in places, but generally yields *brackish* water (fresh- and saltwater mixes) because it has good hydraulic connection with the ocean and receives little recharge from percolating precipitation ([Oki et al. 1999](#)). In some areas, weathered volcanic rock and overlying sedimentary deposits have combined to form a low permeability material called caprock. Where caprock is present, it can confine water in adjacent volcanic rocks. Though it has low permeability, caprock can still be saturated, primarily with water from the ocean, and can result in brackish water overlying fresh water in the volcanic rock ([Gingerich and Oki 2000](#)).

Sedimentary deposits and some types of volcanic rocks, such as pyroclastic material, are typically productive aquifers in the conterminous United States, but are commonly confining units or aquifers with poor production in Hawai'i ([Gingerich and Oki 2000](#)).

3.3.2.1.2 Recharge and Primary Aquifer Systems

Recharge

Rainfall (or snowfall in some high elevations) and fog drip are the natural sources of fresh water for the islands. Fog drip, which is cloud vapor that condenses on vegetation and drips to the ground, commonly occurs at elevations between 2,000 and 6,000 feet ([Gingerich and Oki 2000](#)). In very simple terms, water reaching the islands soaks into the ground, collects and moves as surface runoff, or is lost to *evapotranspiration*. The amount of water going to these three pathways can vary greatly depending on the location. Runoff can be very high in areas of steep slopes that receive a lot of rain and in areas where the surface has low permeability. Attempting to estimate the amount of water partitioned to the three pathways is further complicated by the fact that streams created by runoff can contribute to, or be fed by, groundwater at different locations along their course. Likewise, groundwater or surface water used for irrigation can be a significant source for groundwater at its point of use. With these factors in mind and noting that some areas can be much different than typical, recharge to groundwater typically is about 10 to 50 percent of the rainfall, fog drip, and irrigation water; runoff typically is 10 to 40 percent of rainfall; and evapotranspiration can exceed 50 percent of rainfall ([Gingerich and Oki 2000](#)).

EVAPOTRANSPIRATION

Loss of water to the atmosphere by a combination of transpiration of plants and direct evaporation.

Most groundwater is recharged at high elevations, so regional movement of fresh groundwater is from the interior toward the ocean, and water diffuses to the ocean or discharges at springs near sea level ([Oki et al. 1999](#)). The average total rainfall on the Hawaiian Islands is about 21 billion gallons per day ([Gingerich and Oki 2000](#)), so the average amount of water moving through this recharge-discharge cycle can be

estimated at 10 to 50 percent of this value. That is, on a Statewide basis, a rough estimate of the amount of groundwater discharging to the ocean could be on the order of 2 to 10 billion gallons of water per day.

Primary Aquifer Systems

Basal groundwater and high-level groundwater are the terms often used to describe the two most significant types of groundwater in the Hawaiian Islands ([UH Hilo 1998](#)). [Figure 3-26](#) simplistically depicts these groundwater types. The basal water is found in the large flank areas of the islands where the layered volcanic materials can form very productive aquifers. The high-level water is generally found in the central areas (or rift zones) where the presence of volcanic dikes influence where water is present and where it can move. The figure also shows how sediments, if present, might be positioned along the coastal areas.

The largest bodies of fresh groundwater on the islands are the basal waters that float on salt water within the aquifers. This type of groundwater is also referred to as a freshwater lens due to its lenticular shape ([Oki et al. 1999](#)). Because of the difference in density between fresh water and salt water, fresh groundwater can build up in elevations above the surrounding sea water and still be in pressure equilibrium at the base. A 41-foot column of fresh water weighs about the same as a 40-foot column of the salty seawater. So if fresh groundwater accumulates on top of the saline groundwater that moves in from the ocean, and there is minimal mixing, the fresh groundwater can build up to 41 feet and displace only a 40-foot depth of the saline groundwater. As a result of this relationship, if a person on an island drills for groundwater and encounters fresh water at an elevation of 1 foot above sea level, it can be assumed there is an underlying 41-foot thick lens of fresh water at that location. In literature, this is often referred to as the Ghyben-Herzberg principal, named after the two scientists who independently described the relationship ([Oki et al. 1999](#)). Correspondingly, if fresh water is first encountered at 10 feet above sea level, there should be a 410-foot lens of fresh water below. Of course mixing does occur to some extent at the base of the fresh groundwater and the thickness of the freshwater lens predicted by the Ghyben-Herzberg principal is actually closer to the thickness down to the mid-point of the mixing or transition zone as shown in [Figure 3-27](#) ([Oki et al. 1999](#)). In the transition zone, water is brackish and ranges in chloride concentration from 250 milligrams per liter (the level commonly considered the maximum for fresh water) to about 19,500 milligrams per liter (the chloride concentration of seawater) ([Gingerich and Oki 2000](#)).

As would be expected, and as shown in [Figure 3-27](#), the water table of basal aquifers slopes toward the level of the ocean and the thickness of the lens decreases accordingly. However, it can be imagined that if the sediments shown in the figure were the low permeability caprock material described previously, and if the caprock extended further up the shoreline, the freshwater lens would be at least partially confined and would build up to greater heights. This is what happens in some island areas and results in a very productive and thick aquifer. Since the caprock materials are generally more interconnected with the ocean than the groundwater on the other side, the water they contain is often quite brackish. Imagining the caprock extending further up the shoreline, one could visualize why drilling through those materials could encounter brackish groundwater first, then fresh water at greater depths. The presence of the caprock or other layers with low permeability can also result in artesian conditions, where water will come up in the well to a level higher than first encountered. As depicted in the figure, drilling wells too deep results in pumping saline or brackish water. Similarly, pumping wells too hard that are near the transition zone can pull brackish water toward the well.

Figure 3-27. Stylized Depiction of Typical Hawai'i Aquifers (Source: [CWRM 2013](#))

In the island areas with dike complexes, aquifers and the associated water tables occur at fairly high elevations; up to about 3,300 feet above sea level on Maui and Hawai'i, and about 1,600 feet above sea level on O'ahu. Because of the controlling influence of the dikes, these elevations do not translate into a corresponding depth of fresh water below sea level and, in general, the depth to which fresh water extends in these areas is not known ([Oki et al. 1999](#)). These high-level aquifers represent an important source of fresh water on some of the islands. Not only do they often feed surface waters, even keeping some streams flowing during periods of low runoff, in some cases shafts have been constructed into the dike complexes to intercept water for transport to other parts of the island. The island geologic maps presented in [Section 3.1.1](#) of this PEIS generally identify those areas where significant numbers of dikes are located.

There are instances of high-level aquifers, such as in eastern Kaua'i, that might be considered almost a cross between the basal- and dike-influenced aquifers. They are vertically extensive, with water tables several hundreds or even thousands of feet above sea level, but instead of being associated with dike systems, they are in low-permeability volcanic rock. Because of the vertical hydraulic-head gradients present in these aquifers, the Ghyben-Herzberg principle is not valid for estimating the depth to underlying salt water ([Oki et al. 1999](#)).

Whereas it is believed that groundwater in dike zones is continuous all the way down to the water table of the surrounding flank areas, there are places on the island with perched water tables, which are places where downward percolating water is held up by a layer of material with low permeability, and the water

accumulates above that layer. As described previously, there are several means by which layers of materials with low permeability form within the more permeable volcanic materials. Some perched water bodies are large enough to supply usable quantities of waters to wells and can be of local importance ([Oki et al. 1999](#)).

The distribution and characteristics of these aquifer systems vary by island. The following are a few generalities (in addition to those already discussed) that may help in understanding these variations ([Oki et al. 1999](#)):

- Islands receiving little precipitation and having permeable rock likely will have a very thin lens of fresh water. Islands with heavy recharge and less permeable rock will have a thicker lens.
- Water tables in permeable rocks are generally no more than several tens of feet above sea level. In rocks of low permeability, water table levels typically are greater than several tens of feet above sea level.
- Larger islands have very productive freshwater aquifers, but their hydrologic properties vary widely.
- In some places there is significant mixing between fresh water and salt water and, as a result, brackish water may exist immediately below the water table.
- Groundwater levels fluctuate based on the tide, season, and pumping.

3.3.2.1.3 Groundwater Quality

The source of Hawai‘i’s fresh water is precipitation of water evaporated from the surrounding ocean. As a result, the groundwater has sodium and chloride as its dominant ions. The salinity of groundwater tends to decrease with distance inland and increase with depth. As noted previously, wells pumped too hard or drilled too deep experience increased concentrations of sodium and chloride ([Oki et al. 1999](#)).

Manmade sources of groundwater contamination are typical of inhabited areas and include waste disposal (septic tanks and drainage fields), underground storage tanks, and pesticide and fertilizer applications in agricultural areas. Whether contaminants from these types of activities have reached groundwater is site specific. In some areas, groundwater used for municipal supplies is treated before being put into the distribution system. For example, carbon filters are sometimes used on O‘ahu and aeration has been used on Maui ([Oki et al. 1999](#)).

In the past, HDOH developed and made available groundwater contamination maps (<http://health.hawaii.gov/sdwb/gwprotection/>) that identify locations where contaminants have been detected in wells and springs throughout the State. Tables with the detected concentrations and, as applicable, drinking water standards are also made available with the maps. Contaminant concentrations are generally below Federal and State drinking water standards, but if standards are exceeded, HDOH takes appropriate measures to protect human health.

3.3.2.1.4 Groundwater Use and Availability

[Section 3.3.1](#) discussed total water use (groundwater and surface water). As shown in [Table 3-15](#), the total amount of fresh groundwater used in the State averaged just under 400 million gallons per day in 2005. Along with this was the use of more than 1,400 million gallons per day of saline groundwater. The saline or brackish water was used for cooling in thermoelectric plants.

Groundwater is considered a renewable resource because it is constantly being replenished by natural recharge. In very broad terms, the amount of groundwater that can be safely developed in Hawai‘i generally is considered the amount of recharge less whatever is needed to prevent seawater intrusion (by maintaining aquifer storage volumes) and to maintain stream flow. The amount of groundwater that can be safely developed is termed the *sustainable yield*, which is defined in State law as “the maximum rate at which water may be withdrawn from a water source without impairing the utility or quality of the water source as determined by the [Hawai‘i Commission on Water Resource Management]” ([HRS 174C-3](#)).

As a means to manage its groundwater resources, the Hawai‘i Commission on Water Resource Management (CWRM) has performed extensive data evaluation and groundwater modeling to develop estimates of recharge, groundwater and surface water interaction, and sustainable yield. These efforts and the results are described in the *Hawai‘i Water Plan – Water Resource Protection Plan* ([CWRM 2008a](#)). These concepts must be applied within each island and within portions of each island to be effective. For example, an attempt to manage an entire island through an island-wide sustainable yield might result in a concentration of water wells in a local populous or heavy water use area that could lead to upwelling and intrusion of underlying salt water. To avoid this situation and optimize island-wide pumpage, as well as to provide a consistent basis for managing groundwater resources, the State has established *groundwater hydrologic units*. Each island is divided into aquifer sector areas that are based, to the extent possible, on hydrographic, topographic, and historical boundaries. These sector areas are then divided into smaller sub-regions designated aquifer system areas. These subdivisions are each assigned a five-digit numerical code, with the first digit designating the island (as with the previously described surface water numbering system). The second and third digits designate the sector area, and the last two digits designate the systems area. The sections below discuss groundwater on an island-by-island basis, including the aquifer

Table 3-28. Groundwater Sustainable Yield for the Entire State

Island	Sustainable Yield (in million gallons per day)
Kaua‘i	312
O‘ahu	407
Moloka‘i	79
Lāna‘i	6
Maui	427
Hawai‘i	2,410
TOTAL	3,641

Source: [CWRM 2008a](#).

sector and system areas and the respective identifying codes.

The estimated sustainable yield for the entire State is more than 3.6 billion gallons of water per day ([Table 3-28](#)). This is far more than the 400 million gallons per day of the groundwater used in 2005. However, this comparison provides no indication of whether there are groundwater availability issues in portions of the State. That issue is addressed in the sections below. The discussions below provide estimates of sustainable yields and water use down to the aquifer sector areas for each of the islands. Although this level of detail is considered adequate for this discussion, the source of this information, *Water Resource Protection Plan* ([CWRM 2008a](#)), includes the same

information down to the aquifer system area. It may be noted in some instances that the 2005 groundwater use figures included in the preceding surface water discussions differ slightly from those presented in the groundwater use discussions of this section even though they come from the same reference. Such differences are attributed to differences in the pumping period being represented. Annual water use values in this section are based on 12-month moving averages as of July 2005.

3.3.2.3 Kaua'i

3.3.2.3.1 Aquifer Systems

The basal aquifer system is the primary source of groundwater in Kaua'i. On the eastern side of the island there is a large area of high-level groundwater. Wells that penetrate to below sea level in this area have shown the aquifer to be vertically extensive (not a perched water table) and it is not within any known rift system (not a known dike complex). An extensive caprock in western Kaua'i impedes discharge of groundwater to the ocean and supports a thickening of the basal aquifer in this area ([Gingerich and Oki 2000](#)).

3.3.2.3.2 Groundwater Quality

Chemicals associated with agricultural activities have been detected occasionally in Kaua'i groundwater samples collected from areas downgradient of those activities. The 2005 groundwater contamination map HDOH developed ([HDOH 2006](#)) identifies eight wells, all in southern Kaua'i, where contaminants were detected in small concentrations (parts per billion or less). Eight different contaminants were detected, including several that were detected in multiple wells. Seven of the detected contaminants were materials commonly used in agricultural activities and one, atrazine, was reported in one sample at a concentration above its drinking water standard. The single non-agricultural contaminant, trichloroethylene, is a common industrial solvent and was detected in one well at a concentration below 1 part per billion; within drinking water standards.

3.3.2.3.3 Groundwater Use and Availability

[Section 3.3.1.2](#) discusses Kaua'i's total water use (groundwater and surface water) and presents use categories and quantities in [Table 3-17](#). As was described in [Section 3.3.2.1.4](#), the Hawai'i CWRM developed estimates of sustainable yield down to hydrologic areas (that is, the aquifer sector and system areas) to better manage the groundwater resources. [Figure 3-28](#) shows Kaua'i and the aquifer sector and system areas into which it was divided. The figure also shows the sustainable yield for each of the areas as well as for the island in total. A table of water use values, by aquifer sector area, has been inserted into the figure to support direct comparisons of sustainable yield and current water usage. It might be noted that [Table 3-17](#) includes 10.8 million gallons per day of saline groundwater usage that is not shown in [Figure 3-28](#). The State does not include saline groundwater as a resource to be managed against sustainable yield.

The water use data included in [Figure 3-28](#) show that groundwater use in Kaua'i is only a small portion (less than 4 percent) of the island's sustainable yield. The figure also shows that this is true for each of the aquifer sector areas. In 2008, there were 228 production wells on Kaua'i, 130 of those with pumping capacities of greater than 25 gallons per minute. Most wells are located along the southern and eastern coasts ([CWRM 2008a](#)) and correspond to the areas of heaviest water usage. However, as indicated, no areas appear to be approaching availability issues. It should be noted that comparing water use and sustainable yield by aquifer sector is a simplification to support a high-level evaluation. It does not take into account local areas of high demand and it is generally not practicable for estimates of sustainable yield to consider all possible interactions between groundwater and surface water.

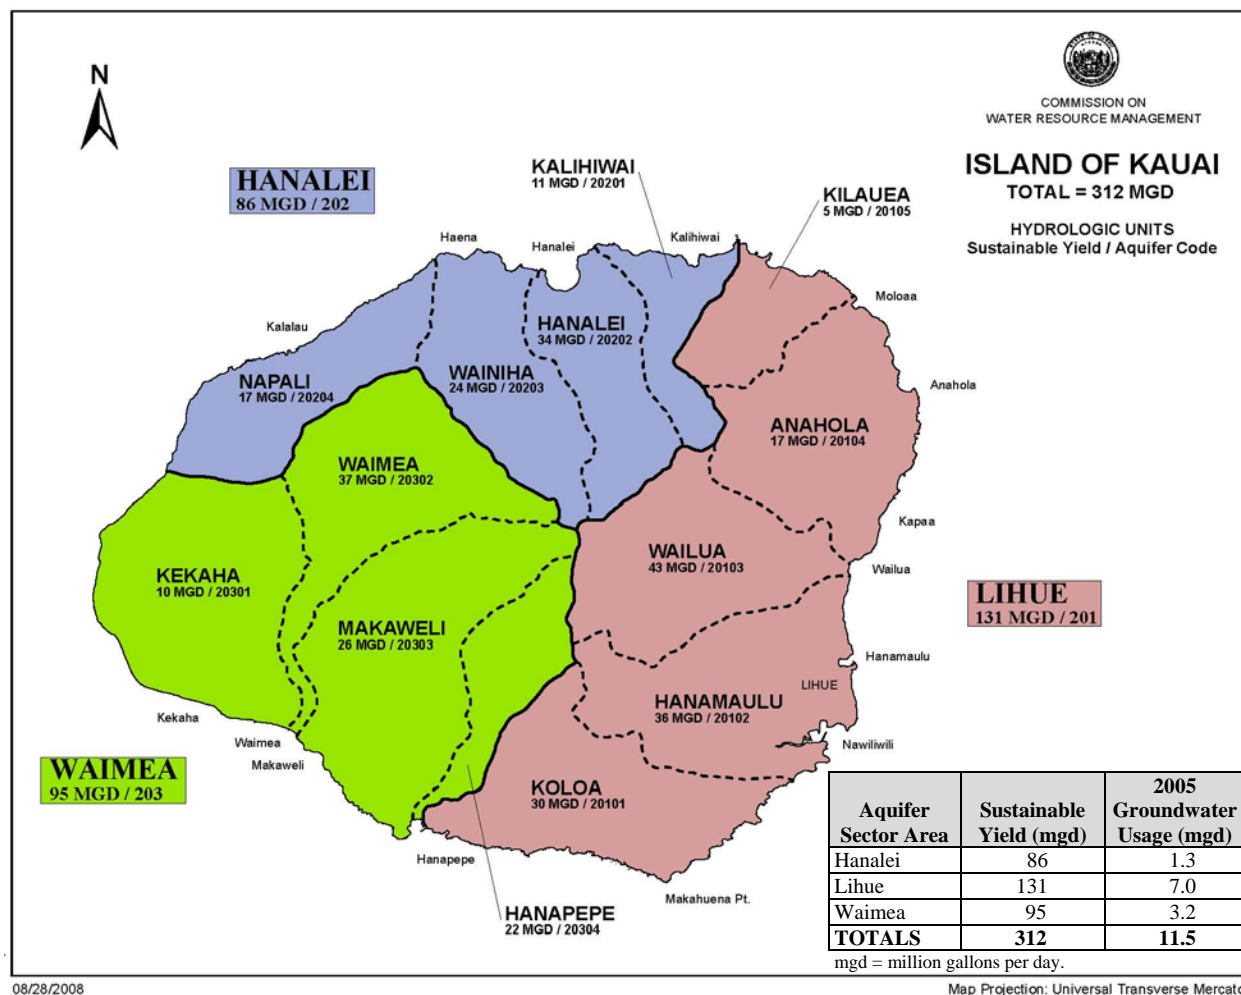

Figure 3-28. Kaua‘i Groundwater Hydrologic Areas, Sustainable Yields, and Water Usage
 [Sources: [CWRM 2008a](#) (water usage); [CWRM 2008b](#) (map)]

3.3.2.4 O‘ahu

3.3.2.4.1 Aquifer Systems

A freshwater lens (basal aquifer system) underlies most of O‘ahu. Around the periphery of the island, water levels in the basal aquifer system are relatively low. In the central part of the island, low permeability features create areas of high-level groundwater. High-level groundwater areas also are present in the rift zones near O‘ahu’s eastern and western sides ([Gingerich and Oki 2000](#)). O‘ahu has larger areas of overlying sedimentary deposits than any other island, including coralline limestone in coastal areas. These deposits have developed into caprock in many of the coastal areas, particularly the area southwest of Pearl Harbor where the large ‘Ewa Caprock is located. In the coastal areas where caprock overlies the highly permeable volcanic rocks, groundwater discharge to the ocean is impeded and the inland wedge of fresh groundwater is thicker than it would be without the caprock. The caprock of the coastal plain contains brackish water, used for cooling and industrial purposes, which overlies the fresh water in the volcanic rocks ([Oki et al. 1999](#)).

Dike systems on O‘ahu impound water at elevations up to about 1,600 feet above sea level and represent an important source of water. Much of the O‘ahu’s precipitation falls along the dike complexes in the

Ko‘olau Range running along the northeastern side of the island. Shafts constructed into the dike complexes are particularly important sources of water on the eastern side of O‘ahu ([Gingerich and Oki 2000](#)). The alluvial deposits of the southern part of O‘ahu contain small areas of perched water, but they are not significant sources of water ([Oki et al. 1999](#)).

Long-term groundwater monitoring records show declining water levels in some areas of O‘ahu. In the Honolulu area, 1880 water levels of about 43 feet above sea level declined to 20 to 25 feet above sea level during the early 1990s. Groundwater in the Pearl Harbor area declined by about 5 feet from 1910 to the early 1990s ([Oki et al. 1999](#)).

3.3.2.4.2 Groundwater Quality

Chemicals associated with agricultural activities have been detected in O‘ahu groundwater samples collected from areas downgradient of those activities. The 2005 groundwater contamination map HDOH developed ([HDOH 2006](#)) identifies 51 wells, predominantly in the central valley area between the two mountain ranges, where contaminants were detected in small concentrations (parts per billion or less). Sixteen different contaminants were detected, most in multiple wells between 1983 and 2005. Fourteen of the detected contaminants were materials commonly used in agricultural activities and two, 1,2-dibromo-3-chloropropane and 1,2,3-trichloropropane, were reported in several samples at a concentration above drinking water standards. The two non-agricultural contaminants were common industrial solvents and one, trichloroethylene, was detected in one sample at a concentration above the drinking water standard.

3.3.2.4.3 Groundwater Use and Availability

[Section 3.3.1.3](#) discusses O‘ahu’s total water use (groundwater and surface water) and presents use categories and quantities in [Table 3-19](#). [Figure 3-29](#) shows O‘ahu and the aquifer sector and system areas into which it was divided to better manage the groundwater resources. The figure also shows the

Table 3-29. O‘ahu Groundwater Availability and Usage in Million Gallons per Day

Aquifer Sector	Sustainable Yield	Existing Permit Allocations	2005 Groundwater Usage
Honolulu	50	53.2	44.1
Pearl Harbor	165	146.3	103.5
Central	23	20.4	9.2
Waianae	16	0	3.6
North	62	40.2	4.2
Windward	91	34.6	23.4
TOTALS	407	294.7	187.9

Source: [CWRM 2008a](#).

sustainable yield for each of the areas as well as for the island in total. [Table 3-29](#) provides water use values, by aquifer sector area, to support direct comparisons of sustainable yield and current water usage. It might be noted that [Table 3-19](#) shows almost 1,380 million gallons per day of saline groundwater usage not shown in [Table 3-29](#). The State does not include saline groundwater as a resource to be managed against sustainable yield. The total 2005 groundwater usage shown here is slightly smaller than that shown in [Table 3-19](#) for the same reason; that is, the [Table 3-19](#) total includes a minor amount of saline groundwater use ([CWRM 2008a](#)).

Because of the high demand and competition for groundwater on O‘ahu (almost half of the State’s fresh groundwater usage occurs on O‘ahu), the Hawai‘i CWRM designated the entire island, except for the Wai‘anae Aquifer Sector Area as a [groundwater management area](#). This authorizes the State to manage the island’s groundwater through a water use permitting process. Water use permits are discretionary approvals and there are seven criteria that must be met in order to obtain a water use permit. (Water permits for well construction and pump installation are required Statewide.) [Table 3-29](#) includes the amount of groundwater allocations the State has issued under this permitting process.

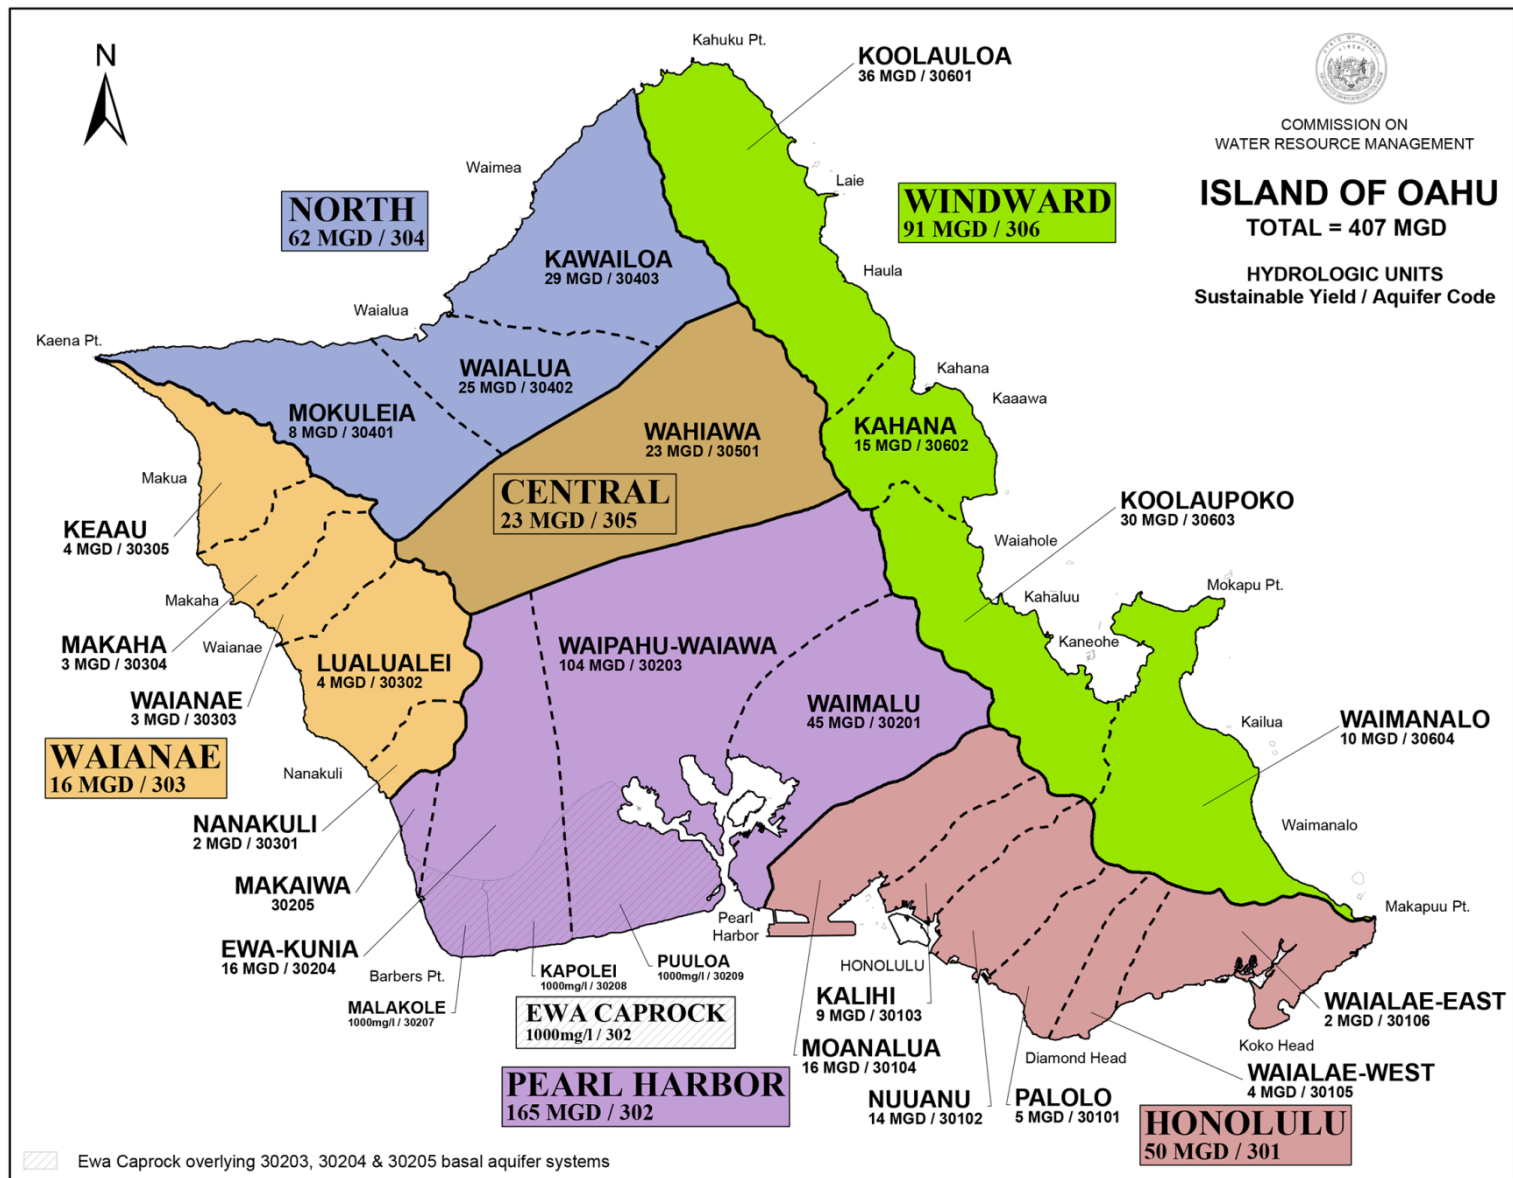

Figure 3-29. O'ahu Groundwater Hydrologic Areas and Sustainable Yields (Source: [CWRM 2008b](#))

The water use data included in [Table 3-29](#) show that the total groundwater use in O‘ahu is 46 percent of the island’s sustainable yield. However, in the Honolulu sector, groundwater use is 88 percent of the area’s sustainable yield, and the permitted allocations are greater than the sustainable yield. This over-allocation situation resulted because declared uses at the time of designation exceeded the subsequent establishment of sustainable yield for some aquifer system areas. CWRM is monitoring the situation in over-allocated aquifers to determine whether adjustments to sustainable yields or water use permit allocations are warranted. Water use in the aquifer sector areas around the west, north, and east peripheries of the island (that is, Wai‘anae, North, and Windward) are notably smaller percentages of the sustainable yield of those areas. In 2008, there were 948 production wells on O‘ahu, 379 of those with pumping capacities greater than 25 gallons per minute. Well locations are heaviest in the Pearl Harbor and Honolulu areas, but are relatively well distributed throughout much of the island.

3.3.2.5 Molokai

3.3.2.5.1 Aquifer Systems

Basal aquifer systems are prevalent throughout Molokai and volcanic dikes are found in the rift zones of both East Molokai and West Molokai, the two volcanoes that formed the island. In the western third of the island, although the volcanic rock may be permeable, there is little potable water available because it receives little recharge ([Oki et al. 1999](#)). The northern part of Molokai has areas of high-level groundwater associated with the northwest rift zone of the East Molokai volcano ([Gingerich and Oki 2000](#)). The bulk of the island’s groundwater resources occur in the high-level and basal aquifers of East Molokai.

3.3.2.5.2 Groundwater Quality

The 2005 groundwater contamination maps HDOH developed ([HDOH 2006](#)) identify no contamination issues for Molokai.

3.3.2.5.3 Groundwater Use and Availability

[Section 3.3.1.4](#) discusses Molokai’s total water use (groundwater and surface water) and presents use categories and quantities in [Table 3-21](#). [Figure 3-30](#) shows Molokai and the aquifer sector and system areas into which it was divided to better manage the groundwater resources. The figure also shows the sustainable yield for each of the areas as well as for the island in total. A table of water use values, by Aquifer Sector Area, has been inserted into the figure to support direct comparisons of sustainable yield and current water usage.

Because of the groundwater resource concerns on Molokai (disputes and concerns regarding future planned uses), the CWRM designated the entire island as a groundwater management area. This authorizes the State to manage the island’s groundwater through a water use permitting process. The table inserted in [Figure 3-30](#) includes the amount of groundwater allocations issued under this permitting process.

The water use data included in [Figure 3-30](#) show that groundwater use in Molokai is only a small portion (less than 4 percent) of the island’s sustainable yield. However, in the Central sector, groundwater use is 23 percent of the area’s sustainable yield and the permitted allocations are more than 60 percent of the sustainable yield. In 2008, there were 99 production wells on Molokai, 34 of those with pumping capacities greater than 25 gallons per minute. Most wells are located along the island’s southern coast in the Central and Southeast sectors ([CWRM 2008a](#)), corresponding to the areas of highest groundwater usage.

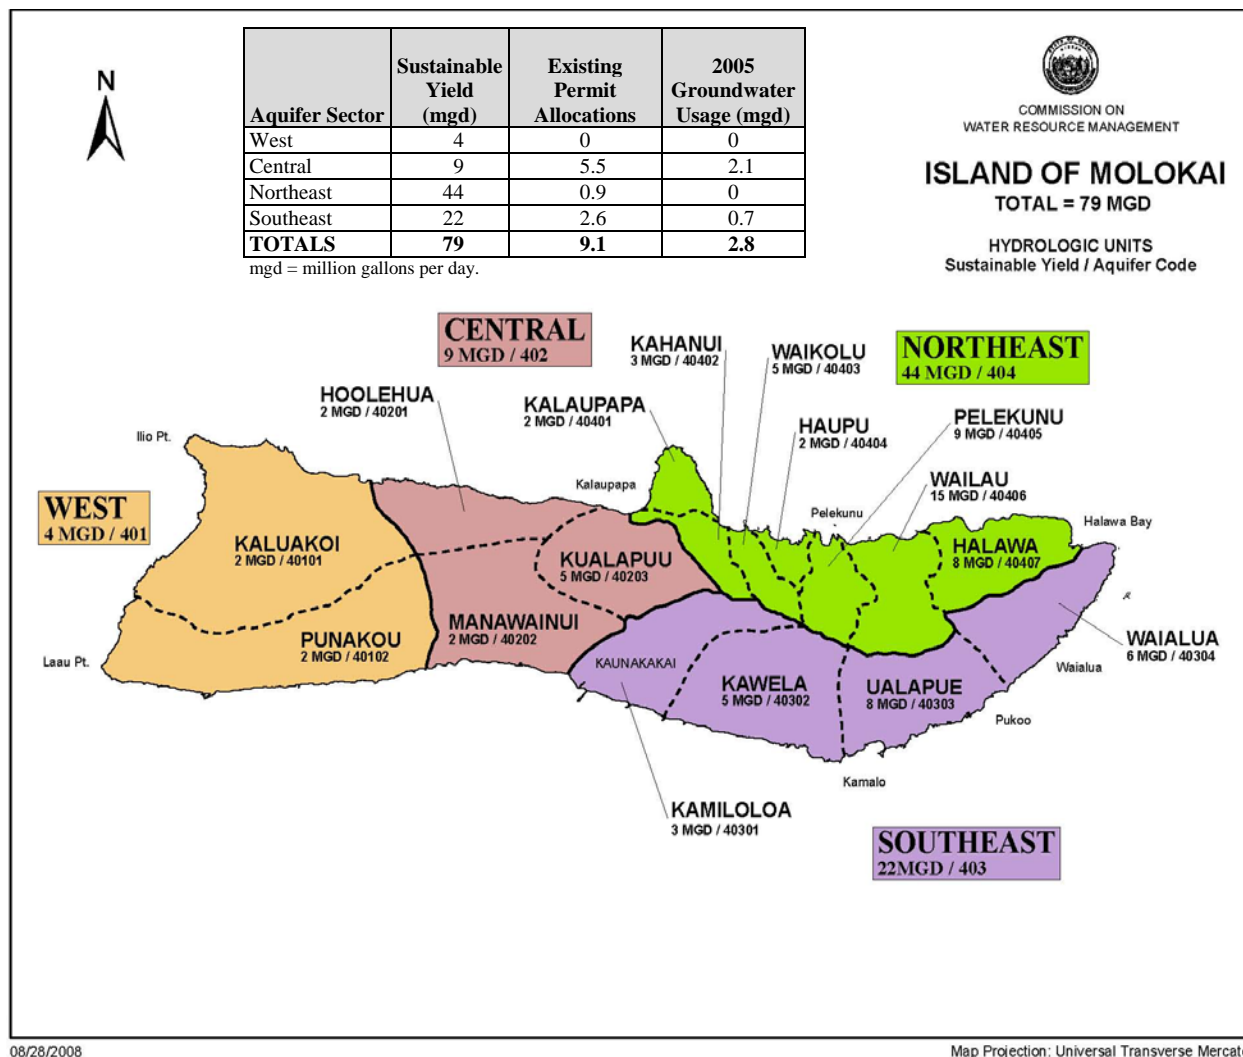

Figure 3-30. Molokai Groundwater Hydrologic Areas, Sustainable Yields, and Water Usage
 [Sources: [CWRM 2008a](#) (water usage); [CWRM 2008b](#) (map)]

3.3.2.6 Lāna‘i

3.3.2.6.1 Aquifer Systems

Basal aquifer systems are prevalent throughout Lāna‘i and volcanic dikes are present in the three rift zones that radiate from the volcano summit. The island is in the rain shadow of Maui and Molokai, so it receives less rain and recharge than the larger islands ([Oki et al. 1999](#)). There is high-level groundwater in the island’s interior within the rift zone and caldera complex ([Gingerich and Oki 2000](#)). This interior portion of the island is the only area with sufficient recharge to have sustainable yield.

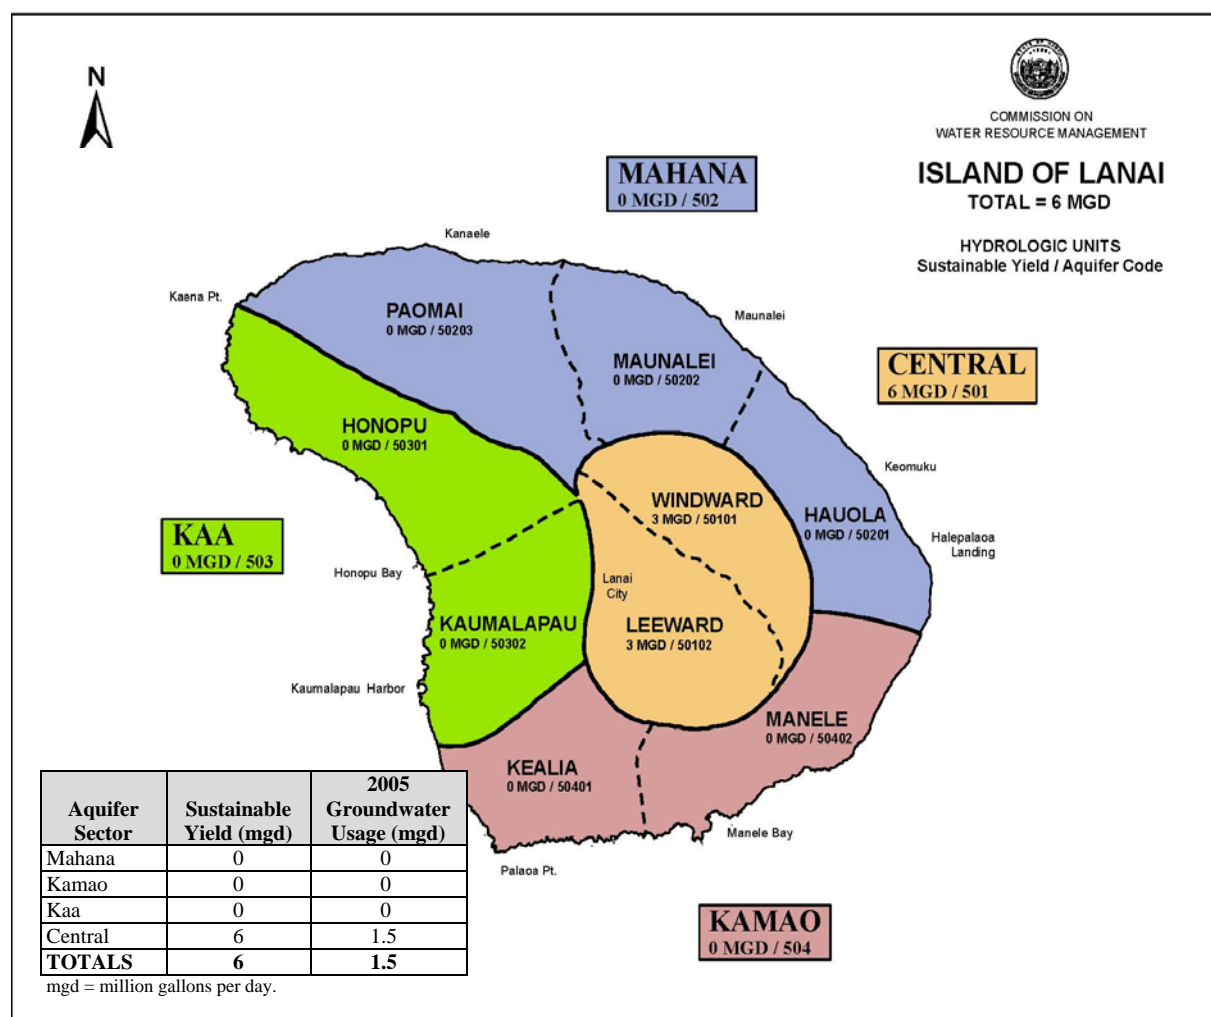

3.3.2.6.2 Groundwater Quality

The 2005 groundwater contamination maps HDOH developed ([HDOH 2006](#)) identify no contamination issues for Lāna‘i. As with other island areas with low recharge, some groundwater areas are affected by degradation of fresh water by salt water ([Oki et al. 1999](#)).

3.3.2.6.3 Groundwater Use and Availability

Section 3.3.1.5 discusses Lāna‘i’s total water use (groundwater and surface water) and presents use categories and quantities in Table 3-23. Figure 3-31 shows Lāna‘i and the aquifer sector and aquifer system areas into which it was divided to better manage the groundwater resources. The figure also shows the sustainable yield for each of the areas as well as for the island in total. A table of water use values, by aquifer sector area, was inserted into the figure to support direct comparisons of sustainable yield and current water usage. It might be noted that Table 3-23 shows a slightly higher groundwater use than that in Figure 3-31. This is because the water use in Table 3-23 includes a small amount of saline groundwater, and the State does not include saline groundwater as a resource to be managed against sustainable yield (CWRM 2008a).

The water use data included in Figure 3-31 show that groundwater use in Lāna‘i is small, but because recharge is so small, it equates to 25 percent of the island’s sustainable yield. In 2008, there were 16 production wells on Lāna‘i, 12 of those with pumping capacities of greater than 25 gallons per minute. The wells are primarily located within the island’s Central sectors (CWRM 2008a).

08/28/2008

Map Projection: Universal Transverse Mercator

Figure 3-31. Lāna‘i Groundwater Hydrologic Areas, Sustainable Yields, and Water Usage

3.3.2.7 Maui

3.3.2.7.1 Aquifer Systems

The central isthmus (the low area lying between the two volcanoes that formed the island) and most coastal areas of Maui have low-level groundwater with water tables less than 50 feet above sea level, which is consistent with a freshwater lens system (basal groundwater system). High-level groundwater is present in the interior of the West Maui Volcano along with dikes (dike groundwater system) that impound water as high as 3,300 feet above sea level ([Oki et al. 1999](#)). High-level groundwater also is present on the northern flanks of East Maui Volcano in areas of high rainfall. Areas along the northern rift zone of the east volcano have both high- and low-level groundwater, indicating a perched groundwater zone above the freshwater lens. Farther to the east, outside of the rift zone, there is an area of high-level groundwater where wells have penetrated to below sea level and shown the aquifer to be a vertically extensive freshwater lens system ([Gingerich and Oki 2000](#)).

Sediments, including coralline limestone, overlie the isthmus area of the island, but these rocks are not a significant source of potable water. These materials have helped form the caprock within Maui's central coast lines. Where present, the caprock impedes discharge of groundwater to the ocean and supports a thickening of the basal aquifer ([Gingerich and Oki 2000](#)).

3.3.2.7.2 Groundwater Quality

Chemicals associated with agricultural activities have been detected occasionally in Maui groundwater samples collected from areas downgradient of those activities. The 2005 groundwater contamination map HDOH developed ([HDOH 2006](#)) identifies 21 wells, predominantly in the northern, central, and northwestern coastal areas, where contaminants were detected in small concentrations (parts per billion or less). Eight different contaminants were detected, most in multiple wells between 1985 and 2005. All of the detected contaminants were materials commonly used in agricultural activities, and three, 1,2-dibromo-3-chloropropane, ethylene dibromide, and 1,2,3-trichloropropane, were reported in several samples at a concentration above drinking water standards.

3.3.2.7.3 Groundwater Use and Availability

[Section 3.3.1.6](#) discusses Maui's total water use (groundwater and surface water) and presents use categories and quantities in [Table 3-25](#). [Figure 3-32](#) shows Maui and the aquifer sector and aquifer system areas into which it was divided to better manage the groundwater resources. The figure also shows the sustainable yield for each of the areas as well as for the island in total. A table of water use values, by aquifer sector area, has been inserted into the figure to support direct comparisons of sustainable yield and current water usage. It might be noted that [Table 3-25](#) shows almost 55 million gallons per day of saline groundwater usage not shown in the water usage table inside [Figure 3-32](#). The State does not include saline groundwater as a resource to be managed against sustainable yield. The total 2005 groundwater usage shown in the figure is slightly smaller than that shown in [Table 3-25](#) for the same reason; that is, the [Table 3-25](#) total includes a minor amount of saline groundwater use ([CWRM 2008a](#)).

The water use data included in [Figure 3-32](#) show that the total groundwater use in Maui is 18 percent of the island's sustainable yield. However, in the Central sector, the sector with the highest water demand, groundwater use is 174 percent of the sector's sustainable yield. Further, most of the sector's water use occurs in the Kahului Aquifer System Area, which has the lowest sustainable yield of any system area on the island. The sustainability of the aquifers can be attributed to large amounts of recharge from the irrigation of the area's sugar cane crops. The sector with the next heaviest water demand, Wailuku, uses about 64 percent of the sector's sustainable yield. The CWRM designated the 'Iao groundwater system,

within the Wailuku Sector, as a groundwater management area, which authorizes the State to manage the 'Iao system through a water use permitting process. In 2008, there were 450 production wells on Maui, 191 of those with pumping capacities greater than 25 gallons per minute. The northern and western coastal areas and the isthmus area of the island are the areas where well distribution is most dense (that is, the highest number of wells per area of land) ([CWRM 2008a](#)).

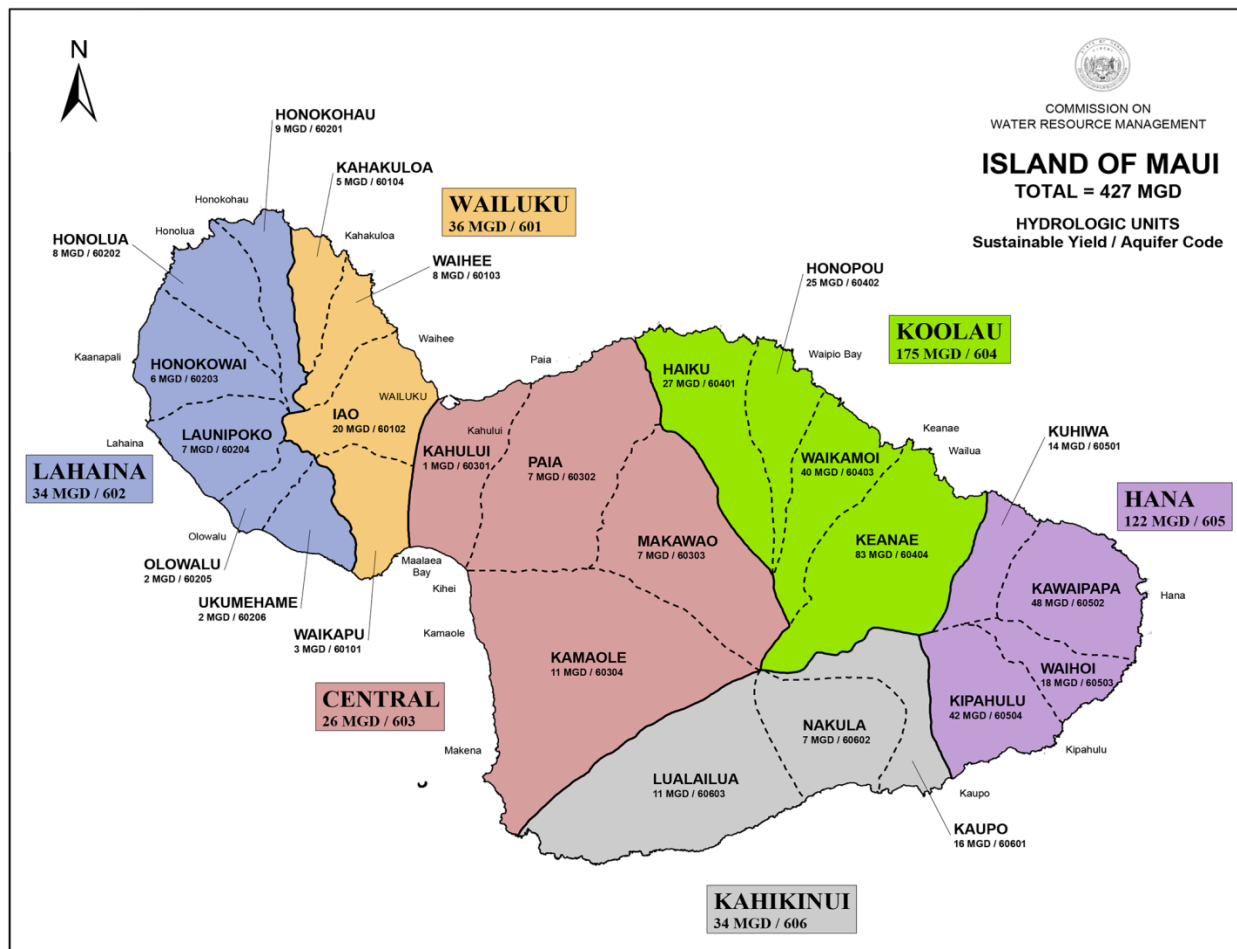

Figure 3-32. Maui Groundwater Hydrologic Areas, Sustainable Yields, and Water Usage [Sources: [CWRM 2008a](#) (water usage); [CWRM 2008b](#) (map)]

3.3.2.8 Hawai'i

3.3.2.8.1 Aquifer Systems

Basal aquifer systems (or freshwater lens systems) are extensive throughout most of the island. In some of the western parts of Hawai'i, however, a freshwater lens is very thin to non-existent, as brackish water overlies salt water because of tidal fluctuations, low recharge and lack of a coastal caprock. High-level groundwater is present in the rift zones of the Kīlauea and Kohala volcanoes (the volcanoes at the southeastern and northwestern extents of the island). The dike complexes impound water to great heights in these areas, as much as 3,300 feet above sea level ([Oki et al. 1999](#)). There is high-level groundwater along the western coast of the island, possibly associated with a buried rift zone of Hualālai Volcano. There also is high-level groundwater along the northern and eastern flanks of Mauna Kea near Hilo and on the southeastern flank of Mauna Loa ([Gingerich and Oki 2000](#)).

Deep drilling was performed in the Hilo area in the 1990s and 2000s as part of the Hawai‘i Scientific Drilling Project to study the geochemical and geophysical processes within the mantle that form volcanoes, such as Hawai‘i, in the middle of tectonic plates. The drilling extended primarily into rocks of the Mauna Kea volcano and found groundwater of the site to be much more complicated than previously envisioned. The second, deeper borehole of the project was drilled to a depth of almost 9,900 feet below sea level in 1999 and extended to about 11,500 feet below sea level in 2007 ([Stopler et al. 2009](#)). Different than the traditional view of a fresh water lens sitting atop salt-water that extends to the island’s base, the project encountered several layers of rock saturated with freshwater that were below saline groundwater. Evidence of fresh, formation water was reported as deep as about 9,800 feet below sea level. The project also found layers where groundwater was more saline than sea water. Closer to the surface, the drilling encountered multiple artesian aquifers and the site has no sedimentary caprock that supports the artesian conditions on O‘ahu. More studies are required to determine how extensive any of these conditions might be, but one implication of the study is that there may be much more freshwater within Mauna Kea’s geologic formations than previously estimated ([Stopler et al. 2009](#)).

3.3.2.8.2 Groundwater Quality

Chemicals associated with agricultural activities have been detected occasionally in Hawai‘i groundwater samples collected from areas downgradient of those activities. The 2005 groundwater contamination map HDOH developed ([HDOH 2006](#)) identifies 32 wells or springs, predominantly along the northeastern coastal area, where contaminants were detected in small concentrations (parts per billion or less). Ten different contaminants were detected, most in multiple sample locations between 1984 and 2005. Nine of the detected contaminants were materials commonly used in agricultural activities, and all were reported at concentrations that met drinking water standards. The single non-agricultural contaminant, tetrachloroethylene, is a common industrial solvent that was detected in a single sample at a concentration that met the drinking water standard.

3.3.2.8.3 Groundwater Use and Availability

[Section 3.3.1.7](#) discussed Hawai‘i island’s total water use (groundwater and surface water) and presented use categories and quantities in [Table 3-27](#). [Figure 3-33](#) shows the island of Hawai‘i and the aquifer sector areas and aquifer system areas into which it was divided to better manage the groundwater resources. The figure also shows the sustainable yield for each of the areas as well as for the island in total. [Table 3-30](#) provides water use values, by aquifer sector area, to support direct comparisons of sustainable yield and current water usage.

Table 3-30. Hawai‘i Groundwater Availability and Usage in Million Gallons per Day

Aquifer Sector	Sustainable Yield	2005 Groundwater Usage
Kohala	140	1.4
E. Mauna Kea	388	2.0
N.E. Mauna Loa	744	56.3
Kīlauea	621	1.5
S.E. Mauna Loa	293	0.1
S.W. Mauna Loa	114	2.1
Hualālai	56	14.4
N.W. Mauna Loa	30	4.9
W. Mauna Kea	24	9.2
TOTALS	2,410	91.9

Source: [CWRM 2008a](#).

The water use data in [Table 3-30](#) show that the total groundwater use in Hawai‘i is a small portion, less than 4 percent, of the island’s sustainable yield. The sector with the highest groundwater usage, N.E. Mauna Loa, uses less than 8 percent of its sustainable yield. The sector using most of its sustainable yield is W. Mauna Kea at 38 percent. In 2008, there were 400 production wells on Hawai‘i, 204 of those with pumping capacities greater than 25 gallons per minute. The coastal areas of the northern half of the island are where well distribution is most dense ([CWRM 2008a](#)).

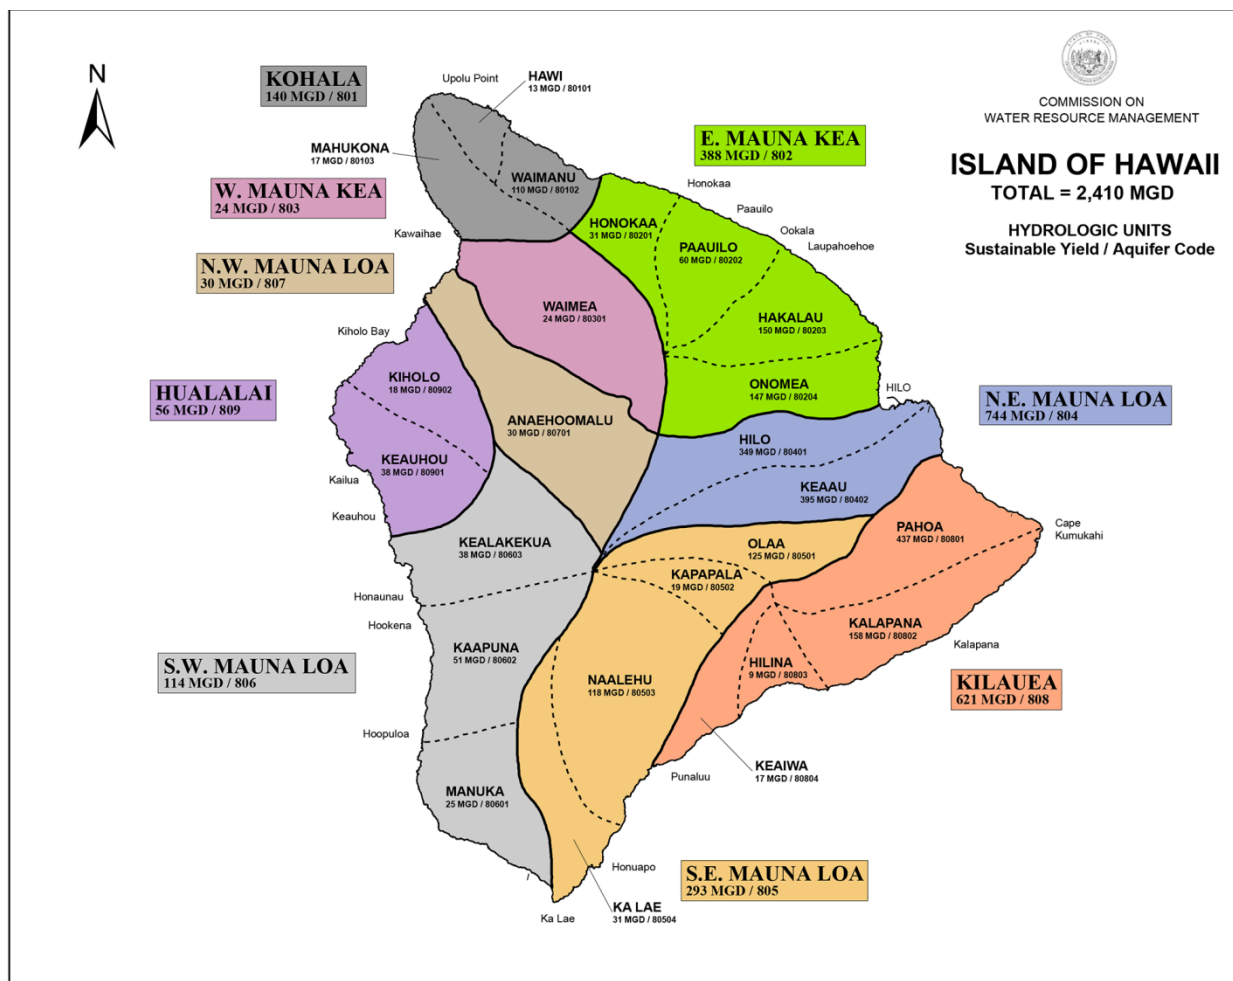

Figure 3-33. Island of Hawai‘i Groundwater Hydrologic Areas and Sustainable Yields (Source: [CWRM 2008b](#))

3.3.3 FLOODPLAINS AND WETLANDS

3.3.3.1 Floodplains

Floodplains are lowland and flat areas adjoining inland and coastal waters. These areas often are prone to flooding, and the amount of adjacent land inundated depends on the magnitude of the flooding event. The Federal Emergency Management Agency (FEMA)-administered [National Flood Insurance Program](#) has set the “100-year flood” as the national standard for purposes of requiring flood insurance and regulating new development and substantial improvements ([FEMA 2013](#)). A 100-year flood is a flood with a 1 percent chance of occurring in any single year. A flood with a probability of occurring less often than this, for example a 500-year flood, would be a larger magnitude flood and would inundate more floodplain area than a 100-year flood. Conversely, a flood with a probability of occurring more often, for example a 10-year flood, would be of smaller magnitude and would inundate less area of the floodplain.

FEMA has developed Flood Insurance Rate Maps for most of the United States that show areas prone to inundation by 100-year floods. This information for the State of Hawai‘i is available via the State’s Flood Hazard Assessment Tool (<http://www.hidlnr.org/eng/nfip/NfipHome.aspx>), which allows the user to navigate to any location on any of the islands and, where data are available, zoom into any area to view

flood zones. The tool also allows the user to generate a Flood Hazard Assessment Report, like that shown in [Figure 3-34](#).

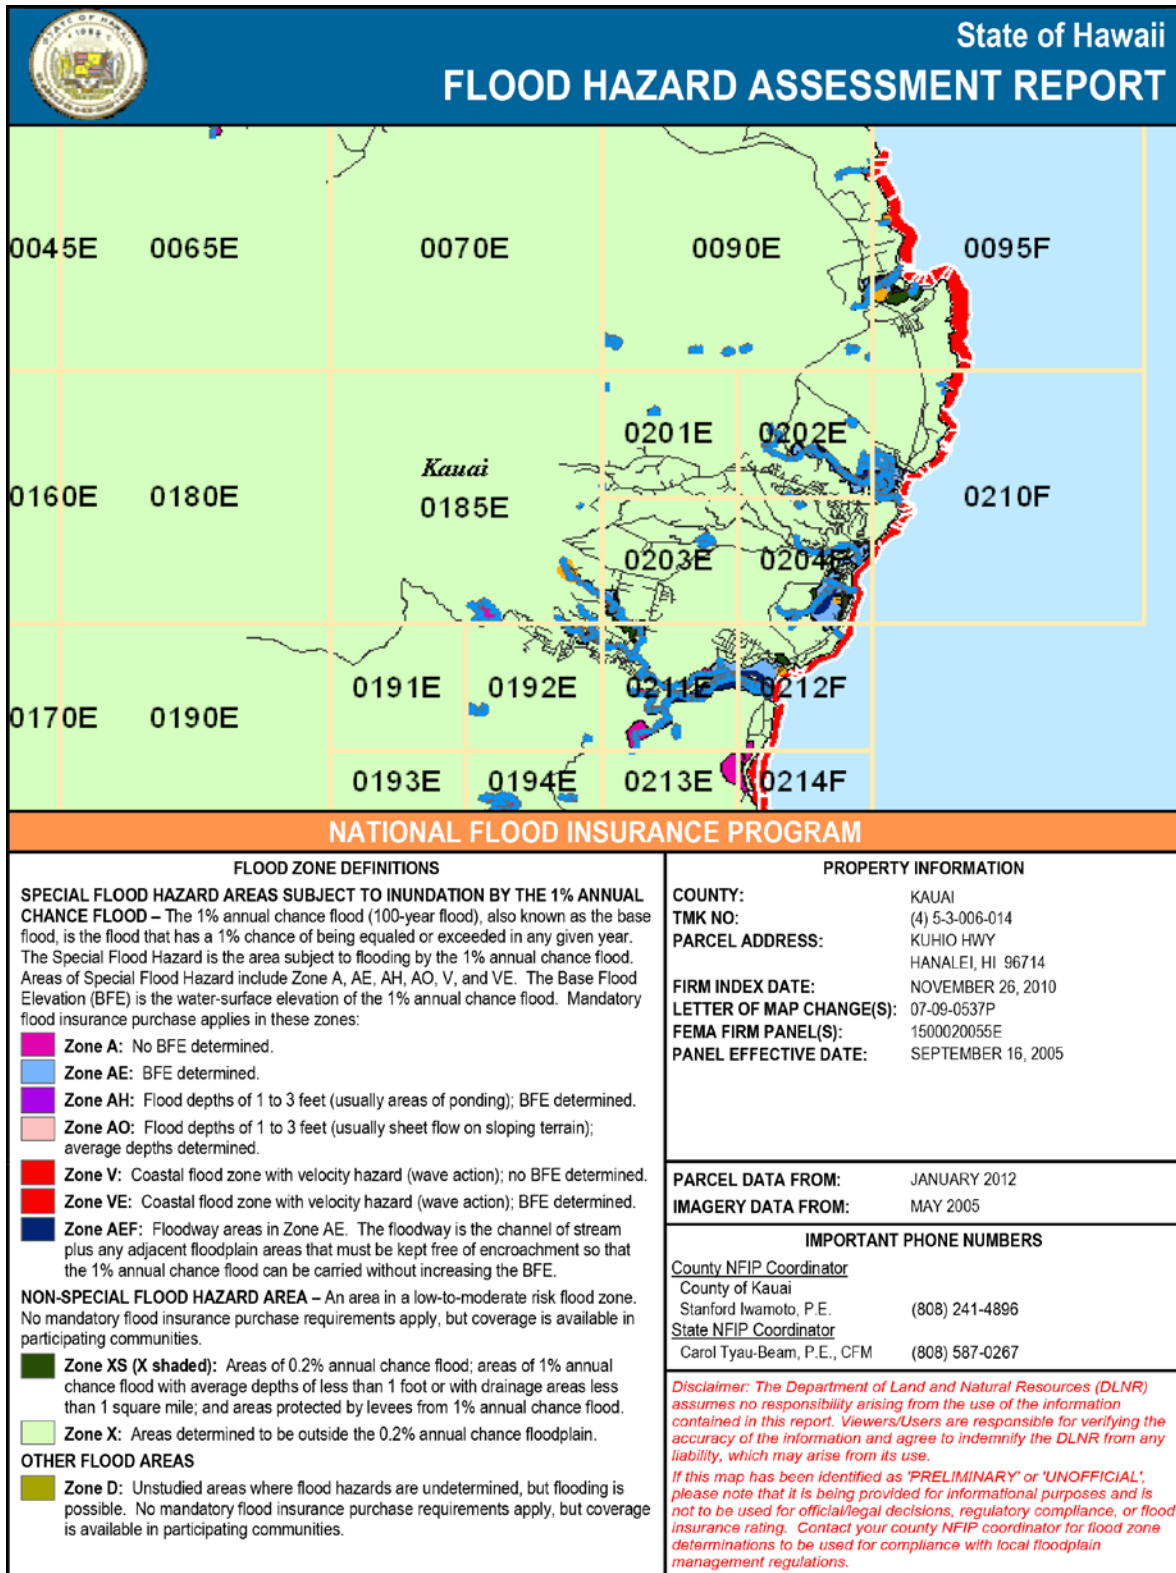

Figure 3-34. Example Report Generated from the State’s Flood Hazard Assessment Tool

The land area shown in [Figure 3-34](#) is on the eastern coastline of Kaua‘i. The figure shows coastal areas (in red), inland stream areas, and inland reservoirs or low accumulation areas prone to flooding. Even in this relatively small portion of an island, a more zoomed in view is necessary to get any real detail on flood zone boundaries. It is not practical for this PEIS to show the level of detail in [Figure 3-34](#) for all areas of each of the islands, let alone more detailed information. Accordingly, interested parties are directed to the State’s Flood Hazard Assessment Tool to obtain more information on the location and extent of floodplains in Hawai‘i.

3.3.3.2 Wetlands

[Wetlands](#) are areas periodically or permanently inundated by surface water or groundwater and that support vegetation adapted for life in saturated soil. For a location to qualify as a wetland, it must have hydric soils, hydrology indicators, and wetland vegetative species ([USACE 2013](#)). Wetlands are valued for their contributions in reducing flooding impacts; filtering or absorbing nutrients, sediments, and even pollutants before they reach streams and marine areas; facilitating recharge to groundwater; providing wildlife habitat; enhancing scenic landscapes; and providing recreational opportunities ([PCJV 2009](#)).

The wetlands most common in Hawai‘i are as follows ([PCJV 2009](#)):

- [Riverine wetlands](#) – These are the surface water systems found along the edges of rivers and streams.
- [Palustrine wetlands](#) – These include marshes and bogs and generally are found in depressions where rain and groundwater collect. Hawai‘i’s rare montane bogs, which take millions of years to form, are in this group.
- [Estuarine wetlands](#) – These include swamps and mudflats that occur on coasts where streams empty to the ocean. These areas typically are influenced by tides, are brackish, and provide habitat for fish, shellfish, and waterbirds.
- [Marine wetlands](#) – These include intertidal shorelines, seagrass beds, and tidepools. They are saltwater systems that often provide habitat for many species harvested by humans for food.

The U.S. Fish and Wildlife Service (USFWS) maintains an electronic inventory of wetlands within the United States through a “Wetlands Mapper” tool (<http://www.fws.gov/wetlands/Data/Mapper.html>). Like the State’s Flood Hazard Assessment Tool, the USFWS online mapper tool allows the user to navigate to any location on any of the islands and zoom into any area to view potential wetlands areas. The tool also allows the user to generate digital maps of the areas of interest like that shown in [Figure 3-35](#).

The land area shown in the example map in [Figure 3-35](#) is on the northwestern tip of Hawai‘i island (the Kohala Volcano area). The figure shows a large area and several smaller areas of potential palustrine freshwater forested/shrub wetlands (green) and several small areas of potential palustrine emergent wetlands (light green). As with the online flood hazard tool, a more zoomed in view is necessary to get better detail on the wetlands areas. For example, in closer views, USFWS data include codes for the colored wetlands areas that provide additional detail on their characteristics. Again, it is not practical for this PEIS to show the level of detail in [Figure 3-35](#) for all areas of each of the islands, and certainly not for more detailed information. Accordingly, interested parties are directed to the USFWS online Wetlands Mapper tool to obtain more information on the location and nature of potential wetlands in Hawai‘i.

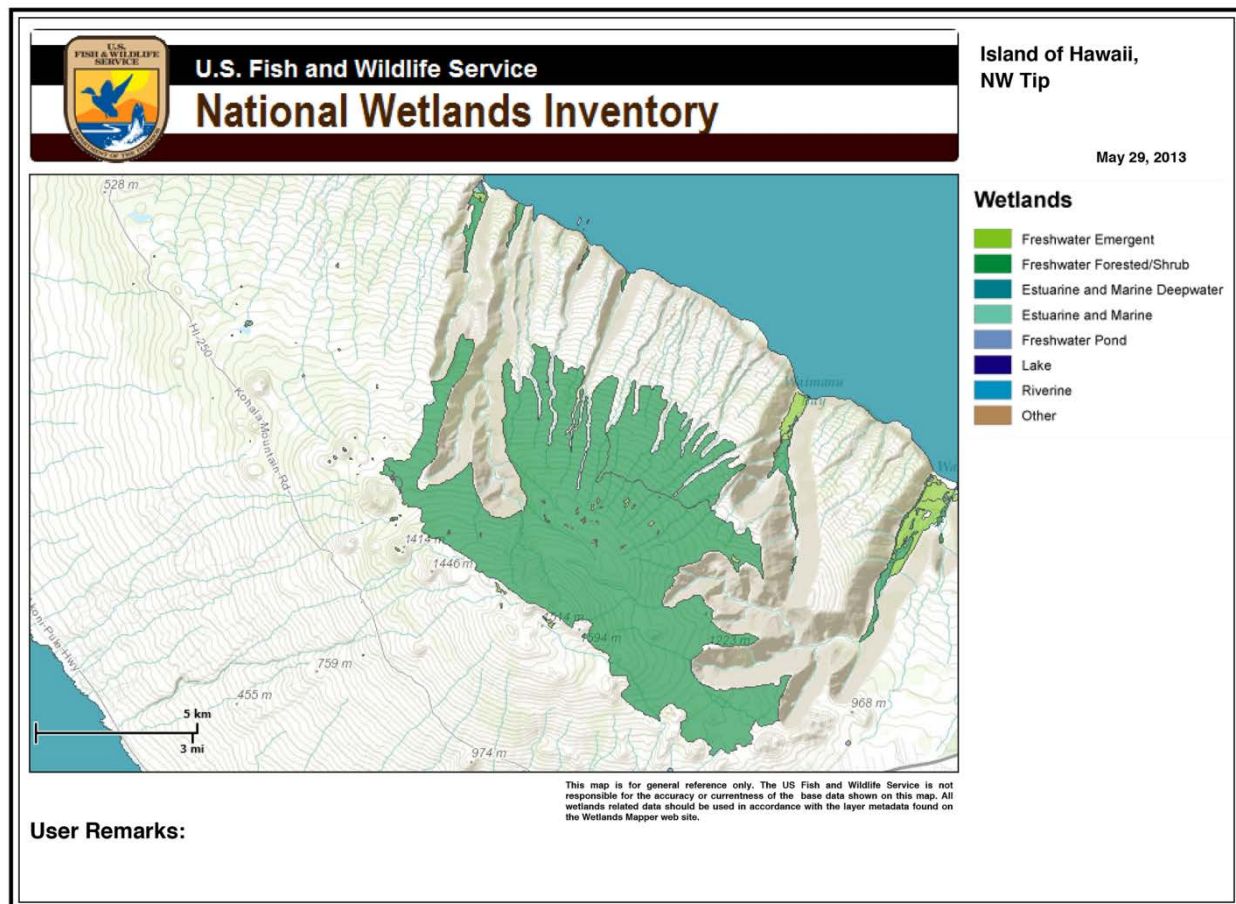

Figure 3-35. Example Wetland Map Generated from the USFWS’s Wetlands Mapper

The USFWS Wetlands Mapper tool is based on reconnaissance-level information, generally prepared from the analysis of high-altitude imagery and based on vegetation, visible hydrology, and geography (USFWS 2014). Highlighted areas identified through use of the online tool are best described as potential wetlands areas. Activities that could involve dredging, filling, or other land disturbance in these or other areas of potential wetlands should include field surveys to verify whether project areas meet the criteria to be wetlands.

Jurisdictional wetlands are those associated with a Water of the United States (e.g., a traditional navigable water or a relatively permanent tributary to one) and are regulated by the USACE under Section 404 of the CWA. Any action involving discharge of dredge or fill materials into a jurisdictional wetland requires a permit (commonly referred to as a Section 404 permit) from USACE to do so. Such a permit may be accompanied by a requirement to establish, or contribute to the establishment of, replacement wetlands at some other location.

The State of Hawai‘i regulates wetlands under its surface water regulations (HAR 11-54) and the general policy of water quality anti-degradation. In its regulatory definitions, the State indicates “wetlands may be fresh, brackish, or saline and generally include swamps, marshes, bogs, and associated ponds and pools, mud flats, isolated seasonal ponds, littoral zones of standing water bodies, and alluvial floodplains.” Any wetland action that requires a Section 404 permit from the USACE also requires certification from the State pursuant to Section 401 of the CWA. Individual certification applications are required if the project cannot be authorized under one of the State’s conditional blanket Section 401 certifications. In either

case, the certification dictates BMPs and monitoring and assessment plans to ensure project discharges comply with State water quality standards ([ELI 2008](#)). Wetlands are also known to attract and house protected species, warranting a biological review prior to project development of any renewable project to be sited in a wetland.

3.3.4 OCEAN

3.3.4.1 Surface Temperatures and Salinity

Surface water temperatures in the North Pacific have a strong north-to-south gradient, but in the area of the Hawaiian Islands, the isothermal lines depicting that gradient tend to veer from an east-west path to one that almost parallels the island chain. As a result, there is not as much difference in ocean surface temperatures between the islands as might be expected based just on the north-south distances involved. The annual cycle of surface water temperatures is relatively small. On O‘ahu, surface water is coldest from February to April and warmest from August to October, but the difference in average temperature between the two extremes is only about 6°F (3°C). During the cold period, the surface water temperature averages 75°F (24°C) and during the warm period, the average is 81°F (27°C) ([UH Hilo 1998](#)).

The salinity of the ocean’s surface water is affected by the relationship of the region’s evaporation and precipitation rate. In the large ocean band between latitudes 15 and 36 degrees north, which includes the Hawaiian Islands, evaporation exceeds precipitation so salinity is slightly higher than either to the south or north of the band. At about 26 degrees north, roughly midway in the band, ocean water salinity is at its highest, at about 35.2 parts per thousand. Whereas, at a latitude of 10 degrees north, the surface water’s salinity reaches a minimum of 34.3 parts per thousand ([UH Hilo 1998](#)).

3.3.4.2 Vertical Profiles of Water Properties

The surface of the ocean is subject to wind and wave mixing so the water temperature stays fairly constant within a turbulent layer. During the stormy winter periods, this layer can be nearly 400 feet (120 meters) thick; in the calmer summer time, it can be less than 100 feet (30 meters) thick. Below the mixed layer, there is a zone called a *thermocline*, where the temperature decreases rapidly with depth. In the thermocline, temperature drops from about 77°F (25°C) in the turbulent layer to 41°F (5°C) at a depth of 2,300 feet (700 meters). The water temperature decreases at a much more gradual rate below the thermocline until it reaches the temperature at the ocean floor, which is at about 35°F (1.5°C). [Figure 3-36](#) shows a typical, average ocean temperature profile for the area of Hawai‘i. This profile is based on a NOAA weather buoy monitoring site located at latitude 23 degrees, 24 minutes north and longitude 162 degrees, 20 minutes west ([PacIOOS 1996](#)), which is about 280 miles northwest of Kaua‘i.

[Figure 3-36](#) shows that the average vertical profile for salinity has some similarities with that of temperature, but also notable differences. Salinity concentrations are high in the turbulent surface layer due to the evaporation-precipitation relationship described above. The changes in concentration are then due primarily to sinking of lower-salinity water coming in from the north. The initial increase from the surface down to about the 500-foot (150-meter) depth is attributed to higher salinity surface water north of Hawai‘i; the lower salinity water is from farther to the northwest. Below the depth of influence from water from the north, salinity levels increase gradually with depth toward a concentration of 34.7 parts per thousand for the deep ocean ([PacIOOS 1996](#)).

[Figure 3-36](#) also shows a vertical profile for nutrients as measured by concentrations of nitrite and nitrate. Nutrients are depleted in the upper layer where there is enough sunlight for photosynthesis and the growth of phytoplankton to occur. The nutrient levels then increase with depth as the amount of light decreases and photosynthesis diminishes. At locations and times of vertical motions at these depths, nutrients brought up from below can result in increased biological activity in the near surface layers. Vertical distributions of phosphate and silicate concentrations are similar to those shown for and NO_3 nutrients ([UH Hilo 1998](#)).

Figure 3-36. Vertical Profiles of Several Ocean Properties (Source: [PacIOOS 1996](#))

3.3.4.3 Ocean Currents

The depth of the thermocline varies in different parts of the ocean and the variations in temperature are associated with changes in water density and water column pressures. These variations in pressure are responsible for ocean currents. The pressure-driven currents and the earth's rotation combine to result in geostrophic (related to the force caused by the earth's rotation) currents that form large, basin-scale, circulations called a gyre. In the northern hemisphere, these gyres have a clockwise circulation. The main Hawaiian Islands are in the southern portion of the North Pacific Gyre, which is centered at about 26 degrees north latitude. At the Islands' location, ocean water circulation is roughly from east to west, with the current intensifying to the south of the islands. At the surface, however, these currents are greatly influenced by wind and result in much more complicated flow patterns ([UH Hilo 1998](#)).

The ocean currents around the islands are further complicated when the gyre currents and winds interact with the island masses. The gyre currents and winds move in between islands, forcing increased velocities in both and basically generating systems of eddies on the leeward sides of the islands. This is particularly true of Hawai'i island, where eddies can cause significant changes in circulation over relatively short distances. This can include large differences in the depth of the thermoclines within different eddies. Satellite images of surface temperatures even show upwelling of cold water in this area ([UH Hilo 1998](#)).

In the early 2000s, the National Aeronautics and Space Administration (NASA) announced some unexpected findings with regard to ocean currents and Hawai'i. NASA found evidence from a satellite using microwave radar to measure wind that Hawai'i's wake (the disturbance in the westerly flow of wind and water caused by their encounter with the islands) stretches nearly 5,000 miles across the ocean to Asia. It is believed a disturbance of such great length was able to develop because the winds and current at Hawai'i's location are so predominantly east to west. It is also speculated that the countercurrent generated within the wake may have provided the route by which Polynesians were able to reach the Hawaiian Islands thousands of years ago against the prevailing currents ([NASA 2002](#)).

3.3.4.4 Tides and Surface Waves

3.3.4.4.1 Tides

Tides are predictable because they are caused by the positions of the moon and, to a lesser extent, the sun. The gravitational attraction of the moon creates a bulge of water in the nearest ocean. At the same time on the opposite side of the earth, where the gravitational influence of the moon is at its lowest, another ocean bulge is formed. In this case the bulge is formed by the force of inertia that results from the earth's rotation ([NOAA 2008](#)). During the earth's daily rotation, a location on the ocean's surface passes through these two bulges of water, so there is a semidiurnal (or half-daily) component to the tides. Since the moon is not positioned directly over the equator (in that it is not in a constant position with regard to the earth's rotation), a single point on the ocean experiences one of the bulges as larger than the other as it rotates. This results in a diurnal (or daily) component to tides. Accordingly, most locations subjected to tides experience two high tides (one higher than the other) and two low tides each day. These tides are basically very long period waves that move through the ocean in response to the forces exerted by the moon and sun ([NOAA 2008](#)) coupled with those resulting from the earth's rotation.

Although tide levels are predictable, they are also quite complicated. For example, the two bulges on the opposite sides of the earth are aligned with the positions of the moon, and to a lesser extent the sun, but the moon and sun's positions change over time with respect to their angle from the equator. This causes the locations of the bulges' high areas to change over time in addition to the daily cycles. Also, it takes 24 hours and 50 minutes for the earth to rotate such that the same location is positioned beneath the moon. This is because the moon is orbiting in the same direction as the earth's rotation and progresses farther (50 minutes of Earth rotation time) when the earth has rotated to its starting point in 24 hours. As a result, the semidiurnal and diurnal periods of the tides do not quite match up with true daily cycles. Added to this are the cycles by which the sun affects the tides. When the moon and the sun are in alignment on the same side of the earth (that is, at the time of the new or full moon), the added gravitational pull of the sun results in extra-high high tides, referred to as spring tides, and very-low low tides. A week later, when the sun and moon are at right angles to each other in relation to the earth, the tidal bulges are lowest and are referred to as neap tides. So two sets of spring tides and two sets of neap tides occur during each lunar month. As the distance from the earth to the sun changes over the seasons, the sun's influence on the tides also changes.

The tidal currents resulting from tidal variations in sea level are relatively weak in the open ocean, but near inlets or narrow straits, their speeds can be significant, often stronger than the large-scale currents described above. The tidal currents off O'ahu, Maui, and Hawai'i tend to align with shorelines, as shown in [Figure 3-37](#). But there is significant variability in the tidal currents due to the variability of the tides themselves and the other currents affecting the islands. In [Figure 3-37](#), current speeds are presented in metric units of centimeters per second. As a point of reference, 45 centimeters per second is equal to a velocity of 1 mile per hour.

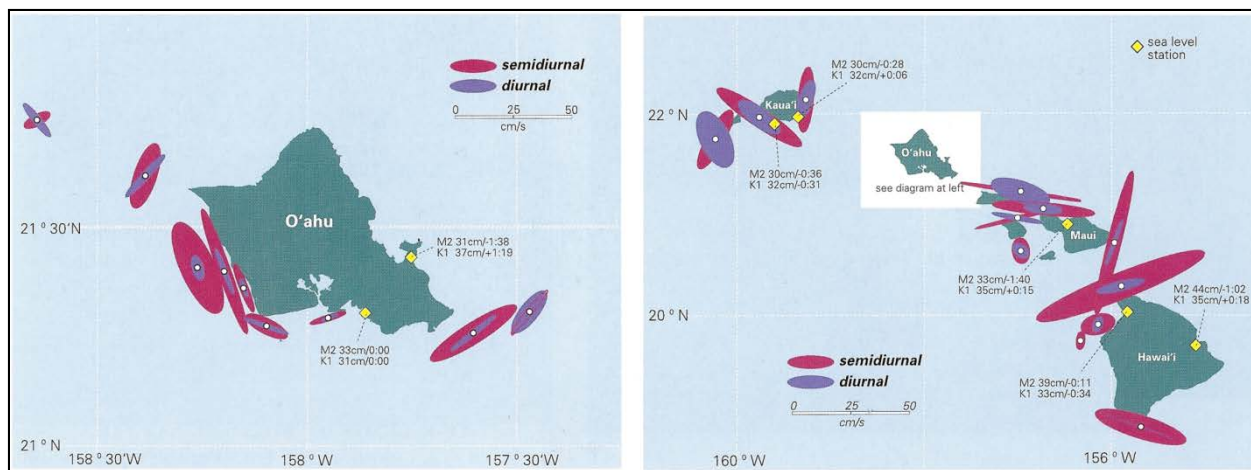

Figure 3-37. Tidal Current Directions and Velocity Ranges within the Hawaiian Islands (Source: UH Hilo 1998)

3.3.4.4.2 Waves

The open seas offshore of the Hawaiian Islands are moderately rough with wave heights of 3 to 14 feet depending on the season and the intensity of the trade winds. Moving between islands, the seas intensify, and on the leeward sides of the islands, the seas are generally calmer. Sea conditions outside of these norms can occur during winter when the winds can shift to the northwest or southwest.

The northeastern shores of the islands typically are exposed to moderate trade wind seas and the associated waves. The northwestern shores receive some of these waves, but their highest exposures are from the large swells generated in the northwest Pacific during winter. The famous North Shore of Oahu occasionally gets breaking waves with heights over 50 feet. The northern shores of the islands are calmer in summer.

Southern shores of the islands are shielded from the northwest swells and are usually calm in winter. In the summer, however, these shores are subject to swells from storms in the southern hemisphere. These waves generally have lost much of their energy by the time they reach the Hawaiian Islands and rarely approach anything like the heights seen on the northwestern shores (PacIOOS 1996).

3.3.5 COMMON CONSTRUCTION AND OPERATION IMPACTS

Common construction and operation impacts are addressed in terms of surface water, groundwater, and floodplains and wetlands.

3.3.5.1 Surface Water

Effects on surface water from common construction actions would be limited primarily to the potential for storm water runoff from construction areas to carry sediments or other contaminants away from the site and to receiving waters. Sediments or other contaminants reaching a receiving water could cause that water to exceed applicable water quality standards, possibly posing a threat to the stream's biota or its designated uses. In some locations, the displacement of contaminants or sediments could have adverse impacts on traditional and customary native Hawaiian practices, such as lo'i taro farming, loko i'a (fishponds), and loko i'a kalo (combination fish and taro farming), which are addressed in Section 3.6. As described in HAR 11-55, "Water Pollution," any construction activity that would disturb one or more

acres of land is required to obtain an NPDES permit for storm water discharges before beginning construction. The common construction actions addressed here are assumed to involve land disturbance of one or more acres, which would be applicable to most of the utility-scale renewable energy projects. To obtain this storm water NPDES permit, the action proponent must develop a construction site BMP plan that includes (Appendix C of [HAR 11-55](#)):

- A county-approved erosion and sediment control plan,
- A site-specific plan to minimize erosion of soil and discharge of other pollutants into State waters, and
- Descriptions of measures that will minimize the discharge of pollutants via storm water after construction operations have been finished.

These would be considered the minimum requirements because, depending on the project location, the proponent may also be subject to county permitting requirements and, if discharging to an already impaired water, NPDES permits typically carry additional requirements. For example, in stormwater discharges to streams where TMDLs (see [Section 3.3.1.1.3](#)) have been established, these added requirements would include the permittee's incorporation of measures or controls to comply with those TMDLs. Also, on O'ahu, construction activities on or adjacent to State highway rights-of-way would have additional storm water permitting requirements because of the Hawai'i Department of Transportation (HDOT) NPDES permit for the O'ahu municipal separate storm sewer system (MS4).

In general, the construction activities associated with renewable energy projects would not be expected to involve unusual activities or sources of potential contamination, so common BMPs would be implemented and would be expected to provide appropriate protection for the area's storm water collection system and receiving waters. The primary concern with regard to pollutants for common construction actions would be spills or leaks of fuel and lubricants from vehicles and equipment, and the types of precautions normally implemented (such as response plans, cleanup equipment, and secondary containment) would keep the potential for storm water runoff contamination at a minimum.

Storm water runoff from the construction site would likely be decreased when there were large areas of loosened, disturbed soil present, but these would be only temporary changes. The long-term effects from construction would be expected to involve increases in the amount of impervious surfaces with associated increases in runoff. On a large scale this could result in impacts to surrounding streams, rivers, and ultimately the ocean. But the design of new facilities would be required to address and provide for appropriate storm water runoff collection and control systems. This could consist of measures such as connections to existing storm water collection systems; controlled and, as applicable, permitted discharges to existing surface drainage systems; or collection areas designed for groundwater recharge. In most cases, storm water runoff from a single, operating renewable energy project would be relatively minor, but storm water management would still need to be an element of its design.

3.3.5.2 Groundwater

Normal construction actions would not be expected to impact groundwater. If excavations required for construction of foundations were to encounter groundwater and if dewatering measures were required, the removed water would have to be discharged under a NPDES permit. The permit would require BMPs in dealing with the water, which could include treatment such as settling ponds or filtration systems in order to meet discharge standards. The excavation and construction actions would not be expected to involve any unusual sources of contamination, so BMPs should be well defined and there would be little potential for either surface water or groundwater contamination from any dewatering actions. As noted above for

O‘ahu construction activities on or adjacent to State highway rights-of-way, there would be additional permitting requirements for discharges if they involved the storm sewer system because of the HDOT NPDES permit for the O‘ahu municipal separate storm sewer system (MS4).

Periods during construction when loosened soil conditions result in decreased storm water runoff, as described above, would also represent periods when there would be more storm water soaking into the ground and potentially providing additional recharge to groundwater. As noted previously, these would be temporary conditions with little potential to have any notable effect on groundwater.

Water needs during construction would be expected to come from groundwater resources, either via municipal water systems or private wells, but they would be minor, involving such uses as for dust suppression and in soil compaction.

3.3.5.3 Floodplains and Wetlands

The proponent of a renewable energy project would be expected to avoid floodplain and wetland areas if only to reduce costs and minimize regulatory requirements. However, were the project located in a floodplain or wetland area, certain requirements and potential effects can be described.

If the project were in a floodplain, construction activities would be temporary and unlikely to be impacted by flooding or to impact flood zone boundaries. It is assumed that facilities and equipment would be designed to incorporate appropriate flood protection measures. This could be no more than keeping critical items above flood levels. To meet Federal Emergency Management standards, flood protection measures could also involve having elevated platforms for sensitive equipment and breakaway walls for areas of the structure below the base flood elevation. It is reasonable to assume such actions would be taken because they protect the value of the facilities and equipment and would likely be required by building permits as well as insurers. If in a floodplain, facilities would take up space that would otherwise be available for flood water. Without features such as the breakaway walls below the base flood elevation, the action would therefore change the height and area of inundation for a given magnitude flood. Depending on the characteristics of the flood zone and the proximity of other facilities, flood level changes could adversely impact other facilities. County agencies responsible for issuing building permits would be considering these types of concerns and would be expected to deny building permits or require mitigation measures if potential effects to flood levels were anything but minor. If the representative project was part of a Federal action or if it was, in whole or in part, Federally funded, the applicable Federal agency would be required to adhere to requirements of [Executive Order 11988](#), “Floodplain Management,” which requires Federal agencies to take actions to reduce the risk of flood damage; minimize the impact of floods on human safety, health, and welfare; and restore and preserve the natural and beneficial values served by floodplains.

If wetlands were present in the construction area, there is a high probability they would be jurisdictional wetlands (for example, associated with a traditional navigable Water of the United States or a relatively permanent tributary to one) and regulated by the USACE under Section 404 of the CWA. Accordingly, if it could not be avoided, any action involving discharge of dredge or fill materials into the wetland would require a permit from the USACE to do so. Such a permit could be accompanied by a requirement to establish, or contribute to the establishment of, a replacement wetland at some other location. Any wetland action that requires a Section 404 permit from the USACE must also obtain certification from the State pursuant to Section 401 of the CWA. The certification dictates BMPs and monitoring and assessment plans to ensure project actions associated with the wetlands area comply with State water quality standards. If there was any question about the applicability of a Section 404 permit, discussion with the USACE would be the appropriate course of action.

In the unlikely event that either floodplains or wetlands were present in the project area, permitting requirements and anticipated building restrictions would minimize the potential for any serious environmental consequences.

3.3.6 COMMON BEST MANAGEMENT PRACTICES

BMPs associated with water resources are presented in two categories: general BMPs and BMPs specific to construction.

General BMPs

- Prioritize technologies that minimize water use.
- Promote the sustainable use of water resources through appropriate technology selection and implementation of conservation practices that protect and preserve the function, acreage, and quality of the existing natural water bodies (including streams, wetlands, ephemeral washes, and floodplains, as well as groundwater aquifers and recharge areas).
- Consider the use of rain, gray, and/or other recycled water for facility operations, including plant cooling, steam generation, irrigation, maintenance, and dust suppression.
- To the extent practicable, minimize the use of and impacts on surface and groundwater resources (including sole source aquifers) during construction and operations.
- Avoid groundwater resource project requirements that would result in over appropriation or over drafting of any groundwater basin.
- Identify source capacity, prior water rights, and adequacy of capacity to serve project requirements and dependent biological resources in the area.
- Avoid or minimize the use of land within an identified 100-year floodplain or identify engineering controls to mitigate potential impacts.
- Avoid locating facilities on steep slopes, in alluvial fans, and in other areas prone to landslides or flash floods, or within gullies or washes.
- Compare preliminary site grading, drainage, erosion, and sediment control plans with applicable county jurisdiction requirements
- Consult Federal, State, and county “water-wise” guidelines, as applicable, for project development in the arid areas.
- Coordinate with the USACE to discuss the reach and extent of [waters of the United States](#) on the proposed project site. As appropriate, present a reasonable range of on- and offsite alternatives and an analysis that evaluates alternatives to avoid impacts on waters in compliance with Section 404 of the CWA.

Construction BMPs

BMPs that would be considered during construction actions to prevent storm water runoff from carrying sediments off the site are basically the same as those described in [Section 3.1.4](#) for controlling soil erosion and include the following (from Appendix C of [HAR 11-55](#)):

- Construction management techniques:
- Hold clearing and grubbing to the minimum necessary for grading and equipment operations.
- Sequence construction actions to minimize the exposure time for any cleared surface area. For large projects, phase construction actions so that areas disturbed in one phase can be stabilized (that is, protecting disturbed soil from rainfall impacts and runoff) before another phase is initiated.
- Have erosion and sediment control measures in place and functional before beginning earth moving operations and ensure their proper monitoring and maintenance throughout the construction period. This includes establishing a monitoring schedule that is consistent with the use of the control measures; for example monitor the control measures weekly during dry periods, within 24-hours of rainfall, and daily during prolonged rainfall. Maintain records of monitoring checks and repairs.
- Maintain records of the duration and estimated volume of storm water discharges.
- Assign a specific individual to be responsible for erosion and sediment controls at each project site.
- Vegetation controls:
 - Avoid disturbance of existing vegetation more than 20 days prior to land disturbance.
 - If disturbed areas are to remain unfinished for more than 30 days, apply temporary soil stabilization using appropriate vegetation.
 - Apply permanent soil stabilization, with perennial vegetation or pavement, as soon as practical after final grading. If perennial vegetation is used, provide irrigation and maintenance for 30 days or until the vegetation takes root.
- Structural controls:
 - Divert storm water flows away from the construction area using appropriate control measures, as practical.
 - Design erosion control measures according to the size of the disturbed or drainage areas to detain runoff and trap sediment.
 - Discharge water in a manner that does not cause or contribute to a violation of water quality criteria established for the specific location.

BMPs that would be considered during construction actions to minimize the potential for storm water runoff carrying contaminants off the site include the following ([EPA 2007](#)):

- Design and implement waste management procedures and practices that address actions such as trash disposal, recycling, proper material handling, and cleanup measures. Provide toilet facilities that are regularly inspected and serviced and located away from storm drain inlets and waterways.
- Establish comprehensive procedures for the handling and management of building materials, particularly those that may be hazardous or toxic (e.g., paints, solvents, pesticides, and fuels and oils) and store such materials indoors or under cover whenever possible or in areas with secondary containment. Designate staging areas for activities such as fueling vehicles/equipment, mixing paints, and mixing mortar.
- Designate washout areas for concrete operations as well as for operations such as painting or stucco use and keep such areas at least 50 yards from storm drains and watercourses whenever possible.
- If equipment/vehicle fueling and maintenance actions must be performed on-site, create a clean and dry site, covered if possible, with a spill kit present and staff that know how to use it.
- Establish procedures and practices for equipment/vehicle washing that include use of off-site facilities; washing in designated, contained areas only; eliminating discharges to storm drain by using infiltration systems or routing to the sanitary sewer; and training staff in proper washing procedures.
- Develop a spill prevention and response plan that identifies ways to reduce the chance of spills, stop the source of spills, contain and clean up spills, dispose of spill residues, and train appropriate personnel.

Although the above measures are designated BMPs, it should be noted that the intent of the storm water NPDES permit described in [Section 3.3.5](#) is that the proponent develop plans that identify the control measures they will be implementing. Those plans and the control measures then become requirements under the permit, unless there are more stringent requirements in the permit's standard conditions.

3.4 Biological Resources

Hawai'i is an island chain located 20 degrees north of the equator, more than 2,000 miles from the nearest continent. Despite its small size (4.1 million acres) Hawai'i is characterized by a wide variation in elevation, temperature, precipitation, and habitat and, therefore, biological communities.

3.4.1 TERRESTRIAL ECOSYSTEMS

The terrestrial ecosystems of Hawai'i are the result of multiple factors including geography, geology, topography, climate, and humans. The geographic isolation from continental land masses and other oceanic archipelagos has had a major influence on the composition and development of the flora and fauna. Because the Hawaiian Islands are oceanic islands built by volcanic eruptions from the seafloor, the flora and fauna (i.e., prior to human habitation) had to arrive by long-distance dispersal. The biota lacks representation of many plant and animal species that populate continental land masses. Those species with the best dispersal capabilities, such as species capable of flight such as birds and bats and plants dispersed by wind, birds, or water (e.g., floating seeds), are well represented while those groups lacking the ability to cross ocean waters (amphibians and mammals) are rare or absent ([Juvik 1998](#)). Geographic isolation also allowed the speciation and development of biota unique to the Hawaiian Islands. This resulted in a native biota composed of a large number of [endemic species](#) (i.e., species that occur only in Hawai'i) and smaller numbers of [indigenous species](#) (i.e., species that occur elsewhere but colonized

Hawai‘i without human assistance). Local topography (shaped by geological processes) through elevation, slope, and aspect and climate (temperature, wind, and precipitation patterns) influence the distribution of biota within and among the islands.

Humans have affected the biota of Hawai‘i dating back to the arrival of the first Polynesian settlers approximately 1,500 years ago. Because Hawai‘i ecosystems developed in isolation from many of the large herbivores, predators, and biological competitors found on continental systems, many Hawaiian plant and animal species have been significantly affected by human-assisted introduction of *nonnative* animals and plants. Early settlers introduced largely domesticated species whose impacts were largely confined to lower elevation cultivated areas. As European human habitation increased, agriculture, forestry, and urbanization physically altered the landscape and the rate and establishment of newly *introduced species* and resulting impacts on both flora and fauna greatly increased. New plant and animal species were introduced both intentionally and accidentally. Intentional introductions have included plants and animals for food production, fiber, forestry, and landscaping. Other introductions were made as biological control responses to species previously introduced that had become invasive species. Other species arrived unintentionally in soil or as seeds through the importation of other products and plants.

3.4.1.1 Flora

The origins of the Hawaiian flora are derived from multiple sources but primarily by plants with origins in the Indo-Pacific, the Americas, and the South Pacific regions. However, the native Hawaiian flora developed largely in isolation from a relatively small number of indigenous species as evidenced by the high degree of *endemism* (85 to 95 percent). The present day flora contains a great number of introduced species (i.e., *alien species*), many of which have become established, some of which have become invasive. Other introduced species exist only in forestry and cultivated plantings and have not established self-sustaining populations.

The vegetation of Hawai‘i is complex in part because of the large environmental variations over short distances. A case in point is on Kaua‘i where over a distance of 15 to 20 miles, average annual rainfall varies from about 20 inches (semiarid) along the leeward southern coast to 450 inches (over 37 feet) on the windward side of Mount Wai‘ale‘ale (elevation 5,066 feet) in the center of the island. Through many efforts to develop vegetation classification systems for the Hawaiian vegetation, one system that has been commonly used is to classify plant communities into broader vegetation zones or habitats based on topography, moisture regimes, elevation, and substrate ([Pratt and Gon 1998](#)).

Understanding the roles of climate and topography is important in appreciating the types and distribution of the vegetation zones. Because of Hawai‘i’s geographic position between 18 to 22 degrees north latitude, the overall climate is subtropical with warm temperatures along the coasts and lower elevations featuring little daily or seasonal variations. The surrounding ocean moderates temperatures because it heats and cools much slower than land surfaces. However, because of mountainous terrain, Hawai‘i has areas that frequently experience freezing temperatures.

A significant feature of the climate is Hawai‘i’s geographic position relative to the global atmospheric circulation pattern ([Section 3.2.1](#)). The prevailing winds are the descending northeasterly trade winds. When the winds intersect mountainous terrain of the islands, the moist air is forced to rise, cooling and saturating the air, resulting in heavier precipitation on the windward side (i.e., places with north and northeasterly exposures). In contrast, the leeward sides of the mountains are substantially drier because the mountains either block the moisture or the moisture is lost as precipitation before it reaches the leeward side (i.e., these areas are in a rain shadow). The rain shadow causes significant variation in rainfall over relatively short distances.

Another important aspect of the descending northeasterly trade winds is the creation of a mid-altitude (i.e., 5,000 to 10,000 feet) temperature inversion. The trade winds warm as they descend creating a warm air layer above rising warm, moist surface air that forms clouds as the air rises and cools. The warm trade wind layer inhibits the rising surface air and prevents the formation of deep clouds that are more effective at producing precipitation. The consequence of this temperature inversion is that the upper slopes of Hawai‘i’s higher mountains such as those on Maui and Hawai‘i often experience clear skies (i.e., above the cloud layer), low humidity, and low precipitation. Therefore, the subalpine and alpine vegetation zones are typically cool and dry.

Hawai‘i has five major ecological zones defined by elevation ([Pratt and Gon 1998](#)) (see [Table 3-31](#)). Although considered a subtropical climate, Hawai‘i does have vegetation zones that experience frost and freezing temperatures. Within these five ecological zones are vegetation zones that are more specifically defined by the amount of precipitation (classified as dry, mesic, or wet). Vegetation zones classified as “dry” typically receive less than 50 inches of annual rainfall and may have seasonal dry periods (e.g., summer months) with limited precipitation. Mesic (moist) zones receive about 50 to 100 inches of annual rainfall. Wet zones average more than 100 inches of rainfall per year.

Table 3-31. Ecological Zones of the Hawaiian Islands Based on Elevation Range

Ecological Zone	Elevation Range (feet)	Key Environmental Factor
Alpine	> 9,000	Frost common
Subalpine	6,000 – 9,000	Frost frequent
Montane	3,000 – 6,000	Frost infrequent
Lowland	0 – 3,000	Frost-free
Coastal	0 – 100	Sea spray

Source: [Pratt and Gon 1998](#).

In addition to the ecological and vegetation zones, a third level of classification uses vegetation physiognomy or structure (e.g., grassland, shrubland, and forest). The classification and description of Hawai‘i vegetation zones presented in the following sections was adopted from multiple sources but largely follows the 10 broadly defined ecological systems from *An Ecoregion Assessment of Biodiversity Conservation for the Hawaiian High Islands* ([TNC 2006](#)). The primary difference among native vegetation zone classification schemes involves the amount of grouping versus partitioning of zones by elevation, precipitation amount (dry, mesic, or wet), or vegetation physiognomy (grassland, shrubland, and forest). For example, some authors may ignore elevation differences and simply combine the lowland wet and montane wet forest zones into a wet forest or rainforest. Others may separate a lowland dry community but include both dry shrublands and dry forests within the same classification. Still others may separate lowland dry shrubland from lowland dry forest.

3.4.1.1.1 Coastal Vegetation

The coastal zone is a relatively narrow strip of vegetation that encircles each island up to an elevation of about 100 feet. Vegetation in this zone is greatly influenced by the ocean, particularly sea spray, and in some areas there exist plant communities composed of salt-tolerant species. This zone is sometimes divided into two zones: strand and coastal. The strand zone is those areas affected by sea spray and occurs along the edge of the ocean while the coastal zone occurs just inland from the strand zone. This PEIS considers these as one vegetation zone. The substrates in this zone are highly variable and include sandy beaches, basaltic and coral boulders, basaltic cliffs, and coral substrates. Rainfall may vary between less than 30 inches to around 120 inches depending on whether the location is on the leeward or windward side of the island. Coastal forests may occur on some mesic windward shores. These forests were most often dominated by hala (*Pandanus tectorius*) but many of these coastal forests have been eliminated. Naupaka kakahakai (*Scaevola sericea*) is an important native shrub throughout the coastal system. The

diversity of species in this zone was related to the variety of substrates and variation in rainfall. Coastal plant communities have been severely altered by humans because most of the urbanization and tourist industry has developed along the coasts. Many of the plant species now observed along the coastal regions are introduced species especially near population centers and resorts ([Sohmer and Gustafson 1987](#)).

3.4.1.1.2 Lowland Dry Forest and Shrub

The lowland dry ecosystem occurs below about 3,000 feet and above the coastal vegetation zone on the leeward side of the islands. This vegetation zone has annual precipitation between 20 to 50 inches and is seasonally dry. This zone has a variety of natural plant communities including grasslands, shrublands, and forest. This zone was once one of the most diverse vegetation zones on the islands but has been extensively altered by human activity because of its proximity to the coast and because the moderate topography makes it suitable to human development. Remnants of native lowland dry forest and shrubland occur across the islands but most of this zone contains urban development, resorts, and land modified for agriculture and rangeland. The lowland dry forest and shrub zone, like many of the other vegetation zones, has been negatively impacted by feral ungulates. Some of the formerly dominant species include 'ohi'a (*Metrosideros polymorpha*), lama (*Diospyros sandwicensis*), olopuia (*Nestegis sandwicensis*), and wiliwili (*Erythrina sandwicensis*) trees, 'a'ali'i shrubs (*Dodonaea spp.*), and pili grass (*Heteropogon contortus*) ([Mitchell et al. 2005](#)).

3.4.1.1.3 Lowland Mesic Forest and Shrub

Mesic forest and shrub vegetation occurs in lowland areas with about 50 to 75 inches of annual precipitation and can be found on both windward and leeward sides of the islands up to elevations of 4,000 feet. It typically occurs above the Lowland Dry Forest and Shrub zone. The lowland mesic forest and shrub zone is the most species-rich of the vegetation zones on the Hawaiian Islands. However, like the lowland dry forest and shrub zone, it is highly disturbed or entirely eliminated in many areas. The lowland mesic forest and shrub zone does not suffer extended dry periods like some of the lowland dry and coastal zone communities but receives less rainfall than the rainforests (wet forest). This vegetation typically consists of open-canopy forest with a mixture of trees and shrubs and contains many endemic plant species. The line of demarcation between the lowland dry forest and mesic forest is often difficult to define. Some authors define a lowland dry shrub and grassland zone and then combine the lowland dry and mesic forest into one vegetation zone. In the remaining lowland mesic communities, dominant plants include kāwelu (*Eragrostis variabilis*), pūkiawe (*Styphelia tameiameiae*), 'a'ali'i (*Dodonaea viscosa*), and ulei (*Osteomeles anthyllidifolia*) shrubs, and koa (*Acacia koa*), 'ohi'a, and lama (*Diospyros sandwicensis*) trees ([Sohmer and Gustafson 1987](#); [Mitchell et al. 2005](#)).

3.4.1.1.4 Dry Cliff

The dry cliff vegetation zone occupies steep (greater than 65-percent) slopes in areas receiving less than 75 inches of annual rainfall or where the cliff has a dry substrate and is generally best developed on the leeward side of the islands. The dry cliff zone typically occurs below or adjacent to the lowland mesic or lowland dry forest and shrub vegetation zones. The communities within the dry cliff zone are usually composed of grasses and shrubs as the slopes are too steep to support forests. Some authors include dry cliffs as a community type with the lowland dry or mesic zones. Biological diversity is lower than many of the other vegetation zones and is relatively inaccessible to human activity. Several species have adapted to this environment including Hawaiian wormwood (*Artemisia australis*), 'akoko (*Euphorbia celastroides*), and species of *Schiedea* and *Bidens*. *Tetramolopium filiforme*, an endangered aster, occurs on dry cliffs on O'ahu.

3.4.1.1.5 Lowland Wet Forest

The lowland wet forest and montane wet forest zones together compose Hawai‘i’s rainforests. Some authors treat these two vegetation zones as one. Because of large elevation range over which rainforest occurs in Hawai‘i (sea level to 6,000 feet), the lower and upper rainforest zones have been impacted differently by human activity. For the purposes of understanding potential impacts of renewable energy technologies, the wet forest, or rainforest, is described as two separate zones. The boundary between the lowland and montane wet forest is generally not agreed upon by ecologists but probably ranges from 1,500 to 3,000 feet. Defining the boundary is complicated by the human disturbance that has occurred in the lowlands. Lowland wet forest is a vegetation zone of the windward side of the higher islands and to the summits of lower islands. Annual precipitation is typically greater than 80 inches and is often 150 to 300 inches. Similar to other lowland ecosystems of Hawai‘i, the lowland wet forest has been greatly modified by human activity for agriculture and urban development, particularly in windward valleys and gently sloping tablelands. However, where lowland wet forest still exist, biological diversity is high. Dominant plants include ‘ohi‘a and koa trees, mamaki (*Pipturus albidus*) and uluhe (*Dicranopteris linearis*) shrubs, and hāpu‘u ferns are an important component of the native understory.

3.4.1.1.6 Montane Wet Forest

The montane wet forest occupies mountain slopes at elevations of about 3,000 to 6,000 feet either on the windward side of higher mountains and the summit regions of lower mountains. Annual precipitation exceeds 80 inches and is often much higher without a dry period. For example, the summit region of Mount Wai‘ale‘ale on Kaua‘i receives about 450 inches (over 37 feet) of rainfall. Many areas of the montane wet forest are frequently enveloped in clouds or mist for long periods of time. Montane wet forest still covers large areas on some islands and has been less modified by human activities than lower elevation ecosystems. The upper elevation, steep topography, and climate have made the montane wet forest less accessible and conducive to human activity and habitation. This vegetation zone still faces impacts by both introduced plants and animals (for example, nonnative feral ungulates). This zone also includes bogs that form in generally small, poorly drained areas and has open vegetation composed primarily of grasses, sedges, and stunted woody plants. Important native plants include the ferns hāpu‘u (*Cibotium* spp.) and ‘ama‘u (*Sadleria* spp.), sedges (*Carex* spp.), *Oreobolus furcatus* (found in many bogs), and the ‘ohi‘a tree.

3.4.1.1.7 Wet Cliff

The wet cliff vegetation zone occupies steep slopes (greater than 65-degree angle) in wet forest zones (both lowland and montane wet forest) located typically on windward sides of the islands where annual rainfall exceeds 80 inches. Some authors include this vegetation zone as a community type within the wet forest zones. Biological diversity is lower than the surrounding wet forest because the steep slopes and shallow soils prevent establishment of forests and many shrubs. Communities in the wet cliff vegetation zone include grasslands and shrublands. Dwarf shrubs such as ‘ohi‘a (*Metrosideros polymorpha*), ‘ōhelo ‘ai (*Vaccinium reticulatum*), and the endemic species of the genus *Brighamia* ([Sohmer and Gustafson 1987](#)). Wet cliffs have been less impacted by human activity because of lack of access and steep topography and contain a variety of endemic species.

3.4.1.1.8 Montane Mesic Forest

The montane mesic forest zone typically occurs above the montane wet forest zone where annual rainfall is between 50 and 75 inches but is best developed on the leeward side of the islands. It also occurs on the windward side near the temperature inversion layer that creates drier conditions at higher elevations and occurs below the montane dry forest and subalpine zones. Montane mesic forest has a restricted

distribution based on elevation and precipitation. ‘Ōhia, koa, olopua (*Nestegis sandwicensis*), and a‘e (*Sapindus saponaria*) are dominant trees, and the understory is composed of diverse trees, shrubs, sedges, and ferns. The montane mesic forest also has been impacted through browsing, grazing, and soil disturbance by feral ungulates.

3.4.1.1.9 Montane Dry Forest

Montane dry forest is the primary vegetation zone of the leeward montane zone (3,000 to 6,000 feet) and annual precipitation is usually greater than 50 inches. This zone is restricted to the islands of Hawai‘i and east Maui. Dominant plants include ‘ohi‘a, ‘a‘ali‘i (*Dodonaea viscosa*), lovegrass (*Eragrostis atropioides*), and pili grass (*Panicum tenuifolium*). Feral ungulates also have impacted the montane dry forest zone.

3.4.1.1.10 Subalpine Woodland and Shrubland

Subalpine vegetation occurs between 6,000 to 9,000 feet and is restricted to Maui and Hawai‘i and occupies the near-summit regions of the highest mountains just below the alpine zone. This vegetation zone includes forest, shrubland, and grass communities. The subalpine is characterized by frequent frost, large diurnal (daily) variation in temperatures, clear skies, and relatively low annual precipitation (20 to 50 inches). High elevation zones in Hawai‘i are dry because the temperature inversion layer created by the northeasterly trade winds between 5,000 to 8,000 feet inhibits development of clouds at higher elevations. Biological diversity is not high but specialized plants and invertebrates exist here. Forests are dry and open woodlands of mamane-naio (*Sophora chrysophylla* and *Myoporum sandwicense*) and occur on older lavas ([Sohmer and Gustafson 1987](#)). On younger, less weathered substrates on Hawai‘i island, open forests of low-statured ‘ohi‘a are common. Subalpine grasslands are dominated by the endemic bunchgrass *Deschampsia nubigena*. A variety of shrub species occur in the subalpine zone. Pukiawe (*Styphelia tameiameiae*) and ‘ōhelo ‘ai (*Vaccinium reticulatum*) are often dominant with ‘a‘ali‘i (*Dodonaea viscosa*) and naenae (*Daubautia ciliolata*) as important components. A distinct dry shrubland of primarily ‘āweoweo (*Chenopodium O‘ahuense*) occurs in the saddle between Mauna Loa and Mauna Kea. Scattered silverswords occur on cinder cone substrates. Feral ungulates have had impacts on the vegetation of the subalpine zone.

3.4.1.1.11 Alpine Desert

The alpine vegetation zone occurs above 9,000 feet and is restricted to the islands of Maui and Hawai‘i and occupies summits of the highest mountains, Mauna Loa and Mauna Kea on Hawai‘i and Haleakalā on Maui. The alpine zone is characterized by frequent frost and freezing temperatures, large diurnal temperature variation, clear skies, and very low annual precipitation (less than 20 inches). Snow occurs in this vegetation zone. Communities in this vegetation zone are limited and consist of alpine lake, aeolian desert, and a sparse shrubland. Common shrub species include pūkiawe (*Styphelia tameiameiae*) and ‘ōhelo ‘ai (*Vaccinium reticulatum*). Also occurring in the alpine zone is the unique endemic ‘āhinahina or silversword (*Argyroxiphium sandwicense*). Very high elevation sites have very few plants and support a few mosses and lichens and some grasses (*Trisetum glomeratum* and *Agrostis sandwicensis*). Alpine zones have been impacted by feral and domestic ungulates.

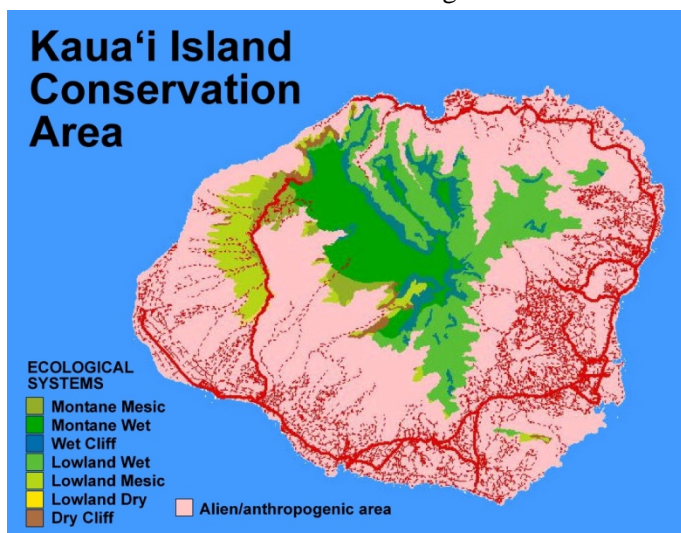

3.4.1.1.12 Alien and Anthropogenic Areas

Many of the vegetation zones have been severely altered by clearing of vegetation for agriculture crops, pasture, firewood, urbanization, resort development, and by the introduction of nonnative plants and animals ([Cuddihy and Stone 1990](#); [Warshauer et al. 2009](#); [Pratt and Gon 1998](#)). This impact has been most significant along coastal areas and lower elevation zones with less severe topography that is most

suitable for human habitation and agricultural production (TNC 2006). Most of the vegetation along the coastal zone is nonnative species (Sohmer and Gustafson 1987). The least impacted vegetation zones are those at higher elevations and in regions with steep topography. However, even these more remote locations have been impacted either by introductions of nonnative plants or animals such as goats, sheep, pigs, and deer that have established self-sustaining populations (Cuddihy and Stone 1990).

3.4.1.2 Existing Vegetation by Island

Vegetation patterns across the islands follow a common theme. Most of the native vegetation at lower elevations from the coastline onto the flanks of the more mountainous terrain on each island has been greatly modified by vegetation clearing, introduction of nonnative species, and human development (i.e., urban, industrial, commercial, residential, and resorts). Within these areas, many of the native plant species have been replaced by introduced species. Most of the remaining native vegetation on each island is confined to upper elevations, mountainous terrain that is less accessible and amenable to human development. However, there are areas where native lowland vegetation communities still exist.

3.4.1.2.1 Kaua'i

Most of the lowland dry and mesic forest and shrubland vegetation on Kaua'i has been altered by human activity. This area was developed for agriculture such as sugarcane, resorts, and human habitation. Approximately 38 percent of the island is dominated by native vegetation (Mitchell et al. 2005). Most of the remaining native ecosystems occur in the central highlands and consists of montane mesic and wet forest, bogs, and cliff ecosystems (Figure 3-38) (TNC 2006). On the west side of island, an area of native lowland mesic and wet forest remains. The highest elevation on Kaua'i is 5,243 feet and no subalpine or alpine ecosystems exist on the island. Annual precipitation in the central highlands is about 450-plus inches.

Figure 3-38. Location of Native Plant Communities on Kaua'i

3.4.1.2.2 O'ahu

O'ahu comprises two volcanoes with a central plateau between them. O'ahu is the most populous island of the State. The lowland dry and mesic forest and shrublands have almost all been altered

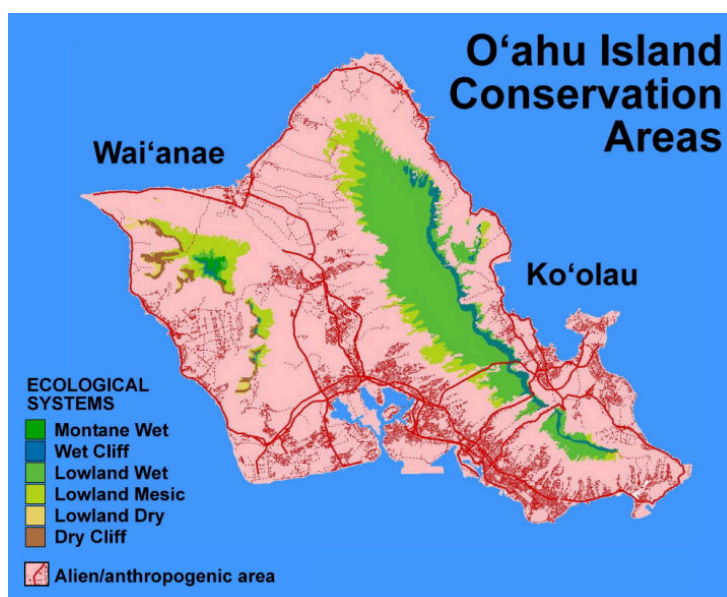

Figure 3-39. Location of Native Plant Communities on O'ahu

by human activity. The remaining native ecosystems are associated with the upper elevations of the Ko‘olau and Wai‘anae mountain ranges on the northeast and southwest sides, respectively, of the island (Figure 3-39) (TNC 2006). These are characterized by steep topography and poor access. Maximum elevation in the Ko‘olau range is 3,105 feet and 4,003 feet in the Wai‘anae Mountains. Therefore, O‘ahu does not have any subalpine or alpine ecosystems. Lowland wet ecosystem covers an extensive area of the Ko‘olau Mountains while the Wai‘anae Mountains are sufficiently high to have a small area of montane wet ecosystem. Small areas of lowland mesic ecosystems remain along lower elevations of both mountain ranges. An extensive wet cliff ecosystem remains on the steep windward (northeast) side of the Ko‘olau range. Areas of the dry cliff ecosystem still exist along the steep southwest slopes of the Wai‘anae range.

3.4.1.2.3 Molokai

The maximum elevation on Molokai is 4,970 feet on the east end of the island, too low for subalpine and alpine ecosystems. Like the other islands, the lowland dry and mesic forest and shrubland ecosystems have been largely altered by human activity, particularly in the less mountainous western part of the island. The mountains of eastern Molokai are cut into deep valleys by perennial streams, and due largely to their inaccessibility contain much of the remaining native vegetation on the island (Figure 3-40). Some areas of lowland mesic forest remain on the south slopes of the east Molokai volcano with larger areas of lowland wet and montane wet forest at higher elevations (TNC 2006). Areas of the wet cliff ecosystem still remain on the steep north (windward side) slopes of the volcano. The coastal strand along Molokai’s northwest coast contains the State’s last intact dune systems.

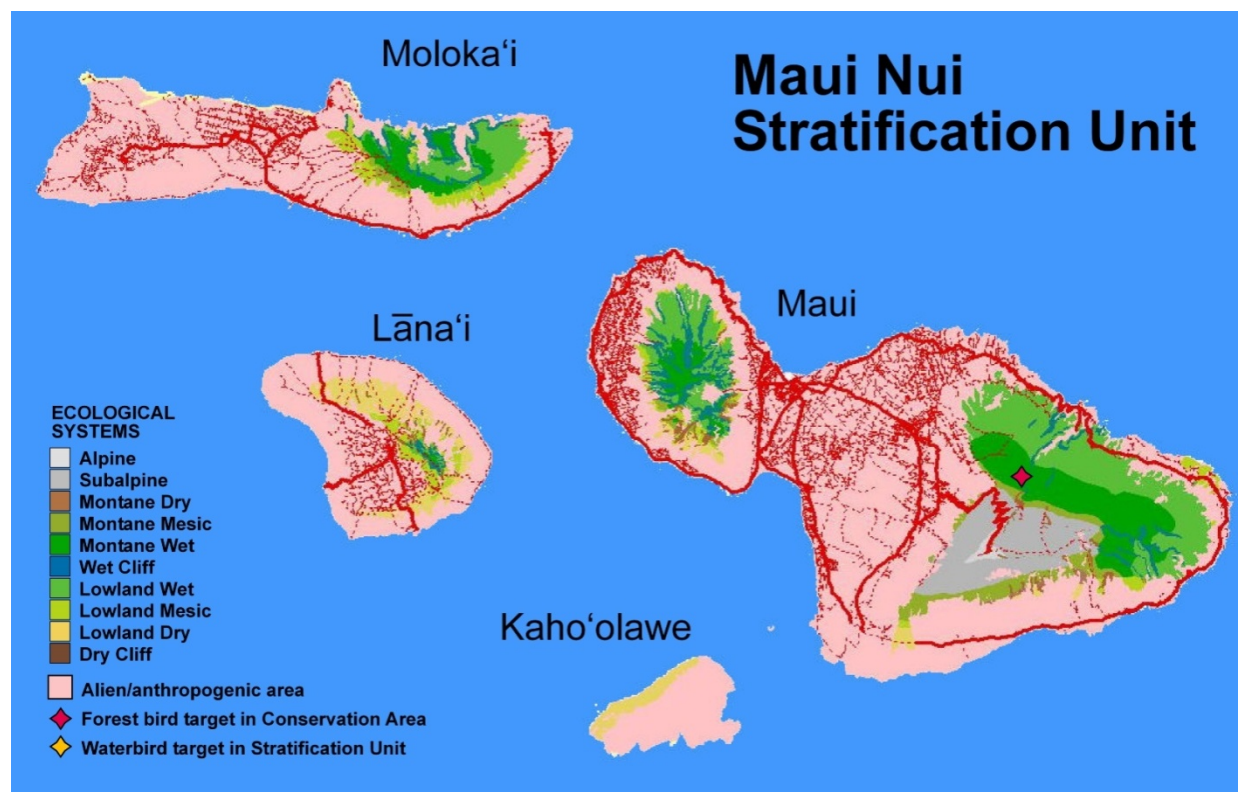

Figure 3-40. Location of Native Plant Communities on Molokai, Maui, and Lāna‘i (Source: TNC 2006)

3.4.1.2.4 Maui

The island of Maui comprises two volcanic mountains connected by an isthmus. The West Maui Mountains is the oldest volcano with an elevation of 5,788 feet at Pu‘u Kukui. Haleakalā or East Maui Volcano is larger and taller at an elevation of 10,023 feet. Approximately 30 percent of the island is dominated by native vegetation with the largest area occurring in East Maui (Mitchell et al. 2005). Native vegetation remains primarily on peaks and slopes of the two mountains. The lowland dry forest and shrub, lowland mesic forest, and montane dry and mesic forest have been replaced by anthropogenic vegetation although areas of native lowland vegetation exist in both East and West Maui. Areas of montane wet forest still remain in both East and West Maui. At 10,023 feet, Haleakalā supports a subalpine zone comprising forests, woodlands, and shrublands. A small alpine zone is present at the peak of the mountain. Some of these higher elevation zones have been impacted by feral ungulates such as goats, pigs, sheep, and deer.

3.4.1.2.5 Lāna‘i

Lāna‘i is the smallest of the six main Hawaiian Islands being evaluated in this PEIS. The highest point on the island, Lāna‘ihale, is 3,370 feet near the center of the island. The upland area surrounding Lāna‘ihale contains most of the remaining native vegetation, primarily mesic montane forest (Figure 3-41). Small areas of wet montane forest occur on the windward side of Lāna‘ihale. However, vegetation is dominated by coastal and lowland dry communities as much of the island is lower elevation with low annual precipitation. The last major remnant of olopuia and lama dryland forest that once covered large portions of Maui, Molokai, and Lāna‘i occurs on Lāna‘i (Mitchell et al. 2005). The vegetation on Lāna‘i has been greatly modified in the past by agriculture (e.g., pineapples) and grazing by cattle, goats, and axis deer.

3.4.1.2.6 Hawai‘i

The island of Hawai‘i is the largest and tallest of the islands and is composed of five volcanoes, three that are still active. The two tallest mountains are Mauna Kea at 13,796 feet and Mauna Loa at 13,677 feet. Because of the large elevation gradient and spatial variation in annual rainfall from windward and leeward aspects, as well as the presence of active volcanoes, Hawai‘i has a great diversity of vegetation. Hawai‘i has relatively large alpine and subalpine zones surrounding the summits and slopes of Mauna Kea and Mauna Loa. Like the other islands, the lowland dry forest and shrub and lowland mesic forests on Hawai‘i have been mostly altered by urban and resort development, agriculture, and ranching. However, sugarcane is no longer produced on the island. Hawai‘i still retains significant areas of native ecosystems (approximately 60 percent), primarily in the center of the island around Mauna Kea and Mauna Loa (Pratt and Gon 1998; TNC 2006) (Figure 3-41). Remaining native ecosystems include wet forests, montane dry and mesic forest, subalpine, and alpine vegetation zones.

3.4.1.3 Fauna

The extreme isolation of the Hawaiian Archipelago—it is 2,000 miles to the nearest continental land mass—greatly influenced the development and composition of the terrestrial fauna. Those taxa adapted to long distance migration (e.g., birds) are well represented while those who are not, such as land mammals are not. Birds, invertebrates (i.e., spiders and insects), and mollusks (e.g., land snails) are well-represented groups. Because of its abundant and unique biodiversity, Hawai‘i has been referred to as the “Endangered Species Capital of the World” (see Bishop Museum, Hawai‘i Biological Survey website: <http://hbs.bishopmuseum.org/endangered/endangered.html>).

3.4.1.3.1 Terrestrial Mammals

Only one terrestrial mammal species, the ‘ōpe‘ape‘a or Hawaiian hoary bat (*Lasiurus cinereus semotus*) is native to Hawai‘i and is an *endemic* subspecies of the hoary bat found throughout North and South America. The Hawaiian hoary bat is Federally *listed* as endangered (see [Section 3.4.3](#)). It is known from the islands of Hawai‘i, Maui, O‘ahu, Kaua‘i, and Molokai. Little is known of population numbers but the species is regularly observed on Hawai‘i, Kaua‘i, and Maui, but ongoing research is improving the information on this poorly understood species ([USFWS 1998a](#); [Bonaccorso 2010](#)). The Hawaiian hoary bat is solitary and forages in open areas, near edges of native forests and over open water.

Other terrestrial mammals have been introduced to the Hawaiian Islands with often deleterious effects on other native animal and plants species. Several ungulate species that were introduced for food or sport (hunting) and have now established self-sustaining populations and include feral pigs (*Sus scrofa*), feral goats (*Capra hircus*), feral sheep (*Ovis aries*), mouflon sheep (*Ovis musimom*), mule deer (*Odocoileus hemionus columbianus*), and axis deer (*Axis axis*). Introduced rodent species include the Norway rat (*Rattus rattus*), Polynesian rat (*Rattus exulans*), and the house mouse (*Mus musculus*). The small Asian mongoose (*Herpestes javanicus*) was introduced to control rats in the sugarcane fields and now has established populations on most of the islands.

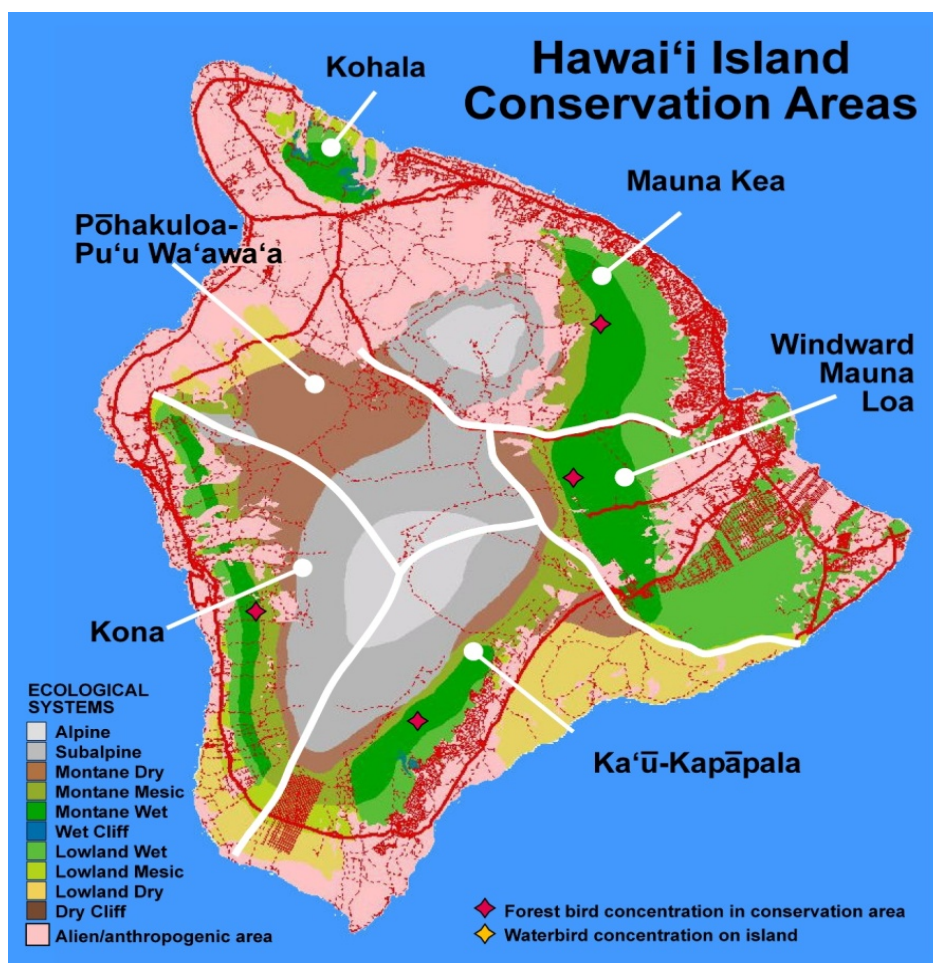

Figure 3-41. Location of Native Plant Communities on Hawai‘i (Source: [TNC 2006](#))

3.4.1.3.2 Birds

Birds (avifauna) are a major component of the vertebrate fauna on the Hawaiian Islands. Because of their flight capability, birds were able to successfully colonize and adapt to the variety of unique habitats on the islands. The original avifauna contained a high proportion of endemic species, including many flightless species (Conant 1998). As a result of human development and habitation on the islands, approximately 50 percent of original Hawaiian avifauna is now extinct and many species are currently listed as threatened or endangered species (see Section 3.4.3). A wide variety of bird species numbering approximately 170 have been introduced to the islands (Conant 1998). Many of the common bird species observed in the lowlands and coastal regions are introduced species. In addition to resident species, Hawai‘i also hosts a variety of migratory species during part of the year.

The avifauna of Hawai‘i is commonly divided into three groups: marine or sea birds, water birds, and land birds. A fourth group is not as well defined but is referred to as open country birds. This latter group contains several introduced game birds but also several native species that are listed as endangered. Each of these groups is briefly described in the following sections. It is beyond the scope of this PEIS to describe any of the groups or species in detail. The focus of the discussion is on habitats, specific locations, and life-history characteristics that are important to evaluating potential impacts from reasonable future renewable energy projects.

Seabirds

Marine or seabirds are a collection of many different families of birds that share the trait of making their living at sea (Table 3-32). However, seabirds return to land to nest and rear young before returning to their ocean habitat. Many seabird species are colonial nesters where individuals gather in concentrated areas to nest. The land-based nesting habitat of seabirds is an important resource. Seabirds often use islets

Table 3-32. Species of Seabirds that Occur in the Main Hawaiian Islands

Common Name	Scientific Name
Laysan Albatross	<i>Phoebastria immutabilis</i>
Black-footed Albatross	<i>Phoebastria nigripes</i>
Wedge-tailed Shearwater	<i>Puffinus pacificus</i>
Christmas Shearwater	<i>Puffinus nativitatis</i>
Newell’s Shearwater	<i>Puffinus auricularis newelli</i>
Bulwer’s Petrel	<i>Bulweria bulwerii</i>
Bonin Petrel	<i>Pterodroma hypoleuca</i>
Hawaiian Petrel	<i>Pterodroma sandwichensis</i>
Band-rumped Storm Petrel	<i>Oceanodroma castro</i>
Sooty Shearwater	<i>Puffinus griseus</i>
Red-tailed Tropicbird	<i>Phaethon rubricauda</i>
White-tailed Tropicbird	<i>Phaethon lepturus dorotheae</i>
Great Frigatebird	<i>Fregata minor</i>
Masked Booby	<i>Sula dactylatra</i>
Brown Booby	<i>Sula leucogaster</i>
Red-footed Booby	<i>Sula sula</i>
Sooty Tern	<i>Sterna fuscata</i>
Gray-backed Tern	<i>Sterna lunata</i>
White Tern	<i>Gygis alba</i>
Black Noddy	<i>Anous minutus</i>
Brown Noddy	<i>Anous stolidus pileatus</i>
Blue-gray Noddy	<i>Procelsterna cerulean</i>

Source: Harrison 1990.

(near-shore rock islands), cliffs, beaches, volcanic crater walls, rock piles or crevices, burrows, under vegetation, and shrubs as nesting areas. Many species of petrels and shearwaters use burrows for nesting while other species are adaptable and may nest on bare ground, under shrubs, or in crevices. Information about islets surrounding the Hawaiian Islands, including information on seabirds, can be found at <http://www.Hawai'i.org/OIRC-ISLETS.htm> and in [Harrison \(1990\)](#) and [Mitchell et al. \(2005\)](#). Although islets are important seabird nesting areas, seabirds nest in parts of the mainland islands, including volcanic crater walls, steep mountainous terrain, and sea cliffs.

Waterbirds

Waterbirds include species that primarily use a variety of wetland habitats including freshwater marshes and ponds, coastal estuaries and ponds, artificial water reservoirs, irrigation ditches, streams, and swamplands. The Hawaiian Islands historically supported a diverse array of waterbirds in both wetland and forest habitats ([USFWS 2011a](#)). However, many of species have become extinct during the past 2,000 years of human presence on the islands. The six endemic species of waterbirds that persist today are the Hawaiian duck or koloa maoli (*Anas wyvilliana*), Laysan duck (*A. laysanensis*), Hawaiian coot or 'alae ke'oke'o (*Fulica alai*), Hawaiian common moorhen or 'alae 'ula (*Gallinula chloropus sandvicensis*), Hawaiian stilt or ae'ō (*Himantopus mexicanus knudseni*), and the Hawaiian goose or nēnē (*Branta sandvicensis*) ([USFWS 2011a](#)). All six species are listed as endangered (see [Section 3.4.3](#)). The Laysan duck historically occurred in the main Hawaiian Islands about 1,500 years ago but now exists only on Laysan Island and Midway Atoll ([USFWS 2009a](#)). All but the nēnē require wetlands for survival.

A wide variety of waterbirds inhabit the Hawaiian Islands as seasonal migrants. These species include species of ducks, geese, and shorebirds (plovers and sandpipers). Because of their affinity for fresh and coastal water, wetland, and shoreline habitats, all of these habitats are important to waterbird populations. [Section 3.3.3](#) of this PEIS describes water resources and wetlands.

Forest Birds

The forest birds are the group of bird species that have had the greatest adaptive radiation on the islands and contain the most unique and endemic species of the Hawaiian avifauna. The isolation of the Hawaiian Islands has contributed to the endemism of the forest birds but is also a factor in their extreme vulnerability to outside forces ([Scott et al. 1986](#)). The native forest regions of the islands typically receive 50 to over 500 inches of precipitation each year and range in elevation from sea level to about 6,000 feet. Many of the remaining forest birds are now found in upper elevation forests (higher than 4,000 feet) that have been less affected than lower elevation vegetation zones. This group of birds has been severely impacted by human development and many of these native species are now extinct or listed as endangered species from loss of habitat, predation by introduced species, and mortality from introduced diseases and pathogens ([USFWS 2006a](#); [Scott et al. 1986](#)). Over two-thirds of the remaining forest birds in Hawai'i are Federally listed as threatened or endangered (see [Section 3.4.3](#)). Many of these species are now managed under recovery plans prepared under the *Endangered Species Act* ([16 U.S.C. §§ 1531–1544](#); ESA). Remaining areas of native forest and nonnative forests are important resources for this group of bird species.

Open Country Birds

What consists of open country is not well defined. The vegetation of Hawai'i has been greatly altered, particularly along the coast and areas of lowland dry and mesic shrubland and forests. These areas are now a mosaic of agricultural fields, grazing lands, urban development, resorts, and remnants of native species mixed with introduced species. Open country also occurs in lava fields and at higher elevations on Maui and Hawai'i in the subalpine zone because of the dry climate. A variety of gamebirds introduced to Hawai'i have established populations including chukar (*Alectoris chukar*), three species of francolin (*Francolinus* spp.), wild turkey, (*Meleagris gallopavo*), California quail (*Callipepla californica*), and ring-necked pheasant (*Phasianus colchicus*). Other introduced species of the open country include the

Western meadowlark (*Sturnella neglecta*), skylark (*Alauda arvensis*), and barn owl (*Tyto alba*). Three native bird species that typically occupy more open country include the Hawaiian State bird, the nēnē or Hawaiian goose (*Branta sandvicensis*), the ‘io or Hawaiian hawk (*Buteo solitarius*), and the pueo or short-eared owl (*Asio flammeus sandwichensis*). All three species are listed as endangered (see [Section 3.4.3](#)).

3.4.1.3.3 Freshwater Aquatic Species

Freshwater streams are described in [Section 3.3.1](#). Because of the small size and steep topography of the islands, most streams are relatively small with a steep profile. Waterfalls are common. Stream flow tracks precipitation patterns. The isolation of the Hawaiian Islands has resulted in a sparse freshwater fauna but most are endemic species. Hawaiian streams have only five native species of fish (four endemic, one indigenous), two species of crustacean (both endemic), and three species of mollusk (all endemic) ([Table 3-33](#)). The aquatic species have a mainly diadromous life cycle in that hatched larvae move to the ocean and then return to the freshwater as juveniles. Therefore, maintaining the stream to ocean connection is important for these species. Additional information on Hawai‘i’s freshwater ecosystems can be found in the online *Atlas of Hawaiian Watersheds & Their Aquatic Resources* (Parham et al. 2008).

Table 3-33. Native Freshwater Aquatic Species Found in Hawai‘i Streams and Estuaries

Common Name	Scientific Name	Origin	Habitat
Fish			
‘o‘opu hi‘u kole	<i>Lentipes concolor</i>	Endemic	Upper stream reaches
‘o‘opu nōpili	<i>Sicyopterus stimpsoni</i>	Endemic	Middle stream reaches, fast flowing water
‘o‘opu nākea	<i>Awaous guamensis</i>	Indigenous	Lower to middle stream reaches
‘o‘opu naniha	<i>Stenogobius Hawaiiensis</i>	Endemic	Estuaries and lower stream reaches
‘o‘opu ‘akupa	<i>Eleotris sandwicensis</i>	Endemic	Estuaries and lower stream reaches
Crustaceans			
‘ōpaekala‘ole	<i>Atyoida bisulcata</i>	Endemic	Upper stream reaches, fast flowing water
‘ōpae ‘oeha‘a	<i>Macrobrachium grandimanus</i>	Endemic	Estuaries and lower stream reaches
Mollusks			
hīhīwai	<i>Neritina granosa</i>	Endemic	Lower and middle stream reaches
hapawai	<i>Neritina vespertina</i>	Endemic	Estuaries and lower stream reaches
pipiwai	<i>Theodoxus cariosus</i>	Endemic	Brackish water, estuaries and pools

Source: [Higashi 2014](#).

3.4.2 MARINE ECOSYSTEMS

Important factors shaping the marine ecosystems surrounding the Hawaiian Islands include the volcanic origins of the islands, geographic isolation, subtropical climate, and geographic exposure to storm waves. The islands that compose the Hawaiian Archipelago formed as isolated volcanic seamounts as the Pacific Plate moved northwest over the Hawaiian hotspot (see [Section 3.5.1](#)). As a result, many of the submarine slopes of the main Hawaiian Islands are relatively steep. Shallow ocean floor environments surrounding the islands are relatively limited because of the steep slopes. The exception is the ocean area surrounding Maui County including the islands of Maui, Molokai, Lāna‘i, and the uninhabited island of Kaho‘olawe. Ocean depth is important because of the influence on light penetration, photosynthesis, and secondary productivity. The shallower depths to about 600 feet, called the epipelagic or *euphotic zone* (the sunlit zone), has sufficient light for the production of phytoplankton and zooplankton. The euphotic zone contains much of the ocean’s marine life and is one of the most ecologically important ocean zones. The amount of ocean floor within the euphotic zone is generally limited to 1 to 4 miles offshore on the islands of Kaua‘i, O‘ahu, and Hawai‘i. However, the amount of ocean floor within this highly productive zone is much more extensive surrounding the Maui County islands. Note that some authors consider the euphotic

zone to be shallower (less than 300 feet) with a 300- to 600-foot depth representing a [twilight zone](#), or disphotic zone, where light penetration is insufficient for much plant production and overall marine productivity is more limited.

Similar to terrestrial ecosystems, the geographic isolation of the Hawaiian Islands is an important factor in the development of the marine ecosystems surrounding the islands. The large distance from continents and other major island and reef systems has limited the colonization of the Hawai'i marine ecosystems by many species. Because the islands developed in sequence from the northwest to southeast (i.e., Kaua'i to Hawai'i for the inhabited islands), older islands served as colonizing sources of marine life for the younger islands. As a result, the Hawaiian marine ecosystems have high percentage of endemic species (i.e., found nowhere else) of any tropical archipelago in the Pacific Ocean and possibly the world.

The Hawaiian Islands range in latitude from 19 to 28 degrees north and straddle the [Tropic of Cancer](#). The exposure to cooler winter seawater and destructive waves has created a mostly subtropical marine environment. The mid-ocean location of Hawai'i exposes the islands to periodic storm waves from both the Arctic and Antarctic regions that cause damage to marine habitats such as beaches and reefs ([Friedlander et al. 2008](#)). Tropical cyclones also cause storm surges and waves that disturb coastal and marine environments. Earthquakes and possible tsunamis are other natural disturbances that may impact submarine and coastal habitats.

Water motion in the ocean occurs over a wide range of time and spatial scales. Other than tides that are caused by the gravity of the moon and sun, all other water motion (with the exception of tsunamis) are caused by interactions with the atmosphere through horizontal force of the wind, heating and cooling by the air, and by radiation, precipitation, and evaporation ([Flament et al. 1998](#)). Patterns of water motion and variation in those patterns at different time scales (annual, seasonal, and daily) create horizontal and vertical changes in ocean water characteristics such as temperature, salinity, and nutrient distribution, factors important in shaping marine ecosystems. The annual variation in surface ocean temperature is relatively small varying from 75°F in winter/spring to 81°F in summer/fall near O'ahu. Important to marine life are the vertical profiles in temperature and nutrients. Water temperature at the surface is warm (about 77°F) and the depth of warm water (100 to 400 feet) varies by season and depends on surface mixing from winds. Below this mixed layer of ocean water is a sharp thermocline where water temperature declines rapidly to around 41°F at a depth of 2,300 feet. Vertical distribution nutrients in the ocean water are opposite of the temperature profiles. The near surface warm waters are typically low in nutrients but increase rapidly through the thermocline and are relatively uniform in distribution at depth ([Flament et al. 1998](#)). This pattern limits the productivity of phytoplankton and thence other marine life in the shallower, warm, sun lit zones around the islands. At depth, lack of sunlight limits production in spite of an abundance of nutrients.

Large-scale ocean currents in the vicinity of the Hawaiian Islands generally flow from east to west. The interaction of both the ocean currents and the surface winds with the physical structure of islands creates local or regional variations in ocean currents and depth of the surface mixing layer. For example, the mixed layer of the channels between islands is deeper because of stronger surface winds. On the leeward side of the islands, winds are calmer, mixing is shallower, and surface waters are warmer from lack of mixing. Coupled with the effects of the earth's rotation, varying patterns of winds, currents, and water temperatures can cause localized eddies or circulation of water columns that allows upwelling of colder, nutrient-rich water. Diurnal (daily) tides cause a rise and fall in ocean level along the coast. Tide levels vary throughout the islands but are important to tidepool, [anchialine pond](#), and estuary ecosystems along the coast.

3.4.2.1 Marine Habitats

The Hawaiian Islands have a wide variety of marine habitats. The following habitat descriptions start with marine habitats on or near the coastal zone and proceed to the deep ocean environment. The information is adapted from [Maragos \(1998\)](#).

3.4.2.1.1 Marine Pools (tidepools and anchialine ponds)

Marine pools are found along the rocky coasts of the Hawaiian Islands and may occur up to several hundred meters inland. [Anchialine ponds](#) are inshore landlocked ponds that have a subterranean connection to the ocean and are extremely common worldwide along neo-tropical coastlines where the geology and aquifer system are relatively young and in areas with minimal soil development. Such conditions occur notably where the bedrock is limestone or recently formed volcanic lava such as in Hawai'i. The ponds form in depressions in lava rock. Water levels in anchialine ponds often fluctuate with tidal changes due to the coastal location and the connection with the ocean. The range in water level fluctuations are decreased (damped) and delayed compared to the range and time observed for the adjacent tide depending on the distance from the coast and the hydraulic conductivity of the volcanic lava rock. Water in anchialine ponds typically has marine salinities except in surface layers where the water may be more [brackish](#) depending on the influx of freshwater. Ecological studies of anchialine ponds frequently identify regionally rare and sometimes endemic species living in them. Ponds typically contain marine algae, grasses and rushes if sediments accumulate, shrimp, and a variety of other crustaceans and mollusks.

Tidepools are open and subject to flooding during changing tides. At high tide, tidepools are flooded and continuous with and indistinguishable from the ocean. At low tide, pools are left in depressions in the volcanic rock. Tidepools are an extreme environment including full submersion by the ocean and subject to wave action and currents during high tides, plus exposure to wind, sun, and predators during low tide, as well as changes in water temperature and salinity. However, tidepools are habitats with a high diversity of species.

3.4.2.1.2 Beaches (sandy and rocky)

Beaches occur along shorelines and may either be sandy or rocky. Sandy beaches in Hawai'i occur in a variety of colors depending on the parent material from which the sand was derived. Pink sands are derived from iron-rich cinder cones, green sand from olivine crystals eroded from lava, black sand from tephra particles formed when molten lava flows into the ocean, and white sand primarily from the breakdown of coralline algae and coral. Sandy beaches are subject to wave action and depend on seasonal cycles of erosion, accretion, and alongshore drift of offshore sand reservoirs. Sandy beaches generally are more common on older islands and in locations that favor formation of sand particles or the accumulation of sand. Sandy beaches may serve as resting and nesting habitat for seabirds, clams, crabs, sea turtles, and the Hawaiian monk seal.

Rocky beaches occur on the shorelines of all the Hawaiian Islands where sand is absent owing to constant wave action, currents, steep submarine slopes and lack of offshore sand reservoirs. Most rocky beaches are formed from basalts but may be consolidated limestone formed of cemented beach rock or raised coral reefs. Rocky beaches provide habitat for a variety of algae, limpets, snails, rock crabs, gastropods and urchins. In many areas, the beach area consists of rocky cliffs rising directly from the shoreline.

3.4.2.1.3 Estuaries

Estuaries are formed where fresh and marine water meets along the coastlines. In Hawai‘i, this can occur under several different conditions including at large embayments (naturally protecting inlets) such as Pearl Harbor, where freshwater streams enter the ocean and tidal currents transport salt water in and out of the estuary. Estuary conditions (mixture of fresh and salt water) also can occur where coastal groundwater discharges abundantly offshore. Freshwater is less dense than seawater and floats on the surface until it is mixed by waves and currents. Freshwater brings an abundance of nutrients that stimulates productivity in estuaries which typically have sediment covered bottoms. Estuaries can have abundant herbaceous growth and a wide variety of animal species including crustaceans, mollusks, fish, shorebirds, and waterbirds. Estuaries serve as important nursery areas for native freshwater, estuarine, and marine species by providing habitat, nutrients, and protection.

3.4.2.1.4 Fishponds and Harbors

Fishponds and harbors are human created marine ecosystems. Fishponds were part of the intensive aquaculture practiced by early Hawaiians. Four hundred forty nine ponds have been recorded with the majority on O‘ahu and Molokai ([Kirch 1998](#)). The fishponds were typically constructed with stone walls on shallow reef flats, in embayments, and over submarine springs. Some larger ponds enclosed more than 500 acres. Tidal flows through gates replenished nutrients while fish remained trapped within the pond. Mullet, anchovies, shrimp, clams, oysters, seabirds, shorebirds, and waterbirds inhabit or feed in the ponds.

Harbors are constructed inlets generally built in areas sheltered from heavy waves. Because of the importance of marine transportation (both commercial and recreational) in Hawai‘i, harbors are an important human resource but also can be a source of coastal degradation from erosion, sewage contamination, and oil and litter pollution.

3.4.2.1.5 Mangroves

Mangroves were introduced in Hawai‘i in the early 1900s to south Molokai and Kāne‘ohe Bay on O‘ahu. Mangroves have since spread to muddy reef flats and estuarine waters around most of the major islands and to some rocky coastal waters of Hawai‘i island. Mangrove seeds float in seawater but sink and root in brackish water. Tidal flows and mangrove leaf fall maintain mangrove productivity. Roots and lower trunks are submerged at high tide. Mangroves provide habitat for Samoan crab, oysters, clams, and other crabs that attach to mangrove roots as well as shelter for juvenile fishes. The native black-crowned night heron, cattle egret, and endangered Hawaiian silt nest and feed among mangroves. However, mangroves are considered invasive and displace native species such as marine algae and seagrasses.

3.4.2.1.6 Seagrasses and Microalgae

Seagrasses are found close to shore below the tidal zone. Hawai‘i has two species of seagrass: one (*Halophila Hawaiiiana*) endemic to the islands, a second (*Halophila decipiens*) was collected in 2001 from three separate islands spanning the length of the Hawaiian Island chain ([McDermid et. al. 2002](#)). This species has a global tropical distribution. Widgeon-grass (*Ruppia maritima*) is commonly found with seagrass. Seagrass ecosystems are common off the inner reef flats of south Molokai and Kaua‘i. It is also found in a few other locations. Seagrasses root in sands and muds and are totally submerged. They usually survive best where wave action is not severe. Seagrasses commonly grow in fishponds. Some of the common animal species in this ecosystem include sea cucumbers, gastropods, clams, crabs, shrimps, mullets, and rudderfish. The green sea turtle grazes on seagrasses ([Russell et al. 2003](#)). Seagrasses are an important resource where they occur.

Although not a seagrass, the green macroalgae (*Halimeda kanaloana*) along with several algae species form extensive algal meadows at depths from up to approximately 500 to 650 feet depending on light conditions. These meadows provide important habitat similar to seagrasses. *Halimeda kanaloana* meadows are found growing in sand at depths from about 65 to 300 feet throughout the islands of Molokai, Lānaʻi, Maui, and Kahoʻolawe (or the Maui Nui island complex), while meadows of *Halimeda distorta* (tentative identification) were found throughout Oʻahu and Maui Nui growing over rock from depths from about 200 to 500 feet ([Spalding 2004](#)).

3.4.2.1.7 Shallow Benthic Communities

Shallow benthic communities are found to depths of 160 feet or more within the euphotic (sunlit) zone of the ocean. This community occurs on a variety of substrates including basalts, consolidated limestone (reef carbonates, beach rock), and sediments (sands, gravels, and pebbles). The composition and distribution of the shallow benthic community is determined by the amount of light penetration, temperature, wave action, and substrate (hard or soft). The composition of the community can be diverse ranging from primarily fleshy algae (brown, red, and green) to coralline algae or coral communities. Shallow benthic communities on sand include cone shells, tritons, pen shells, and garden eels. Animals in this community include parrotfishes, wrasses, damselfishes, surgeonfishes, reef fishes, sea urchins, and sea cucumbers.

3.4.2.1.8 Fringing Reefs

Fringing reefs are reefs that grow, terrace-like, offshore to outer slopes of about 165 feet. Fringing reefs are poorly developed on islands where shorelines are rapidly subsiding or are exposed to heavy waves. The State's longest continuous fringing reef (30 miles long) is off the south shore of Molokai. The reefs are composed of calcium carbonate skeletons and sediments produced by corals and coralline algae. On the inner reef flats, sand deposits and seaweeds are common. Living corals and coralline algae dominate on the reefs outer edge. Underneath the outer layer of living reef organisms are the remains of previous reef organisms that are compacted and cemented into a hard limestone, wave-resistant structure. The other biota that lives in the fringing reef is similar to those that live in the shallow benthic communities. The threatened green sea turtle forages in reef areas and the endangered hawksbill turtle feeds where sponges are common. Wave action is a primary force that shapes and alters reefs around the islands ([Friedlander et al. 2008](#)). For example, reefs on the windward side versus leeward side of the islands can differ primarily because of wave stress.

3.4.2.1.9 Barrier Reefs and Lagoons

Barrier reefs lie farther offshore than fringing reefs and may develop through a combination of island subsidence, erosion, and rising sea levels. Between barrier reefs and the shore are deep lagoons where waters are relatively calm because the reef acts as a natural breakwater. Hawaiʻi has two barrier reefs: Kāneʻohe Bay on the northeast coast of Oʻahu and the Mānā reef off the northwest coast of Kauaʻi. Barrier reefs occur to a depth of approximately 165 feet. The lagoons and ocean are connected by cuts through the reef. The barrier reef is composed of consolidated carbonate rock and lagoons have a floor covered with gravel to mud sediments.

The Kāneʻohe Bay barrier reef developed on a shallow offshore platform of land during a period of rising sea levels. Pinnacle and patch reefs occur within the lagoons. The Mānā barrier reef off the northwest coast of Kauaʻi is submerged about 50 feet below the sea level and the lagoon floor is about 100 feet deep. Other biota in the barrier reefs and lagoon ecosystem are similar to those that live in the shallow benthic communities and fringe reefs including the threatened green sea turtle and endangered hawksbill turtle.

3.4.2.1.10 Atolls

Atolls generally form as volcanic islands subside and erode over time leaving behind a coral reef that may have started as a fringing reef, transitioned to a barrier reef and eventually forming an atoll. An atoll typically consists of a raised coral reef, possibly some land area, and a protected lagoon area. The lagoon area may be nearly or only partially encircled by a raised or shallowly submerged coral reef. The lagoon floor is typically covered with sands or mud. Atolls may have some vegetated areas. Wave-driven currents frequently wash over atoll reefs. Below the ocean surface, the upper parts of atolls are composed of reef carbonates, often to great depths (3,300 feet). Below the carbonate, volcanic basalts form the foundation. Sandy beaches are common on the lagoon side of an atoll while rock beaches are common on the ocean side of an atoll.

No atolls exist within the main Hawaiian Islands. Six true atolls exist in the Northwestern Hawaiian Islands northwest of Kaua‘i. This region is outside of the main Hawaiian Islands being considered in this PEIS; therefore, atolls were not evaluated as a potentially affected marine ecosystem.

3.4.2.1.11 Offshore Deep Reefs (twilight zone)

Offshore deep reefs are found at approximate depths of 165 to 660 feet, encircling all of the Hawaiian Islands. Although light penetrates to these depths, it is insufficient for much photosynthesis. This zone is often referred to as the *twilight zone* because of the low light levels. Substrates are often rocky on outcrops and steep slopes but also include areas of sediment deposits. Other biota includes species adapted to deep water such as some species of algae, deep-dwelling fish, corals and other invertebrates. Black corals are concentrated below normal scuba-diving depths. Endangered monk seal and sea turtles forage in these habitats.

3.4.2.1.12 Offshore Islands

Distributed around the main islands are small islets or sea stacks. Small islets are typically more common around larger or older islands because they generally are connected to the mainland island but form through the processes of erosion and subsidence. Limestone islets are typically lithified dunes or relict reefs. Islets are normally separated from the main island by strong currents that effectively isolate them from easy access. Islets are typically characterized by seacliffs, rocky beaches, some sand beach area, rocky submarine slopes, and are usually covered with live coral and coralline algae. The biota of islets is comparable to those of benthic communities, fringing reefs, and barrier reefs. Islets are important seabird rookeries and used as resting sites for the Hawaiian monk seal and sea turtles.

3.4.2.1.13 Neritic Water

The neritic water zone consists of open ocean water to depths of 660 feet associated with the coasts surrounding all of the Hawaiian Islands. There are no substrates in this ecosystem, as the habitat consists solely of open water. Neritic water includes both the euphotic, or sunlit, area and the twilight zone, where light for photosynthesis is limited. The biota includes phytoplankton, floating seaweeds, zooplankton, fish, marine mammals, marine turtles, and seabirds. The endangered hawksbill turtle, Hawaiian monk seal, humpback whale, and threatened green turtle all use the neritic waters around the Hawaiian Islands.

3.4.2.1.14 Pelagic Oceanic and Deep Ocean Floor

The pelagic oceanic zone includes open waters beyond the neritic zone (greater than 660 feet below sea level contour) and the deep ocean floor. The pelagic oceanic zone is often divided into zones based on the amount of sunlight penetration, water pressure, and temperature. The epipelagic zone extends to the same

depth as the neritic zone, which is about the limit of visible light penetration. Below the epipelagic is the mesopelagic zone (600 to 3,300 feet) and is considered the twilight zone as visible light rapidly diminishes. However, the mesopelagic zone contains a wide variety of marine species. Because of the steep submarine slopes of many of the islands, the pelagic oceanic zone is common around the islands, albeit to a lesser extent between the islands of Maui County (i.e., Maui, Molokai, and Lāna‘i). In the ‘Alenuihāhā Channel between the islands of Hawai‘i and Maui, the pelagic zone reaches depths exceeding 6,000, and 10,000 feet in the Kaua‘i Channel between Kaua‘i and O‘ahu.

3.4.2.2 Marine Mammals

The oceanic waters surrounding the main Hawaiian Islands are inhabited by a variety of marine mammals (Table 3-34). Marine mammals are protected by the *Marine Mammal Protection Act* (16 U.S.C. §§ 1361–1407) and others may receive additional protection if listed under the ESA (see Section 3.4.3). Many species of marine mammals are migratory and may occupy areas around the islands only during part of the year.

The National Marine Fisheries Service (NMFS) prepares marine mammal stock assessment reports by species/stock (<http://www.nmfs.noaa.gov/pr/sars/species.htm>). Stock refers to a particular regional area occupied by a species. The stock assessment reports provide information distribution, abundance, and mortality.

Table 3-34. Hawaiian Marine Mammals

Common Name	Scientific Name
Minke whale	<i>Balaenoptera acutorostrata</i>
Sei whale	<i>Balaenoptera borealis</i>
Bryde’s whale	<i>Balaenoptera edeni</i>
Blue Whale	<i>Balaenoptera musculus</i>
Fin whale	<i>Balaenoptera physalus</i>
Northern right whale	<i>Eubaleana japonica</i>
Pygmy killer whale	<i>Feresa attenuata</i>
Short-finned pilot whale	<i>Globicephala macrorhynchus</i>
Risso’s dolphin	<i>Grampus griseus</i>
Longman’s beaked whale	<i>Indopacetus pacificus</i>
Pygmy sperm whale	<i>Kogia breviceps</i>
Dwarf sperm whale	<i>Kogia sima</i>
Fraser’s dolphin	<i>Lagenodelphis hosei</i>
Humpback whale	<i>Megaptera novaeangliae</i>
Blainesville’s beaked whale	<i>Mesoplodon densirostris</i>
Killer whale	<i>Orcinus orca</i>
Melon-headed whale	<i>Peponocephala electra</i>
Sperm whale	<i>Physeter macrocephalus</i>
False killer whale	<i>Pseudorca crassidens</i>
Spotted dolphin	<i>Stenella attenuata</i>
Striped dolphin	<i>Stenella coeruleoalba</i>
Spinner dolphin	<i>Stenella longirostris</i>
Rough-toothed dolphin	<i>Steno bredanensis</i>
Pacific bottlenose dolphin	<i>Tursiops truncatus</i>
Cuvier’s beaked whale	<i>Ziphius cavirostris</i>
Hawaiian monk seal	<i>Neomonachus schauinslandi</i>

Marine mammals are typically divided into two groups: cetaceans (whales and dolphins) and pinnipeds (seals and sea lions). The humpback whale (*Megaptera novaeangliae*) is the most well-known whale species found in Hawaiian waters. Sightings of other whale species may be rare because some primarily live in deeper ocean waters. The humpback whale is listed as an endangered species and is discussed in [Section 3.4.3.1.2](#). Other common cetaceans in Hawaiian waters include the pilot whale, false killer whale (*Pseudorca crassidens*), bottlenose dolphin, and spinner dolphin. The main Hawaiian Islands insular false killer whale distinct population segment was recently listed as endangered ([77 FR 70915, November 28, 2012](#)) (see [Section 3.4.3.1.2](#)). The Hawaiian monk seal [*Neomonachus schauinslandi* (= *Monachus schauinslandi*)] ([79 FR 68371, November 17, 2014](#)) is the most common pinniped in the islands but is considered critically endangered. It is most common in the Northwestern Hawaiian Islands but does occur in the main Hawaiian Islands. Information about individual marine mammal species and their distribution around the Hawaiian Islands can be found in [Mitchell et al. \(2005\)](#).

3.4.2.3 Marine Reptiles

Marine reptiles native to Hawai‘i include five species of sea turtles. All species are listed as threatened or endangered and are discussed in [Section 3.4.3.1.2](#). Three of the species are considered rare or uncommon in Hawai‘i.

3.4.2.4 Marine Fisheries

The marine fisheries of the Hawaiian Islands are classified into five types: bottomfish fisheries, crustacean fisheries, precious coral fisheries, coral reef ecosystem, and pelagic fisheries ([WPRFMC 2009a, 2009b](#)). The deep-slope bottomfish fishery primarily occurs at depths of 180 to 900 feet and includes species of snappers, jacks, and a single species of grouper. The bottomfish fishery is about equally divided between State and Federal waters. Important bottomfish areas of the main Hawaiian Islands include Middle Bank (northwest of Kaua‘i), Penguin Bank (west of Molokai), and the 600-foot deep bottomfish habitat in the Maui-Lāna‘i-Molokai island complex. The crustacean fishery is centered on two species of spiny lobster (*Panulirus marginatus* and *P. penicillatus*) and species of slipper lobster in the Family Scyllaridae. The crustacean fishery around the main Hawaiian Islands is not large ([WPRFMC 2009a](#)). The fishery for precious corals involves primarily black (*Antipathes* spp.), pink (*Corallium*), gold (*Gerardia* spp. and *Narella* spp.), and bamboo (*Lepidisis olapa*) corals from six coral beds: Makapu‘u Point, O‘ahu; the Au‘au Channel bed, Maui; 180-Fathom Bank, Brooks Bank, Ka‘ena Point, and Keahole Point. Precious corals may be divided into deep- and shallow-water species. Deep-water precious corals are generally found between 1000 and 5000 feet and include pink, gold, and bamboo corals. Shallow-water species occur between 100 and 300 feet and consist primarily of three species of black coral. Only black coral is harvested from the Au‘au Channel bed located near Maui. Pink, gold, and bamboo coral are harvested from the other five coral beds except no gold coral is harvested from the Makapu‘u coral bed ([WPRFMC 2009a](#)). Coral reef fish species are the most diverse of the four fisheries ([WPRFMC 2009a](#)). Akule (coastal pelagic scads), soldierfish (*Myripristis* spp.), parrotfish (*Scarid* spp.), surgeonfishes (including *Acanthurus dussumieri*, *A. trostegus* and *Naso* spp.) and goatfishes (including *Mulloidichthys* spp.) are some of the top species by weight and value. The coral reef ecosystem is important to commercial, recreational, and subsistence fishermen. Hawai‘i’s pelagic fisheries, which include the longline, Main Hawaiian Islands troll and handline, offshore handline, and the aku boat (pole and line) fisheries, are the State’s largest and most valuable fishery sector ([WPRFMC 2009b](#)). Tuna (albacore, bigeye, yellowfin, skipjack, and Bluefin), billfish (marlin and swordfish), and other tropical pelagic species supply most of the fresh pelagic fish consumed by Hawai‘i residents and support popular recreational fisheries. The offshore longline fishery currently provides the majority of the pelagic fisheries catch.

3.4.2.5 Marine Birds

Marine birds (sea birds) are discussed under terrestrial birds ([Section 3.4.1.3.2](#)). Although marine birds spend considerable time in neritic and pelagic ocean habitat, they depend on land-based nesting colonies for reproduction and therefore their life-cycle is dependent on terrestrial habitats and impacts to those habitats. For a review of Hawaiian seabirds natural history and ecology, see [Harrison \(1990\)](#).

3.4.3 PROTECTED SPECIES AND HABITATS

Many terrestrial and marine species and their habitats in Hawai‘i are protected under Federal and State laws and regulations. These statutes include the [Federal ESA](#), [Migratory Bird Treaty Act](#), [Marine Mammal Protection Act](#), and [Magnuson-Stevens Fishery Conservation and Management Act](#), and State of Hawai‘i’s ESA ([HRS 195D](#)). These laws have provisions that typically prohibit the take (including habitat), harm, and harassment of any species protected by the respective statute.

The Federal ESA is the primary statute that provides protective status to those species that are either likely to become an endangered species within the foreseeable future (threatened) or is in danger of extinction in the near future (endangered). NMFS and USFWS share responsibility for implementing ESA. Generally, the USFWS regulates activities that may impact threatened and endangered terrestrial and freshwater species, while the NMFS regulates activities that may impact marine and anadromous species. Federal agencies must consult with NMFS and USFWS, under Section 7(a)(2) of the ESA on Federal activities, including Federally funded activities, that might affect a listed species. These interagency consultations, or Section 7 consultations, are designed to assist Federal agencies in fulfilling their duty to ensure Federal actions do not jeopardize the continued existence of a species or destroy or adversely modify critical habitat. Section 7 consultations may conclude with the issuance of Incidental Take Statements, under which the Federal agency is authorized to incidentally take certain members of a listed species but only under certain conditions.

ENDANGERED SPECIES ACT OF 1973 (16 U.S.C. §§ 1531–1544)

TERMINOLOGY

Endangered Species: Any species in danger of extinction throughout all or a significant portion of its range.

Threatened Species: Any species likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

Proposed Species: Any species of fish, wildlife or plant proposed in the Federal Register to be listed under Section 4 of the *Endangered Species Act*.

Critical Habitat: Areas deemed necessary to a species’ conservation and officially designated under the *Endangered Species Act*; provided that the species is legally protected.

Listed Species: Any species of fish, wildlife, or plant determined to be endangered or threatened under Section 4 of the *Endangered Species Act*.

Take: To harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect or attempt to engage in any such conduct.

Distinct Population Segment: A vertebrate population or group of populations that is discrete from other populations of the species and significant in relation to the entire species.

The State of Hawai‘i ESA statute links the species listed under the Federal ESA to protection under State law. The State coordinates its efforts with the USFWS for incidental take permits and habitat conservation plans. As part of its continuing partnership with the USFWS, the DLNR, Division of Forestry and Wildlife prepared a *Comprehensive Wildlife Conservation Strategy* (Mitchell et al. 2005), the goal of which is to guide conservation efforts across the State to ensure protection of Hawai‘i’s wide range of native wildlife and the diverse habitats that support them. In the conservation strategy, the State developed both Statewide (terrestrial) conservation needs and marine conservation needs including identifying species of greatest conservation need that includes but is not limited to those species listed as threatened and endangered. Other reports the State has prepared that address prioritized areas for forest management and conservation include *Hawai‘i Statewide Assessment of Forest Conditions and Trends: An Assessment of the State of Our ‘Aina and Rain Follows the Forest Initiative*. The Statewide assessment, better known as the State of Hawai‘i’s Forest Action Plan, was required by the USDA Forest Service in order to access funding through its programs. The initiative was developed by the Governor of Hawai‘i in November 2011 and focuses on watershed protection across the State through a number of natural resource management actions such as fencing, invasive plant and animal removal, and reforestation of degraded lands. Both documents are available online at <http://dlnr.hawaii.gov/forestry/info/fap/> and <http://dlnr.hawaii.gov/rain/>, respectively.

USFWS also implements the *Migratory Bird Treaty Act* (16 U.S.C. §§ 703–712) and the *Bald and Golden Eagle Protection Act* (16 U.S.C. §§ 668–668c). The unauthorized take of species protected under these statutes is prohibited. As such, the project proponent may need to discuss with USFWS necessary mitigation, minimization, or avoidance measures that would limit the risk of the project proponent violating the statutes. The project proponent may also need to obtain a permit under the applicable statute.

The *Marine Mammal Protection Act* was implemented to provide protection for populations of marine mammals. The Act prohibits take of marine mammals except through special authorization under an incidental take permit or other special permits for such activities as scientific research, population management, and public education. NMFS implements the provisions of the Act

The *Magnuson-Stevens Fishery Conservation and Management Act* (16 U.S.C. §§ 1801–1884) provides for the overall management and protection of the fishery resources in Federal waters of the United States and is administered by NMFS. The Act as amended by the *1996 Sustainable Fisheries Act* required that [essential fish habitat \(EFH\)](#) be identified and described for all Federally managed species. EFH is defined as those waters and substrate necessary to fish for spawning, breeding or growth to maturity. The EFH provisions allow the regional fisheries councils to provide comments and make recommendations to Federal and State agencies that propose actions which may affect habitat, including EFH, of a managed fishery species. The Western Pacific Fishery Management Council has authority for the State of Hawai‘i and the commonwealths, territories, and possessions of the United States in the Pacific Ocean. Whenever Federal agencies authorize, fund, or carry out actions that may adversely impact Federal waters, they must consult with NMFS regarding the impact of their activities on EFH. NMFS must provide the consulting Federal agency with EFH conservation recommendations for any action that would adversely affect EFH. However, conservation recommendations concerning EFH are advisory, but a Federal agency must provide a written explanation if the agency chooses not to adopt the recommendations.

3.4.3.1 Threatened and Endangered Species

Because of the isolation of Hawai‘i from other continental land masses and islands, the flora and fauna of the islands developed a high degree of endemism as species adapted to local environmental conditions. These same factors, small land area and unique species, also made the flora and fauna of the islands highly susceptible to outside influences such as human settlement and introduced species, diseases, and pathogens. A large number of native Hawai‘i plant and animal species are now extinct. Human impacts,

including the alteration of native plant communities and introduction of nonnative plants and animals, has occurred for many years starting first with early Polynesian settlers and then accelerating since Western contact about 200 years ago ([Scott et al. 1986](#)).

As shown in [Table 3-35](#), the State of Hawai‘i has 524 species and subspecies (taxa) of plants and animals listed as threatened and endangered, the highest number in the United States. The list of threatened and endangered species in Hawai‘i is not provided in the PEIS because the list of officially recognized threatened and endangered species is subject to change, as the USFWS and NMFS currently have active proposed threatened and endangered listings and status reviews in progress. The actual number of listed taxa also may vary based on accepted taxonomy of subspecies or species. Some species included on the list may actually be extirpated in the wild. The USFWS recently completed several listing determinations. On September 18, 2012, the USFWS published a final rule in the Federal Register designating 20 Hawaiian plant species and 3 damselflies as endangered ([77 FR 57648, September 18, 2012](#)). In addition, this final rule designated 42,804 acres of critical habitat for 25 species and revised critical habitat for 99 species. On November 28, 2012, NMFS designated the main Hawaiian Islands insular false killer whale (*Pseudorca crassidens*) distinct population segment (DPS) as an endangered species. On May 28, 2013, the USFWS published a final rule in the Federal Register designating 37 plants and 3 species of tree snail on Maui, Molokai, and Lāna‘i as endangered ([78 FR 32014](#)). In addition, the final rule delisted one plant species based on taxonomic error, reaffirmed the endangered status of two previously listed plant species, and discussed the taxonomic revision of several previously listed species. On October 29, 2013, the USFWS published a final rule in the Federal Register designating 13 plant species, 1 picture-wing fly,

Table 3-35. State of Hawai‘i Threatened and Endangered Species

	Quantity	Percent
Terrestrial	516	98
Animals	98	19
Plants	418	81
Marine	8	2
Animals	8	2
Plants	0	0
TOTAL	524	

Note: Numbers are based on best available information and subject to change from [proposed listings](#) and taxonomic revisions.

and 1 anchialine pool shrimp on the island of Hawai‘i as endangered ([78 FR 64638](#)). In addition, the final rule also formally recognizes and corrects the scientific name of a plant species (*Mezoneuron kavaense*) previously [listed](#) as [endangered](#) in 1986. To obtain official lists of threatened and endangered species or information on the status of proposed listing actions, contact the USFWS, Pacific Islands Fish and Wildlife Office (<http://www.fws.gov/pacificislands/>), and the Pacific Islands Regional Office of NMFS (<http://www.fpir.noaa.gov/>).

3.4.3.1.1 Terrestrial Threatened and Endangered Species

The majority of species (98 percent) listed as threatened and endangered in Hawai‘i are terrestrial animal and plant species. This reflects the disproportionate impact on land resources of the Hawaiian Islands compared with the marine ecosystems. Of the 516 terrestrial species listed, 14 are listed as threatened and 502 are classified as endangered. The USFWS has designated [critical habitat](#) for 24 terrestrial animal species and 323 plants. Critical habitat is area considered important for the conservation and recovery of the species and may not be currently occupied by the species.

Plants

The majority of listed terrestrial species (81 percent) are plants. Native Hawaiian plants have been impacted by land clearing for agriculture, pasture, and urbanization, and resort development. These impacts have been particularly severe in coastal and lowland regions where both climate and topography is most suitable for human activity. Hawaiian plants also have been impacted by the introduction of nonnative ungulates such as pigs, goats, deer, and sheep ([Cuddihy and Stone 1990](#); [NPS 2011](#)). Foraging, trampling of plants, and digging by ungulates directly damages plants, causes soil erosion, and destroys native habitat.

Threatened and endangered plant species occur on all the main Hawaiian Islands and vegetation zones. Most of these species are now managed under a series of recovery plans prepared under the ESA ([Table 3-36](#)). The habitat requirements, distribution, and potential threats are discussed in the recovery plans. Recently listed species do not have recovery plans yet. Critical habitat has been designated for 323 of these plant species.

Animals

Thirty bird species are listed as threatened (1) or endangered (29). Listed bird species occur on all the main Hawaiian Islands. Forest birds comprise a large proportion of the threatened and endangered bird species. Many of these species are now confined to the remaining higher elevation native ecosystems. However, some species have adapted to areas with largely nonnative vegetation. Threatened and endangered forest birds are managed in accordance with several recovery plans and outlines ([USFWS 2006a](#), [2009b](#), [2010](#)). The Forest Bird Recovery Plan addresses 21 taxa of forest birds. The recovery plan provides detailed information on life history characteristics, current range and distribution, and recovery

areas for individual species. The endangered Hawaiian crow (*Corvus Hawai'iensis*) is managed under a separate recovery plan ([USFWS 2009b](#)). The Hawaiian crow is endemic to the island of Hawai'i and no individuals are known to exist in the wild; however, two populations remain in captivity at the Keauhou and Maui Bird Conservation Centers on Hawai'i and Maui islands, respectively. The Kaua'i Recovery Outline addresses multiple species including forest birds ([USFWS 2010](#)).

All six endemic species of Hawaiian waterbirds that persist today are listed as endangered ([USFWS 2011a](#)). Five of these six species, the Hawaiian duck or koloa maoli (*Anas wyvilliana*), Hawaiian coot or 'alae ke'oke'o (*Fulica alai*), Hawaiian common moorhen or 'alae 'ula (*Gallinula chloropus sandvicensis*), Hawaiian stilt or ae'o (*Himantopus mexicanus knudseni*), and the Hawaiian goose or nēnē (*Branta sandvicensis*), occur on the main Hawaiian Islands. The sixth species, the Laysan duck (*A. laysanensis*), exists only on Laysan Island and Midway Atoll. Management and recovery goals for these five species are found in two recovery plans ([USFWS 2011a](#), [2004](#)). Four of the species—excepting the Hawaiian goose—require wetlands.

One bird-of-prey, the Hawaiian hawk or 'io (*Buteo solitarius*), is listed as endangered and exists only on the island of Hawai'i ([USFSW 1984](#); [73 FR 45680, August 6, 2008](#)). The Hawaiian hawk had been considered for down listing to threatened in 1993, but that proposal was withdrawn in 2008 with a proposal to remove it from the threatened and endangered species list owing to recovery ([73 FR 45680, August 6, 2008](#); [74 FR 27004, June 5, 2009](#); [79 FR 8413, February 12, 2014](#)). The comment period on the proposal to delist the Hawaiian hawk has been reopened several times, and no final rule on the proposal has been published.

Two of Hawai'i's seabirds are listed as threatened or endangered. The dark-rumped or Hawaiian petrel (*Pterodroma phaeopygia sandwichensis*) is considered endangered and the Newell's shearwater (*Puffinus auricularis newelli*) is listed as threatened ([USFWS 1983](#)). The Newell's shearwater nests primarily on the island of Kaua'i although small colonies may occur on other islands ([USFWS 2011c](#)). The largest nesting colony of Hawaiian petrels occurs on Maui at Haleakala within the National Park. Other colonies of the Hawaiian petrel have been located on Kaua'i, Hawai'i, and Lāna'i ([USFWS 2011d](#)). Introduced predators and ungulates have significantly impacted nesting colonies of both species. Artificial lighting also causes disorientation in flying seabirds causing birds to fly in circles, leading to exhaustion and death (fallout). Recovery efforts have focused on reducing predation, destruction of colonies (e.g., by feral pigs), and artificial lighting.

The one native species of terrestrial mammal in Hawai'i, the Hawaiian hoary bat (*Lasiurus cinereus semotus*), is listed as endangered. The Hawaiian hoary bat is a solitary species that roosts in trees ([USFWS 1998a](#)). It is known from all the main islands except Lāna'i with largest populations thought to exist on Hawai'i, Kaua'i, and Maui. The hoary bat ranges across a wide range of habitats and elevations. Research is currently being performed to better understand the distribution, population status, and ecology of this species ([USFWS 2011e](#)).

Sixty-eight species or subspecies of Hawaiian invertebrates are listed as threatened or endangered ([Table 3-37](#)). Many of these species are managed under recovery plans ([USFWS 1992](#), [2005](#), [2006b](#), [2006d](#), [2011a](#), [2011b](#), [2012](#)). These species include a large group of endangered O'ahu tree snails (*Achatinella* spp.) that exist in dry to wet montane (higher than 1200 feet elevation) forests and shrublands. The most serious threats are predation by the introduced carnivorous snail, *Euglandina rosea*, and rats and loss of native vegetation ([USFWS 1992](#)). Hawai'i's tree snails are well known for their colorful and variable shells.

Another large group of endangered invertebrates is the picture-wing flies of the genus *Drosophila*. Each species of Hawaiian picture-wing fly is found on a single island and depends on a single or few related species of a native host plant ([USFWS 2006c](#)). Species occur on the islands of Kaua'i, O'ahu, Maui, Molokai, and Hawai'i. Critical habitat has been designated for each species.

Proposed Listing Actions

The USFWS and NMFS both have open listing actions in the main Hawaiian Islands that would designate additional species as threatened or endangered and designate critical habitat. On January 24, 2012, USFWS published a 90-day petition finding and initiation of a status review to determine if listing of the 'i'iwi (*Vestiaria coccinea*) as threatened or endangered is warranted ([77 FR 3423](#)). The 'i'iwi is an endemic bird in the Hawaiian honeycreepers subfamily and occurs on Hawai'i, Maui, Molokai, O'ahu, and Kaua'i, primarily in montane-wet, closed canopied forest.

On April 5, 2013 NMFS published a proposed rule for public comment that would designate two of six DPSs of the scalloped hammerhead shark as endangered, two DPS as threatened, and not list two as either threatened or endangered ([78 FR 20718](#)). The Central Pacific DPS that occurs around the Hawaiian Islands was one of the two DPS determined not to warrant listing. On December 7, 2012, NMFS published a proposed rule for public comment on the findings of a status review under the ESA of 82 reef-building coral species ([77 FR 73220](#)). Listing of six species of coral in the main Hawaiian Islands under the ESA was determined to be warranted. These species (*Acropora paniculata*, *Montispora dilatata*, *M. flabellata*, *M. turgescens*, *M. patula*, and *M. verrilli*) are now considered candidates for listing as threatened under the ESA. On March 3, 2015, the NMFS published a 90-day petition finding and initiation of a status review to determine if listing of the common thresher shark as threatened or endangered was warranted ([80 FR 11379](#)). The NMFS and USFWS published a proposed rule change to revise the listing status of the green sea turtle (green turtle) ([80 FR 15271, March 23, 2015](#)). The NMFS and USFWS recognize 11 DPSs of green turtles that qualify for listing under the ESA. The proposed rule would remove the current listing status of all green turtle populations and in its place list eight DPSs as threatened and three DPSs as endangered. The green turtle surrounding the Hawaiian Islands is part of the

Central North Pacific DPS and would remain listed as threatened under the proposed rule, the same status as that under the current listing.

The NMFS published a proposed rule change that would reclassify the global endangered populations of the humpback whale into 14 DPSs ([80 FR 22303, April 21, 2015](#)). The proposed rule would remove the current endangered listing status and in its place list two DPSs as endangered and two DPSs as threatened; the remaining ten DPSs would not be listed under the ESA. The Hawai'i breeding population of humpback whales would be classified as the Hawai'i DPS (Central North Pacific) and be one of the ten DPSs that would be delisted from the threatened or endangered species list. Protection and restoration efforts over the past 40 years have allowed recovery of many populations of the humpback whale. Even if the Hawai'i DPS is formally delisted pending review of the proposed rule, the species would retain the full legal protection of the *Marine Mammal Protection Act* and protected measures afforded by the Hawaiian Islands Humpback Whale National Marine Sanctuary.

3.4.3.1.2 Marine Threatened and Endangered Species

Compared with terrestrial species, Hawai'i has many fewer (8 versus 516) threatened and endangered marine species. These eight species include three endangered marine mammals, two endangered sea turtles, and three threatened sea turtles. NMFS has primary responsibility for threatened and endangered marine and anadromous species under the ESA. However, NMFS shares responsibility with the USFWS, especially for those species that depend on terrestrial habitats for part of their life cycle. Section 6 of the ESA provides for the development of cooperative agreements between either the USFWS or NMFS and individual states that establish and maintain a program of conservation for threatened and endangered species. Through the cooperative agreements, states can receive funding to assist in the recovery of listed species. On August 29, 2006, NMFS and the State of Hawai'i DLNR entered an agreement for the management of two marine mammals and two sea turtles (Hawaiian monk seal, humpback whale, hawksbill sea turtle, and green sea turtle).

The three endangered marine mammals include the humpback whale or kohola (*Megaptera novaeangliae*), Hawaiian monk seal or 'ilio-holo-i-kauaua (*Neomonachus schauinslandi*), and main Hawaiian Islands insular false killer whale (*Pseudorca crassidens*) distinct population segment. Of the five species of sea turtles, the leatherback (*Dermochelys coriacea*), the loggerhead (*Caretta caretta*), and olive-ridley (*Lepidochelys olivacea*) are considered incidental (rare or uncommon) in Hawai'i ([NMFS and USFWS 1998a](#), [1998b](#), [1998c](#), respectively). None of these three species nest in the Hawaiian Islands. Both the hawksbill (*Eretmochelys imbricata*) and green (*Chelonia mydas*) sea turtles nest in the Hawaiian Islands. Although sea turtles spend much of their lives at sea foraging and migrating long distances, some species forage in nearshore habitats and beach nesting habitat is a critical component of their life cycle. Loss of beach nesting habitat, destruction of nests by predators or harvesting by humans, and collection of adults all pose risks to sea turtle populations.

Humpback Whale

The humpback whale is a large (45 to 50 feet, 55,000 to 100,000 pounds) baleen whale that is distributed worldwide but was heavily exploited by commercial whalers and was listed as endangered when the ESA was passed in 1973 ([NMFS 1991](#); [Wilson and Ruff 1999](#)). Baleen whales feed largely on small schooling fish and krill (crustaceans) filtered from the large volume of water with which they fill their mouths. Populations of humpback whale exhibit fidelity between wintering areas and northern latitude summer feeding waters. The humpback whales that winter among the Hawaiian Islands are considered part of the Central North Pacific stock that migrates to summer feeding waters near northern British Columbia/Southeast Alaska, the Gulf of Alaska, and the Bering Sea/Aleutian Islands ([Allen and Angliss 2013](#)). Humpback whale abundance peaks in the February-to-March timeframe, but are common from December through May and seen as early as September and as late as June ([Darling 2001](#)). Humpback whales

usually spend much of their time in shallower water (less than 600 feet). Reproduction and calving typically occurs in the wintering areas, and cows with newborn calves often occupy shallow, inshore waters presumably to separate themselves from mating activity and harassment by males, more turbulent offshore conditions, and predators ([Darling 2001](#)).

The highest densities of humpback whales reportedly occur in the four-island region of Maui, Molokai, Lānaʻi, and Kahoʻolawe, on Penguin Bank west of Molokai, around Niʻihau Island, and the leeward coast of Hawaiʻi ([NMFS 1991](#)). Lower densities occur around Oʻahu and Kauaʻi. Potential threats to humpback whales include collisions with boats and ships, entanglement in fishing gear, and acoustic disturbance. The Hawaiian Islands Humpback Whale National Marine Sanctuary was created by Congress in 1992 to protect humpback whales and their habitat in Hawaiʻi. The sanctuary lies within the shallow (less than 600 feet), warm waters surrounding the main Hawaiian Islands (see [Figure 3-42](#)). Additional information on the Hawaiian Islands Humpback Whale National Marine Sanctuary and restrictions on activities within the sanctuary are provided in [Section 3.4.4.1.2](#).

Hawaiian Monk Seal

Hawaiian monk seals are distributed throughout the Northwestern Hawaiian Islands, with subpopulations at French Frigate Shoals, Laysan Island, Lisianski Island, Pearl and Hermes Reef, Midway Atoll, Kure Atoll, and Necker and Nihoa Islands. They also occur throughout the main Hawaiian Islands ([Carretta et al. 2013](#)). The current best minimum estimate of Hawaiian monk seals' abundance in the main Hawaiian Islands is 153 in 2010 ([Carretta et al. 2013](#)) or approximately 12 percent of the population. Current threats are human disturbance, intentional killing by humans, and entanglement in nearshore fishing gear and other marine debris. However, monk seal abundance is increasing on the main Hawaiian Islands. Monk seals spend nearly two-thirds of their time in the marine environment and are primarily benthic (ocean-floor) foragers. The main terrestrial habitat requirements include: haul-out areas for pupping, nursing, molting, and resting. These are primarily sandy beaches, but virtually all substrates are used at various islands ([NMFS 2007](#)). Monk seals tend to frequent remote areas with limited access and less human presence. The number of monk seal sightings tend to decrease from the northwest (Niʻihau/Kauaʻi) to the southeast (Hawaiʻi).

In 1988, NMFS designated critical habitat for the Hawaiian monk seal around the Northwestern Hawaiian Islands to a depth of 120 fathoms ([53 FR 18988, May 26, 1988](#)). On June 2, 2011, NMFS published a proposed rule to revised critical habitat for the monk seal by extending it out to the 500-meter (1,640-foot) depth in the Northwestern Hawaiian Islands and designating six new areas in the main Hawaiian Islands ([76 FR 32026](#)). Specific areas proposed for the main Hawaiian Islands include terrestrial and marine habitat from 5 meters inland from the shoreline extending seaward to the 500-meter (1,640-foot) depth contour around Kaula Island, Niʻihau, Kauaʻi, Oʻahu, Maui Nui (including Kahoʻolawe, Lānaʻi, Maui, and Molokai), and Hawaiʻi except those areas that have been identified in the Federal Register notice as not included in the designation. Excluded areas are largely related to military operations and have national security benefits. The comment period for the proposed revision of critical habitat was extended on June 25, 2012 for six months ([77 FR 37867](#)). A final rule on the new proposed critical monk seal habitat has not been published.

Insular False Killer Whale

Insular false killer whales are the second largest member of the dolphin family (*Delphinidae*) (3.3- to 6-meters long; maximum weight, 1,360 kilograms) and live in tropical and warm-temperate waters around the world ([Wilson and Ruff 1999](#)). On November 28, 2012, NMFS published a final rule listing the main Hawaiian Islands distinct population segment of the insular false killer whale as endangered ([77 FR 70915](#)). No critical habitat was designated. The insular false killer whale was listed following review of additional scientific information that the population of false killer whales inhabiting the waters surrounding the main Hawaiian Islands met the criteria as a separate stock or distinct population segment

from those inhabiting the waters around the Northwestern Hawaiian Islands ([77 FR 70915](#); [Carretta et al. 2013](#)). Genetic, photographic, and telemetry data suggest that the main Hawaiian Island insular and Northwestern Hawaiian Island distinct population segments may overlap in the region around the island of Kauaʻi. The best estimate of minimum abundance (distinct identified individuals) in the insular population is 129 ([Carretta et al. 2013](#)). Threats to the insular false killer whale include reduction in food availability (fish biomass) from commercial and recreational fisheries and incidental take in fisheries operations ([77 FR 70915](#)).

Hawksbill Turtle

Hawksbill turtle populations have greatly declined. In the central Pacific, nesting is widely distributed but in low numbers. The hawksbill turtle nests on the main island beaches of Hawaiʻi, primarily along the east coast of the island of Hawaiʻi ([NMFS and USFWS 1998d](#)). Two of these sites (Halape and ʻĀpuā Point) are in the Hawaiʻi Volcanoes National Park. Other beaches on Hawaiʻi with recorded hawksbill nesting include Kamehame, Punaluʻu, Horseshoe, Nīnole, Kawa, and Pohue ([NMFS and USFWS 1998d](#)). Nesting is also known to occur on the east end of Molokai. Peak nesting occurs from late July to early September but may occur anywhere from late May to early December. No critical habitat in the Hawaiian Islands has been designated for the hawksbill turtle.

Green Turtle

The green turtle is the most common sea turtle found in the Hawaiian Islands. Green turtles live in nearshore coastal habitats throughout Hawaiʻi with a high degree of fidelity to specific feeding locations ([NMFS and USFWS 1998e](#)). Green turtles are primarily herbivores, feeding largely on sea grasses and algae. Because green turtles live in shallower (less than 100 feet), nearshore habitats, they are vulnerable to habitat deterioration, entanglement in fishing line and other marine debris, boat strikes, and illegal harvesting. Although nesting occurs throughout the Hawaiian Archipelago, over 90 percent of nesting occurs at French Frigate Shoals in the Northwest Hawaiian Islands with minor nesting on Kauaʻi, Oʻahu, Molokai, Lānaʻi, and Maui ([NMFS and USFWS 1998e](#); [Maison et al. 2010](#)). Green turtles exhibit a high degree of fidelity to the beaches on which they were born. Therefore, excessive harvesting of turtles or eggs at a nesting site will not be replenished by recruitment from other nesting sites or necessarily by individuals that use foraging habitats nearby. No critical habitat in the Hawaiian Islands has been designated for the green turtle.

3.4.3.2 Migratory Birds Protection

In addition to those bird species protected under the ESA, those bird species listed as migratory species under the [Migratory Bird Treaty Act](#) are protected against take (including eggs, nests, and feathers), harm, and harassment. Many of the endangered bird species are residents. However, Hawaiʻi also seasonally supports a variety of migratory species that either are migratory transients between summer and winter habitats, winter migratory residents, or temporary residents for nesting (e.g., marine birds).

3.4.3.3 Marine Mammals Protection

All marine mammals ([Section 3.4.2.2](#)) are protected under the [Marine Mammal Protection Act](#). Those species listed as threatened and endangered receive additional protection under the ESA. The [Marine Mammal Protection Act](#) provides for certain authorized take of marine mammals provided that the taking (lethal, injurious, or harassment) is minimal and have a negligible impact on marine mammals. Marine mammals occur in all waters surrounding the main Hawaiian Islands.

3.4.3.4 Essential Fish Habitat

The [Magnuson-Stevens Fishery Conservation and Management Act](#) as amended by the *1996 Sustainable Fisheries Act* required that EFH be identified and described for all Federally managed species. EFH has been designated for the five fisheries (see [Section 3.4.2.4](#)) in Hawai‘i. EFH designations for managed species of bottomfish and seamount groundfish, crustaceans, pelagic fisheries, and precious corals fisheries were approved on February 3, 1999 ([64 FR 19067](#)). EFH designations for the species of the Coral Reef Ecosystem fishery were approved on June 14, 2002 ([69 FR 8336](#)). The EFH designations were made for the broader Western Pacific Regional Fishery which includes the main Hawaiian Islands.

The description of EFH for all five fisheries can be found in the *Fishery Ecosystem Plan for the Hawai‘i Archipelago* ([WPRFMC 2009a](#)) and the *Fishery Ecosystem Plan for the Pacific Pelagic Fisheries of the Western Pacific Region* ([WPRFMC 2009b](#)). The Western Pacific Regional Fishery Management Council designated EFH for adult and juvenile bottomfish as the water column and all bottom habitat extending from the shoreline to a depth of 1,200 feet encompassing the steep drop-offs and high-relief habitats that are important for bottomfish throughout the Western Pacific Region ([WPRFMC 2009a](#)). For the Crustacean fishery, the Council designated EFH for spiny lobster larvae as the water column from the shoreline to the outer limit of the United States exclusive economic zone (EEZ) (i.e., 200 miles) down to a depth of 150 meters (490 feet) throughout the Western Pacific Region. The EFH for juvenile and adult spiny lobster is designated as the bottom habitat from the shoreline to a depth of 100 meters throughout the Western Pacific Region. The EFH for deepwater shrimp eggs and larvae is designated as the water column and associated outer reef slopes between 550 and 700 meters (1,800 and 2,300 feet), and the EFH for juveniles and adults is designated as the outer reef slopes at depths between 300 and 700 meters (990 and 2,300 feet). For the precious coral fishery, the Council designated the six known beds of precious corals as EFH (see [Section 3.4.2.4](#)). In addition, the Council designated three black coral beds between Miloli‘i and South Point on Hawai‘i, Au‘au Channel between Maui and Lāna‘i, and the southern border of Kaula‘i as EFH. Because of the diversity of fish species managed under the Coral Reef fisheries, designation of EFH was more complex. The EFH for both currently harvested and potentially harvested coral reef fish can be summarized as the water column and all benthic (bottom) substrate to a depth of 300 feet from the shoreline to the outer limit of the EEZ ([WPRFMC 2009a](#)). Because of the uncertainty about the life histories and habitat utilization patterns of many pelagic fish species, a precautionary approach was taken by adopting a depth of 3,280 feet as the lower bound of EFH to the outer limits of the EEZ ([WPRFMC 2009b](#)). Collectively, the EFH designated for the five fisheries comprises most of the marine waters and ocean floor habitat surrounding the Hawaiian Islands.

3.4.4 PROTECTED LAND AND MARINE AREAS

Various land and marine areas within and surrounding the Hawaiian Islands are administratively protected, primarily for natural, cultural, and historic resources ([Loope and Juvik 1998](#)). These areas are managed by Federal agencies, State of Hawai‘i, and nongovernment organizations for the resources contained within their boundaries. While some State controlled land areas restrict development for other reasons (e.g., Department of Hawaiian Home Lands land assets designated for homesteading), the focus of protected land and marine areas discussed in this section are those that have high conservation value for biological resources. Some protected areas that have primary value for protecting cultural or historic resources (e.g., National Historical Parks, Trails, and Sites) are not discussed here but included in [Section 3.6](#). However, it is recognized that some protected historical or cultural sites also provide a measure of protection for biological resources. Because of land ownership and management goals for these protected areas, renewable energy development within their boundaries could be restricted and in some cases prohibited.

Information on protected areas was obtained from Federal and State agency websites as noted in the respective sections. As available, information on geographic location is provided for illustrative purposes

to provide geographical context. It is recognized that management goals and area boundaries for protected areas may change with time. Some areas are too small to illustrate in detail. The reader is encouraged to always reference the responsible Federal or State management agencies website or contact the agency for more detailed information for any protected area of interest.

3.4.4.1 Federally Protected Areas

Three Federal agencies manage protected land or marine areas in Hawai‘i. The U.S. National Park Service manages two National Parks and several National Historical Parks. NOAA manages the Hawaiian Islands Humpback Whale National Marine Sanctuary in cooperation with the State of Hawai‘i DLNR. The USFWS manages nine wildlife refuges on the main Hawaiian Islands.

3.4.4.1.1 National Parks

The National Park Service manages the Haleakalā National Park on Maui and Hawai‘i Volcanoes National Park on Hawai‘i. Both parks protect important Hawaiian biological resources in addition to other resources (e.g., water, geology, cultural). The National Park Service also manages several National Historical Parks in the islands (see [Section 3.6](#)).

Haleakalā National Park

[Haleakalā National Park](#), established in 1916, is located on the east side of Maui and extends from the ocean near Hana to the 10,023-foot summit of Mount Haleakalā. The park encompasses 30,183 acres of which 24,719 acres are designated as Wilderness Area. Because of the elevation range the park contains most of the native vegetation zones from alpine to lowland dry forest. However, lowland vegetation zones are represented by small remnant patches because of previous disturbances. A primary mission of the Haleakalā National Park is to manage and protect the remaining native Hawaiian plants and animals that live within the park boundaries. The nesting colony of the Hawaiian petrel or uau located near the top of Mount Haleakalā is the largest known for this seabird. The Hawaiian goose or nēnē also nests at Haleakalā.

Hawai‘i Volcanoes National Park

[Hawai‘i Volcanoes National Park](#), established in 1916, is located on the southern part of the island of Hawai‘i. Hawai‘i Volcanoes National Park protects approximately 333,000 acres of public land which includes some of the most unique geologic, biologic, and cultural landscapes in the world. Extending from sea level to the summit of Mauna Loa at 13,677 feet, the park encompasses the summits and rift zones of two of the world’s most active shield volcanoes—Kīlauea, representing the newest land in the Hawaiian Islands chain, and Mauna Loa, the largest mountain in the world. Because of its extensive elevation range, Hawai‘i Volcanoes National Park contains all of the major vegetation zones and has populations of many endangered species including the ‘āhinahina (Mauna Loa silversword), honu ea (hawksbill turtle), nēnē (Hawaiian goose), uau (Hawaiian petrel), io (Hawaiian hawk) and ‘ōpe‘ape‘a (Hawaiian hoary bat).

In addition to its geological and biological significance, the park also plays a unique role in the history of human development on the Hawaiian Islands and remains an important home to living cultures in Hawai‘i. Just as the volcanic and biological features of the land have shaped the landscape of Hawai‘i Volcanoes National Park, so too have the people who have been a part of its history. Over five centuries before the establishment of the park, Native Hawaiians lived, worked, and worshiped on this sacred ground. Later, in the 19th and early 20th centuries, adventurers, scientists, philanthropists, and other individuals also left their mark on the landscape. Today, ancient petroglyphs, stone walls, and footpaths persist between massive lava flows, and historic housing districts, ranch buildings, and historical roads

dot the developed corridors of the park, together revealing the diverse history and cultures that have been, and continue to play, an integral role in this landscape.

Kalaupapa National Historical Park

[Kalaupapa National Historical Park](#), established in 1980, is located on the northern coast of the island of Molokai. The park is extremely isolated and is accessible only by small aircraft, by mule or foot down the 2,000-foot sea cliffs, and by boat with special use permit. Managed through cooperative agreements between the NPS and the State of Hawai‘i, the park boundary protects 10,725 acres of land and water and includes numerous significant cultural and natural features associated with the Hansen’s disease settlement, Native Hawaiian culture, and sensitive ecosystems. The park includes hundreds of historic buildings, several cemeteries, and thousands of archaeological resources situated in a picturesque, *cultural landscape* that reflects the evolution of the settlement. Viewsheds to and from the park to the surrounding landforms and ocean are virtually unaltered from the historic period, creating an intact setting and feeling of isolation. Because of its high integrity and national cultural significance, the buildings and landscape at Kalaupapa have been designated a National Historic Landmark district. However, the main cultural resources for the park are the Hansen’s disease patients that continue to reside in the settlement today.

The natural resources of the park are similarly significant, with an abundance of geological, terrestrial, aquatic, and marine resources. Typically expanded over an entire island, the natural resources at Kalaupapa National Historical Park are additionally unique since they are concentrated within one location. Geological resources within the park include north shore cliffs that are some of the highest sea cliffs in the world, and are a designated National Natural Landmark. The intervening valleys, volcanic crater and crater lake, lava tubes, caves, and offshore islets are home to a number of terrestrial and aquatic resources, spanning numerous habitats from ohī‘a rain forest to a coastal spray area to freshwater streams. The terrestrial fauna and flora identified in the park comprise nearly 30 Federally listed threatened and endangered species of plants and animals. The park preserves some of the last remaining examples of indigenous plant and animal communities found nowhere else in the world, including the Hawaiian monk seal, loulou palm, montane wet forest, and coral reef communities. Important natural resources are listed as part of the Puu Alii Natural Area Reserve, Forest Reserve, Hawai‘i State Seabird Sanctuary, and National Natural Landmark.

3.4.4.1.2 National Marine Sanctuaries

National marine sanctuaries were established under the *National Marine Sanctuaries Act* ([16 U.S.C. § 1431 et seq.](#)) to protect areas of the marine environment with special national significance due to their conservation, recreational, ecological, historical, scientific, cultural, archeological, educational, or esthetic qualities. The management of national marine sanctuaries is the responsibility of the Office of National Marine Sanctuaries under the NOAA.

Hawaiian Islands Humpback Whale National Marine Sanctuary

The [Hawaiian Islands Humpback Whale National Marine Sanctuary](#) was created by Congress in 1992 to protect humpback whales and their habitat in Hawai‘i (see [Section 3.4.3.1.2](#)). The Hawaiian Islands Humpback Whale National Marine Sanctuary ranges from north to south through six of the eight main Hawaiian Islands ([Figure 3-42](#)). The primary purpose is to protect the endangered humpback whale and its habitat. Other marine species also benefit from this protected area. The sanctuary lies within the shallow warm waters surrounding the islands. Regulations restrict activities within the sanctuary including approach distances to whales by both boats and aircraft. Management includes efforts to reduce entanglement in marine debris (e.g., fishing gear), vessel-whale collisions, acoustic disturbance, and protect water quality. Because approximately 65 percent of the sanctuary waters fall under the jurisdiction of the State of Hawai‘i, the sanctuary is managed in full partnership with State agencies to ensure the coordinated management of sanctuary resources and habitats.

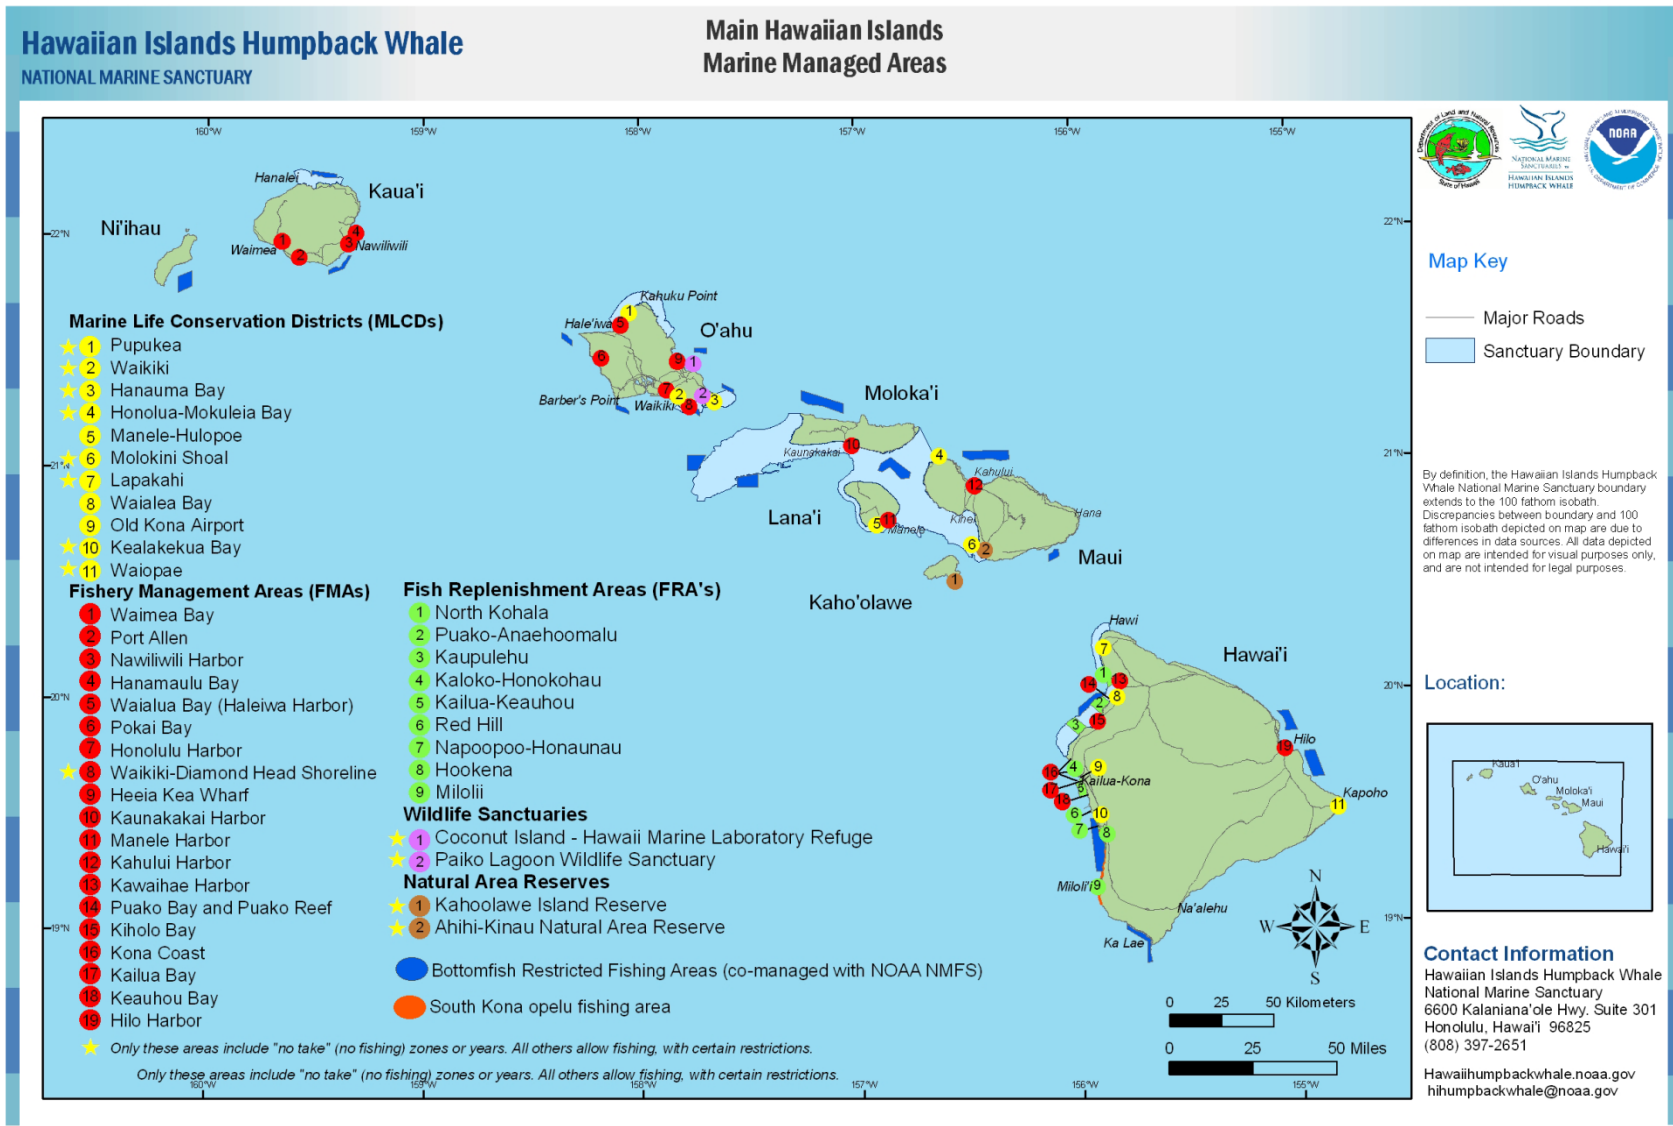

Figure 3-42. Location of the Hawaiian Islands Humpback Whale National Marine Sanctuary and Other Marine Managed Areas (Source: <http://hawaiihumpbackwhale.noaa.gov/documents/maps.html>)

3.4.4.1.3 National Wildlife Refuges

The mission of the [National Wildlife Refuge System](#) is to administer a national network of lands and waters for the conservation, management, and where appropriate, restoration of the fish, wildlife, and plant resources and their habitats within the United States for the benefit of present and future generations of Americans. The administration and management of the National Wildlife Refuge System is the responsibility of the USFWS. Information on the National Wildlife Refuges is from the USFWS Website of Pacific Island Refuges.

Hakalau Forest National Wildlife Refuge

[Hakalau Forest National Wildlife Refuge](#) was established in 1985 to protect and manage endangered Hawaiian forest birds and their rainforest habitat. Located on the windward slope of Mauna Kea, Island of Hawai‘i, the 32,733-acre Hakalau Forest Unit supports a diversity of native birds and plants equaled by only one or two other areas in the State of Hawai‘i.

Eight of the 14 native bird species occurring at Hakalau are endangered. Thirteen migratory bird species and 20 introduced species, including eight game birds, as well as the endangered ‘ōpe‘ape‘a (Hawaiian hoary bat) also frequent the refuge. Twenty-nine rare plant species are known from the refuge and adjacent lands. Twelve are currently listed as endangered. Two endangered lobelias have fewer than five plants known to exist in the wild.

In 1997, the USFWS purchased approximately 5,300 acres of land to create the Kona Forest Unit of Hakalau Forest National Wildlife Refuge. The Kona Forest Unit includes lands within the Hookena and Kalahiki land divisions on the western slopes of Mauna Loa, at elevations between 2,000 and 6,000 feet. Kona Forest Unit is located approximately 23 miles south of Kailua-Kona. The primary purpose for establishing the Kona Forest Unit is to protect, conserve, and manage this native forest for [threatened](#) or [endangered species](#). Of particular concern was the ‘alala (*Corvus Hawai‘iensis*), whose wild population is known only from the west side of Hawai‘i island. The Kona Forest Unit also offers protected areas for other endangered species, including the Hawai‘i ‘akepa (*Loxops coccineus*), Hawai‘i creeper (*Oreomystis mana*), ‘akiapōla‘u (*Hemignathus munroi*), io (Hawaiian hawk), and ‘ōpe‘ape‘a (Hawaiian hoary bat), as well as, several endangered plants and an insect.

Hanalei National Wildlife Refuge

[Hanalei National Wildlife Refuge](#) is located in the Hanalei Valley on the north shore of Kaua‘i. The refuge was established under the ESA to conserve five endangered water birds that rely on the Hanalei Valley for nesting and feeding habitat: the koloa maoli (Hawaiian duck), the ‘alae ke‘oke‘o (Hawaiian coot), the ‘alae ‘ula (Hawaiian moorhen), the ae‘o (Hawaiian stilt), and the nēnē (Hawaiian goose). Forty-five other species of birds (18 of which are introduced species) also use the refuge.

The refuge is a relatively flat river valley ranging from 20 to 40 feet above sea level and surrounded by steep, wooded hillsides, up to 1,000 feet high. The water from the Hanalei River is diverted into an east and west supply ditch. It then flows northwest and irrigates approximately 75 acres of wildlife and impoundments, 180 acres of taro patches, and 90 acres of wet pasture before returning to the river. Hanalei National Wildlife Refuge is closed to the public to minimize disturbance and protect endangered waterbirds.

Huleia National Wildlife Refuge

Located on the southeast side of Kaua‘i, [Huleia National Wildlife Refuge](#) lies adjacent to the Menehune Fish Pond, a registered site on the [National Register of Historic Places](#). The Huleia Refuge is approximately 241 acres and was purchased from the Grove Farm Corporation in 1973 to provide open, productive wetlands for five endangered Hawaiian waterbirds that rely on the Huleia River Valley for

nesting and feeding habitat. The refuge is located in a relatively flat valley along the Huleia River bordered by a steep wooded hillside. This land was used for wetland agriculture including taro and rice, but is managed today as a refuge for wildlife.

Thirty-one species of birds, including endangered ae‘o (Hawaiian stilt), ‘alae ke‘oke‘o (Hawaiian coot), ‘alae ‘ula (Hawaiian moorhen), nēnē (Hawaiian goose), and koloa maoli (Hawaiian duck) can be found here. Twenty-six other species of birds (18 of which are introduced species) also use the refuge. In order to protect the endangered species that live in Huleia National Wildlife Refuge, it is closed to the public but can be viewed at an overlook maintained by the State of Hawai‘i at the historic Menehune Fish Pond.

James Campbell National Wildlife Refuge

[James Campbell National Wildlife Refuge](#) is located near the northernmost point on the North Shore of O‘ahu. It was established in 1976 to provide habitat for Hawai‘i’s four endangered waterbirds: ae‘o (Hawaiian stilt), ‘alae ke‘oke‘o (Hawaiian coot), ‘alae ‘ula (Hawaiian moorhen), and koloa maoli (Hawaiian duck). As part of the O‘ahu National Wildlife Refuge Complex, the refuge consists of both natural and artificially maintained wetlands. Two wetland units are included within the James Campbell Refuge, the Ki‘i Unit (126 acres) and the Punamano Unit (134 acres). The wildlife refuge was expanded to 1,100 acres in 2005.

The refuge provides protection for endangered Hawaiian waterbirds, migratory shorebirds, and waterfowl, as well as native plants that rely on coastal wetlands and surrounding lands. Protection of two miles of the dune and strand vegetation along the coast conserves resting habitat for the endangered Hawaiian monk seal and nesting habitat for threatened green turtles and seabirds. The refuge provides a strategic landfall for migratory birds coming from Alaska, Siberia, and Asia.

Kakahaia National Wildlife Refuge

[Kakahaia National Wildlife Refuge](#) on the island of Molokai is part of the Maui National Wildlife Refuge Complex. It was established in 1976 to permanently protect wetland habitat for endangered waterbirds, primarily Hawaiian stilt and Hawaiian coot, and to provide habitat for wintering migratory wetland birds.

The refuge contains a 15-acre coastal freshwater marsh. This spring-fed pond lies on a narrow plain just above sea level at the foot of volcanic hills. An additional 5.5-acre managed impoundment was constructed in 1983 to provide shallow-water habitat for wading birds. Kamehameha V Highway bisects the southern part of the refuge, allowing access to the coastal portion managed as a park by the County of Maui.

Kealia Pond National Wildlife Refuge

Established in 1992, [Kealia Pond National Wildlife Refuge](#) encompasses approximately 700 acres and is one of the few natural wetlands remaining in the Hawaiian Islands. Located along the south-central coast of the island of Maui, between the towns of Kihei and Mā‘alaea, it is a natural basin for a 56-square-mile watershed from the West Maui Mountains.

The seasonal conditions that occur at Kealia Pond National Wildlife Refuge provide habitat for endangered wetland birds, along with a diversity of migratory birds from as far away as Alaska and Canada, and occasionally from Asia.

Kīlauea Point National Wildlife Refuge

[Kīlauea Point National Wildlife Refuge](#) was established in 1985 to preserve seabird nesting colonies on the steep seaside cliffs. The refuge is located on the northernmost point of Kaua‘i along the island’s north coast ([Figure 3-43](#)). The refuge was expanded in 1988 to include Crater Hill and Mokolea Point. The

refuge is home to some of the largest populations of nesting seabirds in the main Hawaiian Islands. It also contains native Hawaiian coastal plants and Hawai‘i’s State bird, the nēnē or endangered Hawaiian goose.

O‘ahu Forest National Wildlife Refuge

[O‘ahu Forest National Wildlife Refuge](#) is home to at least four species of endangered pupu kani oe (O‘ahu tree snails); 15 endangered plant species; and many native birds, including the O‘ahu ‘elepaio, ‘i‘iwi, pueo, and native honeycreepers. The refuge is located on the upper slopes of the northern Ko‘olau Mountains and contains some of the last remaining native intact forests on O‘ahu. The primary purpose of the refuge is to protect native biodiversity threatened by nonnative plants and animals.

Figure 3-43. Kilauea National Wildlife Refuge, Kilauea Point and Bay

areas most important to fish, wildlife, and plant conservation.

Pearl Harbor National Wildlife Refuge

[Pearl Harbor National Wildlife Refuge](#) was established in 1972 as mitigation for construction of the Honolulu International Airport Reef Runway. The Honouliuli and Waiawa Units are managed under a cooperative agreement with the U.S. Navy. The Kalaeloa Unit was established during military base closure proceedings in 2001.

Pearl Harbor National Wildlife Refuge, in close proximity to historic visitor attractions such as the *USS Arizona* and the *USS Missouri*, serves to protect some of the last remaining wetland areas on O‘ahu. The refuge protects endangered wildlife and sensitive habitats along O‘ahu’s coastal area.

3.4.4.2 State-Protected Areas

The State of Hawai‘i manages a variety of protected areas, each with different management goals and objectives ([Loope and Juvik 1998](#)). Information is provided in the following sections those

3.4.4.2.1 State Forest Reserves

Forest Reserves are multi-use land areas that encompass and incorporate a variety of public uses and benefits. Each forest reserve within the system has different management and use goals depending on the nature of the resources found within the reserve. Management goals include protecting forested watersheds to produce fresh water supplies, maintaining biological integrity of native ecosystems, providing public recreational opportunities, and producing a sustainable supply of forest products. The Hawai‘i Forest Reserve System was created in 1903 and now includes approximately 642,000 acres. The forest reserves are managed by the Division of Forestry and Wildlife within the Hawai‘i DLNR. Management plans have been prepared for some but not all forest reserves. Management plans and more detailed information on individual forest reserves are available on the Hawai‘i Forest Reserve System Website (<http://dlnr.hawaii.gov/forestry/frs/>). The island of Hawai‘i has the most acreage of forest reserves with 443,000 acres. Kaua‘i has the second most acreage with 86,000 acres. Of the six main islands, only Lāna‘i has no forest reserve as the island is mostly privately owned.

3.4.4.2.2 Marine Life Conservation Districts

The variety of marine life and habitats that exist in the nearshore waters of the Hawaiian Islands is one of the important natural resources of the State. Approximately 400 species of inshore and reef fishes inhabit coastal waters of Hawai‘i. Marine Life Conservation Districts were designed to conserve and replenish

marine resources. Fishing and other consumptive uses are limited or may be prohibited in Marine Life Conservation Districts (Table 3-38). They provide fish and other aquatic life with a protected area in which to grow and reproduce, and are home to a great variety of species. Fishes in most Marine Life Conservation Districts are fairly tame and often show little fear of humans. Marine Life Conservation Districts are most popular as sites for snorkeling, diving and underwater photography.

Table 3-38. Marine Life Conservation Districts

Island/Marine Life Conservation District Name	Size (acres)
O'ahu	
Hanauma Bay	101
Pupukea	(a)
Waikīkī	76
Maui County	
Honolua-Mokule'ia Bay	45
Manele-Hulopo'e	309
Molokini Shoal	77
Hawai'i	
Kealakekua Bay	315
Lapakahi	146
Old Kona Airport	217
Waialea Bay	35
Waiopae Tidepools	(a)

a. No acreage available.

The locations of the 11 Marine Life Conservation Districts are illustrated (in yellow) in Figure 3-42. Compared with many land-based conservation areas, Marine Life Conservation Districts are relatively small, the largest being Kealakekua Bay at 315 acres with many being less than 100 acres. The DLNR Division of Aquatic Resources provides detailed descriptions of each Marine Life Conservation District including location, history, marine resources, safety considerations, facilities, and regulations (<http://dlnr.hawaii.gov/dar/marine-managed-areas/hawaii-marine-life-conservation-districts/>).

3.4.4.2.3 Natural Area Reserves

The State of Hawai'i's Natural Area Reserve System was established to preserve in perpetuity specific land and water areas that support natural flora and fauna communities, as relatively unmodified as possible, as well as geological sites, of Hawai'i. The system presently consists of 20 reserves on five islands, encompassing 123,431 acres of the State's most unique ecosystems (Lāna'i is 98 percent privately owned and there are no natural area reserves on the island). The diverse areas found in the Natural Area Reserve System range from marine and coastal environments to lava flows, tropical rainforests, and even an alpine desert. Within these areas one can find rare *endemic* plants and animals, many of which are endangered. The reserves also protect some of the major watershed areas which provide sources of fresh water. The DLNR Division of Forestry and Wildlife administers the Natural Area Reserves System (<http://dlnr.hawaii.gov/ecosystems/nars/>). The following sections briefly discuss the natural area reserves on the five islands.

Kaua'i

Hono O Nā Pali Natural Area Reserve

Hono O Nā Pali Natural Area Reserve occupies 3,579 acres northwest side of the island of Kaua'i and contains lowland mesic forest and shrub, lowland wet forest, and montane wet forest. The Reserve

includes perennial streams, rare plants, endemic stream fauna, and forest bird and seabird habitat. The Reserve stretches from sea level along the Nā Pali coast to the highest point at Pihea (4,284 feet).

Ku'ia Natural Area Reserve

Ku'ia Natural Area Reserve occupies 1,636 acres on the west side of Kaua'i. Elevation ranges from 2,000 to 3,900 feet, encompassing lowland dry shrubland and lowland mesic, montane mesic, and montane wet forest. Many rare plant taxa are found within the Reserve's mesic and wet forests. The Ku'ia Reserve protects important rare native communities and associated rare species).

O'ahu

Ka'ena Point Natural Area Reserve

Ka'ena Point, the westernmost point on O'ahu, is the site of one of the last intact dune ecosystems in the main Hawaiian Islands. The Reserve protects native coastal Hawaiian plants and animals that have been largely displaced on most coastal areas. During the winter breeding season, humpback whales will frequent the waters surrounding Ka'ena Point.

Pahole Natural Area Reserve

The 685 acre Pahole Reserve was established in 1981 on the north end of the Wai'anae Range on the west side of O'ahu. It protects rare Hawaiian plants, animals, and ecosystems of the lowland mesic zone. The mesic gulches are home to more species of native trees than the lush Hawaiian rainforests.

Mount Ka'ala Natural Area Reserve

Mount Ka'ala, the highest peak on the island of O'ahu, rises to 4,025 feet in the Wai'anae Range on the west side of O'ahu. Established in 1981, the Mount Ka'ala Reserve comprises 1,100 acres of rugged mountain terrain. Most of the reserve's area consists of steep-sided gulches and ridges that form the eastern flank of Mount Ka'ala. It protects rare Hawaiian plants, animals, and ecosystems, most found only in Hawai'i. The Reserve contains all the lowland and montane ecosystems including lowland dry forests that once covered the drier portions of O'ahu, but are now nearly gone.

Molokai

Puu Alii Natural Area Reserve

Puu Alii Reserve is located in the mountains of northern Molokai and includes 1,330 acres. It is a wet summit plateau inhabited by wet forests, mixed fern and shrub montane cliff communities, and wet shrublands, and Hawaiian intermittent stream communities. Puu Alii reserve is an important part of the Molokai watershed and contains forest bird habitat. The Puu Alii Reserve is located within the Kalaupapa National Historic Park.

Olokui Natural Area Reserve

Olokui Reserve encompasses 1,620 acres of an isolated, cloud-shrouded mountain plateau with slopes extending down to sea cliffs. The reserve is located in the eastern half of Molokai along the north coast and is one of the few areas left undisturbed by feral ungulates. It contains wet and dry ecosystems and coastal dry grasslands. Lowland and montane wet and mesic forests are also represented. Surveys of this area have confirmed the presence of rare snails.

Maui

'Ahihi-Kina'u Natural Area Reserve

The 'Ahihi-Kina'u Natural Area Reserve is located on the southwest corner of the island of Maui and was the first designated Natural Area Reserve in 1973. The 1,238 acres contain marine ecosystems (807 submerged acres), rare and fragile [*anchialine ponds*](#), and lava fields from the last eruption of Haleakalā 200 to 500 years ago, native plant communities that include naio, wiliwili and native cotton exist in

kipuka, or pockets, but are severely imperiled by the encroachment of weeds and feral ungulates such as goats. A coral reef survey done by the Division of Aquatic Resources in 2007 indicated that the reef community within the NAR boundary waters was the only reef from their test sites that was not declining overall. Preserving the integrity of the anchialine pools is a major management focus. All access to them is closed. Main threats to these wetlands include nonnative invasive species such as fish or prawns, algal mat formations, and human disturbance.

Hanawi Natural Area Reserve

The Hanawi Natural Area Reserve encompasses 7,500 acres on the wet slopes on the north flank of Mount Haleakalā. This Reserve extends into subalpine zones of East Maui and includes rare subalpine grassland, as well as montane and lowland mesic and wet grasslands and forests. The reserve protects rare plants and contains habitat for the State's largest concentration of rare and endangered Hawaiian birds.

Kanaio Natural Area Reserve

Kanaio Natural Area Reserve is 876 acres and located in rough lava terrain on the southeast slope of Mount Haleakalā. The reserve protects a remnant of the native dryland forest that once covered the leeward slope of Mount Haleakalā. Kanaio protects a rich assemblage of native dryland trees and shrubs. There are large stands of halapepe.

Nakula Natural Area Reserve

The Nakula Natural Area Reserve encompasses 1,420 acres. This reserve contains a rare leeward koa-ohia forest and alpine shrublands on the south slope of Haleakalā. The reserve is potential reintroduction site for endangered birds.

West Maui Natural Area Reserve

The West Maui Natural Area Reserve comprises four separate units for a total of 6,702 acres. The reserve encompasses lowland and montane native communities ranging from dry grasslands to wet 'ohi'a forests. The reserve also includes bogs, montane lakes, forest bird habitat, and rare and endangered plants. The areas are extremely important watershed sites which contain the headwaters of perennial streams. This reserve is made up of four noncontiguous sections: Honokōwai, Kahakuloa, Pana'ewa, and Lihau. All sections of the reserve contain rare plants.

The Honokōwai section (750 acres) is on the wet upper northern slopes of the West Maui Mountains. The native communities include two kinds of rare bogs, as well as wet forests, shrublands, and a montane lake. The Kahakuloa section (3,275 acres) lies on wet, windward slopes of the West Maui Mountains. The plateau of Eke Crater is still undisturbed by feral ungulates. This section includes the upper reaches of two perennial streams, and includes a rare montane bog surrounded by 'ohi'a wet forests. Pana'ewa (1,717 acres) includes a rare montane bog, as well as representative 'ohi'a forests and shrublands. The Lihau section is the driest of the four sections of the West Maui Natural Area Reserve. Lihau is a steep-sloped volcanic remnant that extends from dry leeward lowlands to a wet summit with cliffs on all sides.

Hawai'i Island

Kahaualea Natural Area Reserve

Kahaualea Natural Area Reserve (22,520 acres) can be found on the gentle slopes of Kīlauea; site of much recent volcanic activity. Kahaualea includes representatives of pioneer vegetation on lava flows, lowland rainforest and mesic forest. The largest population of *Adenophorus periens*, an endangered fern, is found in Kahaualea.

Kipahoehoe Natural Area Reserve

Kipahoehoe Natural Area Reserve (5,583 acres) is a narrow piece of land running down the southwest slopes of Mauna Loa in the district of South Kona. It includes a rare lowland grassland, as well as mesic and wet forests of 'ohi'a and koa. Recent volcanic flows run through the Reserve, leaving a variety of different aged communities.

Laupahoehoe Natural Area Reserve

Laupahoehoe Natural Area Reserve is located on the windward slopes of Mauna Kea and stretches from just above 1,600 feet to about 4,600 feet in elevation. Hakalau National Wildlife Refuge is adjacent to Laupahoehoe Reserve, and also protects habitat for several endangered forest birds known to occur in Laupahoehoe Reserve. Five native natural communities can be observed in the Reserve, including a tall-stature koa-'ohi'a forest in both montane and lowland zones, 'ohi'a/hapu'u (*Cibotium* spp.) forest, *Carex alligata* wet grassland, and nonnative dominated patches.

Manuka Natural Area Reserve

Manuka Natural Area Reserve is the largest reserve (25,550 acres) in the State's system. Extending from sea level to 5,000 feet in elevation, this reserve features a broad range of habitats. These include subalpine shrublands and forests, mesic montane kipuka forests, wet montane forests, lowland mesic and dry forests, and lava anchialine pools. Recent lava flows add a variety of pioneer vegetation types, as well as uncharacterized and unsurveyed lava tubes. Concentrations of the Hawaiian hoary bat occur in the area.

Mauna Kea Ice Age Natural Area Reserve

Located in the upper, southern flank of Mauna Kea, the 3,894 acre Mauna Kea Ice Age Natural Area Reserve contains a rare alpine aeolian desert dominated by invertebrates and the only alpine lake in Hawai'i. Rare native invertebrates and evidence of Pleistocene glaciation can be found. The area also contains important cultural resources as it was once a Hawaiian adze quarry site.

Puu Makaala Natural Area Reserve

The wet koa and 'ohi'a forest of the Puu Makaala Natural Area Reserve (18,730 acres) on the northeast flank of Mauna Loa are important habitat for some of Hawai'i's rarest birds, as well as several rare plants. Montane wet grassland occurs in the poorly drained portions of the Reserve.

Pu'u O Umi Natural Area Reserve

The Pu'u O Umi Natural Area Reserve (10,142 acres) includes the wet summit lands of the Kohala Mountains in the northern part of the island, with two rare kinds of montane bogs surrounded by 'ohi'a forests, shrublands, and grasslands. The Reserve extends downslope to the Kohala sea cliffs and coastal dry grassland. Rare plants are known from bogs and forests. The steep cliffs of Waipio and Waimanu valleys form part of the Reserve boundary. Numerous streams run through the area. The Reserve is an important watershed for the region. The Reserve contains habitats for several rare plants and animals such as the endangered *koloa* (Hawaiian duck).

Waiakea 1942 Lava Flow Natural Area Reserve

A recent lava flow being recolonized by young 'ohi'a forest dominates this Reserve. Other successional communities in a montane wet 'ohi'a forest ecosystem are also represented. This Reserve (640 acre) is located on the sloping northeast flank of Mauna Kea.

3.4.4.2.4 State Wildlife Sanctuaries

State wildlife sanctuaries or management areas include an array of areas set aside or recognized as important areas to protect individual or groups of rare or endangered animals and plants ([Loope and Juvik](#))

1998). Although most are managed by the Division of Forestry and Wildlife or Division of Aquatic Resources, several exist on military lands or waters (Table 3-39). Two wildlife sanctuaries are discussed and illustrated in the following paragraphs.

Figure 3-44. Kanaha Pond State Wildlife Sanctuary

Kanaha Pond State Wildlife Sanctuary is a 143-acre wetland located on the north coast of Maui near Kahului (Figure 3-44). It is a waterfowl sanctuary, home to three endangered Hawaiian bird species, the Hawaiian coot (‘alae ke‘oke‘o) (*Fulica alai*), the Hawaiian duck (koloa) (*Anas wyvilliana*), and the Hawaiian (or black-winged) stilt (ae‘o) (*Himantopus mexicanus knudseni*). Kanaha Pond was designated a State sanctuary in 1951.

Thirty-eight islets offshore from the Hawaiian Islands have been integrated into a State Seabird Sanctuary for nesting seabirds (Table 3-39). O‘ahu has 17 islets along its windward coast, 13 of which are designated Hawai‘i State Seabird Sanctuaries (DLNR 2006) (Figure 3-45). Approximately 150,000 to 200,000 breeding individuals nest in dense colonies on 11 of these offshore islets and a few on-shore sites. Efforts have been made to restore and improve seabird nesting colonies on these islands through removal of nonnative predators (e.g., rats) that prey on eggs and hatched young and nonnative vegetation that over grow nesting sites. The re

Figure 3-45. Moku Manu (Bird Island) Islet off the Windward Coast of O‘ahu (Source: Starr and Starr 2006)

removal of nonnative predators (e.g., rats) that prey on eggs and hatched young and nonnative vegetation that over grow nesting sites. The re

The Puu Waawaa Forest Bird Sanctuary was established by the State Board of Land and Natural Resources in 1984 to protect habitat for endangered forest birds, especially the Hawaiian crow (*Corvus Hawai‘iensis*) (Griffin 2003). It is located on the leeward side or northern flank of the Hualālai volcano on the island of Hawai‘i. It was officially designated a State wildlife sanctuary in 2002 managed by the Hawai‘i Division of Forestry and Wildlife. In 2007 its designation was officially changed to a forest reserve (see Section 3.4.4.2.1).

Table 3-39. Wildlife Sanctuaries and Wildlife Management Areas

State/Sanctuary or Management Area	Size (acres)	Primary Biological Resource
Kaua'i		
Kawai'ele Wildlife Sanctuary	37	Waterbirds, migratory shorebirds, seabirds, migratory waterfowl
Alaka'i Wilderness Preserve	9,939	Forest birds, short-eared owl, Hawaiian duck, terrestrial invertebrates, rare plants
O'ahu		
Kawai Nui and Hāmākua Marsh Complex	850	Waterbirds, migratory shorebirds, Hawaiian stream gobies, freshwater shrimp
Nuupia Pond Wildlife Management Area, U.S. Marine Corps Base Hawai'i	482	Waterbirds, migratory shorebirds, seabirds, particularly wedge-tailed shearwater
Paiko Lagoon	40	Migratory shorebirds
Pouhala Marsh Wildlife Sanctuary	70	Waterbirds, particularly Hawaiian stilt
Ulupau Wildlife Management Area, U.S. Marine Corps Base Hawai'i	23	Seabirds, particularly red-footed booby
Nearshore waters surrounding Kāne'ohe Marine Corps Base, U.S. Marine Corps Base Hawai'i	(a)	Marine invertebrates, coral reef fishes, and sea turtles
Coconut Island Wildlife Sanctuaries	(a)	Marine species
Molokai		
North and West Shore Coastal Strand	(a)	Seabirds, Hawaiian monk seal, and sea turtles
Ilio Point, State Land	(a)	Seabirds
Maui		
Kanaha Wildlife Sanctuary	235	Seabirds, waterbirds, migratory birds, terrestrial invertebrates
Hawai'i		
Kīpuka Āinahou Nēnē Sanctuary	11,157	Hawaiian goose, forest birds, terrestrial invertebrates, rare plants, and public hunting
Puu Waawaa Wildlife Sanctuary	3,806	Hawaiian hoary bat, forest birds, Hawaiian hawk, short-eared owl, Hawaiian goose, recovery habitat for Hawaiian crow, terrestrial invertebrates, including rare moths and insects, rare plants.
State Seabird Sanctuary		
Kaua'i (3 islets)	(a)	The species vary by island but collectively the State Seabird Sanctuary serves to protect the many species of seabirds that forage in the ocean waters surrounding the Hawaiian Islands and use the islets for breeding and nesting. For island specific information refer to Mitchell et al. 2005 or Harrison 1990 . The islets also serve as habitat for a variety of migratory shorebirds.
O'ahu (13 islets)	(a)	
Molokai (7 islets)	(a)	
Lāna'i (4 islets)	(a)	
Maui (8 islets)	(a)	
Hawai'i (3 islets)	(a)	

(a) = acreage unavailable.

3.4.4.3 Nongovernment Organization Lands and Public-Private Partnerships

In addition to Federal and State administratively protected land areas, a variety of other nongovernment organizations are involved in the management and conservation of biological and other natural resources (e.g., water) of the Hawaiian Islands. These include national conservation organizations such as The Nature Conservancy, corporations with large land holdings, land trusts, and organizations with vested interest in natural resources such as water management companies or irrigation districts. Government

agencies also may form public-private partnerships with nongovernment organizations to develop management plans for particular land units or watersheds.

The Nature Conservancy is actively involved in the management and conservation of biological resources throughout the Hawaiian Islands and manages nature preserves throughout the islands (<http://www.nature.org/ourinitiatives/regions/northamerica/unitedstates/Hawai'i/index.htm>). [Mitchell et al. \(2005\)](#) provides a general list by island of some of the nongovernmental organizations and public-private partnerships that manage land for the purposes of conserving and protecting biological resources. The Farm Service Agency (FSA) in the U.S. Department of Agriculture administers the [Conservation Reserve Program](#), whose purpose is to assist private landowners in conserving soil, water, and wildlife resources on farms and ranches. The Conservation Reserve Program participants enter into 10- to 15-year contracts for converting lands to conservation purposes. In 2006, the FSA prepared a programmatic environmental assessment to evaluate potential impacts of implementing the [Hawai'i Conservation Reserve Enhancement Program Agreement](#) between the U.S. Department of Agriculture and the State of Hawai'i. The Agreement is designed to enroll 30,000 acres of cropland and marginal pastureland in 15-year Conservation Reserve Program agreements on Hawai'i, Molokai, Maui, O'ahu, Maui, and Kaua'i with the primary goal of reducing soil erosion and improving water quality. These agreements would limit the potential land uses on these private lands for the term of the contract.

Conservation practices and agreements (i.e., contracts, management plans, and easements) on private and nongovernment organizations lands may create areas of important biological resources or establish areas where development of renewable energy projects may be restricted. In 2010, 13 land trusts were operating in Hawai'i, protecting approximately 20,000 acres (Land Trust Alliance 2010). In 2011, four land trusts, the Kaua'i Public Land Trust, O'ahu Land Trust, Maui Coastal Land Trust, and the Hawai'i island Land Trust merged to form the Hawaiian Islands Land Trust and oversee approximately 15,000 acres of conservation lands (<http://www.unpo.org/article/12098>).

3.4.4.4 Distribution of Protected Land and Marine Areas

Protected land and marine areas occur throughout the islands and in the surrounding ocean and serve to protect, conserve, or sustainably use biological resources. Protected land and marine areas for each island include a variety of different designations and uses and include national and State parks and monuments, national wildlife refuges, wildlife sanctuaries, marine sanctuaries, forest reserves, natural area reserves, nature preserves, [EFH](#), and designated critical habitat for threatened and endangered species. An overview of these areas is provided for each island in the following sections.

Important biological resources are not limited to protected land and marine areas as many species are highly mobile (e.g., birds, the hoary bat, marine mammals and reptiles) and use any suitable habitat available. Not all areas that contain high quality habitat or have important populations of plants and animals are within land or marine areas that have some level of protective status. However, protected area may be important to the long-term conservation of some species. Protected areas also have restricted uses that would limit or even prohibit their potential use for renewable energy development.

3.4.4.4.1 Kaua'i

Approximately 38 percent of the island is dominated by native vegetation ([Mitchell et al. 2005](#)). Most of the remaining native ecosystems occur in the central highlands and consists of montane mesic and wet forest, bogs, and cliff ecosystems ([Figure 3-46](#)) ([TNC 2006](#)). Much of the central highlands and western part of Kaua'i contains most of the administratively protected land including parks, natural area reserves, forest reserves, and wildlife refuges. There are also several lower elevation forest reserves and wildlife refuges in the east and northern part of the island.

Kaua‘i contains a wide variety of threatened and endangered species including one terrestrial mammal, many species of birds, invertebrates, and several species of marine mammals and reptiles. Approximately 55,000 acres of critical habitat have been designated on Kaua‘i. Much of the designated critical habitat overlaps with many of the administratively protected land areas.

The ocean sea slope surrounding Kaua‘i is relatively steep with the 600 foot contour depth typically only two to five miles offshore. Kaua‘i has one of the two barrier coral reefs in the islands on its west coast. Fringing coral reefs also occur offshore. Part of the Hawaiian Islands Humpback Whale National Marine Sanctuary occurs along the Kaua‘i’s north coast.

The ocean waters surrounding Kaua‘i have been designated EFH for the bottomfish, crustacean, and coral reef fisheries. The south sea slope of Kaua‘i is classified as EFH for the precious coral fishery.

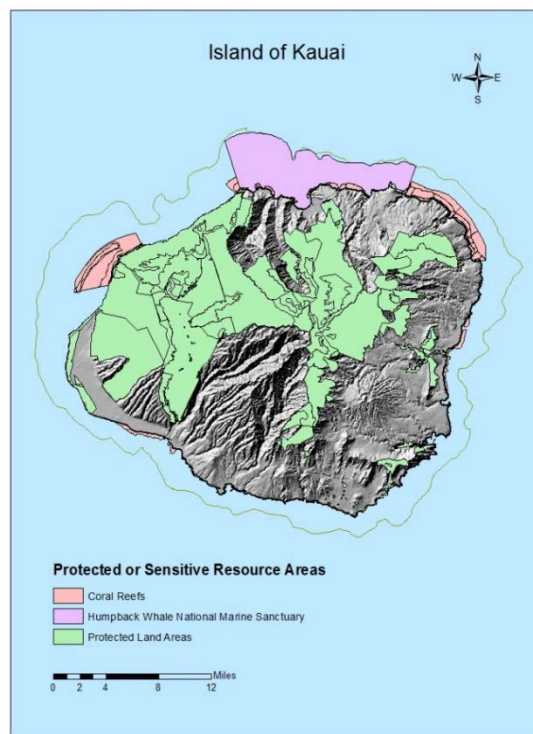

Figure 3-46. Protected or Sensitive Resource Areas on Kaua‘i

3.4.4.4.2 O‘ahu

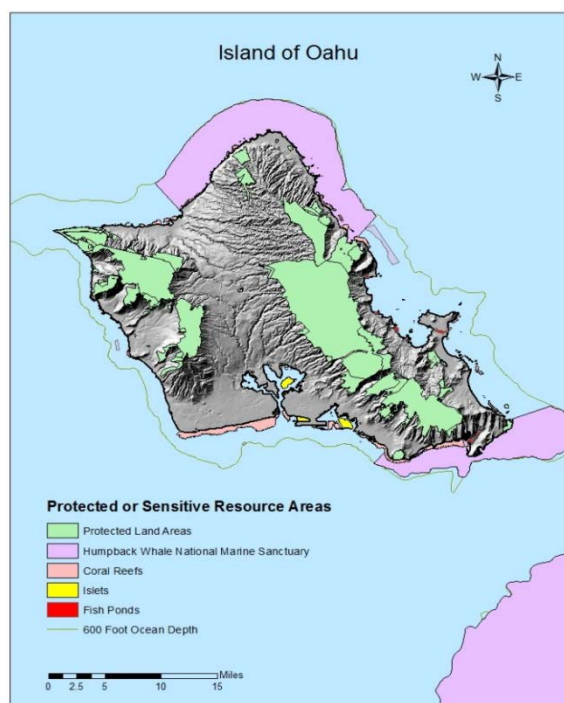

Figure 3-47. Protected or Sensitive Resource Areas on O‘ahu

O‘ahu is the most populous island of the State. The remaining native ecosystems are associated with the upper elevations of the Ko‘olau and Wai‘anae mountain ranges on the northeast and southwest sides, respectively, of the island (TNC 2006). These are characterized by steep topography and poor access. These areas contain most of the protected land areas on O‘ahu (Figure 3-47).

O‘ahu contains a wide variety of threatened and endangered species including one terrestrial mammal, many species of birds, invertebrates, and several species of marine mammals and reptiles. More than 55,000 acres of critical habitat have been designated for plants on O‘ahu. An additional 66,000 acres has been designated for the O‘ahu elepaio (*Chasiempis sandwichensis ibidis*) that overlaps with acreage designated for plant species. Much of the designated critical habitat overlaps with many of the administratively protected land areas.

Portions of the Hawaiian Islands Humpback Whale National Marine Sanctuary border the southeastern and north sides of the island. In addition to the humpback whale, other threatened and endangered species that occur in offshore waters or use beach areas on O‘ahu include the Hawaiian monk seal, insular false killer whale, green turtle, and hawksbill turtle. The island of

O‘ahu has several large estuaries and bays and a barrier reef complex off of the northeast coast near Kāne‘ohe Bay. The island also has fringing reefs in many areas along the coast.

3.4.4.4.3 Molokai

Like the other islands, the lowland dry and mesic forest and shrubland ecosystems have been largely altered by human activity. Most of the remaining native vegetation is on the mountainous east volcanic area with deep valleys that makes access difficult. Some areas of lowland mesic forest remain on the south slopes of the east Molokai volcano with larger areas of lowland wet and montane wet forest at higher elevations (TNC 2006). Areas of the wet cliff ecosystem still remain on the steep north (windward side) slopes of the volcano.

Protected land areas occur primarily in the mountainous eastern portion of the island (Figure 3-48). These areas range from sea level to the highest mountain peak and include critical habitat, parks, natural area reserves, forest reserves, and wildlife refuges. Molokai supports a variety of threatened and endangered species including forest birds, the Hawaiian hoary bat, the Hawaiian goose, and several waterbirds such as the Hawaiian nighthawk and Hawaiian coot. Approximately 25,000 acres of critical habitat has been designated for a variety of plant species and about 3,100 acres has been designated for the Blackburn’s sphinx moth which partially overlaps the plant critical habitat. The coastal strand along the island’s northwest coast contains one of the State’s last intact dune systems and is important to nesting seabirds and marine animals.

The southern coast of Molokai has the longest fringing reef within the State, approximately 30 miles. The ocean waters surrounding Molokai and the neighboring islands of Lāna‘i and Maui are the shallowest among the islands. These waters comprise the largest portion of the Hawaiian Islands Humpback Whale National Marine Sanctuary. Several fish ponds occur along the southern coast. The ocean waters surrounding Molokai have been designated EFH for the bottomfish, crustacean, and coral reef fisheries.

3.4.4.4.4 Lāna‘i

Very little native ecosystem is left on the island. A small area of montane mesic forest and lowland dry and mesic forest remains on Mount Lāna‘ihale. Historically, much of Lāna‘i was covered with coastal, lowland dry forest and shrub, and lowland mesic ecosystems. Much of the vegetation was altered when Lāna‘i was a major producer of pineapples. Lāna‘i is largely privately owned and no State or Federally protected land occurs on the island. However, the State leases approximately 30,000 acres for use as the Lāna‘i Cooperative Game Management Area (Figure 3-49). Like the other islands, Lāna‘i contains multiple threatened and endangered species. The Hawaiian Islands Humpback Whale National Marine Sanctuary surrounds the island.

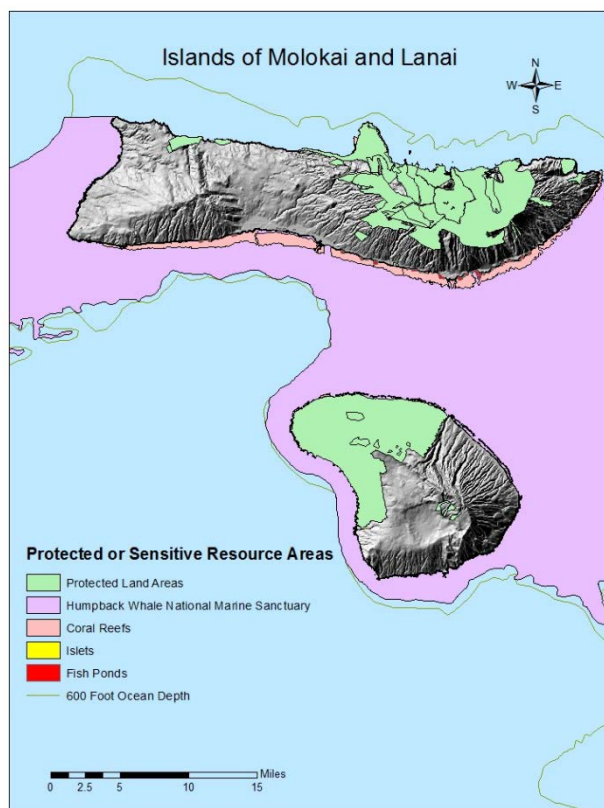

Figure 3-48. Protected or Sensitive Resource Areas on Moloka‘i and Lāna‘i

3.4.4.4.5 Maui

The island of Maui comprises two volcanic mountains. Native vegetation remains primarily on peaks and slopes of the two mountains. The lowland dry forest and shrub, lowland mesic forest, and montane dry and mesic forest have been replaced by anthropogenic vegetation. Areas of montane wet forest still remain in both East and West Maui.

Protected land areas on Maui occur primarily in east and west mountain areas but span the range of habitats from the coast to the alpine zone (Figure 3-49). Approximately, 200,000 acres or 43 percent of Maui is under some form of conservation management (e.g., a management plan exists) or protected. Maui also contains multiple areas of designated critical habitat for threatened and endangered species.

The ocean waters surrounding Maui have been designated EFH for the bottomfish, crustacean, coral reef, and precious coral fisheries. The ocean area west of Maui, between Maui, Molokai and Lānaʻi, is part of the Hawaiian Islands Humpback Whale National Marine Sanctuary.

3.4.4.4.6 Hawaiʻi

The island of Hawaiʻi is the largest and tallest of the islands and comprises five shield volcanoes. The two tallest mountains are Mauna Kea at 13,796 feet and Mauna Loa at 13,677 feet. Hawaiʻi has relatively large alpine and subalpine zones. Like the other islands, the lowland dry forest and shrub and lowland mesic forests on Hawaiʻi have been mostly altered by human activity. However, Hawaiʻi still retains significant areas of native ecosystems, primarily in the center of island around Mauna Kea and Mauna Loa (Pratt and Gon 1998; TNC 2006) (Figure 3-50). Remaining native ecosystems include wet forests, montane dry and mesic forest, subalpine, and alpine vegetation zones.

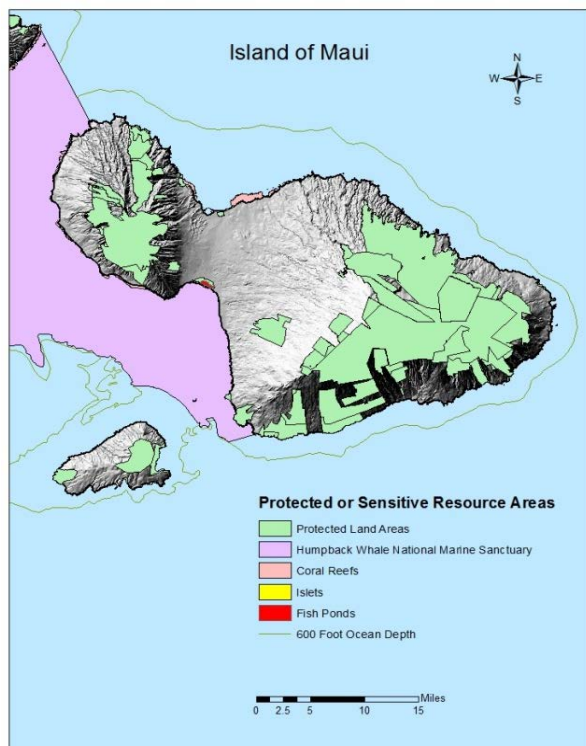

Figure 3-49. Protected or Sensitive Resource Areas on Maui

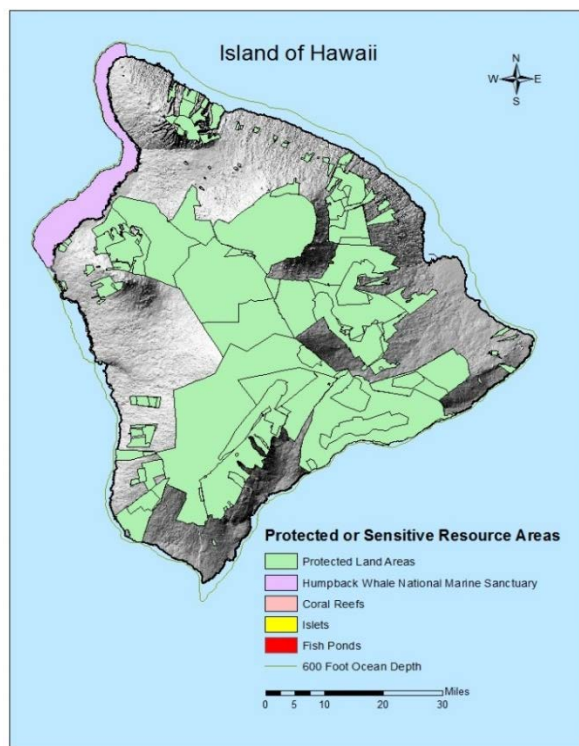

Figure 3-50. Protected or Sensitive Resource Areas on Hawaiʻi

Protected land areas on Hawai‘i range from the ocean to the peaks of Mauna Loa and Mauna Kea. Most of the protected land area occurs in uplands areas. Approximately 38 percent of the island is under State or Federal Management. The National Park Service manages a relatively larger area (406,000 acres) on Hawai‘i. Most of this land is in Hawai‘i Volcanoes National Park. Like its neighboring islands, Hawai‘i has designated critical habitat for threatened and endangered habitats.

EFH has been designated around the island and the waters off of the northwest coast out to the 600 foot depth have been designated as part of the Hawaiian Islands Humpback Whale National Marine Sanctuary.

3.4.5 COMMON CONSTRUCTION AND OPERATION IMPACTS

This section contains a discussion of common impacts that could occur to terrestrial and marine ecosystems from the development of renewable energy technologies. The impacts discussed in this section are those impacts that are not unique to a particular energy technology. Impacts discussed in Chapters 4 through 8 are those impacts to terrestrial and marine ecosystems that are more specific to the implementation of a particular technology. This approach to discussing impacts is done to avoid repeated discussion of common impacts for each technology but does not assume that either common impacts or impacts unique to a particular technology are any less or more important. [Section 3.4.6](#) discusses BMPs that could be implemented to reduce, minimize, or avoid potential impacts.

3.4.5.1 Terrestrial Ecosystems

Land disturbance is a common impact associated with most land-based renewable energy technologies including clearing or modification of vegetation, soil disturbance, and loss of wildlife habitat. These impacts are not limited to the footprint of the facilities but could include access roads, utility corridors, and a buffer zone around the facility. Development of some energy technologies have an exploratory or data collection phase that could require construction of access roads, drilling, and field studies that also could disturb land and wildlife. The potential amount of land and habitat that could be disturbed varies among energy technologies. Development of distributed renewable energy projects may often involve smaller land disturbances than utility-scale projects because they are usually smaller and are often developed in close proximity to existing commercial or industrial facilities where the land may already be disturbed or the vegetation has been previously modified. The potential impact of land disturbance on vegetation communities, wildlife habitat, and individual wildlife species will depend on specific development locations and the size of the land disturbance. Threatened and endangered species, both plants and animals, could be killed or disturbed by land disturbances. Locations that have been previously disturbed or contain less valuable wildlife habitat would be preferred sites and would minimize potential impacts.

Where vegetation is cleared and bare soil is exposed the potential exists for the establishment of invasive and weedy species. These species can establish either through wind and water dispersal or by human transport on equipment (i.e., tires) or vehicles. Access roads and transmission line corridors could provide potential corridors for nonnative species to become established in new areas that could then in turn provide a source of invasive species into nearby undisturbed areas. Revegetation or landscaping with native or non-invasive species soon after completion of facility construction would minimize potential impacts.

Human activity (both physical presence of workers and associated noise) during construction of renewable energy facilities could cause wildlife species to temporarily avoid a construction area. This impact could be minimized by locating energy facilities away from high wildlife use areas and important habitats (e.g., wetlands, nesting sites, and roost trees) and scheduling construction during times of minimum wildlife use. Disturbance of important habitats even though they may be small in size such as a

roost tree or nesting site (e.g., sea bird colony or beach) can have disproportionately large impacts on a species.

Sea bird species including the threatened Newell's shearwater, endangered Hawaiian petrel, and the candidate band-rumped storm-petrel are nocturnal flyers and become disoriented by bright outdoor night lighting. The birds eventually become exhausted and fall to the ground (i.e., fallout). Sea turtles also are susceptible to artificial light visible from the beach and disorient turtles away from the ocean. Most renewable energy facilities would require some type of lighting whether it is for worker visibility or safety (e.g., lighting of tall structures). [HRS 205A-30.5](#) prohibits the direct illumination of the shoreline and ocean waters by artificial light or lighting. Lighting regulations also have been established in some counties (e.g., Hawai'i) to minimize potential impacts of light on wildlife as well as "dark night skies." Following lighting guidelines and lighting regulations should minimize potential impacts.

3.4.5.2 Marine Ecosystems

Disturbance of the ocean floor or benthic environment would be a common impact associated with development of most renewable energy technologies in marine ecosystems. Disturbance impacts could occur from laying pipelines (e.g., water intake and discharge pipes), power cables, anchors for floating platforms, and placement of marine kinetic energy devices on the ocean floor. Suspension of sediments in the water and could impact surrounding marine organisms through sediment deposition which can block sunlight and decrease photosynthesis. Of particular concern is sediment deposition on coral reefs. Impacts also could include displacement or mortality of bottom organisms. However, avoidance of high value ocean habitats such as coral reefs, marine pools, estuaries, and sea grass habitat would minimize potential impacts. These construction impacts would be temporary until benthic organism's recolonized disturbed areas, but sediment deposition on coral reefs could have longer lasting impacts. Placement of structures in the ocean, either on the ocean floor or as floating platforms, creates surfaces that are often colonized by marine organisms in a process called biofouling. These structures often serve as artificial reefs and fish aggregation devices as fish and marine mammals are attracted to the increase in marine productivity and the potential shelter of the structure. Although the artificial reef effect may generally have a positive effect on local marine productivity surrounding the structures, structures with moving parts, such as marine kinetic energy devices, may pose a hazard to some marine animals.

Installation of energy devices in the ocean may have localized negative effects from human disturbance and underwater noise during construction. Some marine mammals are attracted to activity (e.g., whales are curious) in the ocean which may increase the probably of collisions with construction boats and ships. These impacts could be mitigated through having marine mammal monitors during construction. Many marine species have well developed sound communication and may be sensitive to acute construction noise. However, those effects would be temporary and limited to the construction period. During operation, any ocean energy device with rotating or oscillating parts would create sound waves that could cause marine mammals, reptiles, and fish to avoid an area surrounding the project. Sufficiently loud sounds can cause auditory injures but it is not known whether hydrokinetic energy devices produce sounds capable of causing auditory injury. Hydrokinetic energy devices with moving parts also could cause physical injury to marine mammals and fish or cause species to avoid the area creating loss of habitat.

Offshore renewal energy projects would need a power transmission cable to transfer energy produced to the islands. Installation of power cables across the coastline and onshore power stations could disturb a variety coastal marine habitats such as marine pools (tidal and anchialine), beaches, estuaries, fishponds, and reefs. Potential impacts (i.e., disturbance and mortality) to wildlife species and threatened and endangered species could occur in the vicinity of the construction. During construction, disturbance from cable installation and human activity could impact nesting sea turtles and sea birds. Monk seals also use

remote beaches as resting places and could be disturbed. Sea turtles also can become disoriented by artificial light along beaches. Locating power cable crossings and associated transformer stations away from remote, undeveloped coastlines that would be more favored by marine and terrestrial wildlife species and minimizing lighting could reduce potential impacts (see [HRS 205A-30.5](#); <http://www.Kaua'i-seabirdhcp.info/minimization/lights/index.html>).

Another potential impact from undersea power cables is related to electromagnetic fields (EMF) on marine organisms along the cable. Although potential impacts to and responses of marine organisms to EMFs are not fully understood, many marine species such as sharks, marine mammals, sea turtles, and some bony fishes have well developed electrosensory systems that may be involved in orientation, homing, and navigation or life functions such as detection of prey and predators ([Normandeau et al. 2011](#)). The potential strength of the EMF surrounding the cable is a function of the voltage, cable shielding, and whether the cable is buried or laid along the ocean floor. However, the EMF attenuates relatively quickly with distance from the cable (15 and 30 feet for AC and DC cables, respectively) along and above the seafloor, and the potential impacts to those species most sensitive to EMFs is likely to be relatively small ([Normandeau et al. 2011](#)).

3.4.6 COMMON BEST MANAGEMENT PRACTICES

The following sections discuss BMPs that could be implemented to minimize and avoid potential impacts to terrestrial and marine ecosystems from the construction and operation of renewable energy technologies.

3.4.6.1 Terrestrial Ecosystems

- Review Federal and State databases and technical reports for regulatory requirements for protection of special status animal and plant species and habitats. Being aware of the applicable regulations and potential biological resources issues and concerns will help avoid unwanted surprises during the planning and implementation phases of the project. This also improves the potential for productive and informative coordination with Federal and State environmental agencies.
- Coordinate with the USFWS (i.e., begin early consultation processes) and State environmental and fish and wildlife agencies early in the planning phase of the project for identification of potential issues, and ensure ongoing communication in the course of project development. USFWS can also inform the developer whether the NMFS also should be consulted for a particular project. Both agencies share jurisdictional responsibility for some threatened and endangered species such as sea turtles. This BMP is one of the best ways to avoid or minimize potential environmental issues early in the project planning. Note that it best to coordinate with agencies prior to performing any exploratory field investigations as those studies also could have potential impacts.
- Become aware of possible pre- and post-construction environmental monitoring BMPs and mitigation measures through agency and public interactions. Depending on the particular issues associated with a project, there may be monitoring requirements for a particular species or group of species. For example, the adults and larvae of the endangered Blackburn's sphinx moth feed on specific host plants and the developing pupae occupy the soil in the vicinity of the host plants for a year or longer. If a project could disturb the host plants, surveys to map their location and identify evidence of larval feeding may be recommended. Identifying these types of recommendations or requirements early will allow integration into the project.

- Locate project facilities and ancillary components so that environmentally sensitive areas (e.g., riparian habitats, streams, wetlands, critical wildlife habitats, and migration corridors, and other protected areas) are avoided. Potential impacts discussed in this PEIS are often dependent on location. Location of a project within a landscape will often determine the real potential for impacts to terrestrial ecosystems. For example, species that fly comprise a large proportion of the Hawaiian fauna and airspace is a valuable resource to these species that is difficult to identify and describe. Coordination with Federal and State wildlife agencies is a good way to identify project development locations from a landscape perspective that would minimize potential impacts.
- Develop biological survey protocols and plans in consultation with regulatory agencies to ensure that specific regional and other requirements are met. For example, acoustic monitoring devices are recommended for surveys for the presence of the Hawaiian bat. However, survey requirements (e.g., a onetime survey or a continuous survey over a longer time period) may vary depending on the specific project and type of action that would occur. Different plant and animal species may require different survey techniques and sampling designs.
- Consider potential impacts on indigenous and special status plant species while addressing controls for nonnative/invasive species and noxious weeds.
- Consider using a weed risk assessment tool such as the Hawai'i Pacific Weed Risk Assessment (<https://sites.google.com/site/weedriskassessment/home>) to evaluate any introduced species proposed for biomass fuel production. Some species with characteristics such as rapid growth, high productivity, and adaptable to a wide range of environmental conditions (e.g., precipitation, temperature, and soils) that make them good biomass fuel candidates, also are characteristics that could make them invasive species. Introduced species that are used for biomass fuels production should be evaluated prior to use and monitored during use to detect potential spread beyond the production fields.
- Consider reclamation and conservation initiatives for disturbed lands after construction. Use native species or non-invasive species to restore bare soil. Establishing a plant cover not only restores potential wildlife habitat but also helps prevent establishment of weedy or invasive species.
- Consider developing habitat restoration and management plans and compensatory mitigation and monitoring plans.
- If lighting is required on renewable energy facilities for either worker or public safety, the lighting design should follow recommended guidelines such as those listed at <http://www.Kaua'i-seabirdhcp.info/minimization/lights/index.html>, in applicable county regulations, or provided by Federal or State agencies. Generally lights should be positioned low to the ground, be motion-triggered, and be shielded or full cut-off. Effective light shields should be completely opaque, sufficiently large, and positioned so that the bulb is only visible from below bulb-height. Nighttime lighting during construction should be avoided if at all possible, particularly from mid-September through mid-December when sea birds are most susceptible to fallout.
- Use screens on freshwater diversion channels for small-scale hydroelectric power plants to prevent entrainment of freshwater fish species through the power generation system (i.e., forebay reservoir, penstock pipe, and turbine). Establish minimum stream flows for the diverted stream segment to ensure adequate flow for fish passage.

- Collect preconstruction data on bird and bat flight paths and activity in the vicinity of a wind energy project site. The flight paths of many seabirds from mountain nesting sites to the ocean are not well understood.

3.4.6.2 Marine Ecosystems

- Review Federal and State databases and technical reports for regulatory requirements for protection of special status animal and habitats. Being aware of the applicable regulations and potential biological resources issues and concerns will help avoid unwanted surprises during the planning and implementation phases of the project. This also improves the potential for productive and informative coordination with Federal and State environmental agencies.
- Coordinate with the NMFS (i.e., begin early consultation processes) and State environmental and fish and wildlife agencies early in the planning phase of the project for identification of potential issues, and ensure ongoing communication in the course of project development. NMFS can also inform the developer whether the USFWS also should be consulted for a particular project. This BMP is one of the best ways to avoid or minimize potential environmental issues early in the project planning. Note that it best to coordinate with agencies prior to performing any exploratory field investigations as those studies also could have potential impacts.
- Become aware of possible pre- and post-construction environmental monitoring BMPs and mitigation measures through agency and public interactions. Depending on the particular issues associated with a project, there may be monitoring requirements for a particular species or group of species. Identifying these requirements early will allow integration into the project.
- Locate project facilities and ancillary components so that environmentally sensitive areas (e.g., estuaries, coral reefs, critical habitats, and migration corridors, and other protected areas) are avoided. Potential impacts discussed in this PEIS are often dependent on location. Location of a project within the marine environment will often determine the real potential for impacts. Coordination with Federal and State fish and wildlife agencies is a good way to identify project development locations that would minimize potential impacts.
- Develop biological survey protocols and plans in consultation with regulatory agencies to ensure that specific regional and other requirements are met.
- Use observers during construction to avoid potential collisions of boats and ships with marine mammals. Performing construction during times when marine mammals are least likely to be present also would minimize potential collisions.
- If lighting is required on offshore renewable energy facilities for either worker or public safety, they should follow recommended guidelines such as those listed at <http://www.Kaua'i-seabirdhcp.info/minimization/lights/index.html>, in applicable county regulations, or provided by Federal or State agencies. Pursuant to [HRS 205A-30.5](#), artificial light or lighting shall not directly illuminate the shoreline and ocean waters. Generally, lights should be positioned low to the surface, be motion-triggered, and be shielded or full cut-off. Effective light shields should be completely opaque, sufficiently large, and positioned so that the bulb is only visible from below bulb-height. Flashing safety lighting should follow guidelines to reduce the potential for attracting sea birds. Construction and operational lighting should be limited or not used along beach areas when installing power cables from offshore energy projects, particularly from May through December when sea turtles nest on beaches.

- EMF exposure can be reduced, if necessary, by shielding and sheathing undersea cables, as well as by burying the cables in the ocean floor. Concrete or other material placed over an undersea cable may also provide shielding, but would cause seafloor and habitat disturbance and changes. Many marine species have electro and magnetic senses and use those senses to navigate. BOEM's report *Effects of EMFs from Undersea Power Cables on Elasmobranchs and other Marine Species* ([BOEM 2011](#)) addresses this topic, concluding that more research needs to be done to better understand these interactions.
- Use horizontal direction drilling technology to cross the coastline to lay pipelines and power cabling to avoid impacts to both terrestrial and marine habitats and organisms. However, caution needs to be used in application of HDD technology along the shore because some marine habitats such as landlocked anchialine pools are dependent on an underground connection to the ocean tide. Drilling could potentially disturb this underground ocean connection and HDD efforts should be located to avoid anchialine pools that may contain threatened and endangered species.

3.5 Land and Submerged Land Use

[Sections 3.5.1](#) and [3.5.2](#) present information on land ownership and land use for each of the six major islands, respectively. The sections begin with an overview from the State perspective. [Section 3.5.3](#) presents information on submerged land uses by category rather than by each island.

3.5.1 LAND OWNERSHIP

Hawai'i public trust or "ceded" lands were transferred to the United States by the Republic of Hawai'i under the 1898 annexation of Hawai'i as a territory of the United States, following the end of the Hawaiian monarchy. The *Admissions Act of 1959* ([Public Law 86-3](#)), which granted Hawai'i Statehood, established the State as trustee of the ceded lands and defined five purposes for their use, including the betterment of conditions for native Hawaiians. The 1963 *Ceded Lands Act* allowed the transfer of title to the State of Hawai'i for all ceded lands (less those parts retained by the Federal Government for national parks, military bases, and other public purposes) ([aloha4all.org](#)). In 1978, voters approved constitutional amendments to create the Office of Hawaiian Affairs (OHA) and fund it with a share of the money derived from the use of ceded lands.

Ceded lands in Hawai'i comprise approximately 1.8 million acres of property throughout the State, or about 43 percent of the State's total land area. [Figure 3-51](#) shows approximate areas of ceded lands (light green).

Because the exact amount of ceded lands was unknown, the 2000 State Legislature adopted Act 125 to facilitate the establishment of a comprehensive information system for inventorying and maintaining information about the ceded lands. In 2011, the Legislature amended Act 125 to require the State auditor to initiate and coordinate all efforts to establish a public land trust information system. Unfortunately for numerous reasons, development of the information system was overcome by events

The following sections provide land ownership information for each island for State, Federal, and private lands, including land ownership maps depicting the largest owners in terms of land acreage. DBEDT maintains listings of each landowner on each island on the following website:
http://files.hawaii.gov/dbedt/op/gis/data/large_landowners_tables.xls.

Figure 3-51. Approximate Areas of Ceded Lands (light green)

3.5.1.1 Kaua‘i

Kaua‘i, with an area of about 562 square miles (approximately 359,680 acres), is the fourth largest of the six main Hawaiian Islands. [Figure 3-52](#) shows the largest landowners on the island of Kaua‘i ([Hawai‘i 2013a](#)).

Land ownership on Kaua‘i is distributed as follows ([Hawai‘i 2013a](#)):

State Government:	167,257 acres
Federal Government:	3,074 acres
Private:	135,067 acres

Kaua‘i is home to the U.S. Navy’s Barking Sands Pacific Missile Range. The Range includes the majority of Federal lands on the island. The base itself is about 2,400 acres and includes a 6,000-foot runway. Support facilities at Port Allen, Makaha Ridge, and Kokee State Park make up the rest of Federal acreage on Kaua‘i.

3.5.1.2 O‘ahu

O‘ahu, with an area of about 597 square miles (approximately 382,080 acres), is the third largest of the six main Hawaiian Islands. [Figure 3-53](#) shows the largest landowners on the island of O‘ahu ([Hawai‘i 2013a](#)).

Land ownership on O‘ahu is distributed as follows ([Hawai‘i 2013a](#)):

State Government:	156,661 acres
Federal Government:	61,050 acres
Private:	63,544 acres
